## 19.3 Another Tree Notation

In this section, we present an alternative to the method of representing the structure of ordered rooted trees given in section 19.2. *Trees*, which is based on the observation that any node of such a tree can be thought of as the root of the subtree that it dominates. Thus subtrees can be thought of as the same type as the trees they are embedded in, hence the designation `<eTree>`, for *embedding tree*. Whereas in a `<tree>` the relationship among the parts is indicated by the *children* attribute, and by the names of the elements `<root>`, `<iNode>`, and `<leaf>`, the relationship among the parts of an `<eTree>` is indicated simply by the arrangement of their content. However, we have chosen to enable encoders to distinguish the terminal elements of an `<eTree>` by means of the empty `<eLeaf>` element, though its use is not required; the `<eTree>` element can also be used to identify the terminal nodes of `<eTree>` elements. We also provide a `<triangle>` element, which can be thought of as an underspecified `<eTree>`, i.e. an `<eTree>` in which certain information has been left out. In addition, we provide a `<forest>` element, which consists of one or more `<tree>`, `<eTree>`, or `<triangle>` elements, and a `<listForest>` element, which consists of one or more `<forest>` elements. The elements used for the encoding of embedding trees and the units containing them have the following descriptions and attributes.

**<eTree>** (embedding tree) provides an alternative to tree element for representing ordered rooted tree structures.

*@value* provides the value of an embedding tree, which is a feature structure or other analytic element.

**<triangle>** (underspecified embedding tree, so called because of its characteristic shape when drawn) provides for an underspecified eTree, that is, an eTree with information left out.

*@value* supplies a value for the triangle, in the form of the identifier of a feature structure or other analytic element.

**<eLeaf>** (leaf or terminal node of an embedding tree) provides explicitly for a leaf of an embedding tree, which may also be encoded with the eTree element.

*@value* indicates the value of an embedding leaf, which is a feature structure or other analytic element.

**<forest>** provides for groups of rooted trees.

**<listForest>** provides for lists of forests.

Like the `<root>`, `<iNode>`, and `<leaf>` of a `<tree>`, the `<eTree>`, `<triangle>` and `<eLeaf>` elements may also have *value* attributes and `<label>` children.

To illustrate the use of the `<eTree>` and `<eLeaf>` elements, here is an encoding of the second example in section 19.2. *Trees*, repeated here for convenience.

```

<eTree n="ex1">
  <label>PP</label>
  <eTree>
    <label>P</label>
    <eLeaf>
      <label>with</label>
    </eLeaf>
  </eTree>
  <eTree>
    <label>NP</label>
    <eTree>
      <label>Art</label>
      <eLeaf>
        <label>the</label>
      </eLeaf>
    </eTree>
    <eTree>
      <label>N</label>
      <eLeaf>
        <label>periscope</label>
      </eLeaf>
    </eTree>
  </eTree>
</eTree>
  
```

Next, we provide an encoding, using the <triangle> element, in which the internal structure of the <eTree> labeled NP is omitted.

```

<eTree n="ex2">
  <label>PP</label>
  <eTree>
    <label>P</label>
    <eLeaf>
      <label>with</label>
    </eLeaf>
  </eTree>
  <triangle>
    <label>NP</label>
    <eLeaf>
      <label>the periscope</label>
    </eLeaf>
  </triangle>
</eTree>

```

Ambiguity involving alternative tree structures associated with the same terminal sequence can be encoded relatively conveniently using a combination of the *exclude* and *copyOf* attributes described in sections 16.8. *Alternation* and 16.6. *Identical Elements and Virtual Copies*. In the simplest case, an `<eTree>` may be part of the content of exactly one of two different `<eTree>` elements. To mark it up, the embedded `<eTree>` may be fully specified within one of the embedding `<eTree>` elements to which it may belong, and a virtual copy, specified by the *copyOf* attribute, may appear on the other. In addition, each of the embedded elements in question is specified as excluding the other, using the *exclude* attribute. To illustrate, consider the English phrase *see the vessel with the periscope*, which may be considered to be structurally ambiguous, depending on whether the phrase *with the periscope* is a modifier of the phrase *the vessel* or a modifier of the phrase *see the vessel*. This ambiguity is indicated in the sketch of the ambiguous tree by means of the dotted-line arcs. The markup using the *copyOf* and *exclude* attributes follows the sketch.

```

<eTree n="ex3">
  <label>VP</label>
  <eTree>
    <label>V</label>

```

```

    <eLeaf>
      <label>see</label>
    </eLeaf>
  </eTree>
</eTree>
<eTree>
  <label>NP</label>
  <eTree>
    <label>Art</label>
    <eLeaf>
      <label>the</label>
    </eLeaf>
  </eTree>
  <eTree>
    <label>N</label>
    <eLeaf>
      <label>vessel</label>
    </eLeaf>
  </eTree>
<eTree xml:id="GD-PPA" exclude="#GD-PPB">
  <label>PP</label>
  <eTree>
    <label>P</label>
    <eLeaf>
      <label>with</label>
    </eLeaf>
  </eTree>
  <eTree>
    <label>NP</label>
    <eTree>
      <label>Art</label>
      <eLeaf>
        <label>the</label>
      </eLeaf>
    </eTree>
    <eTree>
      <label>N</label>
      <eLeaf>
        <label>periscope</label>
      </eLeaf>
    </eTree>
  </eTree>
</eTree>
<eTree xml:id="GD-PPB" copyOf="#GD-PPA"
  exclude="#GD-PPA">
  <label>PP</label>
</eTree>
</eTree>

```

To indicate that one of the alternatives is selected, one may specify the *select* attribute on the highest <eTree> as either #GD-PPA or #GD-PPB; see section 16.8. *Alternation*.

Depending on the grammar one uses to associate structures with examples like *see the man with the periscope*, the representations may be more complicated than this. For example, adopting a version of the *X-bar* theory of phrase structure originated by Jackendoff,<sup>116</sup> the attachment of a modifier may require the creation of an intermediate node

<sup>116</sup>Jackendoff (1977)

```

  </eTree>
</eTree>
</eTree>

```

A *derivation* in a generative grammar is often thought of as a set of trees. To encode such a derivation, one may use the <forest> element, in which the trees may be marked up using the <tree>, the <eTree>, or the <triangle> element. The *type* attribute may be used to specify what kind of derivation it is. Here is an example of a two-tree forest, involving application of the ‘wh-movement’ transformation in the derivation of *what you do* (as in *this is what you do*) from the underlying *you do what*.<sup>117</sup>

<sup>117</sup>The symbols *e* and *t* denote special theoretical constructs (*empty category* and *trace* respectively), which need not concern us here.

```

<forest n="ex5" type="derivation-syntactic">
  <eTree n="Stage 1" xml:id="S1SBAR">
    <label>S'</label>
    <eTree xml:id="S1COMP">
      <label>COMP</label>
      <eLeaf xml:id="S1E">
        <label>e</label>
      </eLeaf>

            <label>do</label>
          </eLeaf>
        </eTree>
        <eTree xml:id="S1NP2">
          <label>NP</label>
          <eLeaf xml:id="S1WH">
            <label>what</label>
          </eLeaf>
        </eTree>
      </eTree>
    </eTree>
  </eTree>
  <eTree n="Stage 2" xml:id="S2SBAR">

```

```

corresp="#S1SBAR">
<label>S'</label>
<eTree xml:id="S2COMP" corresp="#S1COMP">
  <label>COMP</label>
  <eTree copyOf="#S1NP2" corresp="#S1E">
    <label>NP</label>
  </eTree>
</eTree>
<eTree xml:id="S2S" corresp="#S1S">
  <label>S</label>
  <eTree xml:id="S2NP1" copyOf="#S1NP1">
    <label>NP</label>
  </eTree>
  <eTree xml:id="S2VP" corresp="#S1VP">
    <label>VP</label>
    <eTree xml:id="S2V" copyOf="#S1V">
      <label>V</label>
    </eTree>
    <eTree xml:id="S2NP2" corresp="#S1NP2">
      <label>NP</label>
      <eLeaf corresp="#S1WH">
        <label>t</label>
      </eLeaf>
    </eTree>
  </eTree>
</eTree>
</eTree>
</forest>

```

In this markup, we have used *copyOf* attributes to provide virtual copies of elements in the tree representing the second stage of the derivation that also occur in the first stage, and the *corresp* attribute (see section 16.4. *Correspondence and Alignment*) to link those elements in the second stage with corresponding elements in the first stage that are not copies of them.

If a group of forests (e.g. a full grammatical derivation including syntactic, semantic, and phonological subderivations) is to be articulated, the grouping element `<listForest>` may be used.

## 19.4 Representing Textual Transmission

A *stemma codicum* (sometimes called just *stemma*) is a tree-like graphic structure that has become traditional in manuscript studies for representing textual transmission. Consider the following hypothetical stemma:

The nodes in this stemma represent manuscripts; each has a label (a letter) which identifies it and also distinguishes whether the manuscript is extant, lost, or hypothetical. Extant manuscripts are identified by uppercase Latin letters or words beginning with uppercase Latin letters, e.g., L, shown as aqua in this example; manuscripts no longer existing, but providing readings which are attested e.g. by note or copy made before their disappearance, are identified by lowercase Latin letters, e.g., t, shown as magenta in this example; hypothetical stages in the textual transmission, which do not necessarily correspond to real manuscripts, are given lowercase Greek letters, e.g.,  $\alpha$  and shown as gold in this example. The stemma shown above thus suggests that (on the basis of similarities in the readings of the extant and lost manuscripts) L and t share textual material that is not shared with other manuscripts (represented in this case by  $\delta$ ) even though no physical manuscript attesting this stage in the textual transmission has ever been identified.

Manuscripts are copied from other manuscripts. The preceding stemma represents the hypothesis that all manuscripts go back to a common ancestor ( $\alpha$ ), that the tradition split after that stage into two ( $\beta$  and  $\gamma$ ), etc. Descent by copying is indicated with a solid line. According to this model,  $\alpha$  is the earliest common hypothetical stage that can be reconstructed, and all nodes below  $\alpha$  have a single parent, that is, were copied from a single other stage in the tradition.

Figure 27: Example stemma

This familiar tree model is complicated because manuscripts sometimes show the influence of more than one ancestor. They may have been produced by a scribe who checked the text in one manuscript of the same work whilst copying from another, or perhaps made changes from his memory of a slightly different version of the text that he had read elsewhere. Alternatively, perhaps scribe A copied a manuscript from one source, scribe B made changes in it in the margins or between the lines (either by consulting another source directly or from memory), and another scribe then copied that manuscript, incorporating the changes into the body. Whatever the specific scenario, it is not uncommon for a manuscript to be based primarily on one source, but to incorporate features of another branch of the tradition. This mixed result is called *contamination*, and it is reflected in a stemma by a dotted line. Thus, the example above asserts that A is copied within the  $\epsilon$  tradition, but is also contaminated from the  $\gamma$  tradition.

The utility of a stemma as a visualization tool is inversely proportional to the degree of contamination in the manuscript tradition. A tradition completely without contamination (called a *closed tradition*) yields a classic tree, easily represented graphically by a stemma. An *open tradition*, with substantial contamination, yields a spaghetti-like stemma characterized by crossing dotted lines, which is both difficult to read and not very informative.

The `<eTree>` element introduced in this chapter can be used to represent a closed tradition in a straightforward manner. Each non-terminal node is represented by a typed `<eTree>` element and each terminal node by an `<eLeaf>`. A `<label>` element provides a way of identifying each node, complementary to the global attributes `n` and `xml:id` attributes. For example, the closed part of the tradition headed by the label  $\delta$  may be encoded as follows:

```

<eTree type="hypothetical">
  <label> $\delta$ </label>
  <eLeaf type="extant">
    <label>L</label>
  </eLeaf>
  <eLeaf type="lost">
    <label>t</label>
  </eLeaf>
</eTree>

```

To complete this representation, we need to show that the node labelled A is not derived solely from its parent node (labelled  $\epsilon$ ) but also demonstrates contamination from the node labelled  $\gamma$ . The easiest way to accomplish this is to include an appropriately-typed `<ptr>` element within the node in question, the *target* of which points to the

node labelled  $\gamma$ . This requires that this latter node be supplied with a value for its *xml:id* attribute. The complete representation is thus:

```
<eTree type="hypothetical">
  <label> $\alpha$ </label>
  <eTree type="hypothetical">
    <label> $\beta$ </label>
    <eTree type="hypothetical">
      <label> $\delta$ </label>
      <eLeaf type="extant">
        <label>L</label>
      </eLeaf>
      <eLeaf type="lost">
        <label>t</label>
      </eLeaf>
    </eTree>
  </eTree>
  <eTree type="hypothetical">
    <label> $\epsilon$ </label>
    <eLeaf type="extant">
      <label>R</label>
    </eLeaf>
    <eLeaf type="extant">
      <label>A</label>
      <ptr type="contamination"
        target="#gamma"/>
    </eLeaf>
  </eTree>
</eTree>
<eTree xml:id="gamma" type="hypothetical">
  <label> $\gamma$ </label>
  <eLeaf type="extant">
    <label>I</label>
  </eLeaf>
  <eLeaf type="extant">
    <label>X</label>
  </eLeaf>
</eTree>
</eTree>
```

In any substantial codicological project, it is likely that significantly more data will be required about the individual witnesses than indicated in the simple structures above. These Guidelines provide a rich variety of additional elements for representing such information: see in particular chapters 10. *Manuscript Description*, 11. *Representation of Primary Sources*, and 12. *Critical Apparatus*.

## 19.5 Module for Graphs, Networks, and Trees

The module described in this chapter makes available the following components:

**Module nets: Graphs, networks, and trees**

- *Elements defined:* arc eLeaf eTree forest graph iNode leaf listForest node root tree triangle

The selection and combination of modules to form a TEI schema is described in 1.2. *Defining a TEI Schema*.

## 20 Non-hierarchical Structures

XML employs a strongly hierarchical document model. At various points, these Guidelines discuss problems that arise when using XML to encode textual features that either do not naturally lend themselves to representation in a strictly hierarchical form or conflict with other hierarchies represented in the markup. Examples of such situations include:

- Conflict between the hierarchy established by the physical structure of a document (e.g., volume, page, column, line) and its rhetorical or linguistic structure (e.g., chapters, paragraphs, sentences, acts, scenes, etc.)
- Conflict between a verse text's metrical structure (e.g., its arrangement in stanzas and metrical lines) and its rhetorical or linguistic structure (e.g., phrases, sentences, and, for plays, acts, scenes, and speeches).
- Conflict between metrical, rhetorical, or linguistic structure and the representation of direct speech, especially if the quoted speech is interrupted by other elements (e.g., 'What', she asked, 'was that all about') or crosses metrical, rhetorical, or linguistic boundaries.
- Conflict between different analytical views or descriptions of a text or document, e.g., markup intended to encode diplomatic information about a word's appearance in a manuscript with markup intended to describe its morphology or pronunciation.

Non-nesting information poses fundamental problems for any XML-based encoding scheme, and it must be stated at the outset that no current solution combines all the desirable attributes of formal simplicity, capacity to represent all occurring or imaginable kinds of structures, suitability for formal or mechanical validation. The representation of non-hierarchical information is thus necessarily a matter of trade-offs among various sets of advantages and disadvantages.

These Guidelines support several methods for handling non-hierarchical information:

- redundant encoding of information in multiple forms (discussed in *20.1. Multiple Encodings of the Same Information*)
- the use of empty elements to delimit the boundaries of a non-nesting structure (discussed in *20.2. Boundary Marking with Empty Elements*)
- the division of a logically single non-nesting element into segments that nest properly in their immediate hierarchical context but can also be reconstituted virtually across these hierarchical boundaries (discussed *20.3. Fragmentation and Reconstitution of Virtual Elements*)
- stand-off markup: the annotation of information by pointing at it, rather than by placing XML tags within it (discussed in *20.4. Stand-off Markup*)

Some of these methods can be used in TEI-conformant documents. Others require extension.

In the sections which follow these techniques are described and their advantages and disadvantages are briefly discussed. The various solutions to the problem will be exemplified using extracts from two poems. The first is the opening quatrain from William Wordsworth's 'Scorn not the sonnet':

Scorn not the sonnet; critic, you have frowned,  
Mindless of its just honours; with this key  
Shakespeare unlocked his heart; the melody

Of this small lute gave ease to Petrarch's wound.

The second example is the third stanza from the fourth section of Robert Pinsky's 'Essay on Psychiatrists':

Catholic woman of twenty-seven with five children  
And a first-rate body—pointed her finger  
at the back of one certain man and asked me,  
"Is that guy a psychiatrist?" and by god he was! "Yes,"  
She said, "He *looks* like a psychiatrist."

Grown quiet, I looked at his pink back, and thought.

These two texts can be analysed in various ways. The first, which we might describe as the 'Metrical View', encodes the text according to its metrical features: line divisions (as here), stanzas or cantos in larger poems, and perhaps

prosodic features like stress or syllable patterns, alliteration, or rhyme. A second view, which we might describe as the ‘Grammatical’, encodes linguistic and rhetorical features: phonemes, morphemes, words, phrases, clauses, and sentences. A third view, the ‘Dialogic’, might concentrate on narrative voice: distinguishing between the narrator and their interlocutors and identifying individual segments as direct quotations. In our examples, we will restrict ourselves to relatively simple conflicts: for the *Metrical View* we will encode only metrical lines and line groups; for the *Grammatical View* we will restrict ourselves to encoding sentences; and for the *Dialogic View*, we only will distinguish direct quotation from other narration.

## 20.1 Multiple Encodings of the Same Information

Conceptually, the simplest method of disentangling two (or more) conflicting hierarchical views of the same information is to encode it twice (or more), each time capturing a single view.

Thus, for example, the *Metrical View* of ‘Scorn not the sonnet’ might be encoded as follows, using the `<l>` element to encode each metrical line:

```
<l>Scorn not the sonnet; critic, you have frowned,</l>
<l>Mindless of its just honours; with this key</l>
<l>Shakespeare unlocked his heart; the melody</l>
<l>Of this small lute gave ease to Petrarch's wound.</l>
```

The *Grammatical View* would be encoded by taking the same text and replacing the metrical markup with information about its sentence structure:

```
<p>
  <seg>Scorn not the sonnet;</seg>
  <seg>critic, you have frowned, Mindless of its just honours;</seg>
  <seg>with this key Shakespeare unlocked his heart;</seg>
  <seg>the melody Of this small lute gave ease to Petrarch's wound.</seg>
</p>
```

Likewise, the more complex passage from Pinsky could be encoded in three different ways to reflect the different metrical, grammatical, and dialogic views of its text:

```
<lg>
  <l>Catholic woman of twenty-seven with five children</l>
  <l>And a first-rate body–pointed her finger</l>
  <l>at the back of one certain man and asked me,</l>
  <l>"Is that guy a psychiatrist?" and by god he was! "Yes,"</l>
  <l>She said, "He <emph>looks</emph> like a psychiatrist."</l>
  <l>Grown quiet, I looked at his pink back, and thought.</l>
</lg>
```

```
<p>
  <seg>Catholic woman of twenty-seven with five children And a
    first-rate body–pointed her finger at the back of one certain man and
    asked me, "Is that guy a psychiatrist?" and by god he was!</seg>
</p>
<p>
  <seg>"Yes," She said, "He <emph>looks</emph> like a
    psychiatrist."</seg>
</p>
<p>
  <seg>Grown quiet, I looked at his pink back, and thought.</seg>
</p>
```

```
<ab>Catholic woman of twenty-seven with five children And a first-rate
body-pointed her finger at the back of one certain man and asked me,
<said>Is that guy a psychiatrist?</said> and by god he was!
<said>Yes,</said> She said, <said>He <emph>looks</emph> like a
psychiatrist.</said> Grown quiet, I looked at his pink back, and
thought.</ab>
```

This method is TEI-conformant. Its advantages are that each way of looking at the information is explicitly represented in the data and that the individual views are simple to process. The disadvantages are that the method requires the maintenance of multiple copies of identical textual content (an invitation to inconsistency) and that there is no explicit indication that the various views, which might be in separate files, are related to each other: it might prove difficult to combine the views or access information from one view while processing the file that contains the encoding of another.<sup>118</sup>

## 20.2 Boundary Marking with Empty Elements

A second method for accommodating non-hierarchical objects in an XML document involves marking the start and end points of the non-nesting material. This prevents textual features that fall outside the privileged hierarchy from invalidating the document while identifying their beginnings and ends for further processing. The disadvantage of this method is that no single XML element represents the non-nesting material and, as a result, processing with XML technologies is significantly more difficult.

The empty elements used at each end are called *segment-boundary elements* or *segment-boundary delimiters*. There are several variations on this method of encoding.

For some common structural features, the TEI provides milestone elements that can be used to mark the beginning of a textual feature. These include `<lb>`, `<pb>`, `<cb>`, `<handShift>`, and the generic `<milestone>`. Using `<lb>`, for example, it is possible to indicate both the physical lineation of a poem on the page and its grammatical division into sentences:

```
<p>
  <seg>
    <lb n="1"/>Scorn not the sonnet;</seg>; <seg>critic, you have
      frowned, <lb n="2"/>Mindless of its just honours;</seg>
  <seg>with this
    key <lb n="3"/>Shakespeare unlocked his heart;</seg>
  <seg>the melody
    <lb n="4"/>Of this small lute gave ease to Petrarch's
      wound.</seg>
</p>
```

The use of these elements is by definition TEI-conformant. Care should be taken, however, that the meaning of the milestone elements is preserved: semantically, for example, `<lb>` is used to mark the start of a new (typographical) line. While in much modern poetry, typographical and metrical line divisions correspond, `<lb>` does not itself make a metrical claim: in encoding verse from sources, such as Old English manuscripts, where physical line breaks are not used to indicate metrical lineation, the correspondence would break down entirely.

The segment boundaries also may be delimited by the generic `<anchor>` element. Attributes can then be used to indicate the type of feature being delimited and whether a given instance opens or closes the feature.

```
<l>
  <anchor subtype="sentenceStart"
    type="delimiter"/>
```

<sup>118</sup>It has been shown, however, that it is possible to relate the different annotations in an indirect way: if the textual content of the annotations is identical, the very text can serve as a means for linking the different annotations, as described in Witt (2002).

```

Scorn not the sonnet;
<anchor subtype="sentenceEnd"
  type="delimiter"/>
  <anchor subtype="sentenceStart"
    type="delimiter"/> critic, you have frowned,
</l>
<l>Mindless of its just honours; <anchor subtype="sentenceEnd"
  type="delimiter"/>
  <anchor subtype="sentenceStart"
    type="delimiter"/> with this key</l>
<l>Shakespeare unlocked his heart; <anchor subtype="sentenceEnd"
  type="delimiter"/>
  <anchor subtype="sentenceStart"
    type="delimiter"/> the melody</l>
<l>Of this small lute gave ease to Petrarch's wound. <anchor subtype="sentenceEnd"
  type="delimiter"/>
</l>

```

This method is TEI-conformant.

Another approach is to design custom elements that provide richer information about the feature being delimited or its boundaries. This information can be included as attribute values or as part of the element name itself: e.g., <boundaryStart element="sentence"/>... <boundaryEnd element="sentence"/>, <sentenceBoundary position="start"/>... <sentenceBoundary position="end"/>, or <sentenceBoundaryStart/>... <sentenceBoundaryEnd/>:

```

<l
  xmlns:n="http://www.example.org/ns/nonTEI">
  <n:sentenceBoundaryStart/>Scorn not the sonnet;
<n:sentenceBoundaryEnd/>
  <n:sentenceBoundaryStart/>critic, you have frowned,
</l>
<l>Mindless of its just honours; <n:sentenceBoundaryEnd/>
  <n:sentenceBoundaryStart/>with this key</l>
<l>Shakespeare unlocked his heart; <n:sentenceBoundaryEnd/>
  <n:sentenceBoundaryStart/>the melody</l>
<l>Of this small lute gave ease to Petrarch's wound. <n:sentenceBoundaryEnd/>
</l>

```

If the custom elements can be replaced by TEI elements and attributes without loss of information, this method is TEI-conformant (see 23.4. *Conformance*); if the custom elements introduce information or distinctions that cannot be captured using standard TEI elements, the method is an extension.

Finally, elements that are normally used to encode nesting textual features (e.g., <said>, <seg>, <l>, etc.) can be adapted so that they serve as empty segment boundary delimiters when the features they encode cross-hierarchical boundaries. Additional attributes (*sID* and *eID* in the example below) are added to these elements in order to allow the unambiguous correlation of start and end points. This method has been introduced in the markup literature under various names, including Trojan milestones, HORSE markup, CLIX, and COLT. It is described in detail by DeRose (2004):

```

<lg
  xmlns:hr="http://www.example.org/ns/nonTEI">
  <l>
  <seg>Scorn not the sonnet;</seg>
  <hr:s sID="s02"/>critic, you have frowned, </l>

```

```

<l>Mindless of its just honours; <hr:s eID="s02"/>
  <hr:s sID="s03"/>with this key </l>
<l>Shakespeare unlocked his heart; <hr:s eID="s03"/>
  <hr:s sID="s04"/>the melody </l>
<l>Of this small lute gave ease to Petrarch's wound. <hr:s eID="s04"/>
</l>
</lg>

```

Depending on how the modifications are carried out, this method may be TEI-conformant, may represent an extension of the TEI, or may produce a non-conformant document.

- The method is TEI-conformant if the modified elements and attributes can be mapped without loss of information to existing TEI markup structures such as milestone or anchor elements automatically (see 23.4. *Conformance*).
- The method represents an Extension if the modified elements are placed in a distinct, non-TEI namespace (see 23.4. *Conformance*).
- The method is non-conformant—and indeed strongly deprecated—if the modified elements and attributes are not placed in a distinct, non-TEI namespace (see 23.4.3. *Conformance to the TEI Abstract Model*).

In each of the above examples (except the last), the relationship between the start and end delimiters (where these exist) of a given feature is implicit: it is assumed that "end" delimiters close the nearest preceding "start" delimiter, or, in the case of milestones, that the milestone marks both the end of the preceding example and the beginning of the next. Complications arise, however, when the non-nesting text overlaps with other non-nesting text of the same type, as, for example, in a grammatical analysis of the various possible interpretations of the noun phrase *fast trains and planes*. In this case, the adjective *fast* can be understood as either modifying *trains and planes* or just *trains*:

Figure 28: Two interpretations of the phrase *Fast trains and planes*

In order to encode the possible analyses of this phrase, an unambiguous method of associating opening and closing segment boundary delimiters is required:

```

<phr function="NP">
  <anchor type="delimiter" subtype="NPstart"

```

```

    xml:id="NPInterpretationB"/>
  <w function="A">Fast</w>
  <anchor type="delimiter" subtype="NPstart"
    xml:id="NPInterpretationA"/>
  <w function="N">trains</w>
  <anchor type="delimiter" subtype="NPend"
    corresp="#NPInterpretationB"/>
  <w function="C">and</w>
  <w function="N">planes</w>
  <anchor type="delimiter" subtype="NPend"
    corresp="#NPInterpretationA"/>
</phr>

```

In this encoding, the first interpretation, in which *fast* modifies the NP *trains and planes*, the NP *trains and planes* is opened using an `<anchor>` tag with the *xml:id* value *NPInterpretationA* and closed with an `<anchor>` with the same value on *corresp*; in the second interpretation, in which *fast* forms a NP with *trains*, the NP *fast cars* is opened using an `<anchor>` tag with the *xml:id* value *NPInterpretationB* and closed with an `<anchor>` tag that has the same value on *corresp*.

Despite their advantages, segment boundary delimiters incur the disadvantage of cumbersome processing: since the elements of the analysis (e.g., the sentences in the poems, or phrases in the above example) are not uniformly represented by nodes in the document tree, they must be reconstituted by software in an ad hoc fashion, which is likely to be difficult and may be error prone.

Most important for some encoders, the method also disguises the relationship between the beginning and the ending of each logical element. This makes it impossible for standard validation software to provide the same kind of validation possible elsewhere in the encoding. When using grammar-based schema languages it is not possible to define a content model for the range limited by empty elements.<sup>119</sup>

### 20.3 Fragmentation and Reconstitution of Virtual Elements

A third method involves breaking what might be considered a single logical (but non-nesting) element into multiple smaller structural elements that fit within the dominant hierarchy but can be reconstituted virtually. For example, if a passage of direct discourse begins in the middle of one paragraph and continues for several more paragraphs, one could encode the passage as a series of `<said>` elements, each fitting within a `<p>` element. The resulting encoding is valid XML, but the text in each `<said>` element represents only a portion of the complete passage of direct discourse. For this reason these elements are sometimes called ‘partial elements’.

In the case of our selection from Pinsky’s poem, for example, the second passage of direct quotation, which crosses a line boundary and is broken up by a *She said* in the narrator’s voice, can be made to fit within the hierarchy established by the metrical lineation by using two `<said>` elements:

```

<lg>
  <l>Catholic woman of twenty-seven with five children</l>
  <l>And a first-rate body-pointed her finger</l>
  <l>at the back of one certain man and asked me,</l>
  <l>
    <said n="quotation1">Is that guy a psychiatrist?</said> and by god he was!
    <said n="quotation2">Yes,</said>
  </l>
  <l>She said, <said n="quotation2">He <emph>looks</emph> like a
    psychiatrist.</said>
  </l>

```

<sup>119</sup>Grammar based schema languages (e.g., DTD, W3C Schema, and RELAX NG) are used to define markup languages (e.g., XHTML or TEI). Rule-based schema languages (e.g., Schematron) can be used to define further constraints. Such a rule-based schema language permits a sequence of certain elements between empty elements to be legitimized or prohibited.

```
<l>Grown quiet, I looked at his pink back, and thought.</l>
</lg>
```

Similarly, the sentences in our example from Wordsworth could be encoded:

```
<l>
  <seg n="sentence1">Scorn not the sonnet;</seg>
  <seg n="sentence2">critic, you have frowned,</seg>
</l>
<l>
  <seg n="sentence2">Mindless of its just honours;</seg>
  <seg n="sentence3">with this key</seg>
</l>
<l>
  <seg n="sentence3">Shakespeare unlocked his heart;</seg>
  <seg n="sentence4">the melody</seg>
</l>
<l>
  <seg n="sentence4">Of this small lute gave ease to Petrarch's wound.</seg>
</l>
```

There are two main problems with this type of encoding. The first is that it invariably means that the encoding will have more elements claiming to represent a feature than there are actual instances of that feature in the text. Thus, for example, the passage from ‘Scorn not the sonnet’ marks seven spans of text using `<seg>`, even though there are only four linguistic sentences in the passage.

The second problem is that it can be semantically misleading. Although they are tagged using the element for *sentence*, for example, very few of the textual features encoded using `<seg>` in this example represent actual linguistic sentences: *with this key*, for example, is a prepositional phrase, not a sentence; *Of this small lute gave ease to Petrarch's wound* is a string corresponding to no single grammatical category.

Taken together, these problems can make automatic analysis of the fragmented features difficult. An analysis that intended to count the number of sentences in Wordsworth's poem, for example, would arrive at an inflated figure if it understood the `<seg>` elements to represent complete rhetorical sentences; if it wanted to do an analysis of his syntax, it would not be able to assume that `<seg>` delimited linguistic sentences.

The technique of fragmentation is often complemented by the technique of virtual joins. Virtual joins may be used to combine objects in the text to a new hierarchy. Here is ‘Scorn not the sonnet’ again; this time the relationship between the parts of the fragmented sentences is indicated explicitly using the *next* and *prev* attributes described in 16.7. *Aggregation*.

```
<l>
  <seg>Scorn not the sonnet;</seg>
  <seg next="#s2b" xml:id="s2a">critic, you have frowned,</seg>
</l>
<l>
  <seg prev="#s2a" xml:id="s2b">Mindless of its just honours;</seg>
  <seg next="#s3b" xml:id="s3a">with this key</seg>
</l>
<l>
  <seg prev="#s3a" xml:id="s3b">Shakespeare unlocked his heart;</seg>
  <seg next="#s4b" xml:id="s4a">the melody</seg>
</l>
<l>
  <seg prev="#s4a" xml:id="s4b">Of this small lute gave ease to Petrarch's wound.</seg>
</l>
```

This method of virtually joining partial elements is sometimes called ‘chaining’.

For fragments encoded using <ab>, <l>, <lg>, <div>, or elements that belong to the `att.segLike` class, an even simpler mechanism for virtually joining fragments exists: the use of the *part* attribute with the value *I* (Initial), *M* (Medial), or *F* (Final) as described in 16.3. *Blocks, Segments, and Anchors*. Here is the above example recoded to reflect this method:

```
<l>
  <seg>Scorn not the sonnet;</seg>
  <seg part="I">critic, you have frowned,</seg>
</l>
<l>
  <seg part="F">Mindless of its just honours;</seg>
  <seg part="I">with this key</seg>
</l>
<l>
  <seg part="F">Shakespeare unlocked his heart;</seg>
  <seg part="I">the melody</seg>
</l>
<l>
  <seg part="F">Of this small lute gave ease to Petrarch's wound.</seg>
</l>
```

This method is TEI-conformant and simple to use. Its disadvantage is that it does not work well for cases of self-overlap, or if there are nested occurrences of the same element type, as it can become difficult to ascertain which initial, medial, or final partial element should be combined with which others or in which order. This problem becomes evident if we attempt to combine a detailed Grammatical view of the Pinsky example with its metrical encoding:

```
<lg>
  <l>
    <seg part="I">Catholic woman of twenty-seven with five children</seg>
  </l>
  <l>
    <seg part="M">And a first-rate body–pointed her finger</seg>
  </l>
  <l>
    <seg part="M">at the back of one certain man and asked me,</seg>
  </l>
  <l>
    <seg part="F">"<seg>Is that guy a psychiatrist?</seg>" and by god he was!</seg>
    <seg part="I">"<seg part="I">Yes,</seg>"</seg>
  </l>
  <l>
    <seg part="F">She said, "<seg part="F">He <emph>looks</emph> like a psychia-
    trist.</seg>"</seg>
  </l>
  <l>
    <seg>Grown quiet, I looked at his pink back, and thought.</seg>
  </l>
</lg>
```

A third method for aggregating fragmented partial elements involves using markup that is not directly part of the encoding, e.g., the <join> element. In this method, a <join> element is used elsewhere in the document to indicate explicitly the members of the virtual element:

```

<l>
  <w xml:id="w01">Scorn</w>
  <w xml:id="w02">not</w>
  <w xml:id="w03">the</w>
  <w xml:id="w04">sonnet</w>; <w xml:id="w05">critic</w>, <w xml:id="w06">you</w>
  <w xml:id="w07">have</w>
  <w xml:id="w08">frowned</w>,
</l>
<l>
  <w xml:id="w09">Mindless</w>
  <w xml:id="w10">of</w>
  <w xml:id="w11">its</w>
  <w xml:id="w12">just</w>
  <w xml:id="w13">honours</w>; <w xml:id="w14">with</w>
  <w xml:id="w15">this</w>
  <w xml:id="w16">key</w>
</l>
<l>
  <w xml:id="w17">Shakespeare</w>
  <w xml:id="w18">unlocked</w>
  <w xml:id="w19">his</w>
  <w xml:id="w20">heart</w>; <w xml:id="w21">the</w>
  <w xml:id="w22">melody</w>
</l>
<l>
  <w xml:id="w23">Of</w>
  <w xml:id="w24">this</w>
  <w xml:id="w25">small</w>
  <w xml:id="w26">lute</w>
  <w xml:id="w27">gave</w>
  <w xml:id="w28">ease</w>
  <w xml:id="w29">to</w>
  <w xml:id="w30">Petrarch's</w>
  <w xml:id="w31">wound</w>.
</l>
<!-- Elsewhere in the document -->
<p>
  <join result="s" scope="root"
    target="#w01 #w02 #w03 #w04"/>
  <join result="s" scope="root"
    target="#w05 #w06 #w07 #w08 #w09 #w10 #w11 #w12 #w13"/>
  <join result="s" scope="root"
    target="#w14 #w15 #w16 #w17 #w18 #w19 #w20"/>
  <join result="s" scope="root"
    target="#w21 #w22 #w23 #w24 #w25 #w26 #w27 #w28 #w29 #w30 #w31"/>
</p>

```

This use of <join> is TEI-conformant.

The major advantage of fragmentation and virtual joins is that it allows all the hierarchies in the text to be handled explicitly: both the privileged one directly represented and the alternate hierarchy that has been split up and rejoined. The major disadvantages are that (like most of the other methods described here) it privileges one hierarchy over the others, requires special processing to reconstitute the elements of the other hierarchies, and, except in the case of <join>, can be semantically misleading.

## 20.4 Stand-off Markup

Most markup is characterized by the embedding of elements in the text. An alternative approach separates the text and the elements used to describe it. This approach is known as stand-off markup (see section 16.9. *Stand-off Markup*). It establishes a new hierarchy by building a new tree whose nodes are XML elements that do not contain textual content, but rather links to another *layer*: a node in another XML document or a span of text. This approach can be subdivided according to different criteria. A first distinction concerns the link base, i.e. the content to which annotations are to be applied. Sometimes the link target contains markup that can be referred to explicitly, as in the following example where the offset markup uses the *xml:id* values on `<w>` to provide targets for `<xi:include>`<sup>120</sup>:

```
<l>
  <w xml:id="w001">Scorn</w>
  <w xml:id="w002">not</w>
  <w xml:id="w003">the</w>
  <w xml:id="w004">sonnet</w>; <w xml:id="w005">critic</w>, <w xml:id="w006">you</w>
  <w xml:id="w007">have</w>
  <w xml:id="w008">frowned</w>,
</l>
<l>
  <w xml:id="w009">Mindless</w>
  <w xml:id="w010">of</w>
  <w xml:id="w011">its</w>
  <w xml:id="w012">just</w>
  <w xml:id="w013">honours</w>; <w xml:id="w014">with</w>
  <w xml:id="w015">this</w>
  <w xml:id="w016">key</w>
</l>
<l>
  <w xml:id="w017">Shakespeare</w>
  <w xml:id="w018">unlocked</w>
  <w xml:id="w019">his</w>
  <w xml:id="w020">heart</w>; <w xml:id="w021">the</w>
  <w xml:id="w022">melody</w>
</l>
<l>
  <w xml:id="w023">of</w>
  <w xml:id="w024">this</w>
  <w xml:id="w025">small</w>
  <w xml:id="w026">lute</w>
  <w xml:id="w027">gave</w>
  <w xml:id="w028">ease</w>
  <w xml:id="w029">to</w>
  <w xml:id="w030">Petrarch's</w>
  <w xml:id="w031">wound</w>.
</l>
<!-- elsewhere in the current document -->

<p xmlns:xi="http://www.w3.org/2001/XInclude">
  <seg>
    <xi:include xpointer="range(element(w001),element(w004))"/>
  </seg>
  <seg>
    <xi:include xpointer="range(element(w005),element(w013))"/>
  </seg>
</p>
```

<sup>120</sup>A fake namespace is given for XInclude here, to avoid the markup being interpreted literally during processing.

```

<xi:include xpointer="range(element(w014),element(w020))"/>
</seg>
<seg>
<xi:include xpointer="range(element(w021),element(w031))"/>
</seg>
</p>

```

Note that the layer that uses XInclude to build another hierarchy might well be in another document, in which case the value of *href* of `<xi:xinclude>` would need to be the URL of the document that contains the base layer, in this case the `<w>` elements.

This is very similar to the use of `<join>` discussed above. The main advantages of the stand-off method are that it is possible to specify attributes on the aggregate `<seg>` elements, and that there exists off-the-shelf software that will perform appropriate processing. Stand-off markup may be used even when the base text being annotated is plain text, i.e. does not have any XML encoding. In this case, the range of text to be marked up is indicated by character offsets (see 16.2.4. *TEI XPointer Schemes*, in particular 16.2.4.7. *string-range()*). Another distinction concerns the number of files which can serve as link targets. Often, one (dedicated) annotation is used as the link target of all the other annotations. It is also possible to freely interlink several layers.

It has been noted that stand-off markup has several advantages over embedded annotations. In particular, it is possible to produce annotations of a text even when the source document is read-only. Furthermore, annotation files can be distributed without distributing the source text. Further advantages mentioned in the literature are that discontinuous segments of text can be combined in a single annotation, that independent parallel coders can produce independent annotations, and that different annotation files can contain different layers of information. Lastly, it has also been noted that this approach is elegant.

But there are also several drawbacks. First, new stand-off annotated layers require a separate interpretation, and the layers—although separate—depend on each other. Moreover, although all of the information of the multiple hierarchies is included, the information may be difficult to access using generic methods.

Inasmuch as it uses elements not included in the TEI namespace, stand-off markup involves an extension of the TEI.

## 20.5 Non-XML-based Approaches

There exist many non-XML methods of encoding a text that either solve or do not suffer the problem of the inability to encode overlapping hierarchies. These include, but are not limited to, the following proposals.

- Applying the notion of concurrent markup to XML (Hilbert et al. (2005)). This reintroduces the CONCUR feature of SGML, which was omitted from the XML specification.
- Designing a form of document representation in which several trees share all or part of the same frontier, and in which each individual view of the document has the form of a tree (see Dekhtyar and Iacob (2005)).
- The ‘colored XML’ proposal (Jagadish et al. (2004)), which stores a body of information as a set of intertwined XML trees. This approach eliminates unnecessary redundancy and makes the database readily updatable, while allowing the user to exploit different hierarchical access paths.
- The MultiX proposal (Chatti et al. (2007)), which represents documents as directed graphs. Because XML is used to represent the graph, the document is, at least in principle, manipulable with standard XML tools.
- The Just-In-Time-Trees proposal (Durusau and O’Donnell (2002)), which stores documents using XML, but processes the XML representation in non-standard ways and allows it to be mapped onto data structures that are different from those known from XML.
- The Layered Markup and Annotation Language (LMNL) proposal. This offers alternatives to the basic XML linear form as well as its data and processing models. It uses an alternative notation to XML and a data structure based on Core Range Algebra (Tennison and Piez (2002)).
- Markup Languages for Complex Documents (MLCD). This provides a notation (TexMECS) and a data structure

(Goddag) as well as a draft constraint language for the representation of non-hierarchical structures; see Huitfeldt and Sperberg-McQueen (2001).

These approaches are based either on non-standard XML processing or data models, or not based on XML at all. Since TEI is currently based on XML they are not described any further in these Guidelines. Use of these methods with the TEI will certainly involve extensions; in most cases the documents will also be non-conformant.

## 21 Certainty, Precision, and Responsibility

Encoders of text often find it useful to indicate that some aspects of the encoded text are problematic or uncertain, and to indicate who is responsible for various aspects of the markup of the electronic text. These Guidelines provide several methods of recording uncertainty about the text or its markup:

- the `<note>` element defined in section 3.8. *Notes, Annotation, and Indexing* may be used with a value of certainty for its *type* attribute.
- the `<certainty>` element defined in this chapter may be used to record the nature and degree of the uncertainty in a more structured way.
- the `<precision>` element defined in this chapter may be used to record the accuracy with which some numerical value (such as a date or quantity) is provided by some other element or attribute.
- the `<alt>` element defined in the module for linking and segmentation may be used to provide alternative encodings for parts of a text, as described in section 16.8. *Alternation*.

There are three methods of indicating responsibility for different aspects of the electronic text:

- the TEI header records who is responsible for an electronic text by means of the `<respStmt>` element and other more specific elements (`<author>`, `<sponsor>`, `<funder>`, `<principal>`, etc.) used within the `<titleStmt>`, `<editionStmt>`, and `<revisionDesc>` elements.
- the `<note>` element may be used with a value of `resp` or `responsibility` in its *type* attribute.
- the `<respons>` element defined in this chapter may be used to record fine-grained structured information about responsibility for individual tags in the text.

No special steps are needed to use the `<note>` and `<respStmt>` elements, since they are defined in the core module and header respectively. The `<alt>` element is only available when the module for linking has been selected, as described in chapter 16. *Linking, Segmentation, and Alignment*. To use the `<certainty>`, `<precision>` or `<respons>` elements, the module for certainty and responsibility must be selected.

These three elements are all members of an attribute class called `att.scoping` from which they inherit the following attributes:

**att.scoping** provides attributes for selecting particular elements within a document.

`@target` points at one or several elements or sets of elements by means of one or more data pointers, using the URI syntax.

`@match` supplies an arbitrary XPath expression using the syntax defined in Kay (ed.) (2007) which identifies a set of nodes, selected within the context identified by the *target* attribute if this is supplied, or within the context of the parent element if it is not.

These attributes enable statements about certainty, precision, or responsibility to be made with respect to the whole of a document, or any part or parts of it which can be identified using standard XML location methods. Several examples are given in the discussion of the `<certainty>` element below; the same mechanisms are available for all three elements discussed in this chapter.

### 21.1 Levels of Certainty

Many types of uncertainty may be distinguished. The `<certainty>` element is designed to encode the following sorts:

- a given tag may or may not correctly apply (e.g. a given word may be a personal name, or perhaps not)
- the precise point at which an element begins or ends is uncertain
- the value given for an attribute is uncertain
- the content given for an element is unreliable for any reason.

The following types of uncertainty are *not* indicated with the `<certainty>` element:

- the numerical precision associated with a number or date (for this use the `<precision>` element discussed in 21.2. *Indications of Precision*)
- the content of the document being transcribed is identifiable, but may be read or understood in different ways (for this use the transcriptional elements such as `<unclear>`, discussed in chapter 11. *Representation of Primary Sources*)

- a transcriber, editor, or author wishes to indicate a level of confidence in a factual assertion made in the text (for this use the interpretative mechanisms discussed in 17. *Simple Analytic Mechanisms* and 18. *Feature Structures*)

### 21.1.1 Using Notes to Record Uncertainty

The simplest way of recording uncertainty about markup is to attach a note to the element or location about which one is unsure. In the following (invented) paragraph, for example, an encoder might be uncertain whether to mark ‘Essex’ as a place name or a personal name, since both might be plausible in the given context:

Elizabeth went to Essex. She had always liked Essex.

Using `<note>`, the uncertainty here may be recorded quite simply:

```
<persName>Elizabeth</persName> went to <placeName>Essex</placeName>. She had always
liked <placeName>Essex</placeName>.
<note type="certainty" resp="#MSM">It is not
clear here whether <mentioned>Essex</mentioned>
refers to the place or to the nobleman. -MSM</note>
```

Using the normal mechanisms, the note may be associated unambiguously with specific elements of the text, thus:

```
<persName>Elizabeth</persName> went to <placeName xml:id="CE-pla">Essex</placeName>.
She had always liked <placeName xml:id="CE-plb">Essex</placeName>.
<note type="certainty" resp="#MSM"
target="#CE-pla #CE-plb">It
is not clear here whether <mentioned>Essex</mentioned>
refers to the place or to the nobleman. If the latter,
it should be tagged as a personal name. -<name xml:id="MSM">Michael</name>
</note>
```

The advantage of this technique is its relative simplicity. Its disadvantage is that the nature and degree of uncertainty are not conveyed in any systematic way and thus are not susceptible to any sort of automatic processing.

### 21.1.2 Structured Indications of Uncertainty

To record uncertainty in a more structured way, susceptible of at least simple automatic processing, the `<certainty>` element may be used:

**<certainty>** indicates the degree of certainty associated with some aspect of the text markup.

**@locus** indicates more exactly the aspect concerning which certainty is being expressed: specifically, whether the markup is correctly located, whether the correct element or attribute name has been used, or whether the content of the element or attribute is correct, etc.

**@degree** indicates the degree of confidence assigned to the aspect of the markup named by the *locus* attribute.

Returning to the example, the `<certainty>` element may be used to record doubts about the proper encoding of ‘Essex’ in several ways of varying precision. To record merely that we are not certain that ‘Essex’ is in fact a place name, as it is tagged, we use the *target* attribute to identify the element in question, and the *locus* attribute to indicate which aspect of the markup we are uncertain about (in this case, whether we have used the correct ‘name’ for the element used to mark it):

```
Elizabeth went to
<placeName xml:id="CE-pl1">Essex</placeName>.

<!-- ... elsewhere in the document ... -->
<certainty target="#CE-pl1" locus="name">
  <desc>possibly not a placename</desc>
</certainty>
```

There are no particular constraints as to where the `<certainty>` element is placed in a document; it may be placed adjacent to the target element, or elsewhere in the same or another document. Its position is however significant when the *target* attribute is not specified as further discussed below.

We may wish to record the probability, assessed in some subjective way, that ‘Essex’ really is a place name here. The *degree* attribute is used to indicate the degree of confidence associated with the `<certainty>` element, expressed as a number between 0 and 1:

```
<!-- ... --><certainty target="#CE-pl1" locus="name"
  degree="0.6"/>
```

This expresses the point of view that there is a 60 percent chance of ‘Essex’ being a place name here, and hence a 40 percent chance of its being a personal name. We can use two `<certainty>` elements to indicate the two probabilities independently. Both elements indicate the same location in the text, but the second provides an alternative choice of name identifier (in this case `<persName>`), which is given as the value of the *assertedValue* attribute:

```
<!-- ... --><certainty target="#CE-pl1" locus="name"
  degree="0.6">
  <desc>probably a placename, but possibly not</desc>
</certainty>
<certainty target="#CE-pl1" locus="name"
  degree="0.4" assertedValue="persName">
  <desc>may refer to the Earl of Essex</desc>
</certainty>
```

In the simplest case, it is also possible to place the `<certainty>` element within the element concerned:

```
Elizabeth went to
<placeName>Essex
<certainty locus="name" degree="0.6"/>
</placeName>.
```

When no *target* is specified, by default the proposed certainty applies to its parent element, in this case the `<placeName>` element. The *match* attribute discussed below may be used to further vary this behaviour.

### 21.1.2.1 Contingent Conditions

Finally, we may wish to make our probability estimates contingent on some condition. In the passage ‘Elizabeth went to Essex; she had always liked Essex,’ for example, we may feel there is a 60 percent chance that the county is meant, and a 40 percent chance that the earl is meant. But the two occurrences of the word are not independent: there is (we may feel) no chance at all that the first occurrence refers to the county and the second to the earl. We can express this by using the *given* attribute to list the identifiers of `<certainty>` elements.

```
Elizabeth went to <placeName xml:id="CE-PL1">Essex</placeName>.
She had always liked <placeName xml:id="CE-PL2">Essex</placeName>.
```

```
<!-- ... -->
<!-- 60% chance that P1 is a placename,
40% chance a personal name. -->
<certainty xml:id="cert-1" target="#CE-PL1"
  locus="name" degree="0.6">
  <desc>probably a placename, but possibly not</desc>
</certainty>
```

```

<certainty xml:id="cert-2" target="#CE-PL1"
  locus="name" assertedValue="persName" degree="0.4">
  <desc>may refer to the Earl of Essex</desc>
</certainty>
<!-- 60% chance that P2 is a placename,
40% chance a personal name.
100% chance that it agrees with P1. -->
<certainty target="#CE-PL2" locus="name"
  given="#cert-1" degree="1.0">
  <desc>if CE-PL1 is a placename, CE-PL2 certainly is</desc>
</certainty>
<certainty target="#CE-PL2" locus="name"
  assertedValue="persName" degree="1.0" given="#cert-2">
  <desc>if CE-PL1 is a personal name, then so is CE-PL2</desc>
</certainty>

```

When *given* conditions are listed, the <certainty> element is interpreted as claiming a given degree of confidence in a particular markup given the assertional content of the <certainty> elements indicated. That is, a conjectural assertion is being made solely on the assumption that the interpretation indicated by the element named by the *given* attribute is actually correct.

Conditional confidence may be less than 100 percent: given the sentence ‘Ernest went to old Saybrook’, we may interpret ‘Saybrook’ as a personal name or a place name, assigning a 60 percent probability to the former. If it is a place name, there may be a 50 percent chance that the place name actually in question is ‘Old Saybrook’ rather than ‘Saybrook’, while if it is correctly tagged as a personal name, it is much more likely (say, 90 percent certain) that the name is ‘Saybrook’. Hence there is uncertainty about the correct location for the markup as well as about which markup to use. This state of affairs can be expressed using the <certainty> element thus:

```

Ernest went to <anchor xml:id="CE-a1"/> old <persName xml:id="CE-
p2">Saybrook</persName>.

<certainty xml:id="cert1" target="#CE-p2"
  locus="name" degree="0.6"/>
<certainty target="#CE-p2" locus="start"
  given="#cert1" degree="0.9"/>
<certainty xml:id="cert2" target="#CE-p2"
  locus="name" assertedValue="placeName" degree="0.4"/>
<certainty target="#CE-p2" locus="start"
  given="#cert2" degree="0.5"/>
<certainty xml:id="cert3" target="#CE-p2"
  locus="start" assertedValue="#CE-a1" given="#cert1"
  degree="0.1"/>
<certainty xml:id="cert4" target="#CE-p2"
  locus="start" assertedValue="#CE-a1" given="#cert2"
  degree="0.5"/>

```

Note the use of the *assertedValue* on <certainty> elements cert3 and cert4 to reference the <anchor> element placed at the alternative starting point for the element.

Multiplying the numeric values out, this markup may be interpreted as assigning specific probabilities to three different ways of marking up the sentence:

```

Ernest went to old <persName>Saybrook</persName>. (0.6 * 0.9, or 0.54)
Ernest went to old <placeName>Saybrook</placeName>. (0.4 * 0.5, or 0.20)
Ernest went to <placeName>old Saybrook</placeName>. (0.4 * 0.5, or 0.20)

```

The probabilities do not add up to 1.00 because the markup indicates that if ‘Saybrook’ is (part of) a personal name, there is a 10 percent likelihood that the element should start somewhere other than the place indicated, without however giving an alternative location; there is thus a 6 percent chance ( $0.1 \times 0.6$ ) that none of the alternatives given is correct.

### 21.1.2.2 Pervasive Conditions

We may also wish to indicate confidence in some aspect of the tagging throughout a document, rather than (as discussed so far) in one particular instance. The *match* attribute may be used to supply a pattern identifying the portion of a document concerning which certainty is being expressed. The value of the *match* attribute is an XPath expression using the syntax defined in Kay (ed.) (2007). In the following example, we wish to indicate a low degree of confidence that the `<persName>` elements used throughout the whole document have been correctly applied:

```
<certainty locus="name" degree="0.3"
  match="//persName"/>
```

No *target* has been supplied here, and so by default the `<certainty>` expressed would therefore apply to the parent element. However, in this case the XPath supplied as the value for *match* returns a set of all the `<persName>` elements in the document, independent of the current context. By contrast, in the following example

```
<div>
  <p>[...]</p>
</div>
<div>
  <certainty locus="name" degree="0.3"
    match=" ./persName"/>
</div>
```

only the `<persName>` elements within the second `<div>` element are in question. Similarly, we may indicate that we have more confidence in the `<persName>` tagging within those `<div>` elements which have a *type* value of `checked`:

```
<certainty locus="name" degree="0.7"
  match="//div[@type='checked']//persName"/>
```

If an element in a document is matched by more than one match expression, then the most specific pattern applies.

<sup>121</sup> As a simple case, if both the preceding `<certainty>` elements were present in the same document, a `<persName>` occurring within a `<div type="checked">` element would potentially match both pattern expressions. However because the second pattern is more specific than the former, in fact this is the only one that would apply. If multiple patterns match and have the same priority, then the first one (in document order) is applied. Only those statements of certainty which have matched in this sense are available for conditional application using the *given* attribute mentioned above.

When the *match* attribute is processed, the namespace bindings in force are those in effect at that point in the document. For example,

```
<div>
<!-- ... -->
  <certainty match="//my:*" locus="value"
    degree="0.9"/>
</div>
```

might be used to indicate a high degree of certainty about the content of any elements taken the namespace associated with the prefix `my`. This namespace prefix must be associated with an appropriate namespace definition, either on the `<certainty>` element itself, or on one of its ancestor elements.

<sup>121</sup>Specificity of pattern matching is defined further in the XSLT2 reference cited above (see <http://www.w3.org/TR/xslt20/#conflict>)

### 21.1.2.3 Content Uncertainty

Doubts about whether the content of an element is correct may also be expressed by assigning to *locus* the value *value*. For example, if the source is hard to read and so the transcription is uncertain:

```
I have a <emph xml:id="CE-p3">bun</emph>.
<certainty target="#CE-p3" locus="value"
  degree="0.5"/>
```

Degrees of confidence in the proper expansion of abbreviations may also be expressed, as in the following example:

```
You will want to use
<choice>
  <expan xml:id="CE-e1">Standard
    Generalized Markup Language</expan>
  <expan xml:id="CE-e40">Some Grandiose Methodology for Losers</expan>
  <abbr>SGML</abbr>
</choice> ...

<!-- ... -->
<certainty target="#CE-e1" locus="value"
  degree="0.9"/>
<certainty target="#CE-e40" locus="value"
  degree="0.5"/>
```

The *assertedValue* attribute should be used to provide an alternative value for whatever aspect of the markup is in doubt: an alternative name, or the identifier of an alternative starting or ending point, as already shown, an alternative attribute value, or alternative element content, as in this example:

```
I have a <emph xml:id="CE-P3">bun</emph>.
<certainty target="#CE-P3" locus="value"
  assertedValue="gun" degree="0.8">
  <desc>a gun makes more sense in a holdup</desc>
</certainty>
```

Since attribute values have no internal substructure, the *assertedValue* attribute is not generally useful for specifying alternative transcriptions; it cannot for example be used if the alternative reading contains markup of any kind. More robust methods of handling uncertainties of transcription are the `<unclear>` element and the `<app>` and `<rdg>` elements described in chapter 12. *Critical Apparatus*. The `<certainty>` element allows for indications of uncertainty to be structured with at least as much detail and clarity as appears to be currently required in most ongoing text projects.

### 21.1.2.4 Target or Match?

As noted in 16. *Linking, Segmentation, and Alignment*, the *target* attribute may take any general data.pointer as values and may thus also contain an XPath expression of arbitrary complexity. Because full support for XPath is not provided by current processors, it is not generally recommended TEI practice. There are however some simple cases in which XPath syntax is to be preferred, notably those in which the *xml:id* attribute is used to identify a single element occurrence. The usage #A (to indicate the element whose *xml:id* attribute has the value A) is syntactically much simpler than the equivalent xpath2 expression `//*[@xml:id='A']` and is hence preferred throughout these guidelines.

For similar reasons, the `<certainty>` element may specify both a *target* value (expressed as an URI) and a *match* value (expressed as an XPath). The former defines the context within which the latter is to be evaluated. As previously

noted, if no value is supplied for *target*, the context within which the value of *match* should be evaluated is the parent element of the `<certainty>` element itself.

A typical case where it may be convenient to specify both *target* and *match* is that where we wish to indicate that the value of an attribute on some specific element is uncertain. In this case, the *locus* attribute takes the value `value`. For example, supposing there is only a 50 percent chance that the question was spoken by participant A:

```
<u xml:id="CE-u1" who="#A">Have you heard the election results?</u>
<certainty target="#CE-u1" match="@who"
  locus="value" degree="0.5"/>
```

or, equivalently and without the need to define a target,

```
<u who="#A">Have you heard the election results?<certainty match="@who" locus="value"
  degree="0.5"/>
</u>
```

The *match* and *target* attributes together provide a powerful mechanism which can be used to indicate precision for a large number of assertions throughout an encoded document in an economical way. Some further examples follow:

```
<certainty match="//p" locus="location"
  degree="0.2"/>
```

This encoding indicates that there is only a 0.2 certainty that the boundaries of all `<p>` elements in the document have been correctly identified.

```
<certainty target="#a101" match="p"
  locus="location" degree="0.2"/>
```

This encoding indicates that there is only a 0.2 certainty that the boundaries of the `<p>` elements contained by the element with *xml:id* value `a101` have been correctly identified.

```
<persName resp="#LB">Essex
<certainty match="@resp" locus="value"
  degree="0.2"/>
</persName>
```

This encoding indicates that there is only a 0.2 certainty that the value for the *resp* attribute on the given `<persName>` element is correct.

```
<certainty match="//*/@resp" locus="value"
  degree="0.2"/>
```

This encoding indicates that there is only a 0.2 certainty that any value for the *resp* attribute is correct, wherever it appears in the document.

```
<certainty target="#dd001" match="@resp"
  locus="value" degree="0.2"/>
```

This encoding indicates that there is only a 0.2 certainty that the value for the *resp* attribute of the element indicated by the pointer #dd001 is correct

```
<certainty match="//*[@resp='#LB']"
  locus="value" degree="0.2"/>
```

This encoding indicates that there is only a 0.2 certainty that the content of any element the *resp* attribute of which has the value #LB is correct, wherever it appears in the document.

The <certainty> element and the other TEI mechanisms for indicating uncertainty provide a range of methods of graduated complexity. Simple expressions of uncertainty may be made by using the <note> element. This is simple and convenient, and can accommodate either a discursive and unstructured indication of uncertainty, or a complex and structured but probably project-specific expression of uncertainty. In general, however, unless special steps are taken, the <note> element does not provide as much expressive power as the <certainty> element, and in cases where highly structured certainty information must be given, it is recommended that the <certainty> element be preferred.

## 21.2 Indications of Precision

As noted above, certainty about the accuracy of an encoding or its content is not the same thing as the *precision* with which a value is specified. In the case of a date or a quantity, for example, we might be certain that the value given is imprecise, or uncertain about whether or not the value given is correct. The latter possibility would be represented by the <certainty> element discussed in the previous section; the former by the <precision> element discussed in this section.

The elements concerning which statements of precision are to be made are identified using the same *target* and *match* attributes inherited from the `att.scoping` class discussed in the previous section and in the same way.

Other aspects are provided by other attributes as further discussed below.

**<precision>** indicates the numerical accuracy or precision associated with some aspect of the text markup.

*@precision* characterizes the precision of the element or attribute pointed to by the <precision> element.

*@stdDeviation* supplies a standard deviation associated with the value in question

In 3.5.3. *Numbers and Measures* several ways of indicating ranges of values were introduced. For example, if we know that a date falls between 1930 and 1935, without being certain exactly where, this fact may be encoded using attributes *notBefore* and *notAfter*, as in the following example:

```
<date notBefore="1930" notAfter="1935">Early in the 1930s</date>...
```

Equally, if we know that every page of a manuscript has a width of at least 10 cm but no more than 30, we can use the attributes *atLeast* and *atMost*, as in the following examples:

```
<width atLeast="10" atMost="30" unit="cm"
  scope="all"/>
```

Suppose however that the precision with which the value of such an attribute can be specified is variable. For example, suppose an event is dated ‘about fifty years after the death of Augustus’. In this case, the precision of one end of the range (the death of Augustus) is higher than the other, assuming we know when Augustus died. We can say that the latest possible date is probably 50 years after that, but with less confidence than we can attach to the earliest possible date.

The <precision> element allows us to indicate the two attributes concerned and attach different levels of precision to them, using a similar mechanism as that provided for the <certainty> element:

```
<date xml:id="d001" notBefore="0014"
  notAfter="0064">About 50
years after the death of Augustus</date>
<precision target="#d001" match="@notAfter"
  precision="low"/>
<precision target="#d001"
  match="@notBefore" precision="high"/>
```

In much the same way, we may wish to indicate different levels of precision about the dating of either end of a historical period. For example, the elements defined for encoding personal data all bear a similar set of attributes to indicate normalized values for earliest or latest dates, etc. (see section 13.1.2. *Dating Attributes*); the precision of these attribute values may be indicated in exactly the same way. For example,

```
<residence from="1857-03-01"
  notAfter="1857-04-30">From the 1st of March to
some time in April of 1857.
<precision match="@notAfter"
  precision="medium"/>
</residence>
```

It may also be useful to indicate that the precisions given for minimum and maximum quanta differ. For example, to indicate that all pages measure at least 10 cm wide, and at most *about* 30:

```
<width xml:id="w00t" atLeast="10"
  atMost="30" unit="cm" scope="all"/>
<precision target="#w00t" match="@atMost"
  precision="low"/>
```

The *stdDeviation* attribute may be used to indicate the standard deviation for a range of values. The generic `<dim>` element introduced in 10.3.4. *Dimensions* might be used to record the average number of characters per line in a typescript. If in addition we wish to record the standard deviation for the values summarized by that average, this would require an additional `<precision>` element, as in the following example:

```
<dim xml:id="dim1" type="avgLineLength"
  unit="chars" quantity="62.4"/>
<precision target="#dim1" stdDeviation="4"/>
```

## 21.3 Attribution of Responsibility

In general, attribution of responsibility for the transcription and markup of an electronic text is made by `<respStmt>` elements within the header: specifically, within the title statement, the edition statement(s), and the revision history.

In some cases, however, more detailed element-by-element information may be desired. For example, an encoder may wish to distinguish between the individuals responsible for transcribing the content and those responsible for determining that a given word or phrase constitutes a proper noun. Where such fine-grained attribution of responsibility is required, the `<respons>` element can be used.

**<respons>** (responsibility) identifies the individual(s) responsible for some aspect of the content or markup of particular element(s).

*@locus* indicates the specific aspect of the encoding (markup or content) for which responsibility is being assigned.

This element allows one or more aspects of the markup to be attributed to a given individual. This element inherits the *target* and *match* attributes from the `att.scoping` class, in the same way as the `<certainty>` and

<precision> elements. Its *locus* attribute functions in the same way as that on the <certainty> element (see 21.1. *Levels of Certainty*). It inherits the *resp* and *cert* attributes from the `att.global.responsibility` class.

For example, the following encoding indicates that RC is responsible for transcribing an illegible word, and that PMWR is responsible for identifying that word as a proper noun, i.e. deciding to mark it with the <persName> element at the location indicated:

```
Ernest went to old
<persName xml:id="CE-p5" rend="it">Saybrook</persName>.

<!-- ... -->
<respons target="#CE-p5" locus="value"
  resp="#RC"/>
<respons target="#CE-p5"
  locus="name location" resp="#PMWR"/>
<list type="encoders">
  <item xml:id="PMWR"/>
  <item xml:id="RC"/>
</list>
```

Similarly, in the following example, we indicate that RC is responsible for proposing the value of the *rend* attribute:

```
<respons target="#CE-p5" match="@rend"
  locus="value" resp="#RC"/>
```

## 21.4 The Certainty Module

The module described in this chapter makes available the following additional elements:

**Module certainty: Certainty and uncertainty**

- *Elements defined:* certainty precision respons

The selection and combination of modules to form a TEI schema is described in 1.2. *Defining a TEI Schema*.

## 22 Documentation Elements

This chapter describes a module which may be used for the documentation of the XML elements and element classes which make up any markup scheme, in particular that described by the TEI Guidelines, and also for the automatic generation of schemas or DTDs conforming to that documentation. It should be used also by those wishing to customize or modify these Guidelines in a conformant manner, as further described in chapters 23.3. *Personalization and Customization* and 23.4. *Conformance* and may also be useful in the documentation of any other comparable encoding scheme, even though it contains some aspects which are specific to the TEI and may not be generally applicable.

An overview of the kind of processing environment envisaged for the module described by this chapter may be helpful. In the remainder of this chapter we refer to software which provides such a processing environment as an *ODD processor*.<sup>122</sup> Like any other piece of XML software, an ODD processor may be instantiated in many ways: the current system uses a number of XSLT stylesheets which are freely available from the TEI, but this specification makes no particular assumptions about the tools which will be used to provide an ODD processing environment.

As the name suggests, an ODD processor uses a single XML document to generate multiple outputs. These outputs will include:

- formal reference documentation for elements, attributes, element classes, patterns, etc. such as those provided in *Appendix C Elements* below;
- detailed descriptive documentation, embedding some parts of the formal reference documentation, such as the tag description lists provided in this and other chapters of these Guidelines;
- declarative code for one or more XML schema languages, such as RELAX NG, W3C Schema, ISO Schematron, or DTD.

The input required to generate these outputs consists of running prose, and special purpose elements documenting the components (elements, classes, etc.) which are to be declared in the chosen schema language. All of this input is encoded in XML using elements defined in this chapter. In order to support more than one schema language, these elements constitute a comparatively high-level model which can then be mapped by an ODD processor to the specific constructs appropriate for the schema language in use. Although some modern schema languages such as RELAX NG or W3C Schema natively support self-documentary features of this kind, we have chosen to retain the ODD model, if only for reasons of compatibility with earlier versions of these Guidelines. For reasons of backwards compatibility, the ISO standard XML schema language RELAX NG (<http://www.relaxng.org>) may be used as a means of declaring content models and datatypes, but it is also possible to express content models using natively TEI XML constructs. We also use the ISO Schematron language to define additional constraints beyond those expressed in the content model, as further discussed in 22.5.3. *Additional Constraints* below.

In the TEI system, a *schema* is built by combining element and attribute declarations, more or less as required. Each element is documented by an appropriate *specification element* and has an identifier unique across the whole TEI scheme. For convenience, these specifications are grouped into a number of discrete *modules*, which can also be combined more or less as required. Each major chapter of these Guidelines defines a distinct module. Each module declares a number of *elements* specific to that module, and may also populate particular *classes*. All classes are available globally, irrespective of the module in which they are declared; particular modules extend the meaning of a class by adding elements or attributes to it. Wherever possible, element content models are defined in terms of classes rather than in terms of specific elements. Modules can also declare particular *patterns*, which act as short-cuts for commonly used content models or class references.

In the present chapter, we discuss the components needed to support this system. In addition, section 22.1. *Phrase Level Documentary Elements* discusses some general purpose elements which may be useful in any kind of technical documentation, wherever there is need to talk about technical features of an XML encoding such as element names and attributes. Section 22.2. *Modules and Schemas* discusses the elements which are used to document XML *modules* and their high-level components. Section 22.3. *Specification Elements* discusses the elements which document XML elements and their attributes, element classes, and generic patterns or macros. Finally, section 22.9. *Module for Documentation Elements* provides a summary overview of the elements provided by this module.

---

<sup>122</sup>ODD is short for ‘One Document Does it all’, and was the name invented by the original TEI Editors for the predecessor of the system currently used for this purpose. See further Burnard and Sperberg-McQueen (1995) and Burnard and Rahtz (2004).

## 22.1 Phrase Level Documentary Elements

### 22.1.1 Phrase Level Terms

In any kind of technical documentation, the following phrase-level elements may be found useful for marking up strings of text which need to be distinguished from the running text because they come from some formal language:

**<code>** contains literal code from some formal language such as a programming language.  
*@lang* (formal language) a name identifying the formal language in which the code is expressed

**<ident>** (identifier) contains an identifier or name for an object of some kind in a formal language. **<ident>** is used for tokens such as variable names, class names, type names, function names etc. in formal programming languages.

Like other phrase-level elements used to indicate the semantics of a typographically distinct string, these are members of the `model.emphLike` class. They are available anywhere that running prose is permitted when the module defined by this chapter is included in a schema.

The **<code>** and **<ident>** elements are intended for use when citing brief passages in some formal language such as a programming language, as in the following example:

```
<p>If the variable <ident>z</ident> has a value of zero, a statement such as <code>x=y/z</code> will usually cause a fatal error.</p>
```

If the cited phrase is a mathematical or chemical formula, the more specific **<formula>** element defined by the `figures` module (*14.2. Formulæ and Mathematical Expressions*) may be more appropriate.

A further group of similar phrase-level elements is also defined for the special case of representing parts of an XML document:

**<att>** (attribute) contains the name of an attribute appearing within running text.

**<gi>** (element name) contains the name (generic identifier) of an element.

**<tag>** contains text of a complete start- or end-tag, possibly including attribute specifications, but excluding the opening and closing markup delimiter characters.

**<val>** (value) contains a single attribute value.

These elements constitute the `model.phrase.xml` class, which is also a subclass of `model.phrase`. They are also available anywhere that running prose is permitted when the module defined by this chapter is included in a schema.

As an example of the recommended use of these elements, we quote from an imaginary TEI working paper:

```
<p>The <gi>gi</gi> element is used to tag element names when they appear in the text; the <gi>tag</gi> element however is used to show how a tag as such might appear. So one might talk of an occurrence of the <gi>blort</gi> element which had been tagged <tag>blort type='runcible'</tag>. The <att>type</att> attribute may take any name token as value; the default value is <val>spqr</val>, in memory of its creator.</p>
```

Within technical documentation, it is also often necessary to provide more extended examples of usage or to present passages of markup for discussion. The following special elements are provided for these purposes:

**<eg>** (example) contains any kind of illustrative example.

**<egXML>** (example of XML) contains a single well-formed XML fragment demonstrating the use of some XML element or attribute, in which the **<egXML>** element itself functions as the root element.

Like the **<code>** element, the **<egXML>** element is used to mark strings of formal code, or passages of XML markup. The **<eg>** element may be used to enclose any kind of example, which will typically be rendered as a distinct block, possibly using particular formatting conventions, when the document is processed. It is a specialized form of the

more general `<q>` element provided by the TEI core module. In documents containing examples of XML markup, the `<egXML>` element should be used for preference, as further discussed below in 22.4.2. *Exemplification of Components*, since the content of this element can be checked for well-formedness.

These elements are added to the class `model.egLike` when this module is included in a schema. That class is a part of the general `model.inter` class, thus permitting `<eg>` or `<egXML>` elements to appear either within or between paragraph-like elements.

### 22.1.2 Element and Attribute Descriptions

Within the body of a document using this module, the following elements may be used to reference parts of the specification elements discussed in section 22.3. *Specification Elements*, in particular the brief prose descriptions these provide for elements and attributes.

**`<specList>`** (specification list) marks where a list of descriptions is to be inserted into the prose documentation.

**`<specDesc>`** (specification description) indicates that a description of the specified element or class should be included at this point within a document.

**`@atts`** (attributes) supplies attribute names for which descriptions should additionally be obtained.

TEI practice recommends that a `<specList>` listing the elements under discussion introduce each subsection of a module's documentation. The source for the present section, for example, begins as follows:

```
<div>
  <head>Element and Attribute Descriptions</head>
  <p>Within the body of a document using this module, the following elements... <specList>
    <specDesc key="specList"/>
    <specDesc key="specDesc" atts="atts"/>
  </specList>
</p>
<p>TEI practice recommends that a <gi>specList</gi> listing the elements... </p>
<!-- ... -->
</div>
```

When formatting the `<ptr>` element in this example, an ODD processor might simply generate the section number and title of the section referred to, perhaps additionally inserting a link to the section. In a similar way, when processing the `<specDesc>` elements, an ODD processor may recover relevant details of the elements being specified (`<specList>` and `<specDesc>` in this case) from their associated declaration elements: typically, the details recovered will include a brief description of the element and its attributes. These, and other data, will be stored in a specification element elsewhere within the current document, or they may be supplied by the ODD processor in some other way, for example from a database. For this reason, the link to the required specification element is always made using a TEI-defined key rather than an XML IDREF value. The ODD processor uses this key as a means of accessing the specification element required. There is no requirement that this be performed using the XML ID/IDREF mechanism, but there is an assumption that the identifier be unique.

A `<specDesc>` generates in the documentation the identifier, and also the contents of the `<desc>` child of whatever specification element is indicated by its *key* attribute, as in the example above. Documentation for any attributes specified by the *atts* attribute will also be generated as an associated attribute list.

## 22.2 Modules and Schemas

As mentioned above, the primary purpose of this module is to facilitate the documentation and creation of an XML schema derived from the TEI Guidelines. The following elements are provided for this purpose:

**`<schemaSpec>`** (schema specification) generates a TEI-conformant schema and documentation for it.

**`<moduleSpec>`** (module specification) documents the structure, content, and purpose of a single module, i.e. a named and externally visible group of declarations.

**`<moduleRef>`** (module reference) references a module which is to be incorporated into a schema.

**`@include`** supplies a list of the elements which are to be copied from the specified module into the schema being defined.

*@except* supplies a list of the elements which are not to be copied from the specified module into the schema being defined.

**<specGrp>** (specification group) contains any convenient grouping of specifications for use within the current module.

**<specGrpRef>** (reference to a specification group) indicates that the declarations contained by the **<specGrp>** referenced should be inserted at this point.

**<attRef>** (attribute pointer) points to the definition of an attribute or group of attributes.

**<elementRef>** points to the specification for some element which is to be included in a schema

A *module* is a convenient way of grouping together element and other declarations, and of associating an externally-visible name with the resulting group. A *specification group* performs essentially the same function, but the resulting group is not accessible outside the scope of the ODD document in which it is defined, whereas a module can be accessed by name from any TEI schema specification. Elements, and their attributes, element classes, and patterns are all individually documented using further elements described in section 22.3. *Specification Elements* below; part of that specification includes the name of the module to which the component belongs.

An ODD processor generating XML DTD or schema fragments from a document marked up according to the recommendations of this chapter will generate such fragments for each **<moduleSpec>** element found. For example, the chapter documenting the TEI module for names and dates contains a module specification like the following:

```
<moduleSpec ident="namesdates">
  <altIdent type="FPI">Names and Dates</altIdent>
  <desc>Additional elements for names and dates</desc>
</moduleSpec>
```

together with specifications for all the elements, classes, and patterns which make up that module, expressed using **<elementSpec>**, **<classSpec>**, or **<macroSpec>** elements as appropriate. (These elements are discussed in section 22.3. *Specification Elements* below.) Each of those specifications carries a *module* attribute, the value of which is **namesdates**. An ODD processor encountering the **<moduleSpec>** element above can thus generate a schema fragment for the TEI **namesdates** module that includes declarations for all the elements (etc.) which reference it.

In most realistic applications, it will be desirable to combine more than one module together to form a complete *schema*. A schema consists of references to one or more modules or specification groups, and may also contain explicit declarations or redeclarations of elements (see further 22.8.1. *TEI customizations*). Any combination of modules can be used to create a schema<sup>123</sup>

A schema can combine references to TEI modules with references to other (non-TEI) modules using different namespaces, for example to include mathematical markup expressed using MathML in a TEI document. By default, the effect of combining modules is to allow all of the components declared by the constituent modules to coexist (where this is syntactically possible: where it is not—for example, because of name clashes—a schema cannot be generated). It is also possible to over-ride declarations contained by a module, as further discussed in section 22.8.1. *TEI customizations*

It is often convenient to describe and operate on sets of declarations smaller than the whole, and to document them in a specific order: such collections are called *specGrps* (specification groups). Individual **<specGrp>** elements are identified using the global *xml:id* attribute, and may then be referenced from any point in an ODD document using the **<specGrpRef>** element. This is useful if, for example, it is desired to describe particular groups of elements in a specific sequence. Note however that the order in which element declarations appear within the schema code generated from an ODD file element is not in general affected by the order of declarations within a **<specGrp>**.

An ODD processor will generate a piece of schema code corresponding with the declarations contained by a **<specGrp>** element in the documentation being output, and a cross-reference to such a piece of schema code when processing a **<specGrpRef>**. For example, if the input text reads

```
<p>This module contains three red elements: <specGrp xml:id="RED">
  <elementSpec ident="beetroot">
```

<sup>123</sup>The distinction between base and additional tagsets in earlier versions of the TEI scheme has not been carried forward into P5.

```

<!-- ... -->
  </elementSpec>
  <elementSpec ident="east">
<!-- ... -->
  </elementSpec>
  <elementSpec ident="rose">
<!-- ... -->
  </elementSpec>
  </specGrp> and two blue ones: <specGrp xml:id="BLUE">
  <elementSpec ident="sky">
<!-- ... -->
  </elementSpec>
  <elementSpec ident="bayou">
<!-- ... -->
  </elementSpec>
</specGrp>
</p>

```

then the output documentation will replace the two `<specGrp>` elements above with a representation of the schema code declaring the elements `<beetroot>`, `<east>`, and `<rose>` and that declaring the elements `<sky>` and `<bayou>` respectively. Similarly, if the input text contains elsewhere a passage such as

```

<div>
  <head>An overview of the imaginary module</head>
  <p>The imaginary module contains declarations for coloured things: <specGrpRef tar-
get="#RED"/>
  <specGrpRef target="#BLUE"/>
  </p>
</div>

```

then the `<specGrpRef>` elements may be replaced by an appropriate piece of reference text such as ‘The RED elements were declared in section 4.2 above’, or even by a copy of the relevant declarations. As stated above, the order of declarations within the imaginary module described above will not be affected in any way. Indeed, it is possible that the imaginary module will contain declarations not present in any specification group, or that the specification groups will refer to elements that come from different modules. Specification groups are always local to the document in which they are defined, and cannot be referenced externally (unlike modules).

## 22.3 Specification Elements

The following elements are used to specify elements, classes, patterns, and datatypes:

**<elementSpec>** (element specification) documents the structure, content, and purpose of a single element type.

**<classSpec>** (class specification) contains reference information for a TEI element class; that is a group of elements which appear together in content models, or which share some common attribute, or both.

*@generate* indicates which alternation and sequence instantiations of a model class may be referenced. By default, all variations are permitted.

**<macroSpec>** (macro specification) documents the function and implementation of a pattern.

**<dataSpec>** (datatype specification) documents a datatype.

Unlike most elements in the TEI scheme, each of these ‘specification elements’ has a fairly rigid internal structure consisting of a large number of child elements which are always presented in the same order. Furthermore, since these elements all describe markup objects in broadly similar ways, they have several child elements in common. In the remainder of this chapter, we discuss first the elements which are common to all the specification elements, and then those which are specific to a particular type.

Specification elements may appear at any point in an ODD document, both between and within paragraphs as well as inside a <specGrp> element, but the specification element for any particular component may only appear once (except in the case where a modification is being defined; see further 22.8.1. *TEI customizations*). The order in which they appear will not affect the order in which they are presented within any schema module generated from the document. In documentation mode, however, an ODD processor will output the schema declarations corresponding with a specification element at the point in the text where they are encountered, provided that they are contained by a <specGrp> element, as discussed in the previous section. An ODD processor will also associate all declarations found with the nominated module, thus including them within the schema code generated for that module, and it will also generate a full reference description for the object concerned in a catalogue of markup objects. These latter two actions always occur irrespective of whether or not the declaration is included in a <specGrp>.

## 22.4 Common Elements

This section discusses the child elements common to all of the specification elements; some of these are defined in the core module (3.3.4. *Terms, Glosses, Equivalents, and Descriptions*). These child elements are used to specify the naming, description, exemplification, and classification of the specification elements.

### 22.4.1 Description of Components

**<gloss>** identifies a phrase or word used to provide a gloss or definition for some other word or phrase.

**<desc>** (description) contains a brief description of the object documented by its parent element, including its intended usage, purpose, or application where this is appropriate.

**<equiv>** (equivalent) specifies a component which is considered equivalent to the parent element, either by co-reference, or by external link.

**@uri** (uniform resource identifier) references the underlying concept of which the parent is a representation by means of some external identifier

**@filter** references an external script which contains a method to transform instances of this element to canonical TEI

**@name** a single word which follows the rules defining a legal XML name (see <http://www.w3.org/TR/REC-xml/#dt-name>), naming the underlying concept of which the parent is a representation.

**<altIdent>** (alternate identifier) supplies the recommended XML name for an element, class, attribute, etc. in some language.

**<listRef>** (list of references) supplies a list of significant references to places where this element is discussed, in the current document or elsewhere.

**<remarks>** contains any commentary or discussion about the usage of an element, attribute, class, or entity not otherwise documented within the containing element.

The <gloss> element may be used to provide a brief explanation for the name of the object if this is not self-explanatory. For example, the specification for the element <ab> used to mark arbitrary blocks of text begins as follows:

```
<elementSpec module="linking" ident="ab">
  <gloss>anonymous block</gloss>
  <!--... -->
</elementSpec>
```

A <gloss> may also be supplied for an attribute name or an attribute value in similar circumstances:

```
<valList type="open">
  <valItem ident="susp">
    <gloss>suspension</gloss>
    <desc>the abbreviation provides the first letter(s) of the word or phrase, omitting
```

```

the
    remainder.</desc>
</valItem>
<valItem ident="contr">
  <gloss>contraction</gloss>
  <desc>the abbreviation omits some letter(s) in the middle.</desc>
</valItem>
<!--...-->
</vallist>

```

Note that the `<gloss>` element is needed to explain the significance of the identifier for an item only when this is not apparent, for example because it is abbreviated, as in the above example. It should not be used to provide a full description of the intended meaning (this is the function of the `<desc>` element), nor to comment on equivalent values in other schemes (this is the purpose of the `<equiv>` element), nor to provide alternative versions of the *ident* attribute value in other languages (this is the purpose of the `<altIdent>` element).

The contents of the `<desc>` element provide a brief characterization of the intended function of the object being documented in a form that permits its quotation out of context, as in the following example:

```

<elementSpec module="core" ident="foreign">
<!--... -->
  <desc xml:lang="en"
    versionDate="2007-07-21">identifies a word or phrase as belonging to some
    language other than that of the surrounding text. </desc>
<!--... -->
</elementSpec>

```

By convention, a `<desc>` element begins with a verb such as *contains*, *indicates*, *specifies*, etc. and contains a single clause.

Where specifications are supplied in multiple languages, the elements `<gloss>` and `<desc>` may be repeated as often as needed. Each such description or gloss should carry both an *xml:lang* and a *versionDate* attribute to indicate the language used and the date on which the translated text was last checked against its source.

The `<equiv>` element is used to document equivalencies between the concept represented by this object and the same concept as described in other schemes or ontologies. The *uri* attribute is used to supply a pointer to some location where such external concepts are defined. For example, to indicate that the TEI `<death>` element corresponds to the concept defined by the CIDOC CRM category E69, the declaration for the former might begin as follows:

```

<elementSpec module="namesdates"
  ident="death">
  <equiv name="E69"
    uri="http://cidoc.ics.forth.gr/">
  <desc>
<!--... -->
  </desc>
</elementSpec>

```

The `<equiv>` element may also be used to map newly-defined elements onto existing constructs in the TEI, using the *filter* and *name* attributes to point to an implementation of the mapping. This is useful when a TEI customization (see 23.3. *Personalization and Customization*) defines ‘shortcuts’ for convenience of data entry or markup readability. For example, suppose that in some TEI customization an element `<bo>` has been defined which is conceptually equivalent to the standard markup construct `<hi rend='bold'>`. The following declarations would additionally indicate that instances of the `<bo>` element can be converted to canonical TEI by obtaining a filter from the URI specified, and running the procedure with the name `bold`. The *mimeType* attribute specifies the language (in this case XSL) in which the filter is written:

```
<elementSpec ident="bo"
  ns="http://www.example.com/ns/notTEI">
  <equiv filter="http://www.example.com/equiv-filter.xsl"
    mimeType="text/xsl" name="bold"/>
  <gloss>bold</gloss>
  <desc>contains a sequence of characters rendered in a bold face.</desc>
<!-- ... -->
</elementSpec>
```

The `<altIdent>` element is used to provide an alternative name for an object, for example using a different natural language. Thus, the following might be used to indicate that the `<abbr>` element should be identified using the German word *Abkürzung*:

```
<elementSpec ident="abbr" mode="change">
  <altIdent xml:lang="de">Abkürzung</altIdent>
<!-- ... -->
</elementSpec>
```

In the same way, the following specification for the `<graphic>` element indicates that the attribute *url* may also be referred to using the alternate identifier *href*:

```
<elementSpec ident="graphic" mode="change">
  <attList>
    <attDef mode="change" ident="url">
      <altIdent>href</altIdent>
    </attDef>
  </attList>
<!-- ... -->
</elementSpec>
```

By default, the `<altIdent>` of a component is identical to the value of its *ident* attribute.

The `<remarks>` element contains any additional commentary about how the item concerned may be used, details of implementation-related issues, suggestions for other ways of treating related information etc., as in the following example:

```
<elementSpec module="core" ident="foreign">
<!-- ... -->
  <remarks>
    <p>This element is intended for use only where no other element is available to mark the phrase or words concerned. The global <att>xml:lang</att> attribute should be used in preference to this element where it is intended to mark the language of the whole of some text element.</p>
    <p>The <gi>distinct</gi> element may be used to identify phrases belonging to sublanguages or registers not generally regarded as true languages.</p>
  </remarks>
<!-- ... -->
</elementSpec>
```

A specification element will usually conclude with a list of references, each tagged using the standard `<ptr>` element, and grouped together into a `<listRef>` element: in the case of the `<foreign>` element discussed above, the list is as follows:

```
<listRef>
  <ptr target="#COHQHF"/>
</listRef>
```

where the value COHQF is the identifier of the section in these Guidelines where this element is fully documented.

### 22.4.2 Exemplification of Components

**<exemplum>** groups an example demonstrating the use of an element along with optional paragraphs of commentary.

**<eg>** (example) contains any kind of illustrative example.

**<egXML>** (example of XML) contains a single well-formed XML fragment demonstrating the use of some XML element or attribute, in which the <egXML> element itself functions as the root element.

*@valid* indicates the intended validity of the example with respect to a schema.

*@source [att.source]* provides a pointer to the bibliographical source from which a quotation or citation is drawn.

The <exemplum> element is used to combine a single illustrative example with an optional paragraph of commentary following or preceding it. The illustrative example itself may be marked up using either the <eg> or the <egXML> element.

The *source* attribute may be used on either element to indicate the source from which an example is taken, typically by means of a pointer to an entry in an associated bibliography, as in the following example:

```
<exemplum versionDate="2008-04-06" xml:lang="fr">
  <p>L'element <gi>foreign</gi> s'applique également aux termes considérés étrangers.</p>
  <egXML xmlns="http://www.tei-c.org/ns/Examples" source="#fr-ex-Queneau_Journ">
    <p>Pendant ce temps-là, dans le bureau du rez- de-chaussée, les secrétaires faisaient du
      <foreign xml:lang="en">hulla-hoop</foreign>.</p>
  </egXML>
</exemplum>
```

When, as here, an example contains valid XML markup, the <egXML> element should be used. In such a case, it will clearly be necessary to distinguish the markup within the example from the markup of the document itself. In an XML environment, this is easily done by using a different name space for the content of the <egXML> element. For example:

```
<p>The <gi>term</gi> element may be used
to mark any technical term, thus:
<egXML xmlns="http://www.tei-c.org/ns/Examples">
This <term>recursion</term> is
giving me a headache.</egXML></p>
```

Alternatively, the XML tagging within an example may be 'escaped', either by using entity references to represent the opening angle bracket, or by wrapping the whole example in a CDATA marked section:

```
<p>The <gi>term</gi> element may be used
to mark any technical term, thus:
```

```
<egXML xmlns="http://www.tei-c.org/ns/Examples">
This &lt;term&gt;recursion&lt;/term&gt; is
giving me a headache.</egXML></p>
```

or, equivalently:

```
<p>The <gi>term</gi> element may be used
to mark any technical term, thus:
<egXML xmlns="http://www.tei-c.org/ns/Examples"><![CDATA[
This <term>recursion</term> is
giving me a headache.]]></egXML></p>
```

However, escaping the markup in this way will make it impossible to validate, and should therefore generally be avoided.

If the XML contained in an example is not well-formed then it must either be enclosed in a CDATA marked section, or ‘escaped’ as above: this applies whether the `<eg>` or `<egXML>` is used. The *valid* attribute on `<egXML>` may be used to indicate the XML validity of the example with respect to some schema, as being valid, invalid, or feasiably valid.

The `<egXML>` element should not be used to tag non-XML examples: the general purpose `<eg>` or `<q>` elements should be used for such purposes.

### 22.4.3 Classification of Components

In the TEI scheme elements are assigned to one or more *classes*, which may themselves have subclasses. The following elements are used to indicate class membership:

**<classes>** specifies all the classes of which the documented element or class is a member or subclass.

**<memberOf>** specifies class membership of the documented element or class.

**@key** specifies the identifier for a class of which the documented element or class is a member or subclass

The `<classes>` element appears within either the `<elementSpec>` or `<classSpec>` element. It specifies the classes of which the element or class concerned is a member by means of one or more `<memberOf>` child elements. Each such element references a class by means of its *key* attribute. Classes themselves are defined by the `<classSpec>` element described in section 22.6. *Class Specifications* below.

For example, to show that the element `<gi>` is a member of the class `model.phrase.xml`, the `<elementSpec>` which documents this element contains the following `<classes>` element:

```
<classes>
  <memberOf key="model.phrase.xml"/>
</classes>
```

## 22.5 Element Specifications

The `<elementSpec>` element is used to document an element type, together with its associated attributes. In addition to the elements listed above, it may contain the following subcomponents:

**<content>** (content model) contains the text of a declaration for the schema documented.

**@autoPrefix** controls whether or not pattern names generated in the corresponding Relax NG schema source are automatically prefixed to avoid potential nameclashes.

**<constraintSpec>** (constraint on schema) contains a constraint, expressed in some formal syntax, which cannot be expressed in the structural content model

*@scheme* supplies the name of the language in which the constraints are defined

**<attList>** contains documentation for all the attributes associated with this element, as a series of **<attDef>** elements.

*@org* (organization) specifies whether all the attributes in the list are available (*org*="group") or only one of them (*org*="choice")

**<model>** describes the processing intended for a specified element.

*@behaviour* names the process or function which this processing model uses in order to produce output.

These subcomponents are discussed in the following sections.

### 22.5.1 Defining Content Models

The element **<content>** may have three different kinds of content. It may express a content model directly using the TEI elements discussed in the remainder of this section. Alternatively, it may use a schema language of some kind, as defined by a pattern called **macro.schemaPattern**, which is provided by the module defined in this chapter. This is discussed in section 22.5.2. *RELAX NG Content Models* below. As a third possibility, the legal content for an element may be specified using the **<valList>** element or **<dataRef>** elements, described in 22.5.4. *Attribute List Specification* below.

One or more of the following elements are typically used to define a content model:

**<textNode>** indicates the presence of a text node in a content model

**<elementRef>** points to the specification for some element which is to be included in a schema

**<classRef>** points to the specification for an attribute or model class which is to be included in a schema

**<macroRef>** points to the specification for some pattern which is to be included in a schema

In the simplest case, the **<content>** element may be empty. This implies that the element being specified is also empty.

An element may contain nothing but strings of Unicode characters. This is indicated by supplying the special element **<textNode>** within the **<content>** element.

An **<elementRef>** provides the name of an element which may appear at a certain point in a content model. A **<classRef>** provides the name of a class, members of which may appear at a certain point in content model. A **<macroRef>** provides the name of a predefined macro, the expansion of which may be inserted at a certain point in a content model.

These elements are all members of an attribute class which provides attributes that further modify their significance as follows:

**att.repeatable** supplies attributes for the elements which define component parts of a content model.

*@minOccurs* (minimum number of occurrences) indicates the smallest number of times this component may occur.

*@maxOccurs* (maximum number of occurrences) indicates the largest number of times this component may occur.

*@context* supplies an XPath identifying a context within which this component of a content model must be found

Finally, two wrapper elements are provided to indicate whether the components of a content model form a sequence or an alternation:

**<sequence>** sequence of references

**<alternate>** an alternation of references

Here is a simple example:

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <classRef key="model.gLike"/>
  <textNode/>
```

```
</alternate>
</content>
```

This is the content model for the macro `macro.xText`, which is defined as containing any number (including zero) of elements from the `model.gLike` class mixed in with text.

Here is a more complex example:

```
<content>
  <sequence>
    <elementRef key="fileDesc"/>
    <classRef key="model.teiHeaderPart"
      minOccurs="0" maxOccurs="unbounded" expand="alternate"/>
    <elementRef key="revisionDesc"
      minOccurs="0"/>
  </sequence>
</content>
```

This is the content model for the `<teiHeader>` element, which is defined as a sequence of components, firstly a mandatory `<fileDesc>`, followed by any number (including zero) of elements from the `model.teiHeaderPart` class, and finally an optional `<revisionDesc>` element.

## 22.5.2 RELAX NG Content Models

Alternatively, element content models may be defined using RELAX NG patterns, or by expressions in some other schema language, depending on the value of the `macro.schemaPattern` pattern.

Here is a very simple example

```
<content>
  <rng:text/>
</content>
```

The element within whose specification element this `<content>` element appears will have a content model which is expressed in RELAX NG as `text`, using the RELAX NG namespace. This model will be copied unchanged to the output when RELAX NG schemas are being generated. When an XML DTD is being generated, an equivalent declaration (in this case `#PCDATA`) will be output.

Here is a more complex example:

```
<content>
  <rng:group>
    <rng:ref name="fileDesc"/>
    <rng:zeroOrMore>
      <rng:ref name="model.teiHeaderPart"/>
    </rng:zeroOrMore>
    <rng:optional>
      <rng:ref name="revisionDesc"/>
    </rng:optional>
  </rng:group>
</content>
```

This is the content model for the `<teiHeader>` element, expressed in the RELAX NG syntax, which again is copied unchanged to the output during schema generation. The equivalent DTD notation generated from this is `(fileDesc, (%model.teiHeaderPart;)*, revisionDesc?)`.

The RELAX NG language does not formally distinguish element names, attribute names, class names, or macro names: all names are patterns which are handled in the same way, as the above example shows. Within the TEI scheme, however, different naming conventions are used to distinguish amongst the objects being named. Unqualified names (`fileDesc`, `revisionDesc`) are always element names. Names prefixed with `model.` or `att.` (e.g. `model.teiHeaderPart` and `att.typed`) are always class names. In DTD language, classes are represented by parameter entities (`%model.teiHeaderPart`; in the above example); see further 1. *The TEI Infrastructure*.

The RELAX NG pattern names generated by an ODD processor by default include a special prefix, the default value for which is set using the *prefix* attribute on `<schemaSpec>`. The purpose of this is to ensure that the pattern name generated is uniquely identified as belonging to a particular schema, and thus avoid name clashes. For example, in a RELAX NG schema combining the TEI element `<ident>` with another element called `<ident>` from some other vocabulary, the former will be defined by a pattern called `TEI_ident` rather than simply `ident`. Most of the time, this behaviour is entirely transparent to the user; the one occasion when it is not will be where a content model (expressed using RELAX NG syntax) needs explicitly to reference either the TEI `<ident>` or the other one. In such a situation, the *autoPrefix* attribute on `<content>` may be used. For example, suppose that we wish to define a content model for `<term>` which permits either a TEI `<ident>` or the `<ident>` defined by some other vocabulary. A suitable content model would be generated from the following `<content>` element:

```
<content autoPrefix="false">
  <rng:choice>
    <rng:ref name="TEI_ident"/>
    <rng:ref name="ident"/>
  </rng:choice>
</content>
```

### 22.5.3 Additional Constraints

In addition to the `<content>` element, a set of general `<constraintSpec>` elements can be used to express rules about the validity of an element. Like some other specification elements, they are identifiable (using the *ident* attribute) in order that a TEI customization may override, delete or change them individually. Each `<constraintSpec>` can be expressed in any notation which is found useful; the notation used must be recorded using the *scheme* attribute.

Schematron is an ISO standard (ISO/IEC 19757-3:2006) which defines a simple XML vocabulary for an ‘assertion language’, together with a RELAXNG schema to validate it. The Schematron assertion language provides a powerful way of expressing constraints on the content of any XML document in addition to those provided by other schema languages. Such constraints can be embedded within a TEI schema specification using the methods exemplified in this chapter. An ODD processor will typically process any `<constraintSpec>` elements in a TEI specification whose *scheme* attribute indicates that they are expressed in Schematron to create an ISO-conformant Schematron schema which may be used to validate document instances.

The TEI Guidelines include some additional constraints which are expressed using the ISO Schematron language. A conformant TEI document should respect these constraints, although automatic validation of them may not be possible for all processors. A TEI customization may likewise specify additional constraints using this mechanism. Some examples of what is possible using the Schematron language are given below.

Constraints are generally used to model local rules which may be outside the scope of the target schema language. For example, in earlier versions of these Guidelines several constraints on the usage of the attributes of the TEI element `<relation>` were expressed informally as follows: ‘only one of the attributes *active* and *mutual* may be supplied; the attribute *passive* may be supplied only if the attribute *active* is supplied.’. Few schema language support co-occurrence constraints such as the latter. In the current version of the Guidelines, constraint specifications expressed as Schematron rules have been added, as follows:

```
<constraintSpec ident="reforkeyorname"
  scheme="isoschematron"
  xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <constraint>
```

```

    <s:assert test="@ref or @key or @name">One of the
      attributes 'name', 'ref' or 'key' must be supplied</s:assert>
  </constraint>
</constraintSpec>
<constraintSpec ident="activemutual"
  scheme="isoschematron">
  <constraint>
    <s:report test="@active and @mutual">Only one of the
      attributes @active and @mutual may be supplied</s:report>
  </constraint>
</constraintSpec>
<constraintSpec ident="activepassive"
  scheme="isoschematron">
  <constraint>
    <s:report test="@passive and not(@active)">the
      attribute 'passive' may be supplied only if the attribute 'active' is
      supplied</s:report>
  </constraint>
</constraintSpec>

```

The constraints in the preceding example all related to attributes in the empty namespace, and the schematron rules did not therefore need to define a TEI namespace prefix. The Schematron language `<NS>` element should be used to do this when a constraint needs to refer to a TEI element, as in the following example, which models the constraint that a TEI `<div>` must contain either no subdivisions or at least two of them:

```

<constraintSpec ident="subclauses"
  scheme="isoschematron"
  xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <constraint>
    <s:ns prefix="tei"
      uri="http://www.tei-c.org/ns/1.0"/>
    <s:rule context="tei:div">
      <s:report test="count( tei:div ) eq 1">if it contains any subdivisions, a
        division must contain at least two of them</s:report>
    </s:rule>
  </constraint>
</constraintSpec>

```

Schematron rules are also useful where an application needs to enforce rules on attribute values, as in the following examples which check that various types of `<title>` are provided:

```

<constraintSpec ident="introtitle"
  scheme="isoschematron"
  xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <constraint>
    <s:assert test="tei:fileDesc/tei:titleStmt/tei:title[@type='introductory']"> an in-
      troductory component
      of the title is expected </s:assert>
  </constraint>
</constraintSpec>
<constraintSpec ident="maintitle"
  scheme="isoschematron">
  <constraint>
    <s:assert test="tei:fileDesc/tei:titleStmt/tei:title[@type='main']"> a main title

```

```

must be supplied
  </s:assert>
</constraint>
</constraintSpec>

```

As a further example, Schematron may be used to enforce rules applicable to a TEI document which is going to be rendered into accessible HTML, for example to check that some sort of content is available from which the *alt* attribute of an HTML `<img>` can be created:

```

<constraintSpec ident="alt"
  scheme="isoschematron"
  xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <constraint>
    <s:ns prefix="tei"
      uri="http://www.tei-c.org/ns/1.0"/>
    <s:pattern id="altTags">
      <s:rule context="tei:figure">
        <s:report test="not(tei:figDesc or tei:head)"> You should provide information in
a figure from
          which we can construct an alt attribute in HTML </s:report>
        </s:rule>
      </s:pattern>
    </constraint>
  </constraintSpec>

```

Schematron rules can also be used to enforce other HTML accessibility rules about tables; note here the use of a report and an assertion within one pattern:

```

<constraintSpec ident="tables"
  scheme="isoschematron"
  xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <constraint>
    <s:ns prefix="tei"
      uri="http://www.tei-c.org/ns/1.0"/>
    <s:pattern id="Tables">
      <s:rule context="tei:table">
        <s:assert test="tei:head">A <table> should have a caption, using a <head>
element</s:assert>
        <s:report test="parent::tei:body">Do not use tables to lay out the document
body</s:report>
      </s:rule>
    </s:pattern>
  </constraint>
</constraintSpec>

```

Constraints can be expressed using any convenient language. The following example uses a pattern matching language called SPITBOL to express the requirement that title and author should be different.

```

<constraintSpec ident="local"
  scheme="SPITBOL">
  <constraint> (output = leq(title,author) "title and author cannot be the same")
</constraint>
</constraintSpec>

```

Note that the value of *scheme* is SPITBOL. In order to properly constrain and document the values of *scheme* used in their customization file, a project may wish to create a customization that (among other things) adds and explains this value for use in validating their customization file. Thus using schemes other than those provided for by the TEI (currently schematron and isoschematron) may require somewhat more effort when creating a customization file. Such private schemes will generally be even more problematic on implementation of the constraints themselves, as it may require significant programming work. The TEI only provides this capability for the suggested values.

### 22.5.4 Attribute List Specification

The `<attList>` element is used to document information about a collection of attributes, either within an `<elementSpec>`, or within a `<classSpec>`. An attribute list can be organized either as a group of attribute definitions, all of which are understood to be available, or as a choice of attribute definitions, of which only one is understood to be available. An attribute list may thus contain nested attribute lists.

The attribute *org* is used to indicate whether its child `<attDef>` elements are all to be made available, or whether only one of them may be used. For example, the attribute list for the element `<moduleRef>` contains a nested attribute list to indicate that either the *include* or the *except* attribute may be supplied, but not both:

```
<attList>
<!-- other attribute definitions here -->
  <attList org="choice">
    <attDef ident="include">
<!-- definition for the include attribute -->
    </attDef>
    <attDef ident="except">
<!-- definition for the except attribute -->
    </attDef>
  </attList>
</attList>
```

The `<attDef>` element is used to document a single attribute, using an appropriate selection from the common elements already mentioned and the following :

**<attDef>** (attribute definition) contains the definition of a single attribute.

*@usage* specifies the optionality of the attribute.

**<datatype>** specifies the declared value for an attribute, by referring to any datatype defined by the chosen schema language.

*@minOccurs* (minimum number of occurrences) indicates the minimum number of times this datatype may occur in the specification of the attribute being defined

*@maxOccurs* (maximum number of occurrences) indicates the maximum number of times this datatype may occur in the specification of the attribute being defined

**<dataRef>** identifies the datatype of an attribute value, either by referencing an item in an externally defined datatype library, or by pointing to a TEI-defined data specification

**<defaultVal>** (default value) specifies the default declared value for an attribute.

**<valDesc>** (value description) specifies any semantic or syntactic constraint on the value that an attribute may take, additional to the information carried by the `<datatype>` element.

**<valList>** (value list) contains one or more `<valItem>` elements defining possible values.

**<valItem>** documents a single value in a predefined list of values.

The `<attList>` within an `<elementSpec>` is used to specify only the attributes which are specific to that particular element. Instances of the element may carry other attributes which are declared by the classes of which the element is a member. These extra attributes, which are shared by other elements, or by all elements, are specified by an `<attList>` contained within a `<classSpec>` element, as described in section 22.6. *Class Specifications* below.

#### 22.5.4.1 Datatypes

The 'datatype' (i.e. the kind of value) for an attribute may be specified using the elements `<datatype>` and `<dataRef>`. A datatype may be defined in any of the following three ways:

- by reference to an existing TEI datatype definition;
- by use of its name in the widely used schema datatype library maintained by the W3C as part of the definition of its schema language;
- by referencing its URI within some other datatype library.

The TEI defines a number of datatypes, each with an identifier beginning `teidata.`, which are used in preference to the datatypes available natively from a target schema such as RELAX NG or W3C Schema since the facilities provided by different schema languages vary so widely. The TEI datatypes available are described in section DTYPES above. Note that each is, of necessity, mapped eventually to an externally defined datatype such as W3C Schema's `text` or `name`, possibly combined to give more expressivity, or constrained to a particular defined usage.

Attributes `minOccurs` and `maxOccurs` are available for the case where an attribute may take more than one value of the type specified. For example, the `target` attribute provided by the `att.pointing` class has the following declaration:

```
<attDef ident="target">
  <desc versionDate="2010-05-02"
    xml:lang="en">specifies the destination of the reference by
    supplying one or more URI References</desc>
  <datatype minOccurs="1"
    maxOccurs="unbounded">
    <dataRef key="teidata.pointer"/>
  </datatype>
</attDef>
```

indicating that the `target` attribute may take any number of values, each being of the same datatype, namely the TEI data specification `teidata.pointer`. As is usual in XML, multiple values for a single attribute are separated by one or more white space characters. Hence, values such as `#a #b #c` or `http://example.org http://www.tei-c.org/index.xml` may be supplied.

#### 22.5.4.2 Value Specification

The `<valDesc>` element may be used to describe constraints on data content in an informal way: for example

```
<valDesc>must point to another <gi>align</gi>
element logically preceding this one.</valDesc>
```

```
<valDesc>Values should be Library of Congress
subject headings.</valDesc>
```

```
<valDesc>A bookseller's surname, taken from the list
in <title>Pollard and Redgrave</title>
</valDesc>
```

Constraints expressed in this way are purely documentary; to enforce them, the `<constraintSpec>` element described in section 22.5.3. *Additional Constraints* must be used. For example, to specify that an imaginary attribute `ageAtDeath` must take positive integer values less than 150, the datatype `teidata.numeric` might be used in combination with a `<constraintSpec>` such as the following:

```

<attDef ident="age"
  xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <desc>age in years at death</desc>
  <datatype>
    <dataRef key="teidata.numeric"/>
  </datatype>
  <constraintSpec ident="lessThan150"
    scheme="isoschematron">
    <constraint>
      <s:assert test=". < 150"> age at death must be
        a number less than 150 </s:assert>
    </constraint>
  </constraintSpec>
</attDef>

```

The elements <altIdent>, <equiv>, <gloss> and <desc> may all be used in the same way as they are elsewhere to describe fully the meaning of a coded value, as in the following example:

```

<valItem ident="dub">
  <altIdent xml:lang="fr">dou</altIdent>
  <equiv name="unknown"/>
  <gloss>dubious</gloss>
  <desc>used when the application of this element is doubtful or uncertain</desc>
</valItem>

```

Where all the possible values for an attribute can be enumerated, the datatype `teidata.enumerated` should be used, together with a <valList> element specifying the values and their significance, as in the following example:

```

<valList type="closed">
  <valItem ident="req">
    <gloss>required</gloss>
  </valItem>
  <valItem ident="rec">
    <gloss>recommended</gloss>
  </valItem>
  <valItem ident="opt">
    <gloss>optional</gloss>
  </valItem>
</valList>

```

Note the use of the <gloss> element here to explain the otherwise less than obvious meaning of the codes used for these values. Since this value list specifies that it is of type closed, only the values enumerated are legal, and an ODD processor will typically enforce these constraints in the schema fragment generated.

The <valList> element can also be used to provide illustrative examples of the kinds of values expected without listing all of them. In such cases the *type* attribute will have the value open, as in the following example:

```

<attDef ident="type" usage="opt">
  <desc versionDate="2005-01-14"
    xml:lang="en">characterizes the movement, for example as an
    entrance or exit.</desc>
  <desc versionDate="2007-12-20"
    xml:lang="ko">□□ □□ □□ □□ □□ □□, □□□ □□□ □□□□.</desc>

```

```

<datatype>
  <dataRef key="teidata.enumerated"/>
</datatype>
<valList type="open">
  <valItem ident="entrance">
    <desc versionDate="2007-06-27"
      xml:lang="en">character is entering the stage.</desc>
    <desc versionDate="2007-12-20"
      xml:lang="ko">□□□□ □□ □□□ □□.</desc>
  </valItem>
  <valItem ident="exit">
    <desc versionDate="2007-06-27"
      xml:lang="en">character is exiting the stage.</desc>
    <desc versionDate="2007-12-20"
      xml:lang="ko">□□□□ □□□ □□□ □□.</desc>
  </valItem>
  <valItem ident="onStage">
    <desc versionDate="2007-07-04"
      xml:lang="en">character moves on stage</desc>
    <desc versionDate="2007-12-20"
      xml:lang="ko">□□□□ □□□ □□□.</desc>
  </valItem>
</valList>
</attDef>

```

The datatype will be `teidata.enumerated` in either case.

The `<valList>` or `<dataRef>` elements may also be used (as a child of the `<content>` element) to put constraints on the permitted content of an element, as noted at 22.5.2. *RELAX NG Content Models*. This use is not however supported by all schema languages, and is therefore not recommended if support for non-RELAX NG systems is a consideration.

### 22.5.5 Processing Models

As far as possible, the TEI defines elements and their attributes in a way which is entirely independent of their subsequent processing, since its intention is to maximize the reusability of encoded documents and their use in multiple contexts. Nevertheless, it can be very useful to specify one or more possible models for such processing, both to clarify the intentions of the encoder, and to provide default behaviours for a software engineer to implement when documents conforming to a particular TEI customization are processed. To that end, the following elements may be used to document one or more *processing models* for a given element.

**<model>** describes the processing intended for a specified element.

**<modelGrp>** any grouping of model or modelSequence elements with a common output method

**<modelSequence>** any sequence of model or modelSequence elements which is to be processed as a single set of actions

One or more of these elements may appear directly within an element specification to define the processing anticipated for that element, more specifically how it should be processed to produce the kind of output indicated by the *output* attribute. Where multiple such elements appear directly within an `<elementSpec>`, they are understood to document mutually exclusive processing models, possibly for different outputs or applicable in different contexts. Alternatively, the `<modelGrp>` element may be used to group alternative `<model>` elements intended for a single kind of output. The `<modelSequence>` element is provided for the case where a sequence of models is to be processed, functioning as a single unit.

A processing model suggests how a given element may be transformed to produce one or more outputs. The model is expressed in terms of *behaviours* and *parameters*, using high-level formatting concepts familiar to software engineers and web designers, such as ‘block’ or ‘inline’. As such, it has a different purpose from existing TEI mechanisms for documenting the appearance of source materials, such as the global attributes *rend*, *rendition* and *style*, described in sections 2.3.4.1. *Rendition* and 3.3.1. *What Is Highlighting?*. It does not necessarily describe anything present in the original source, nor does it necessarily represent its original structure or semantics. A processing

model is a template description, which may be used to simplify the task of producing or customizing the stylesheets needed by a formatting engine or any other form of processor.

### 22.5.5.1 The TEI processing model

The `<model>` element is used to document the processing model intended for a particular element in an abstract manner, independently of its implementation in whatever processing language is chosen. This is achieved by means of the following attributes and elements:

**`<model>`** describes the processing intended for a specified element.

**`@predicate`** the condition under which this model applies, given as an XPath predicate expression.

**`@behaviour`** names the process or function which this processing model uses in order to produce output.

**`@output`** the intended output.

**`@useSourceRendition`** whether to obey any rendition attribute which is present.

**`@cssClass`** the name of a CSS class which should be associated with this element

**`<outputRendition>`** describes the rendering or appearance intended for all occurrences of an element in a specified context for a specified type of output.

**`@scope`** provides a way of defining ‘pseudo-elements’, that is, styling rules applicable to specific sub-portions of an element.

The mandatory *behaviour* attribute defines in broad terms how an element should be processed, for example as a block or as an inline element. The optional *predicate* attribute may be used to specify a subset of contexts in which this model should be applicable: for example, an element might be treated as a block element in some contexts, but not in others. The *output* attribute supplies a name for the output for which this model is intended, for example for screen display, for a printed reading copy, for a scholarly publication, etc. The way in which an element should be rendered is declared independently of its behaviour, using either the attribute *useSourceRendition* or the element `<outputRendition>`. These Guidelines recommend that `<outputRendition>` be expressed using the W3C Cascading Stylesheet Language (CSS), but other possibilities are not excluded. The particular language used may be documented by means of the `<styleDefDecl>` element described in 2.3.5. *The Default Style Definition Language Declaration*.

### 22.5.5.2 Output Rendition

Here is a simple example of a processing model which might be included in the specification for an element such as `<hi>` or `<foreign>`. The intent is that these elements should be presented inline using an italic font.

```
<model behaviour="inline">
  <outputRendition>font-style: italic;</outputRendition>
</model>
```

If the `<rendition>` element, or the attributes *style*, *rend*, or *rendition* have already been used in the source document to indicate elements that were originally rendered in italic, and we wish simply to follow this in our processing, then there is no need to include an `<outputRendition>` element, and the attribute *useSourceRendition* could be used as follows:

```
<model behaviour="inline"
  useSourceRendition="true"/>
```

Any rendition information present in the source document will be ignored unless the *useSourceRendition* attribute has the value true. If that is the case, then such information will be combined with any rendition information supplied by the `<outputRendition>` element. For example, using CSS, an element which appears in the source as follows

```
<hi style="font-weight:bold;">this is in bold</hi>
```

would appear in bold and italic if processed by the following model

```
<model behaviour="inline"
  useSourceRendition="true">
  <outputRendition>font-style: italic;</outputRendition>
</model>
```

### 22.5.5.3 CSS Class

In a typical workflow processing TEI documents for display on the web, a system designer will often wish to use an externally defined CSS stylesheet. The `cssClass` attribute simplifies the task of maintaining compatibility amongst the possibly many applications using such a stylesheet and also enables a TEI application to specify the names of classes to be used for particular processing models. For example, supposing that the associated CSS stylesheet includes a CSS class called `labeled-list`, the following processing model might be used to request it be used for `<list>` elements containing a child `<label>` element:

```
<elementSpec ident="list" mode="change">
  <model predicate="label" behaviour="list"
    cssClass="labeled-list">
  <!-- ... -->
  </model>
</elementSpec>
```

In the following example, a table will be formatted using renditional information provided in the source if that is available, or by an external stylesheet, using one of the CSS classes specified, if it is not:

```
<elementSpec mode="change" ident="table">
  <!-- Preserve original rendition for tables which contain @rendition hints -->
  <model predicate="//row/@rendition or //cell/@rendition"
    behaviour="table" useSourceRendition="true"/>
  <!-- Use bootstrap for default table styling -->
  <model behaviour="table"
    useSourceRendition="true"
    cssClass="table table-hover table-bordered"/>
</elementSpec>
```

As discussed further below, the input data available to a processing model is by default the content of the element being processed, together with its child nodes.

### 22.5.5.4 Model Contexts and Outputs

Sometimes different processing models are required for the same element in different contexts. For example, we may wish to process the `<quote>` element as an inline italic element when it appears inside a `<p>` element, but as an indented block when it appears elsewhere. To achieve this, we need to change the specification for the `<quote>` element to include two `<model>` elements as follows:

```
<elementSpec ident="quote" mode="change">
  <model predicate="ancestor::p"
    behaviour="inline">
    <outputRendition>font-style: italic;</outputRendition>
  </model>
  <model behaviour="block">
    <outputRendition>left-margin: 2em;</outputRendition>
  </model>
</elementSpec>
```

As noted above, these two models are mutually exclusive. The first processing model will be used only for <quote> elements which match the XPath expression given as value for the *predicate* attribute. All other element occurrences will use the second processing model.

When, as here, multiple behaviours are required for the same element, it will often be the case that the appropriate processing will depend on the context. It may however be the case that the choice of an appropriate model will be made on the basis of the intended output. For example, we might wish to define quite different behaviours when a document is to be displayed on a mobile device and when it is to be displayed on a desktop screen. Different behaviours again might be specified for a print version intended for the general reader, and for a print version aimed at the technical specialist.

The <modelGrp> element can be used to group together all the processing models which have in common a particular intended output, as in the following example:

```
<modelGrp output="mobile">
  <model behaviour="inline">
    <outputRendition>font-size: 7pt;</outputRendition>
  </model>
  <model behaviour="block">
    <outputRendition>text-color: red;</outputRendition>
  </model>
</modelGrp>
<modelGrp output="print">
  <model behaviour="inline">
    <outputRendition>font-size: 12pt;</outputRendition>
  </model>
  <model behaviour="block"
    useSourceRendition="true">
    <outputRendition>text-align: center;</outputRendition>
  </model>
</modelGrp>
```

#### 22.5.5.5 Behaviours and their parameters

In the examples above we have used without explanation or definition two simple *behaviours*: *inline* and *block*, but many other behaviours are possible. A list of recommended behaviour names forms part of the specification for the element <model>. A processing model can specify any named behaviour, some of which have additional *parameters*. The *parameters* of a *behaviour* resemble the arguments of a function in many programming languages: they provide names which can be used to distinguish particular parts of the input data available to the process used to implement the behaviour in question.

The following elements are used to represent and to define parameters:

**<param>** provides a parameter for a model behaviour by supplying its name and an XPath expression identifying the location of its content.

*@name* a name for the parameter being supplied

**<paramList>** list of parameter specifications

**<paramSpec>** supplies specification for one parameter of a model behaviour

By default, a processor implementing the TEI processing model for a particular element has available to it as input data the content of the element itself, and all of its children. One or more <param> elements may be supplied within a <model> element to specify *parameters* which modify this, either by selecting particular parts of the default input data, or by selecting data which would not otherwise be available. In either case, the value supplied for the parameter is given as an XPath expression, evaluated with respect to the element node being processed. An arbitrary name (defined in the corresponding <paramSpec>) is also supplied to a processor to identify each parameter.

For example, an element such as the TEI <ref> element will probably be associated with a processing model which treats it as a hyperlink. But a hyperlink (in most implementations) often has two associated pieces of information: the address indicated, and some textual content serving to label the link. In HTML, the former is provided as value of the *href* element, and the latter by the content of an <a> element. In the following processing model we define

a behaviour called `link`, which will use whatever is indicated by the parameter called `uri` to provide the former, while the latter is provided by the content of the `<ref>` element itself:

```
<elementSpec ident="ref" mode="add">
  <model behaviour="link">
    <param name="uri" value="@target"/>
    <param name="content" value="."/>
  </model>
</elementSpec>
```

The *value* attribute of a `<param>` element supplies an XPath expression that indicates where the required value may be found. The context for this XPath is the element which is being processed; hence in this example, the `uri` parameter takes the value of the `target` attribute on the `<ref>` element being processed. The `content` parameter indicates that the content of that `<ref>` element should be provided as its value. (This parameter is not strictly necessary, since by default the whole content of the element being processed is always available to a processor, but supplying it in this way makes the procedure more explicit).

All the parameters available for a given behaviour are defined as a part of the definition of the behaviour itself, as further discussed in section 22.5.5.8. *Defining a processing model* below.

As a further example, the TEI `<choice>` element requires a different behaviour for which the name `alternate` is proposed as in the following example:

```
<elementSpec ident="choice" mode="change">
  <model predicate="sic and corr"
    behaviour="alternate">
    <param name="default" value="corr"/>
    <param name="alternate" value="sic"/>
  </model>
</elementSpec>
```

The processing model shown here will be selected for processing a `<choice>` element which has both `<sic>` and `<corr>` child elements. The names `default` and `alternate` here are provided for convenience. The `default` parameter provides the value of the child `<corr>` element, and the `alternate` parameter will provide that of the child `<sic>` elements. If neither `<param>` element was supplied, both elements would still be available to an application, but the application would need to distinguish them for itself.

A `<choice>` element might contain multiple corrections, each with differing values for their `cert` attribute. In the following processing model, we will accept as value of the `default` attribute only those child `<corr>` elements which have a value high for that attribute:

```
<elementSpec ident="choice" mode="change">
  <model predicate="sic and corr"
    behaviour="alternate">
    <param name="default"
      value="corr[@cert='high']"/>
    <param name="alternate" value="sic"/>
  </model>
</elementSpec>
```

A `<choice>` element might contain several different pairs of alternate elements (`<abbr>` and `<expan>`, `<orig>` and `<reg>`, etc.) We might wish to group together a set of processing models for these, for example to determine which of the possible alternatives is displayed by default whenever a `<choice>` element is processed for output to the web:

```

<elementSpec ident="choice" mode="change">
  <modelGrp output="web">
    <model predicate="sic and corr"
      behaviour="alternate">
      <param name="default"
        value="corr[@cert='high']"/>
      <param name="alternate" value="sic"/>
    </model>
    <model predicate="abbr and expan"
      behaviour="alternate">
      <param name="default" value="expan[1]"/>
      <param name="alternate" value="abbr"/>
    </model>
    <model predicate="orig and reg"
      behaviour="alternate">
      <param name="default" value="reg"/>
      <param name="alternate" value="orig"/>
    </model>
  </modelGrp>
</elementSpec>

```

If nothing matches the XPath defining the value of a particular parameter (e.g. if in the above example there is no correction with *cert=high*) then the **default** parameter has no value. It is left to implementors to determine how null-valued parameters should be processed.

#### 22.5.5.6 Outputs

As noted above, the *output* attribute is used to associate particular processing models with a specific type of output. The following example documents a range of processing intentions for the <date> element, intended to cope with at least the following three situations:

1. there is text inside the element, and the output is print;
2. there is no text inside the element but there is a *when* attribute, and the output is print;
3. there is a *when* attribute, there is text inside the element, and the output is web

```

<elementSpec ident="date" mode="change">
  <modelGrp output="print">
    <model predicate="text()"
      behaviour="inline"/>
    <model predicate="@when and not(text())"
      behaviour="inline">
      <param name="content" value="@when"/>
    </model>
  </modelGrp>
  <model output="web" predicate="@when"
    behaviour="alternate">
    <param name="default" value="."/>
    <param name="alternate" value="@when"/>
  </model>
</elementSpec>

```

For output to print we supply two processing models, one for the simplest case where the content of the <date> is to be treated as an inline element, and the other for the case where there is no content and the value of the *when* attribute is to be used in its place. This is specified by a parameter, called **content** in this example. For output to web, we use the **alternate** behaviour discussed in the previous section to indicate that by default the content of

the element will be used, while retaining access to the value of the *when* attribute, this time via a parameter called *alternate*.

#### 22.5.5.7 Model sequence

As well as being combined to form model groups, several models may be combined to form a *model sequence*. All of the individual components of a model sequence are understood to be applied, rather than considered to be mutually exclusive alternatives. For example, we might wish to define two different behaviours for a `<note>` element: the inline behaviour should be used to display the value of the note number (given by its *n* attribute), while a different behaviour (here called *footnote*) should be used to display the content of the element at a specified place, given by the parameter *place*. Because both of these actions are required, the two models are grouped by a `<modelSequence>` element:

```
<elementSpec ident="note" mode="change">
  <modelSequence output="print">
    <model behaviour="inline">
      <param name="content" value="@n"/>
    </model>
    <model behaviour="footnote">
      <param name="place" value="'foot'"/>
    </model>
  </modelSequence>
</elementSpec>
```

The value of the parameter called *place* above is an XPath expression supplying an arbitrary string ('foot'), which is therefore quoted. It is left to implementors to validate or constrain the possible values for such expressions.

#### 22.5.5.8 Defining a processing model

The processing model for an element is defined using some combination of `<model>`, `<modelSequence>`, or `<modelGroup>` elements within the `<elementSpec>` element containing its specification. The processing to be carried out is defined by means of the behaviour specified for each `<model>` element, possibly supplying specified values for a number of named parameters. The parameters available for a given behaviour are specified using a number of `<param>` elements grouped together in a `<paramList>` element. This `<paramList>` is supplied within the `<valItem>` used to document and name the behaviour. Here for example is the `<valItem>` which defines the *link* behaviour presented above:

```
<valItem ident="link">
  <desc>create a hyperlink</desc>
  <paramList>
    <paramSpec ident="content">
      <desc>supplies the location of some content describing the link</desc>
    </paramSpec>
    <paramSpec ident="uri">
      <desc>supplies the location of the intended hyperlink</desc>
    </paramSpec>
  </paramList>
</valItem>
```

Similarly the `<valItem>` which defines the behaviour named *alternate* includes specifications for two parameters: one also called *alternate* and the other called *default*

```
<valItem ident="alternate">
  <desc versionDate="2015-08-21"
    xml:lang="en">support display of alternative visualisations, for
    example by displaying the preferred content, by displaying both in parallel, or by
```

```

toggling
  between the two.</desc>
<paramList>
  <paramSpec ident="default">
    <desc versionDate="2015-08-21"
      xml:lang="en">supplies the location of the preferred
      content</desc>
  </paramSpec>
  <paramSpec ident="alternate">
    <desc versionDate="2015-08-21"
      xml:lang="en">supplies the location of the alternative
      content</desc>
  </paramSpec>
</paramList>
</valItem>

```

The suggested behaviours provided by the <model> element are informally defined using commonly understood terminology, but specific details of how they should be implemented are left to the implementor. Such decisions may vary greatly depending on the kind of processing environment, the kind of output envisaged, etc. The intention is to reduce as far as possible any requirement for the implementor to be aware of TEI-specific rules, and to maximize the ability of the ODD to express processing intentions without fully specifying an implementation.

#### 22.5.5.9 Implementation of Processing Models

As elsewhere in these Guidelines, the recommendations of this section are intended to be implementation-agnostic, not favouring any particular implementation method or technology. An implementor may choose, for example, whether to pre-process processing model specifications into a free standing ‘pipeline’, or to extract and process them dynamically during document processing. However, although implementors are generally free to interpret the processing model documentation according to their own requirements, some general assumptions underlie the recommendations made here:

- If a <model> element has no child <param> elements, the action specified by its behaviour should be applied to the whole element node concerned, including its child nodes of whatever type. If that behaviour requires distinguishing particular parts of the input, an implementation may choose either to make those distinctions itself, or to raise an error.
- If a <model> element has no *predicate* or *output* attribute then it is assumed to apply to all instances of the element defined in its parent <elementSpec> for all outputs. Otherwise its applicability depends on these attributes.
- Individual <model> elements are processed independently, except when they appear within a <modelSequence>
- Consequently, if there are two or more <model> elements provided for an <elementSpec>, and none of them has a *predicate* or an <output> attribute, then an implementation may either choose to regard this as an error, or apply their own algorithm to determine the priorities; the nature of that algorithm (first found, last found, etc.) should form part of the implementation's documentation.
- If there are two or more <model> elements provided for an <elementSpec> but they have different *output* attributes then the implementation should choose the <model> appropriate to the desired output.
- If there are two or more <model> elements provided for an <elementSpec> but they have different *predicate* attributes then the implementation should choose the <model> whose *predicate* provides the most specific context (where *specific* is understood in the same way as in XSLT)

In the following example, which shows part of the element specification for the <head> element, there are two <model> elements, one with and one without a *predicate* attribute:

```

<model behaviour="inline"
  predicate="parent::list">
  <desc versionDate="2015-03-02"
    xml:lang="en">Model for list headings</desc>

```

```

<!-- ... -->
</model>
<model behaviour="heading">
  <desc versionDate="2016-03-02"
    xml:lang="en">Default model for all headings.</desc>
<!-- ... -->
</model>

```

In this example, an implementation should use the first processing model only for <head> elements with a <list> element as parent; for all other <head> elements, the second processing model should be used.

## 22.6 Class Specifications

The element <classSpec> is used to document either an *attribute class* or a ‘model class’, as defined in section 1.3. *The TEI Class System*. A corresponding <classRef> element may be used to select a specific named class from those available.

**<classSpec>** (class specification) contains reference information for a TEI element class; that is a group of elements which appear together in content models, or which share some common attribute, or both.

**@type** indicates whether this is a model class or an attribute class

**<classRef>** points to the specification for an attribute or model class which is to be included in a schema

**@expand** indicates how references to this class within a content model should be interpreted.

**<attList>** contains documentation for all the attributes associated with this element, as a series of <attDef> elements.

**@org** (organization) specifies whether all the attributes in the list are available (org="group") or only one of them (org="choice")

A model class specification does not list all of its members. Instead, its members declare that they belong to it by means of a <classes> element contained within the relevant <elementSpec>. This will contain a <memberOf> element for each class of which the relevant element is a member, supplying the name of the relevant class. For example, the <elementSpec> for the element <hi> contains the following:

```

<classes>
  <memberOf key="model.hiLike"/>
</classes>

```

This indicates that the <hi> element is a member of the class with identifier `model.hiLike`. The <classSpec> element that documents this class contains the following declarations:

```

<classSpec type="model"
  ident="model.hiLike">
  <desc>groups phrase-level elements related to highlighting that have no specific
  semantics </desc>
  <classes>
    <memberOf key="model.highlighted"/>
  </classes>
</classSpec>

```

which indicate that the class `model.hiLike` is actually a member (or subclass) of the class `model.highlighted`.

The function of a model class declaration is to provide another way of referring to a group of elements. It does not confer any other properties on the elements which constitute its membership.

The attribute *type* is used to distinguish between ‘model’ and ‘attribute’ classes. In the case of attribute classes, the attributes provided by membership in the class are documented by an <attList> element contained within the

`<classSpec>`. In the case of model classes, no further information is needed to define the class beyond its description, its identifier, and optionally any classes of which it is a member.

When a model class is referenced in the content model of an element (i.e. by means of a `<classRef>` element within the `<content>` of an `<elementSpec>`), its meaning will depend on the value of its *expand* attribute.

If this attribute is not specified, the `<classRef>` is interpreted to mean an alternated list of all the current members of the class named. For example, suppose that the members of the class `model.hiLike` are elements `<hi>`, `<it>`, and `<bo>`. Then a content model such as

```
<content>
  <classRef key="model.hiLike"/>
</content>
```

would be equivalent to the explicit content model:

```
<content>
  <alternate>
    <elementRef key="hi"/>
    <elementRef key="it"/>
    <elementRef key="bo"/>
  </alternate>
</content>
```

(or, to use RELAX NG compact syntax, `(hi|it|bo)*`). However, a content model of `<classRef expand="sequence"/>` would be equivalent to the following explicit content model:

```
<content>
  <sequence>
    <elementRef key="hi"/>
    <elementRef key="it"/>
    <elementRef key="bo"/>
  </sequence>
</content>
```

(or, in RELAX NG compact syntax, `(hi,it,bo)*`).

An attribute class (a `<classSpec>` of *type* `atts`) contains an `<attList>` element which lists the attributes that all the members of that class inherit from it. For example, the class `att.interpLike` defines a small set of attributes common to all elements which are members of that class: those attributes are listed by the `<attList>` element contained by the `<classSpec>` for `att.interpLike`. When processing the documentation elements for elements which are members of that class, an ODD processor is required to extend the `<attList>` (or equivalent) for such elements to include any attributes defined by the `<classSpec>` elements concerned. There is a single global attribute class, `att.global`, to which some modules contribute additional attributes when they are included in a schema.

## 22.7 Macro Specifications

The `<macroSpec>` element is used to declare and document predefined strings or patterns not otherwise documented by the elements described in this section. A corresponding `<macroRef>` element may be used to select a specific named pattern from those available. Patterns are used as a shorthand chiefly to describe common content models and datatypes, but may be used for any purpose. The following elements are used to represent patterns:

**`<macroSpec>`** (macro specification) documents the function and implementation of a pattern.

*@type* indicates which type of entity should be generated, when an ODD processor is generating a module using XML DTD syntax.

**`<macroRef>`** points to the specification for some pattern which is to be included in a schema

*@key* the identifier used for the required pattern within the source indicated.

## 22.8 Building a TEI Schema

The specification elements, and some of their children, are all members of the `att.identified` class, from which they inherit the following attributes:

**att.identified** provides the identifying attribute for elements which can be subsequently referenced by means of a *key* attribute.

`@ident` supplies the identifier by which this element may be referenced.

`@predeclare` says whether this object should be predeclared in the `tei` infrastructure module.

`@module` supplies a name for the module in which this object is to be declared.

This attribute class is a subclass of the `att.combinable` class from which it (and some other elements) inherits the following attribute:

**att.combinable** provides attributes indicating how multiple references to the same object in a schema should be combined

`@mode` specifies the effect of this declaration on its parent object.

This attribute class, in turn, is a subclass of the `att.deprecated` class, from which it inherits the following attribute:

**att.deprecated** provides attributes indicating how a deprecated feature will be treated in future releases.

`@validUntil` provides a date before which the construct being defined will not be removed.

The `validUntil` attribute may be used to signal an intent to remove a construct from future versions of the schema being specified.

The `<elementSpec>`, `<attDef>` and `<schemaSpec>` specification elements also have an attribute which determines which namespace to which the object being created will belong. In the case of `<schemaSpec>`, this namespace is inherited by all the elements created in the schema, unless they have their own *ns*.

**att.namespaceable** provides an attribute indicating the target namespace for an object being created

These attributes are used by an ODD processor to determine how declarations are to be combined to form a schema or DTD, as further discussed in this section.

### 22.8.1 TEI customizations

As noted above, a TEI schema is defined by a `<schemaSpec>` element containing an arbitrary mixture of explicit declarations for objects (i.e. elements, classes, patterns, or macro specifications) and references to other objects containing such declarations (i.e. references to specification groups, or to modules). A major purpose of this mechanism is to simplify the process of defining user customizations, by providing a formal method for the user to combine new declarations with existing ones, or to modify particular parts of existing declarations.

In the simplest case, a user-defined schema might just combine all the declarations from two nominated modules:

```
<schemaSpec ident="example">
  <moduleRef key="core"/>
  <moduleRef key="linking"/>
</schemaSpec>
```

An ODD processor, given such a document, should combine the declarations which belong to the named modules, and deliver the result as a schema of the requested type. It may also generate documentation for the elements declared by those modules. No source is specified for the modules, and the schema will therefore combine the declarations found in the most recent release version of the TEI Guidelines known to the ODD processor in use.

The value specified for the *source* attribute, when it is supplied as a URL, specifies any convenient location from which the relevant ODD files may be obtained. For the current release of the TEI Guidelines, a URL in the form `http://www.tei-c.org/Vault/P5/x.y.z/xml/tei/odd/p5subset.xml` may be used, where *x.y.z* represents the P5 version number, e.g. `1.3.0`. Alternatively, if the ODD files are locally installed, it may be more convenient to supply a value such as `../ODDs/p5subset.xml`.

The value for the *source* attribute may be any form of URI. A set of TEI-conformant specifications in a form directly usable by an ODD processor must be available at the location indicated. When no *source* value is supplied, an ODD processor may either raise an error or assume that the location of the current release of the TEI Guidelines is intended.

If the source is specified in the form of a private URI, the form recommended is `aaa:x.y.z`, where `aaa` is a prefix indicating the markup language in use, and `x.y.z` indicates the version number. For example, `tei:1.2.1` should be used to reference release 1.2.1 of the current TEI Guidelines. When such a URI is used, it will usually be necessary to translate it before such a file can be used in blind interchange.

The effect of a `<moduleRef>` element is to include in the schema all declarations provided by that module. This may be modified by means of the attributes *include* and *except* which allow the encoder to supply an explicit lists of elements from the stated module which are to be included or excluded respectively. For example:

```
<schemaSpec ident="example">
  <moduleRef key="core"
    except="add del orig reg"/>
  <moduleRef key="linking"
    include="linkGroup link"/>
</schemaSpec>
```

The schema specified here will include all the elements supplied by the core module except for `<add>`, `<del>`, `<orig>`, and `<reg>`. It will also include only the `<linkGroup>` and `<link>` elements from the linking module.

Alternatively, the element `<elementRef>` may be used to indicate explicitly which elements are to be included in a schema. The same effect as the preceding example might thus be achieved by the following:

```
<schemaSpec ident="example">
  <moduleRef key="core"
    except="add del orig reg"/>
  <elementRef key="linkGroup"/>
  <elementRef key="link"/>
</schemaSpec>
```

Note that in this last case, there is no need to specify the name of the module from which the two element declarations are to be found; in the TEI scheme, element names are unique across all modules. The module is simply a convenient way of grouping together a number of related declarations.

A schema may also include declarations for new elements, as in the following example:

```
<schemaSpec ident="example">
  <moduleRef key="teiheader"/>
  <moduleRef key="verse"/>
  <elementSpec ident="soundClip">
    <classes>
      <memberOf key="model.pPart.data"/>
    </classes>
  </elementSpec>
</schemaSpec>
```

A declaration for the element `<soundClip>`, which is not defined in the TEI scheme, will be added to the output schema. This element will also be added to the existing TEI class `model.pPart.data`, and will thus be available in TEI conformant documents.

A schema might also include re-declarations of existing elements, as in the following example:

```
<schemaSpec ident="example">
  <moduleRef key="teiheader"/>
  <moduleRef key="teisttructure"/>
  <elementSpec ident="head" mode="change">
    <content>
```

```

    <rng:ref name="macro.xtext"/>
  </content>
</elementSpec>
</schemaSpec>

```

The effect of this is to redefine the content model for the element `<head>` as plain text, by over-riding the `<content>` child of the selected `<elementSpec>`. The attribute specification `mode="change"` has the effect of over-riding only those children elements of the `<elementSpec>` which appear both in the original specification and in the new specification supplied above: `<content>` in this example. Note that if the value for `mode` were `replace`, the effect would be to replace all children elements of the original specification with the the children elements of the new specification, and thus (in this example) to delete all of them except `<content>`.

A schema may not contain more than two declarations for any given component. The value of the `mode` attribute is used to determine exactly how the second declaration (and its constituents) should be combined with the first. The following table summarizes how a processor should resolve duplicate declarations; the term *identifiable* refers to those elements which can have a `mode` attribute:

| mode value | existing declaration | effect   |
|------------|----------------------|--|
| add        | no                   | add new declaration to schema; process its children in add mode  |
| add        | yes                  | raise error  |
| replace    | no                   | raise error  |
| replace    | yes                  | retain existing declaration; process new children in replace mode; ignore existing children  |
| change     | no                   | raise error  |
| change     | yes                  | process identifiable children according to their modes; process unidentifiable children in replace mode; retain existing children where no replacement or change is provided |
| delete     | no                   | raise error  |
| delete     | yes                  | ignore existing declaration and its children   |

### 22.8.2 Combining TEI and Non-TEI Modules

In the simplest case, all that is needed to include a non-TEI module in a schema is to reference its RELAX NG source using the `url` attribute on `<moduleRef>`. The following specification, for example, creates a schema in which declarations from the non-TEI module `svg11.rng` (defining Standard Vector Graphics) are included. To avoid any risk of name clashes, the schema specifies that all TEI patterns generated should be prefixed by the string `"TEI_"`.

```

<schemaSpec prefix="TEI_" ident="testsvg"
  start="TEI svg">
  <moduleRef key="header"/>
  <moduleRef key="core"/>
  <moduleRef key="tei"/>
  <moduleRef key="textstructure"/>
  <moduleRef url="svg11.rng"/>
</schemaSpec>

```

This specification generates a single schema which might be used to validate either a TEI document (with the root element `<TEI>`), or an SVG document (with a root element `<svg:svg>`), but would *not* validate a TEI document containing `<svg:svg>` or other elements from the SVG language. For that to be possible, the `<svg:svg>` element must become a member of a TEI model class (1.3. *The TEI Class System*), so that it may be referenced by other TEI elements. To achieve this, we modify the last `<moduleRef>` in the above example as follows:

```

<moduleRef url="svg11.rng">
  <content>
    <rng:define name="TEI_model.graphicLike"
      combine="choice">
      <rng:ref name="svg"/>
    </rng:define>
  </content>
</moduleRef>

```

This states that when the declarations from the `svg11.rng` module are combined with those from the other modules, the declaration for the model class `model.graphicLike` in the TEI module should be extended to include the element `<svg:svg>` as an alternative. This has the effect that elements in the TEI scheme which define their content model in terms of that element class (notably `<figure>`) can now include it. A RELAX NG schema generated from such a specification can be used to validate documents in which the TEI `<figure>` element contains any valid SVG representation of a graphic, embedded within an `<svg:svg>` element.

### 22.8.3 Linking Schemas to XML Documents

Schemas can be linked to XML documents by means of the `<?xml-model?>` processing instruction described in the W3C Working Group Note *Associating Schemas with XML documents* (<http://www.w3.org/TR/xml-model/>). `<?xml-model?>` can be used for any type of schema, and may be used for multiple schemas:

```

<?xml-model href="tei_tite.rng" type="application/xml" ?>
<?xml-model href="checkLinks.sch" type="application/xml" schematypens="http://
purl.oclc.org/dsdl/schematron" ?>
<?xml-model href="tei_tite.odd" type="application/tei+xml" schematypens="http://
www.tei-c.org/ns/1.0" ?>

```

This example includes a standard RELAX NG schema, a Schematron schema which might be used for checking that all pointing attributes point at existing targets, and also a link to the TEI ODD file from which the RELAX NG schema was generated. See also 2.3.9. *The Schema Specification* for details of another method of linking an ODD specification into your file by including a `<schemaSpec>` element in `<encodingDesc>`.

## 22.9 Module for Documentation Elements

The module described in this chapter makes available the following components:

### Module tagdocs: Documentation of TEI modules

- *Elements defined:* `altIdent` `alternate` `att` `attDef` `attList` `attRef` `classRef` `classSpec` `classes` `code` `constraint` `constraintSpec` `content` `dataRef` `dataSpec` `datatype` `defaultVal` `eg` `egXML` `elementRef` `elementSpec` `equiv` `exemplum` `gi` `ident` `listRef` `macroRef` `macroSpec` `memberOf` `model` `modelGrp` `modelSequence` `moduleRef` `moduleSpec` `outputRendition` `param` `paramList` `paramSpec` `remarks` `schemaSpec` `sequence` `specDesc` `specGrp` `specGrpRef` `specList` `tag` `textNode` `val` `valDesc` `valItem` `valList`
- *Classes defined:* `att.combinable` `att.deprecated` `att.identified` `att.namespaceable` `att.repeatable` `model.contentPart`
- *Macros defined:* `macro.schemaPattern`

The selection and combination of modules to form a TEI schema is described in 1.2. *Defining a TEI Schema*.

The elements described in this chapter are all members of one of three classes: `model.oddDecl`, `model.oddRef`, or `model.phrase.xml`, with the exceptions of `<schemaSpec>` (a member of `model.divPart`) and both `<eg>` and `<egXML>` (members of `model.common` and `model.egLike`). All of these classes are declared along with the other general TEI classes, in the basic structure module documented in 1. *The TEI Infrastructure*.

In addition, some elements are members of the `att.identified` class, which is documented in *22.8.1. TEI customizations* above, and make use of the `macro.schemaPattern` pattern, which is documented in *22.5. Element Specifications* above.

## 23 Using the TEI

This section discusses some technical topics concerning the deployment of the TEI markup scheme documented elsewhere in these Guidelines. In section 23.3. *Personalization and Customization* we discuss the scope and variety of the TEI customization mechanisms, distinguishing between ‘clean’ modifications, which result in a schema that supports a subset of the distinctions made in the full TEI system, on the one hand, from ‘unclean’ modifications, which result in a schema that does not have this property. In 23.4. *Conformance* we define the notions of *TEI Conformance* and *TEI Extension*. Since the ODD markup description language defined in chapter 22. *Documentation Elements* is fundamental to the way conformance and customization are handled in the TEI system, these two definitional sections are followed by a section (23.5. *Implementation of an ODD System*) which describes the intended behaviour of an ODD processor.

### 23.1 Serving TEI files with the TEI Media Type

In February 2011, the media type `application/tei+xml` was registered with IANA for ‘markup languages defined in accordance with the Text Encoding and Interchange guidelines’ (RFC 6129). We recommend that any XML file whose root element is in the TEI namespace be served with the media type `application/tei+xml` to enable and encourage automated recognition and processing of TEI files by external applications.

### 23.2 Obtaining the TEI Schemas

As discussed in chapter 22. *Documentation Elements*, the modules making up the TEI scheme are generated from a single set of XML source files. Schemas can be generated for TEI customizations in each of XML DTD language, W3C schema language, and RELAX NG schema language. In the body of these Guidelines, only the latter form is presented, using the compact syntax.

The TEI schemas and Guidelines are widely available over the Internet and elsewhere. The canonical home for the TEI source, the schema fragments generated from it, and example modifications, is the TEI repository at <https://github.com/TEIC/TEI>; versions are also available in other formats, along with copies of these Guidelines and related materials, from the TEI web site at <http://www.tei-c.org/>.

### 23.3 Personalization and Customization

These Guidelines provide an encoding scheme suitable for encoding a very wide range of texts, and capable of supporting a wide variety of applications. For this reason, the TEI scheme supports a variety of different approaches to solving similar problems, and also defines a much richer set of elements than is likely to be necessary in any given project. Furthermore, the TEI scheme may be extended in well-defined and documented ways for texts that cannot be conveniently or appropriately encoded using what is provided. For these reasons, it is almost impossible to use the TEI scheme without customizing or personalizing it in some way.

This section describes how the TEI encoding scheme may be customized, and should be read in conjunction with chapter 22. *Documentation Elements*, which describes how a specific application of the TEI encoding scheme should be documented. The documentation system described in that chapter is, like the rest of the TEI scheme, independent of any particular schema or document type definition language.

Formally speaking, these Guidelines provide both syntactic rules about how elements and attributes may be used in valid documents and semantic recommendations about what interpretation should be attached to a given syntactic construct. In this sense, they provide both a *document type definition* and a *document type declaration*. More exactly, we may distinguish between the *TEI Abstract Model*, which defines a set of related concepts, and the *TEI schema* which defines a set of syntactic rules and constraints. Many (though not all) of the semantic recommendations are provided solely as informal descriptive prose, though some of them are also enforced by means of such constructs as datatypes (see DTYPES). Although the descriptions have been written with care, there will inevitably be cases where the intention of the contributors has not been conveyed with sufficient clarity to prevent users of these Guidelines from ‘extending’ them in the sense of attaching slightly variant semantics to them.

Beyond this unintentional semantic extension, some of the elements described can intentionally be used in a variety of ways; for example, the element `<note>` has an attribute *type* which can take on arbitrary string values, depending on how it is used in a document. A new type of ‘note’, therefore, requires no change in the existing model. On the other hand, for many applications, it may be desirable to constrain the possible values for the *type* attribute to a small set of possibilities. A schema modified in this way would no longer necessarily regard as valid the same

set of documents as the corresponding unmodified TEI schema, but would remain faithful to the same conceptual model.

This section explains how the TEI scheme can be customized by suppressing elements, modifying classes of elements, adding elements, and renaming elements. Documents which validate against an application of the TEI scheme which has been customized in this way may or may not be considered ‘TEI-conformant’, as further discussed in section 23.4. *Conformance*.

The TEI scheme is designed to support modification and customization in a documented way that can be validated by an XML processor. This is achieved by writing a small TEI-conformant document, from which an appropriate processor can generate both human-readable documentation, and a schema expressed in a language such as RELAX NG or DTD. The mechanisms used to instantiate a TEI schema differ for different schema languages, and are therefore not defined here. In XML DTDs, for example, extensive use is made of parameter entities, while in RELAX NG schemas, extensive use is made of patterns. In either case, the names of elements and, wherever possible, their attributes and content models are defined indirectly. The syntax used to implement this indirection also varies with the schema language used, but the underlying constructs in the TEI Abstract Model are given the same names.

As further discussed in section 1. *The TEI Infrastructure*, the TEI encoding scheme comprises a set of class and macro declarations, and a number of *modules*. Each module is made up of element and attribute declarations, and a schema is made by combining a particular set of modules together. In the absence of any other kind of personalization, when modules are combined together:

1. all the elements defined by the module (and described in the corresponding section of these Guidelines) are included in the schema;
2. each such element is identified by the canonical name given it in these Guidelines;
3. the content model of each such element is as defined by these Guidelines;
4. the names, datatypes, and permitted values declared for each attribute associated with each such element are as given in these Guidelines;
5. the elements comprising element classes and the meaning of macro declarations expressed in terms of element classes is determined by the particular combination of modules selected.

The TEI personalization mechanisms allow the user to control this behaviour as follows:

1. particular elements may be suppressed, removing them from any classes in which they are members, and also from any generated schema;
2. within certain limits, the name (generic identifier) associated with an element may be changed, without changing the semantic or syntactic properties of the element;
3. new elements may be added to an existing class, thus making them available in macros or content models defined in terms of those classes;
4. additional attributes, or attribute values, may be specified for an individual element or for classes of elements;
5. within certain limits, attributes, or attribute values, may also be removed either from an individual element or for classes of elements;
6. the characteristics inherited by one class from another class may be modified by modifying its class membership: all members of the class then inherit the changed characteristics;
7. the set of values legal for an attribute or attribute class may be constrained or relaxed by supplying or modifying a value list, or by modifying its datatype.

The modification mechanisms presented in this section are quite general, and may be used to make all the types of changes just listed.

The recommended way of implementing and documenting all such modifications is by means of the ODD system described in chapter 22. *Documentation Elements*; in the remainder of this section we give specific examples to illustrate how that system may be applied. An ODD processor, such as the Roma application supported by the TEI, or any other comparable set of stylesheets will use the declarations provided by an ODD to generate appropriate sets of declarations in a specific schema language such as RELAX NG or the XML DTD language. We do not discuss in detail here how this should be done, since the details are schema language-specific; some background information about

the methods used for XML DTD and RELAX NG schema generation is however provided in section 1.2. *Defining a TEI Schema*. Several example ODD files are also provided as part of the standard TEI release: see further section 23.3.4. *Examples of Modification* below.

### 23.3.1 Kinds of Modification

For ease of discussion, we distinguish the following different kinds of modification:

1. deletion of elements;
2. renaming of elements;
3. modification of content models;
4. modification of attribute and attribute-value lists;
5. modification of class membership;
6. addition of new elements.

Each of these is described in the following sections.

Each kind of modification changes the set of documents that will be considered valid according to the resulting schema. Any combination of unchanged TEI modules may be thought of as defining a certain set of documents. Each schema resulting from a modified combination of TEI modules will define a different set of documents. The set of documents valid according to the unmodified schema may or may not be properly contained in the set of documents considered to be valid according to the modified schema. We use the term *clean modification* to describe a modification which regards as valid a subset of the documents considered valid by the same combination of TEI modules unmodified. Alternatively, the set of documents considered valid by the original schema might be disjoint from the set of documents considered valid by the modified schema, with neither being properly contained by the other. Modifications that have this result are called *unclean modifications*. Despite this terminology, unclean modifications are not particularly deprecated, and their use may often be vital to the success of a project. The concept is introduced solely to distinguish the effects of different kinds of modification.

Cleanliness can only be assessed with reference to elements in the TEI namespace.

#### 23.3.1.1 Deletion of Elements

The simplest way to modify the supplied modules is to suppress one or more of the supplied elements. This is simply done by setting the *mode* attribute to delete on an `<elementSpec>` for the element concerned.

For example, if the `<note>` element is not to be used in a particular application, the schema specification concerned will contain a declaration like the following:

```
<elementSpec ident="note" module="core"
  mode="delete"/>
```

The *ident* attribute here supplies the canonical name of the element to be deleted, the *module* attribute identifies the module in which this element is declared, and the *mode* attribute specifies what is to be done with it. Note that the module name must be supplied explicitly, and that the schema specification in which this declaration appears must also contain a reference to the module itself. The full specification for a schema in which this modification is applied would thus be something like the following:

```
<schemaSpec ident="mySchema">
  <moduleRef key="core"/>
  <!-- other modules used by this schema -->
  <elementSpec ident="note" module="core"
    mode="delete"/>
</schemaSpec>
```

In most cases, deletion is a clean modification, since most elements are optional. Documents that are valid with respect to the modified schema are also valid according to the unmodified schema. To say this another way, the set of documents matching the new schema is contained by the set of documents matching the original schema.

There are however some elements in the TEI scheme which have mandatory children; for example, the element <fileDesc> must contain both a <titleStmt> and a <sourceDesc>. A modification which deleted either of these would be unclean, because it would regard as valid documents that the unmodified schema would regard as invalid. Deleting one of the many optional children of <fileDesc> (<editionStmt> or <notesStmt> for example) would not have this effect, and would be a clean modification.

In general, whenever the element deleted by a modification is mandatory within the content model of some other (undeleted) element, the result is an unclean modification, and may also break the TEI Abstract Model (23.4.3. *Conformance to the TEI Abstract Model*). However, the parent of a mandatory child can be safely removed if it is itself optional.

To determine whether or not an element is mandatory in a given context, the user must inspect the content model of the element concerned. In most cases, content models are expressed in terms of model classes rather than elements; hence, removing an element will generally be a clean modification, since there will generally be other members of the class available. If a class is completely depopulated by a modification, then the cleanliness of the modification will depend upon whether or not the class reference is mandatory or optional, in the same way as for an individual element.

### 23.3.1.2 Renaming of Elements

Every element and other named markup construct in the TEI scheme has a *canonical name*, usually in the English language: this name is supplied as the value of the *ident* attribute on the <elementSpec>, <attDef>, <classSpec>, or <macroSpec> used to define it. The element or attribute declaration used within a schema generated from that specification may however be different, thus permitting schemas to be written using elements with generic identifiers from a different language, or otherwise modified. There may be many alternative identifiers for the same markup construct, and an ODD processor may choose which of them to use for a given purpose. Each such alternative name is supplied by means of an <altIdent> element within the specification element concerned.

For example, the following declaration converts <note> to <annotation>:

```
<elementSpec ident="note" module="core"
  mode="change">
  <altIdent>annotation</altIdent>
</elementSpec>
```

Note that the *mode* attribute on the <elementSpec> now takes the value *change* to indicate that those parts of the element specification not supplied are to be inherited from the standard definition. The content of the <altIdent> element will be used in place of the canonical *ident* value in the schema generated.

Renaming in this way is always a *reversible* modification. Although it is an inherently unclean modification (because the set of documents matched by the resulting schema is disjoint with the set matched by its unmodified equivalent), the process of converting any document in which elements have been renamed into an exactly equivalent document using canonical names is completely deterministic, requiring only access to the ODD in which the renaming has been specified. This assumes that the renamed elements used are not placed in the TEI namespace but either use a null namespace or some user-defined namespace, as further discussed in 23.3.2. *Modification and Namespaces*; if this is not the case, care must be taken to avoid name collision between the new name and all existing TEI names. Furthermore, unclean modifications which do not specify a namespace are not conformant (see further 23.3. *Personalization and Customization*)

The TEI provides a systematic set of renamings into languages other than English. These all use a language-specific namespace.

### 23.3.1.3 Modification of Content Models

The content model for an element in the TEI scheme is defined by means of a <content> element within the <elementSpec> which specifies it. As shown elsewhere in these Guidelines, the content model is defined using RELAX NG syntax, whether the resulting schema is expressed in RELAX NG or in some other schema language.

For example, the specification for the element <term> provided by these Guidelines contains a <content> element like the following:

```
<content>
  <rng:ref name="macro.phraseSeq" />
</content>
```

This indicates that the content model contains declarations taken from the RELAX NG namespace, and that it consists of a reference to a pattern called `macro.phraseSeq`. Further examination shows that this pattern in turn expands to an optional repeatable alternation of text (`rng:text`) with references to three other classes (`model.gLike`, `model.phrase`, or `model.global`). For some particular application it might be preferable to insist that `<term>` elements should only contain plain text, excluding these other possibilities.<sup>124</sup> This could be achieved simply by supplying a specification for `<term>` like the following:

```
<elementSpec ident="term" module="core"
  mode="change">
  <content>
    <rng:text />
  </content>
</elementSpec>
```

This is a clean modification which does not change the meaning of a TEI element; there is therefore no need to assign the element to some other namespace than that of the TEI, though it may be considered good practice; see further 23.3.2. *Modification and Namespaces* below.

A change of this kind, which simplifies the possible content of an element by reducing its model to one of its existing components, is always clean, because the set of documents matched by the resulting schema is a subset of the set of documents which would have been matched by the unmodified schema.

Note that content models are generally defined (as far as possible) in terms of references to model classes, rather than to explicit elements. This means that the need to modify content models is greatly reduced: if an element is deleted or modified, for example, then the deletion or modification will be available for every content model which references that element via its class, as well as those which reference it explicitly. For this reason it is not (in general) good practice to replace class references by explicit element references, since this may have unintended side effects.

An unqualified reference to an element class within a content model generates a content model which is equivalent to an alternation of all the members of the class referenced. Thus, a content model which refers to the model class `model.phrase` will generate a content model in which any one of the members of that class is equally acceptable. It is also possible to reference predefined content model fragments based on classes, such as ‘an optional repeatable alternation of all members of a class’, ‘a sequence containing no more than one of each member of the class’, etc. as described further in 22.6. *Class Specifications*.

Content model changes which are not simple restrictions on an existing model should be undertaken with caution. The set of documents matching the schema which results from such changes is likely to be disjoint with the set of documents matching the unmodified schema, and such changes are therefore regarded as unclean. When content models are changed or extended, care should be taken to respect the existing semantics of the element concerned as stated in these Guidelines. For example, the element `<l>` is defined as containing a line of verse. It would not therefore make sense to redefine its content model so that it could also include members of the class `model.pLike`: such a modification although syntactically feasible would not be regarded as TEI-conformant because it breaks the TEI Abstract Model.

#### 23.3.1.4 Modification of Attribute and Attribute Value Lists

The attributes applicable to a given element may be specified in two ways: they may be given explicitly, by means of an `<attList>` element within the corresponding `<elementSpec>`, or they may be inherited from an attribute class, as specified in the `<classes>` element. To add a new attribute to an element, the schema builder should therefore first check to see whether this attribute is already defined by some existing attribute class. If it is, then the simplest method of adding it will be to make the element in question a member of that class, as further discussed below. If this is not possible, then a new `<attDef>` element must be added to the existing `<attList>` for the element in question.

<sup>124</sup>Excluding `model.gLike` is generally inadvisable however, since without it the resulting schema has no way of referencing non-Unicode characters.

Whichever method is adopted, the modification capabilities are the same as those available for elements. Attributes may be added or deleted from the list, using the *mode* attribute on `<attDef>` in the same way as on `<elementSpec>`. The ‘content’ of an attribute is defined by means of the `<datatype>`, `<valList>`, or `<valDesc>` elements within the `<attDef>` element. Any of these elements may be changed.

Suppose, for example, that we wish to add two attributes to the `<eg>` element (used to indicate examples in a text), *type* to characterize the example in some way, and *source* to indicate where the example comes from. A quick glance through the Guidelines indicates that the attribute class `att.typed` could be used to provide the *type* attribute, but there is no comparable class which will provide a *source* attribute. The existing `<eg>` element in fact has no local attributes defined for it at all: we will therefore need to add not only an `<attDef>` element to define the new attribute, but also an `<attList>` to hold it.

We begin by adding the new *source* attribute:

```
<elementSpec ident="eg" module="tagdocs"
mode="change">
  <attList>
    <attDef ident="source" mode="add"
      ns="http://www.example.com/ns/nonTEI">
      <desc>specifies the source of an example by pointing to a single bibliographic
        reference for it</desc>
      <datatype maxOccurs="1">
        <rng:ref name="data.pointer"/>
      </datatype>
    </attDef>
  </attList>
</elementSpec>
```

The value supplied for the *mode* attribute on the `<attDef>` element is `add`; if this attribute already existed on the element we are modifying this should generate an error, since a specification cannot have more than one attribute of the same name. If the attribute is already present, we can replace the whole of the existing declaration by supplying `replace` as the value for *mode*; alternatively, we can change some parts of an existing declaration only by supplying just the new parts, and setting `change` as the value for *mode*.

Because the new attribute is not defined by the TEI, we must specify a namespace for it on the `<attDef>`; see further 23.3.2. *Modification and Namespaces*.

As noted above, adding the new *type* attribute involves changing this element's class membership; we therefore discuss that in the next section (23.3.1.5. *Class Modification*).

The canonical name for the new attribute is *source*, and is supplied on the *ident* attribute of the `<attDef>` element. In this simple example, we supply only a description and datatype for the new attribute; the former is given by the `<desc>` element, and the latter by the `<datatype>` element. (There are of course many other pieces of information which could be supplied, as documented in 22. *Documentation Elements*). The content of the `<datatype>` element, like that of the `<content>` element, uses patterns from the RELAX NG namespace, in this case to select one of the predefined TEI datatypes (DTYPES).

It is often desirable to constrain the possible values for an attribute to a greater extent than is possible by simply supplying a TEI datatype for it. This facility is provided by the `<valList>` element, which can also appear as a child of the `<attDef>` element. Suppose for example that, rather than supplying them as pointers to a bibliography, all that we wish to indicate about the source of our examples is that each comes from one of three predefined sources, which we call A, B, and C. A declaration like the following might be appropriate:

```
<elementSpec ident="eg" module="tagdocs"
mode="change">
  <attList>
    <attDef ident="source"
      ns="http://www.example.com/ns/notTEI" mode="add">
      <desc>specifies the source of an example by supplying one of three predefined
```

```

        codes for it.</desc>
<datatype maxOccurs="1">
  <rng:ref name="data.word"/>
</datatype>
<valList type="closed">
  <valItem ident="A">
    <desc>Examples taken from the A-list</desc>
  </valItem>
  <valItem ident="B">
    <desc>Examples taken from the B-list</desc>
  </valItem>
  <valItem ident="C">
    <desc>Examples taken from the C-list</desc>
  </valItem>
</valList>
</attDef>
</attList>
</elementSpec>

```

The same technique may be used to replace or extend the <valList> supplied as part of any attribute in the TEI scheme.

Depending on the modification, the set of documents matched by a schema generated from an ODD modified in this way, may or may not be a subset of the set of documents matched by the unmodified schema. As such, it is difficult to tell in principle whether such modifications are intrinsically unclean.

#### 23.3.1.5 Class Modification

The concept of element classes was introduced in 1.3.2. *Model Classes*; an understanding of it is fundamental to successful use of the TEI scheme. As noted there, we distinguish *model classes*, the members of which all have structural similarity, from *attribute classes*, the members of which simply share a set of attributes.

The part of an element specification which determines its class membership is an element called <classes>. All classes to which the element belongs must be specified within this, using a <memberOf> element for each.

To add an element to a class in which it is not already a member, all that is needed is to supply a new <memberOf> element within the <classes> element for the element concerned. For example, to add an element to the `att.typed` class, we include a declaration like the following:

```

<elementSpec ident="eg" module="tagdocs"
  mode="change" ns="http://www.example.com/ns/notTEI">
  <classes mode="change">
    <memberOf key="att.typed"/>
  </classes>
</elementSpec>

```

Any existing class memberships for the element being changed are not affected because the *mode* attribute of the <classes> element is set to change (rather than its default value of replace). Consequently, in this case, the <eg> element retains its membership of the two classes (`model.common` and `model.graphicLike`) to which it already belongs.

Equally, to remove the attributes which an element inherits from its membership in some class, all that is needed is to remove the relevant <memberOf> element. For example, the element <term> defined in the core module is a member of two attribute classes, `att.typed` and `att.declaring`. It inherits the attributes *type* and *subtype* from the former, and the attribute *decls* from the latter. To remove the last of these attributes from this element, we need to remove it from that class:

```
<elementSpec ident="term" module="core"
  mode="change">
  <classes mode="change">
    <memberOf key="att.declaring"
      mode="delete"/>
  </classes>
</elementSpec>
```

If the intention is to change the class membership of an element completely, rather than simply add or remove it to or from one or more classes, the value of *mode* attribute of `<classes>` can be set to `replace` (which is the default if no value is specified), indicating that the memberships indicated by its child `<memberOf>` elements are the only ones applicable. Thus the following declaration:

```
<elementSpec ident="term" module="core"
  mode="change" ns="http://www.example.com/ns/notTEI">
  <classes mode="replace">
    <memberOf key="att.interpLike"/>
  </classes>
</elementSpec>
```

would have the effect of removing the element `<term>` from both its existing attribute classes, and adding it to the `att.interpLike` class.

If however the *mode* attribute is set to `change`, the implication is that the memberships indicated by its child `<memberOf>` elements are to be combined with the existing memberships for the element.

To change or remove attributes inherited from an attribute class for all members of the class (as opposed to specific members of that class), it is also possible to modify the class specification itself. For example, the class `att.global` defines several attributes which are available for all elements, notably `xml:id`, `xml:lang`, `rend`, and `rendition` among others. If we decide that we never wish to use the `rend` attribute, the simplest way of removing it is to supply a modified class specification for `att.global` as follows:

```
<classSpec ident="att.global" type="atts"
  mode="change">
  <attList>
    <attDef ident="rend" mode="delete"/>
  </attList>
</classSpec>
```

Because the *mode* attribute on the `<classSpec>` defining the attributes inherited through membership of this class has the value `change`, any of its existing identifiable components not specified in the modification above will remain unchanged. The only effect will therefore be to delete the `rend` attribute from the class, and hence from all elements which are members of the class.

The classes used in the TEI scheme are further discussed in chapter 1. *The TEI Infrastructure*. Note in particular that classes are themselves classified: the attributes inherited by a member of attribute class A may come to it directly from that class, or from another class of which A is itself a member. For example, the class `att.global` is itself a member of the classes `att.global.linking` and `att.global.analytic`. By default, these two classes are predefined as empty. However, if (for example) the `linking` module is included in a schema, a number of attributes (*corresp*, *sameAs*, etc.) are defined as members of the `att.global.linking` class. All elements which are members of `att.global` will then inherit these new attributes (see further section 1.3.1. *Attribute Classes*). A new attribute may thus be added to the global class in two ways: either by adding it to the `<attList>` defined within the class specification for `att.global`; or by defining a new attribute class, and changing the class membership of the `att.global` class to reference it.

Such global changes should be undertaken with caution: in general removing existing non-mandatory attributes from a class will always be a clean modification, in the same way as removing non-mandatory elements. Adding

a new attribute to a class however can be a clean modification only if the new attribute is labelled as belonging to some namespace other than the TEI.

The same mechanisms are available for modification of model classes. Care should be taken when modifying the model class membership of existing elements since model class membership is what determines the content model of most elements in the TEI scheme, and a small change may have unintended consequences.

### 23.3.1.6 Addition of New Elements

To add a completely new element into a schema involves providing a complete element specification for it, the `<classes>` element of which includes a reference to at least one TEI model class. Without such a reference, the new element will not be referenced by the content model of any other TEI element, and will therefore be inaccessible within a TEI document.

For example, the three elements `<bibl>`, `<biblFull>`, and `<biblStruct>` are all defined as members of the class `model.biblLike`. To add a fourth member (say `<myBibl>`) to this class, we need to include in the `<elementSpec>` defining our new element a `<memberOf>` element which nominates the intended class:

```
<elementSpec ident="myBibl" mode="add"
  ns="http://www.example.com/ns/notTEI">
  <classes>
    <memberOf key="model.biblLike"/>
  </classes>
<!-- other parts of the new declaration here -->
</elementSpec>
```

The other parts of this declaration will typically include a description for the new element and information about its content model, its attributes, etc., as further described in 22. *Documentation Elements*.

### 23.3.2 Modification and Namespaces

All the elements defined by the TEI scheme are labelled as belonging to a single *namespace*, maintained by the TEI and with the URI `http://www.tei-c.org/ns/1.0`.<sup>125</sup> Only elements which are unmodified or which have undergone a clean modification may use this namespace. In a TEI-conformant document, it is assumed that all attributes not explicitly labelled with a namespace (such as, for example `xml:id`) also belong to the TEI namespace, and are defined by the TEI.

This implies that any other modification (including a renaming or reversible modification) must either specify a different namespace or specify no namespace at all. The `ns` attribute is provided on elements `<schemaSpec>`, `<elementSpec>`, and `<attDef>` for this purpose.

Suppose, for example, that we wish to add a new attribute *topic* to the existing TEI element `<p>`. In the absence of namespace considerations, this would be an unclean modification, since `<p>` does not currently have such an attribute. The most appropriate action is to explicitly attach the new attribute to a new namespace by a declaration such as the following:

```
<elementSpec ident="p" mode="change">
  <attList>
    <attDef ident="topic" mode="add"
      ns="http://www.example.org/ns/nonTEI">
      <desc>indicates the topic of a TEI paragraph</desc>
      <datatype>
<!-- ... -->
      </datatype>
    </attDef>
  </attList>
</elementSpec>
```

<sup>125</sup>This is not strictly the case, since the element `<egXML>` used to represent TEI examples has its own namespace, `http://www.tei-c.org/ns/Examples`; this is the only exception however.

Document instances using a schema derived from this ODD can now indicate clearly the status of this attribute:

```
<div
  xmlns:my="http://www.example.org/ns/nonTEI">
<!-- ... -->
  <p n="12" my:topic="rabbits">Flopsy, Mopsy, Cottontail, and Peter...</p>
</div>
```

Since *topic* is explicitly labelled as belonging to something other than the TEI namespace, we regard the modification which introduced it as clean. A namespace-aware processor will be able to validate those elements in the TEI namespace against the unmodified schema.<sup>126</sup>

Similar considerations apply when modification is made to the content model or some other aspect of an element, or when a new element is declared. Clean modification requires that all such changes be explicitly labelled as belonging to some non-TEI name space or to no name space at all.

If the *ns* attribute is supplied on a `<schemaSpec>` element, it identifies the namespace applicable to all components of the schema being specified. Even if such a schema includes unmodified modules from the TEI namespace, the elements contained by such modules will now be regarded as belonging to the namespace specified on the `<schemaSpec>`. This can be useful if it is desired simply to avoid namespace processing. For example, the following schema specification results in a schema called `noName` which has no namespace, even though it comprises declarations from the TEI `header` module:

```
<schemaSpec ns="" ident="noName">
  <moduleRef key="header"/>
<!-- ... -->
</schemaSpec>
```

In addition to the TEI canonical namespace mentioned above, the TEI may also define namespaces for approved translations of the TEI scheme into other languages. These may be used as appropriate to indicate that a customization uses a standardized set of renamings. The namespace for such translations is the same as that for the canonical namespace, suffixed by the appropriate ISO language identifier (*vi.1 Language Identification*). A schema specification using the Chinese translation, for example, would use the namespace `http://www.tei-c.org/ns/1.0/zh`

### 23.3.3 Documenting the Modification

The elements used to define a TEI customization (`<schemaSpec>`, `<moduleRef>`, `<elementSpec>`, etc.) will typically be used within a TEI document which supplies further information about the intended use of the new schema, the meaning and application of any new or modified elements within it, and so on. This document will typically conform to a TEI (or other) schema which includes the module described in chapter 22, *Documentation Elements*.<sup>127</sup>

Where the customization to be documented simply consists in a selection of modules, perhaps with some deletion of unwanted elements or attributes, the documentation need not specify anything further. Even here however it may be considered worthwhile to replace some of the semantic information provided by the unmodified TEI specification. For example, the `<desc>` element of an unmodified TEI `<elementSpec>` may describe an element in terms more general than appropriate to a particular project, or the `<exemplum>` elements within it may not illustrate the project's actual intended usage of the element, or the `<remarks>` element may contain discussions of matters irrelevant to the project. These elements may therefore be replaced or deleted within an `<elementSpec>` as necessary.

Radical revision is also possible. It is feasible to produce a modification in which the `<teiHeader>` or `<text>` elements are not required, or in which any other rule stated in these Guidelines is either not enforced or not enforceable. In fact, the mechanism, if used in an extreme way, permits replacement of all that the TEI has to say about every component of its scheme. Such revisions would result in documents that are not TEI-conformant in even the broadest sense, and it is not intended that encoders use the mechanism in this way. We discuss exactly what is meant by the concept of *TEI conformance* in the next section, 23.4. *Conformance*.

<sup>126</sup>Full namespace support does not exist in the DTD language, and therefore these techniques are available only to users of more modern schema languages such as RELAX NG or W3C Schema.

<sup>127</sup>This module can be used to document any XML schema, and has indeed been used to document several non-TEI schemas.

### 23.3.4 Examples of Modification

Several examples of customizations of the TEI are provided as part of the standard release. They include the following:

**tei\_bare** The schema generated from this customization is the minimum needed for TEI Conformance. It provides only a handful of elements.

**tei\_all** The schema generated from this customization combines all available TEI modules, providing 564 elements.

**tei\_allPlus** The schema generated from this customization combines all available TEI modules with three other non-TEI vocabularies, specifically MathML, SVG, and XInclude.

It is unlikely that any project would wish to use any of these extremes unchanged. However, they form a useful starting point for customization, whether by removing modules from *tei\_all* or *tei\_allPlus*, or by replacing elements deleted from *tei\_bare*. They also demonstrate how an ODD document may be constructed to provide a basic reference manual to accompany schemas generated from it.

Shortly after publication of the first edition of these Guidelines, as a demonstration of how the TEI encoding scheme might be adopted to meet 90% of the needs of 90% of the TEI user community, the TEI editors produced a brief tutorial defining one specific ‘clean’ modification of the TEI scheme, which they called TEI Lite. This tutorial and its associated DTD became very popular and are still available from the TEI web site at <http://www.tei-c.org/Guidelines/Customization/Lite/>. The tutorial and associated schema specification is also included as one of the exemplars provided with TEI P5.

The exemplars provided with TEI P5 also include a customization file from which a schema for the validation of other customization files may be generated. This ODD, called *tei\_odds*, combines the four basic modules with the tagdocs, dictionaries, gaiji, linking, and figures modules as well as including the (non-TEI) module defining the RELAX NG language. This enables schemas derived from this customization file to validate examples contained within them in a number of ways, further described within the document.

## 23.4 Conformance

The notion of *TEI Conformance* is intended to assist in the description of the format and contents of a particular XML document instance or set of documents. It may be found useful in such situations as:

- interchange or integration of documents amongst different researchers or users;
- software specifications for TEI-aware processing tools;
- agreements for the deposit of texts in, and distribution of texts from, archives;
- specifying the form of documents to be produced by or for a given project.

It is not intended to provide any other evaluation, for example of scholarly merit, intellectual integrity, or value for money. A document may be of major intellectual importance and yet not be TEI-conformant; a TEI-conformant document may be of no scholarly value whatsoever.

In this section we explore several aspects of conformance, and in particular attempt to define how the term *TEI-conformant* should be used. The terminology defined here should be considered normative: users and implementors of the TEI Guidelines should use the phrases ‘TEI-conformant’ and ‘TEI Extension’ only in the senses given and with the usages described.

A document is *TEI-conformant* if it:

- is a well-formed XML document (23.4.1. *Well-formedness Criterion*)
- can be validated against a *TEI Schema*, that is, a schema derived from the TEI Guidelines (23.4.2. *Validation Constraint*)
- conforms to the TEI Abstract Model (23.4.3. *Conformance to the TEI Abstract Model*)
- uses the *TEI Namespace* (and other namespaces where relevant) correctly (23.4.4. *Use of the TEI Namespace*)
- is documented by means of a TEI-conformant *ODD file* (23.4.5. *Documentation Constraint*) which refers to the TEI Guidelines

Each of these criteria is discussed in more detail below.

A document is said to use a *TEI Extension* if it is a well-formed XML document which is valid against a TEI Schema which contains additional distinctions, representing concepts not present in the TEI Abstract Model, and therefore

not documented in these Guidelines. Such a document cannot, in general, be algorithmically conformant since it cannot be automatically transformed without loss of information. However, since one of the goals of the TEI is to support extensions and modifications, it should not be assumed that no TEI document can include extensions: an extension which is expressed by means of the recommended mechanisms is also a TEI document provided that those parts of it which are not extensions are TEI-conformant.

A TEI-conformant document is said to follow *TEI Recommended Practice* if, wherever these Guidelines prefer one encoding practice to another, the preferred practice is used.

### 23.4.1 Well-formedness Criterion

These Guidelines mandate the use of well-formed XML as representation format. Documents must conform to the World Wide Web Consortium recommendation of the *Extensible Markup Language (XML) 1.0 (Fourth Edition)* or successor editions found at <http://www.w3.org/TR/xml/>. Other ways of representing the concepts of the TEI Abstract Model are possible, and other representations may be considered appropriate for use in particular situations (for example, for data capture, or project-internal processing). But such alternative representations should not be considered in any way TEI-conformant.

Previous versions of these Guidelines used SGML as a representation format. With the release of P5, the only representation format supported by these Guidelines became valid XML; legacy documents in SGML format should therefore be converted using appropriate software.

A TEI-conformant document must use the TEI namespace, and therefore must also include an XML-conformant namespace declaration, as defined below (23.4.4. *Use of the TEI Namespace*).

The use of XML greatly reduces the need to consider hardware or software differences between processing environments when exchanging data. No special packing or interchange format is required for an XML document, beyond that defined by the W3C recommendations, and no special ‘interchange’ format is therefore proposed by these Guidelines. For discussion of encoding issues that may arise in the processing of special character sets or non-standard writing systems, see further chapter *vi Languages and Character Sets*.

In addition to the well-formedness criterion, the W3C defines the notion of a *valid* document, as being a well-formed document which matches a specific set of rules or syntactic constraints, defined by a *schema*. As noted above, TEI conformance implies that the schema used to determine validity of a given document should be derived from the present Guidelines, by means of an ODD which references and documents the schema fragments which these Guidelines define.

### 23.4.2 Validation Constraint

All *TEI-conformant* documents must validate against a schema file that has been derived from the published TEI Guidelines, combined and documented in the manner described in section 23.3. *Personalization and Customization*. We call the formal output of this process a *TEI Schema*.

The TEI does not mandate use of any particular schema language, only that this schema<sup>128</sup> should have been generated from a *TEI ODD file* that references the TEI Guidelines. Currently available tools permit the expression of schemas in any or all of the XML DTD language, W3C XML Schema, and RELAX NG (both compact and XML formats). Some of what is syntactically possible using the ODD formalism cannot be represented by all schema languages; and there are some features of some schema languages which have no counterpart in ODD. No single schema language fully captures all the constraints implied by conformance to the TEI Abstract Model. A document which is valid according to a TEI schema represented using one schema language may not be valid against the same schema expressed in other languages; in particular the DTD language does not fully support namespaces. Features which cannot be represented in all schema languages are documented in chapters 22. *Documentation Elements* and 23.5. *Implementation of an ODD System*.

As noted in section 23.3. *Personalization and Customization*, many varieties of TEI schema are possible and not all of them are necessarily *TEI-conformant*; derivation from an ODD is a necessary but not a sufficient condition for TEI Conformance.

### 23.4.3 Conformance to the TEI Abstract Model

The *TEI Abstract Model* is the conceptual schema instantiated by the TEI Guidelines. These Guidelines define, both formally and informally, a set of abstract concepts such as ‘paragraph’ or ‘heading’, and their structural relationships,

<sup>128</sup>Here and elsewhere we use the word *schema* to refer to any formal document grammar language, irrespective of the formalism used to represent it.

for example stating that ‘paragraph’s do not contain ‘heading’s. These Guidelines also define classes of elements, which have both semantic and structural properties in common. Those semantic and structural properties are also a part of the TEI Abstract Model; the class membership of an existing TEI element cannot therefore be changed without changing the model. Elements can however be removed from a class by deletion, and new non-TEI elements within their own namespaces can be added to existing TEI classes.

### 23.4.3.1 Semantic Constraints

It is an important condition of TEI conformance that elements defined in the TEI Guidelines as having one specific meaning should not be used with another. For example, the element <l> is defined in the TEI Guidelines as containing a line of verse. A schema in which it is redefined to mean a typographic line, or an ordered queue of objects of some kind, cannot therefore be TEI-conformant, whatever its other properties.

The semantics of elements defined in the TEI Guidelines are conveyed in a number of ways, ranging from formally verifiable datatypes to informal descriptive prose. In addition, a mapping between TEI elements and concepts in other conceptual models may be provided by the <equiv> element where this is available.

A schema which shares equivalent concepts to those of the TEI conceptual model may be mappable to the TEI Schema by means of such a mechanism. For example, the concept of paragraph expressed in the TEI scheme by the <p> element is probably the same concept as that expressed in the DocBook scheme by the <para> element. Such areas of overlap facilitate interoperability, because elements from one namespace may be readily integrated with those from another, but do not affect the definition of conformance.

A document is said to conform to the *TEI Abstract Model* if features for which an encoding is proposed by the TEI Guidelines are encoded within it using the markup and other syntactic properties defined by means of a valid *TEI-conformant* schema. Hence, even though the names of elements or attributes may vary, a TEI-conformant document must respect the TEI Semantic Model, and be valid with respect to a TEI-conformant Schema. Although it may be possible to transform a document which follows the *TEI Abstract Model* into a *TEI-conformant* document, such a document is not itself necessarily conformant.

As noted above, the notion of semantic conformance cannot be completely enforced in a formal way. The TEI conceptual model is expressed by means of formal specification in a customization file, by means of descriptive prose in the body of these Guidelines, and implicitly by examples of usage. Any inconsistency between, for example, the text of these Guidelines and a part of a specification should be considered an error and reported to the TEI Council for correction.

### 23.4.3.2 Mandatory Components of a TEI Document

It is a long-standing requirement for any *TEI-conformant* document that it should contain a <teiHeader> element. To be more specific a *TEI-conformant* document must contain

- a single <teiHeader> element followed by one or more elements from the `model.resourceLike` class; or
- in the case of a corpus or collection, a single overall <teiHeader> element followed by a series of <TEI> elements each with its own <teiHeader>

All <teiHeader> elements in a *TEI-conformant* document must include elements for:

**Title Statement** This should include the title of the TEI document expressed using a <titleStmt> element.

**Publication Statement** This should include the place and date of publication or distribution of the TEI document, expressed using the <publicationStmt> element.

**Source Statement** For a document derived from some previously existing document, this must include a bibliographic description of that source. For a document not so derived, this must include a brief statement that the document has no pre-existing source. In either case, this will be expressed using the <sourceDesc> element.

### 23.4.4 Use of the *TEI Namespace*

The Namespaces Recommendation of the W3C (Bray et al. (eds.) (2006)) provides a way for an XML document to combine markup from different vocabularies without risking name collision and consequent processing difficulties. While the scope of the TEI is large, there are many areas in which it makes no particular recommendation, or where it recommends that other defined markup schemes should be adopted, such as graphics or mathematics. It is also considered desirable that users of other markup schemes should be able to integrate documents using TEI markup with their own system. To meet these objectives without compromising the reliability of its encoding, a TEI-conformant document is required to make appropriate use of the TEI namespace.

Essentially all elements in a TEI Schema which represents concepts from the TEI Abstract Model belong to the TEI namespace, <http://www.tei-c.org/ns/1.0>, maintained by the TEI. A TEI-conformant document is required to declare the namespace for all the elements it contains whether these come from the TEI namespace or from other schemes.

A TEI Schema may be created which assigns TEI elements to some other namespace, or to no namespace at all. A document using such a schema must be regarded as a TEI extension and cannot be considered TEI-conformant. A document which places non-TEI elements or attributes within the TEI namespace cannot be TEI-conformant; such practices are strongly deprecated as they may lead to serious difficulties for processing or interchange.

### 23.4.5 Documentation Constraint

As noted in 23.4.2. *Validation Constraint* above, a TEI Schema can only be generated from a TEI ODD, which also serves to document the semantics of the elements defined by it. A TEI-conformant document should therefore always be accompanied by (or refer to) a valid *TEI ODD file* specifying which modules, elements, classes, etc. are in use together with any modifications or renamings applied, and from which a TEI Schema can be generated to validate the document. The TEI supplies a number of predefined *TEI Customization exemplar ODD files* and the schemas already generated from them (see 23.3.4. *Examples of Modification*), but most projects will typically need to customize the TEI beyond what these examples provide. It is assumed, for example, that most projects will customize the TEI scheme by removing those elements that are not needed for the texts they are encoding, and by providing further constraints on the attribute values and element content models the TEI provides. All such customizations must be specified by means of a valid *TEI ODD file*.

As different sorts of customization have different implications for the interchange and interoperability of TEI documents, it cannot be assumed that every customization will necessarily result in a schema that validates only TEI-conformant documents. The ODD language permits modifications which conflict with the TEI Abstract Model, even though observing this model is a requirement for TEI Conformance. The ODD language can in fact be used to describe many kinds of markup scheme, including schemes which have nothing to do with the TEI at all.

Equally, it is possible to construct a TEI Schema which is identical to that derived from a given TEI ODD file without using the ODD scheme. A schema can be constructed simply by combining the predefined schema language fragments corresponding with the required set of TEI modules and other statements in the relevant schema language. The status of such a schema with respect to the `tei_all` schema cannot however be determined, in general; it may therefore be impossible to determine whether such a schema represents a clean modification or an extension. This is one reason for making the presence of a TEI ODD file a requirement for conformance.

### 23.4.6 Varieties of TEI Conformance

The conformance status of a given document may be assessed by answering the following questions, in the order indicated:

1. Is it a valid XML document, for which a TEI Schema exists? If not, then the document cannot be considered TEI-conformant in any sense.
2. Is the document accompanied by a TEI-conformant ODD specification describing its markup scheme and intended semantics? If not, then the document can only be considered TEI-conformant if it validates against a predefined TEI Schema and conforms to the TEI abstract model.
3. Does the markup in the document correctly represent the TEI abstract model? Though difficult to assess, this is essential to TEI conformance.
4. Does the document claim that all of its elements come from some namespace other than the TEI (or no namespace)? If so, the document cannot be TEI-conformant.
5. If the document claims to use the TEI namespace, in part or wholly, do the elements associated with that namespace in fact belong to it? If not, the document cannot be TEI-conformant; if so, and if all non-TEI elements and attributes are correctly associated with other namespaces, then the document may be TEI-conformant.
6. Is the document valid according to a schema made by combining all TEI modules as well as valid according to the schema derived from its associated ODD specification? If so, the document is TEI-conformant.
7. Is the document valid according to the schema derived from its associated ODD specification, but not according to `tei_all`? If so, the document uses a TEI extension.

8. Is it possible automatically to transform the document into a document which is valid according to `tei_all`, using only information supplied in the accompanying ODD and without loss of information? If so, the document is TEI-conformant.

In the following table, we examine more closely some specific, though imaginary, cases:

|  | A | B | C | D | E | F | G | H |
|--|---|---|---|---|---|---|---|---|
| Conforms to TEI Abstract Model   | Y | N | Y | Y | ? | Y | N | ? |
| Valid ODD present  | Y | Y | Y | Y | Y | Y | Y | N |
| Uses only non-TEI namespace(s) or none   | N | N | N | N | Y | N | Y | N |
| Uses TEI and other namespaces correctly  | Y | Y | N | Y | N | Y | N | Y |
| Document is valid as a subset of <code>tei_all</code>  | Y | N | Y | N | N | Y | N | Y |
| Document can be converted automatically to a form which is valid as a subset of <code>tei_all</code> | Y | N | Y | N | N | Y | N | ? |

We assume firstly that each sample document assessed here is a well-formed XML document, and that it is valid against some schema.

The document in column A is TEI-conformant. Its tagging follows the TEI Abstract Model, both as regards syntactic constraints (its `<l>` elements appear within `<div>` elements and not the reverse) and semantic constraints (its `<l>` elements appear to contain verse lines rather than typographic ones). It is accompanied by a valid ODD which documents exactly how it uses the TEI. All the TEI-defined elements and attributes in the document are placed in the TEI namespace. The schema against which it is valid is a 'clean' subset of the `tei_all` schema.

The document in column B is not a TEI document. Although it is accompanied by a valid TEI ODD, the resulting schema includes some 'unclean' modifications, and represents some concepts from the TEI Abstract Model using non-TEI elements; for example, it re-defines the content model of `<p>` to permit `<div>` within it, and it includes an element `<pageTrimming>` which appears to have the same meaning as the existing TEI `<fw>` element, but the equivalence is not made explicit in the ODD. It uses the TEI namespace correctly to identify the TEI elements it contains, but the ODD does not contain enough information automatically to convert its non-TEI elements into TEI equivalents.

The document in column C is TEI conformant. It is almost the same as the document in column A, except that the names of the elements used are not those specified for the TEI namespace. Because the ODD accompanying it contains an exact mapping for each element name (using the `<altIdent>` element) and there are no name conflicts, it is possible to make an automatic conversion of this document.

The document in column D is a TEI Extension. It combines elements from its own namespace with unmodified TEI elements in the TEI namespace. Its usage of TEI elements conforms to the TEI Abstract Model. Its ODD defines a new `<blort>` element which has no exact TEI equivalent, but which is assigned to an existing TEI class; consequently its schema is not a clean subset of `tei_all`. If the associated ODD provided a way of mapping this element to an existing TEI element, then this would be TEI-conformant.

The document in column E is superficially similar to document D, but because it does not use any namespace declarations (or, equivalently, it assigns unmodified TEI elements to its own namespace), it may contain name collisions; there is no way of knowing whether a `<p>` within it is the same as the TEI's `<p>` or has some other meaning. The accompanying ODD file may be used to provide the human reader with information about equivalently named elements in the TEI namespace, and hence to determine whether the document is valid with respect to the TEI Abstract Model but this is not an automatable process. In particular, cases of apparent conflict (for example use of an element `<p>` to represent a concept not in the TEI Abstract Model but in the abstract model of some other system, whose namespace has been removed as well) cannot be reliably resolved. By our current definition therefore, this is not a TEI document.

The document in column F is TEI-conformant. The difference between it and that in column D is that the new element `<blort>` which is used in this document is a specialization of an existing TEI element, and the ODD in which it is defined specifies the mapping (a `<my:blort>` may be automatically converted to a `<tei:seg type="blort">`, for example). For this to work, however, the `<blort>` must observe the same syntactic constraints as the `<seg>`; if it does not, this would also be a case of TEI Extension.

The document in column G is not a TEI document. Its structure is fully documented by a valid TEI ODD, but it does not claim to represent the TEI Abstract Model, does not use the TEI namespace, and is not intended to validate against any TEI schema.

The document in column H is very like that in column A, but it lacks an accompanying ODD. Instead, the schema used to validate it is produced simply by combining TEI schema fragments in the same way as an ODD processor would, given the ODD. If the resulting schema is a clean subset of `tei_all`, such a document is indistinguishable from a TEI-conformant one, but there is no way of determining (without inspection) whether this is the case if any modification or extension has been applied. Its status is therefore, like that of Text E, impossible to determine.

## 23.5 Implementation of an ODD System

This section specifies how a processing system may take advantage of the markup specification elements documented in chapter 22. *Documentation Elements* of these Guidelines in order to produce project specific user documentation, schemas in one or more schema languages, and validation tools for other processors.

The specifications in this section are illustrative but not normative. Its function is to further illustrate the intended scope and application of the elements documented in chapter 22. *Documentation Elements*, since it is believed that these may have application beyond the areas directly addressed by the TEI.

An ODD processing system has to accomplish two main tasks. A set of selections, deletions, changes, and additions supplied by an ODD customization (as described in 23.3. *Personalization and Customization*) must first be merged with the published TEI P5 ODD specifications. Next, the resulting unified ODD must be processed to produce the desired outputs.

An ODD processor is not required to do these two stages in sequence, but that may well be the simplest approach; the ODD processing tools currently provided by the TEI Consortium, which are also used to process the source of these Guidelines, adopt this approach.

### 23.5.1 Making a Unified ODD

An ODD customization must contain a single `<schemaSpec>` element, which defines the schema to be constructed.

**<schemaSpec>** (schema specification) generates a TEI-conformant schema and documentation for it.

**@start** specifies entry points to the schema, i.e. which patterns may be used as the root of documents conforming to it.

**@prefix** specifies a default prefix which will be prepended to all patterns relating to TEI elements, unless otherwise stated.

**@targetLang** (target language) specifies which language to use when creating the objects in a schema if names for elements or attributes are available in more than one language

**@docLang** (documentation language) specifies which languages to use when creating documentation if the description for an element, attribute, class or macro is available in more than one language

Amongst other attributes inherited from the `att.identified` class, this element also carries a required *ident* attribute. This provides a name for the generated schema, which other components of the processing system may use to refer to the schema being generated, e.g. in issuing error messages or as part of the generated output schema file or files. The *ns* attribute may be used to specify the default namespace within which elements valid against the resulting schema belong, as discussed in 23.3.2. *Modification and Namespaces*.

The `<schemaSpec>` element contains an unordered series of specialized elements, each of which is of one of the following four types:

**specifications** elements from the class `model.oddDecl` (by default `<elementSpec>`, `<classSpec>`, `<moduleSpec>`, and `<macroSpec>`); these must have a *mode* attribute which determines how they will be processed.<sup>129</sup> If the value of *mode* is *add*, then the object is simply copied to the output, but if it is *change*, *delete*, or *replace*, then it will be looked at by other parts of the process.

**references to specifications** `<specGrpRef>` elements refer to `<specGrp>` elements that occur elsewhere in this, or another, document. A `<specGrp>` element, in turn, groups together a set of ODD specifications (among other things, including further `<specGrpRef>` elements). The use of `<specGrp>` and `<specGrpRef>` permits the ODD

<sup>129</sup>An ODD processor should recognize as erroneous such obvious inconsistencies as an attempt to include an `<elementSpec>` in *add* mode for an element which is already present in an imported module.

markup to occur at the points in documentation where they are discussed, rather than all inside `<schemaSpec>`. The *target* attribute of any `<specGrpRef>` should be followed, and the `<elementSpec>`, `<classSpec>`, and `<macroSpec>`, elements in the corresponding `<specGrp>` should be processed as described in the previous item; `<specGrpRef>` elements should be processed as described here.

**references to TEI Modules** `<moduleRef>` elements with *key* attributes refer to components of the TEI. The value of the *key* attribute matches the *ident* attribute of the `<moduleSpec>` element defining a TEI module. The *key* must be dereferenced by some means, such as reading an XML file with the TEI ODD specification (either from the local hard drive or off the Web), or looking up the reference in an XML database (again, locally or remotely); whatever means is used, it should return a stream of XML containing the element, class, and macro specifications collected together in the specified module. These specification elements are then processed in the same way as if they had been supplied directly within the `<schemaSpec>` being processed.

**references to external modules** a `<moduleRef>` element may also refer to a compatible external module by means of its *url* attribute; the content of such modules, which must be available in the RELAX NG XML syntax, are passed directly and without modification to the output schema when that is created.

Each object obtained from the TEI ODD specification using `<moduleRef>` by means of the *key* attribute must be checked against objects in the customization `<schemaSpec>` according to the following rules:

1. if there is an object in the ODD customization with the same value for the *ident* attribute, and a *mode* value of delete, then the object from the module is ignored;
2. if there is an object in the ODD customization with the same value for the *ident* attribute, and a *mode* value of replace, then the object from the module is ignored, and the one from the ODD customization is used in its place;
3. if there is an object in the ODD customization with the same value for the *ident* attribute, and a *mode* value of change, then the two objects must be merged, as described below;
4. if there is an object in the ODD customization with the same value for the *ident* attribute, and a *mode* value of add, then an error condition should be raised;
5. otherwise, the object from the module is copied to the result.

To merge two objects with the same *ident*, their component attributes and child elements must be looked at recursively. Each component may fall into one of the following four categories:

1. Some components may occur only once within the merged object (for example attributes, and `<altIdent>`, `<content>`, or `<classes>` elements). If such a component is found in the ODD customization, it will be copied to the output; if it is not found there, but is present in the TEI ODD specification, then that will be copied to the output.
2. Some components are grouping objects (`<attList>`, `<valList>`, for example); these are always copied to the output, and their children are then processed following the rules given in this list.
3. Some components are ‘identifiable’: this means that they are members of the `att.identified` class from which they inherit the *ident* attribute; examples include `<attDef>` and `<valItem>`. A component of this type will be processed according to its *mode* attribute, following the rules given above.
4. Some components may occur multiple times, but are neither grouped nor identifiable. Examples include the members of `model.glossLike` such as `<equiv>`, `<desc>`, `<gloss>`, the `<exemplum>`, `<remarks>`, `<listRef>`, `<datatype>` or `<defaultVal>` elements. These should be copied from both the TEI ODD specification and the ODD customization, and all occurrences included in the output.

A special problem arises with elements which are members of attribute classes, as they are permitted to override attributes inherited from a class. For example, consider this simple modification:

```
<elementSpec ident="p">
  <classes>
    <memberOf key="att.typed"/>
```

```

</classes>
<content>
<!--...-->
</content>
</elementSpec>

```

The effect of its membership in the `att.typed` class is to provide `<p>` with a *type* attribute and a *subtype* attribute. If we wish `<p>` to *not* have *subtype*, we could extend the customization in our schema as follows:

```

<elementSpec ident="p">
  <classes>
    <memberOf key="att.typed"/>
  </classes>
  <content>
<!--...-->
  </content>
  <attList>
    <attDef ident="subtype" mode="delete"/>
  </attList>
</elementSpec>

```

This means that when `<memberOf key="att.typed"/>` is processed, that class is looked up, each attribute which it defines is examined in turn, and the customization is searched for an override. If the modification is of the attribute class itself, work proceeds as usual; if, however, the modification is at the element level, the class reference is deleted and a series of `<attRef>` elements is added to the element, one for each attribute inherited from the class. Since attribute classes can themselves be members of other attribute classes, membership must be followed recursively.

The effect of the concatenation of unidentifiable components should be considered carefully. An original may have

```

<elementSpec ident="p">
  <desc>marks paragraphs in prose.</desc>
<!--...-->
</elementSpec>

```

which would usefully be extended with this:

```

<elementSpec ident="p" mode="change">
  <desc xml:lang="es">marca párrafos en prosa.</desc>
<!--...-->
</elementSpec>

```

to provide an alternate description in another language. Nothing prevents the user from supplying `<desc>` several times in the same language, and subsequent applications will have to decide what that may mean.

Similar considerations apply to multiple example elements, though these are less likely to cause problems in documentation. Note that existing examples can only be deleted by supplying a completely new `<elementSpec>` in replace mode, since the `<exemplum>` element is not identifiable.

In the processing of the content models of elements and the content of macros, deleted elements may require special attention.<sup>130</sup> A content model like this:

<sup>130</sup>The carthago program behind the Pizza Chef application, written by Michael Sperberg-McQueen for TEI P3 and P4, went to very great efforts to get this right. The XSLT transformations used by the P5 Roma application are not as sophisticated, partly because the RELAX NG language is more forgiving than DTDs.

```

<elementSpec ident="person">
<!--...-->
  <content>
    <rng:choice>
      <rng:oneOrMore>
        <rng:ref name="model.pLike"/>
      </rng:oneOrMore>
      <rng:zeroOrMore>
        <rng:choice>
          <rng:ref name="model.personPart"/>
          <rng:ref name="model.global"/>
        </rng:choice>
      </rng:zeroOrMore>
    </rng:choice>
  </content>
<!--...-->
</elementSpec>

```

requires no special treatment because everything is expressed in terms of model classes; if deletions result in `model.personPart` having no members, then `model.global` is left as the only child of `<rng:choice>`. An ODD processor may or may not elect to simplify the resulting choice between nothing and `model.global` by removing the wrapper `<rng:choice>` element. However, such simplification may be considerably more complex in the general case (if for example the `<rng:choice>` is itself inside an `<rng:zeroOrMore>` inside a `<rng:group>`), and an ODD processor is therefore likely to be more successful in carrying out such simplification as a distinct stage during processing of ODD sources.

If an element refers directly to an element child, like this:

```

<elementSpec ident="figure">
<!--...-->
  <content>
    <rng:zeroOrMore>
      <rng:choice>
        <rng:ref name="model.pLike"/>
        <rng:ref name="model.global"/>
        <rng:ref name="figure"/>
        <rng:ref name="figDesc"/>
        <rng:ref name="model.graphicLike"/>
        <rng:ref name="model.headLike"/>
      </rng:choice>
    </rng:zeroOrMore>
  </content>
<!--...-->
</elementSpec>

```

and `<figDesc>` has been deleted,<sup>131</sup> it will be necessary to remove that reference, or the resulting schema will be invalid. Surrounding constructs, such as a `<rng:zeroOrMore>` (which cannot be empty), may also have to be removed.

The result of the work carried out should be a new `<schemaSpec>` which contains a complete and internally consistent set of element, class, and macro specifications, possibly also including `<moduleRef>` elements with `url` attributes identifying external modules.

<sup>131</sup>Note that deletion of required elements will cause the schema specification to accept as valid documents which cannot be TEI-conformant, since they no longer conform to the TEI Abstract Model; conformance topics are addressed in more detail in 23.4. *Conformance*.

### 23.5.2 Generating Schemas

Assuming that any modifications have been resolved, as outlined in the previous section, making a schema is now a four stage process:

1. all datatype and other macro specifications must be collected together and declared at the start of the output schema;
2. all classes must be declared in the right order (since some classes reference others, the order is significant);
3. all elements are declared;
4. any <moduleRef> elements with a *url* attribute identifying an external schema must be processed.

Working in this order gives the best chance of successfully supporting all the schema languages. However, there are a number of obstacles to overcome along the way.

An ODD processor may use any desired schema language or languages for its schema output. The TEI ODD specification uses RELAX NG to express content models, and is therefore biased towards this language. However, the current TEI ODD processing system is capable of producing schema output in the three main schema languages, as follows:

- A RELAX NG (XML) schema is generated by creating wrappers around the content models taken directly from the ODD specification; a version re-expressed in the RELAX NG compact syntax is generated using James Clark's *trang* application.
- A DTD schema is generated by converting the RELAX NG content models to DTD language, often simplifying it to allow for the less-sophisticated output language.
- A W3C Schema schema is created by generating a RELAX NG schema and then using James Clark's *trang* application.

Note that the method used to generate W3C Schema means that a processor must ensure that the RELAX NG it generates follows the subset which *trang* is able to translate properly (see further below)—this may involve simple trial and error.

Other projects may decide to follow a different route, perhaps implementing a direct ODD to W3C Schema translator.

Secondly, it is possible to create two rather different styles of schema. On the one hand, the schema can try to maintain all the flexibility of ODD by using the facilities of the schema language for parameterization; on the other, it can remove all customization features and produce a flat result which is not suitable for further manipulation. The TEI project currently generates both styles of schema; the first as a set of schema fragments in DTD and RELAX NG languages, which can be included as modules in other schemas, and customized further; the second as the output from a processor such as *Roma*, in which many of the parameterization features have been removed.

The difference between the schema styles may be illustrated by considering this ODD specification:

```
<elementSpec module="drama"
  ident="performance">
<!-- ... -->
  <classes>
    <memberOf key="model.frontPart.drama"/>
  </classes>
  <content>
    <rng:group>
      <rng:zeroOrMore>
        <rng:choice>
          <rng:ref name="model.divTop"/>
          <rng:ref name="model.global"/>
        </rng:choice>
      </rng:zeroOrMore>
      <rng:oneOrMore>
        <rng:group>
          <rng:ref name="model.common"/>
        </rng:group>
      </rng:oneOrMore>
    </rng:group>
  </content>
</elementSpec>
```

```

    </rng:group>
    <rng:zeroOrMore>
      <rng:ref name="model.global"/>
    </rng:zeroOrMore>
  </rng:oneOrMore>
  <rng:zeroOrMore>
    <rng:ref name="model.divBottom"/>
    <rng:zeroOrMore>
      <rng:ref name="model.global"/>
    </rng:zeroOrMore>
  </rng:zeroOrMore>
</rng:group>
</content>
<!-- ... -->
</elementSpec>

```

A simple rendering to RELAX NG produces this:

```

performance =
element performance {
(model.divTop | model.global)*,
(model.common, model.global)*+,
(model.divBottom, model.global)*
att.global.attribute.xmlspace,
att.global.attribute.xmlid,
att.global.attribute.n,
att.global.attribute.xmllang,
att.global.attribute.rend,
att.global.attribute.xmlbase,
att.global.linking.attribute.corresp,
att.global.linking.attribute.synch,
att.global.linking.attribute.sameAs,
att.global.linking.attribute.copyOf,
att.global.linking.attribute.next,
att.global.linking.attribute.prev,
att.global.linking.attribute.exclude,
att.global.linking.attribute.select
}

```

In the above, a subsequent redefinition of the attribute class (such as `att.global`) would have no effect, since references to such classes have been expanded to reference their constituent attributes.

The equivalent parameterized version might look like this:

```

performance =
element performance { performance.content, performance.attributes }
performance.content =
(model.divTop | model.global)*,
(model.common, model.global)*+,
(model.divBottom, model.global)*
performance.attributes = att.global.attributes, empty

```

Here, the attribute class `att.global` is provided via an explicit reference (`att.global.attributes`), and can therefore be redefined. Moreover, the attributes are separated from the content model, allowing either to be overridden.

In the remainder of these section, the terms *simple schema* and *parameterized schema* are used to distinguish the two schema types. An ODD processor is not required to support both, though the simple schema output is generally preferable for most applications.

Thirdly, the problem of missing components must be resolved. For example, consider this (fictitious) model for `<sp>`:

```
<elementSpec ident="sp">
<!--...-->
  <content>
    <rng:zeroOrMore>
      <rng:ref name="model.global"/>
    </rng:zeroOrMore>
    <rng:optional>
      <rng:ref name="speaker"/>
      <rng:zeroOrMore>
        <rng:ref name="model.global"/>
      </rng:zeroOrMore>
    </rng:optional>
  </content>
<!--...-->
</elementSpec>
```

This proposes anything from the global model class, followed by some `<speaker>` elements, followed by anything from the `model.global` class. What happens if `<speaker>` is removed? The following would result:

```
<elementSpec ident="sp">
<!--...-->
  <content>
    <rng:zeroOrMore>
      <rng:ref name="model.global"/>
    </rng:zeroOrMore>
    <rng:zeroOrMore>
      <rng:ref name="model.global"/>
    </rng:zeroOrMore>
  </content>
<!--...-->
</elementSpec>
```

which is illegal in DTD and W3C schema languages, since for a given member of `model.global` it is impossible to be sure which rule is being used. This situation is not detected when RELAX NG is used, since the language is able to cope with non-deterministic content models of this kind and does not require that only a single rule be used.

Finally, an application will need to have some method of associating the schema with document instances that use it. The TEI does not mandate any particular method of doing this, since different schema languages and processors vary considerably in their requirements. ODD processors may wish to build in support for some of the methods for associating a document instance with a schema. The TEI does not mandate any particular method, but does suggest that those which are already part of XML (the DOCTYPE declaration for DTDs) and W3C Schema (the `xsi:schemaLocation` attribute) be supported where possible.

In order for the `xsi:schemaLocation` attribute to be valid when a document is validated against either a DTD or a RELAX NG schema, ODD processors may wish to add declarations for this attribute and its namespace to the root element, even though these are not part of the TEI *per se*. For DTDs this means adding

```
xsi:schemaLocation CDATA #IMPLIED xmlns:xsi CDATA #FIXED 'http://www.w3.org/2001/
XMLSchema-instance'
```

to the list of attributes on the root element, which permits the non-namespace-aware DTD language to recognize the `xsi:schemaLocation` notation. For RELAX NG, the namespace and attribute would be declared in the usual way:

```
namespace xsi = "http://www.w3.org/2001/XMLSchema-instance"
```

and

```
attribute xsi:schemaLocation { list { data.namespace, data.pointer }+ }
```

inside the root element declaration.

Note that declaration of the `xsi:schemaLocation` attribute in a W3C Schema schema is not permitted. Therefore, if W3C Schemas are being generated by converting the RELAX NG schema (for example, with `trang`), it may be necessary to perform that conversion prior to adding the `xsi:schemaLocation` declaration to the RELAX NG.

It is recognized that this is an unsatisfactory solution, but it permits users to take advantage of the W3C Schema facility for indicating a schema, while still permitting documents to be validated using DTD and RELAX NG processors without any conflict.

### 23.5.3 Names and Documentation in Generated Schemas

When processing class, element, or macro specifications, there are three general rules:

1. If a RELAX NG pattern or DTD parameter entity is being created, its name is the value of the corresponding *ident* attribute, prefixed by the value of any *prefix* attribute on `<schemaSpec>`. This allows for elements from an external schema to be mixed in without risk of name clashes, since all TEI elements can be given a distinctive prefix such as `tei_`. Thus

```
<schemaSpec ident="test" prefix="tei_">
  <elementSpec ident="sp">
    <!--...-->
  </elementSpec>
</schemaSpec>
```

may generate a RELAX NG (compact syntax) pattern like this:

```
tei_ sp = element sp { ... }
```

References to these patterns (or, in DTDs, parameter entities) also need to be prefixed with the same value.

2. If an element or attribute is being created, its default name is the value of the *ident* attribute, but if there is an `<altIdent>` child, its content is used instead.
3. Where appropriate, the documentation strings in `<gloss>` and `<desc>` should be copied into the generated schema. If there is only one occurrence of either of these elements, it should be used regardless, but if there are several, local processing rules will need to be applied. For example, if there are several with different values of `xml:lang`, a locale indication in the processing environment might be used to decide which to use. For example,

```

<elementSpec module="core" ident="head">
  <equiv/>
  <gloss>heading</gloss>
  <gloss xml:lang="fr">en-tête</gloss>
  <gloss xml:lang="es">encabezamiento</gloss>
  <gloss xml:lang="it">titolo</gloss>
  <!-- ... -->
</elementSpec>

```

might generate a RELAX NG schema fragment like the following, if the locale is determined to be French:

```

head =
## en-tête
element head { head.content, head.attributes }

```

Alternatively, a selection might be made on the basis of the value of the *version* attribute which these elements carry as members of the `att.translatable` class.

In addition, there are three conventions about naming patterns relating to classes; ODD processors need not follow them, but those reading the schemas generated by the TEI project will find it necessary to understand them:

1. when a pattern for an attribute class is created, it is named after the attribute class identifier (as above) suffixed by `.attributes` (e.g. `att.editLike.attributes`);
2. when a pattern for an attribute is created, it is named after the attribute class identifier (as above) suffixed by `.attribute`. and then the identifier of the attribute (e.g. `att.editLike.attribute.resp`);
3. when a parameterized schema is created, each element generates patterns for its attributes and its contents separately, suffixing respectively `.attributes` and `.contents` to the element name.

### 23.5.4 Making a RELAX NG Schema

To create a RELAX NG schema, the processor processes every `<macroSpec>`, `<classSpec>`, and `<elementSpec>` in turn, creating a RELAX NG pattern for each, using the naming conventions listed above. The order of declaration is not important, and a processor may well sort them into alphabetical order of identifier.

A complete RELAX NG schema must have an `<rng:start>` element defining which elements can occur as the root of a document. The ODD `<schemaSpec>` has an optional *start* attribute, containing one or more patterns, which can be used to construct the `<rng:start>`. A pattern normally corresponds to an element name, but if a prefix (see above, 23.5.3. *Names and Documentation in Generated Schemas*) is supplied for an element, the pattern consists of the prefix name with the element name.

#### 23.5.4.1 Macros

An ODD macro generates a corresponding RELAX NG pattern simply by copying the body of the `<content>` element. Thus

```

<macroSpec module="tei" type="pe"
  ident="macro.phraseSeq">
  <content>
    <rng:zeroOrMore>
      <rng:choice>
        <rng:text/>
        <rng:ref name="model.gLike"/>
        <rng:ref name="model.phrase"/>
        <rng:ref name="model.global"/>

```

```

    </rng:choice>
  </rng:zeroOrMore>
</content>
</macroSpec>

```

produces

```

<rng:define name="macro.phraseSeq">
  <rng:zeroOrMore>
    <rng:choice>
      <rng:text/>
      <rng:ref name="model.gLike"/>
      <rng:ref name="model.phrase"/>
      <rng:ref name="model.global"/>
    </rng:choice>
  </rng:zeroOrMore>
</rng:define>

```

Although some versions of these Guidelines show the RELAX NG output in the compact syntax, both the content of the `<content>` element and the unified ODD specification generated by the TEI ODD processing software always store RELAX NG in the more verbose XML syntax. However, the two formats are interchangeable.

#### 23.5.4.2 Classes

An ODD model class reference generates a RELAX NG pattern definition listing all the members of the class present in the ODD in alternation. So this example

```

<classSpec module="tei" type="model"
  ident="model.measureLike">
  <!-- ... -->
</classSpec>

```

may produce, for a given customization:

```

<rng:define name="model.measureLike">
  <rng:choice>
    <rng:ref name="num"/>
    <rng:ref name="measure"/>
    <rng:ref name="measureGrp"/>
  </rng:choice>
</rng:define>

```

if the elements `<num>`, `<measure>`, and `<measureGrp>` are included. Depending on the value of the *generate* attribute on the `<classSpec>`, it may also generate a set of sequences as well as alternation patterns. Thus we may also generate the `sequenceOptional`, `sequenceRepeatable`, and `sequenceOptionalRepeatable` patterns:

```

<rng:define name="model.measureLike_sequence">
  <rng:ref name="num"/>
  <rng:ref name="measure"/>
  <rng:ref name="measureGrp"/>
</rng:define>

```

```

<rng:define name="model.measureLike_sequenceOptional">
  <rng:optional>
    <rng:ref name="num" />
  </rng:optional>
  <rng:optional>
    <rng:ref name="measure" />
  </rng:optional>
  <rng:optional>
    <rng:ref name="measureGrp" />
  </rng:optional>
</rng:define>
<rng:define name="model.measureLike_sequenceOptionalRepeatable">
  <rng:zeroOrMore>
    <rng:ref name="num" />
  </rng:zeroOrMore>
  <rng:zeroOrMore>
    <rng:ref name="measure" />
  </rng:zeroOrMore>
  <rng:zeroOrMore>
    <rng:ref name="measureGrp" />
  </rng:zeroOrMore>
</rng:define>
<rng:define name="model.measureLike_sequenceRepeatable">
  <rng:oneOrMore>
    <rng:ref name="num" />
  </rng:oneOrMore>
  <rng:oneOrMore>
    <rng:ref name="measure" />
  </rng:oneOrMore>
  <rng:oneOrMore>
    <rng:ref name="measureGrp" />
  </rng:oneOrMore>
</rng:define>

```

where the pattern name is created by appending an underscore and the name of the generation sequence to the class name.

Attribute classes work by producing a pattern containing definitions of the appropriate attributes. So

```

<classSpec module="verse" type="atts"
  ident="att.enjamb">
  <attList>
    <attDef ident="enjamb" usage="opt">
      <equiv/>
      <desc>indicates whether the end of a verse line is marked by enjambement.</desc>
      <datatype>
        <rng:ref name="data.enumerated" />
      </datatype>
      <valList type="open">
        <valItem ident="no">
          <equiv/>
          <desc>the line is end-stopped </desc>
        </valItem>
        <valItem ident="yes">
          <equiv/>
          <desc>the line in question runs on into the next </desc>
        </valItem>
      </valList>
    </attDef>
  </attList>

```

```

    <valItem ident="weak">
      <equiv/>
      <desc>the line is weakly enjambed </desc>
    </valItem>
    <valItem ident="strong">
      <equiv/>
      <desc>the line is strongly enjambed</desc>
    </valItem>
  </valList>
</attDef>
</attList>
</classSpec>

```

produces

```

<rng:define name="att.enjamb.attributes">
  <rng:ref name="att.enjamb.attribute.enjamb"/>
  <rng:empty/>
</rng:define>
<rng:define name="att.enjamb.attribute.enjamb">
  <rng:optional>
    <rng:attribute name="enjamb">
      <a:documentation>(enjambement) indicates whether the end of a verse line is marked
by
      enjambement. Sample values include: 1] no; 2] yes; 3] weak; 4]
      strong</a:documentation>
    <rng:ref name="data.enumerated"/>
    </rng:attribute>
  </rng:optional>
</rng:define>

```

Since the processor may have expanded the attribute classes already, separate patterns are generated for each attribute in the class as well as one for the class itself. This allows an element to refer directly to a member of a class. Notice that the <desc> element is used to add an <a:documentation> element to the schema, which some editors use to provide help during composition. The <desc> elements in the <valList> are used to create the human-readable sentence ‘Sample values include: 1] no; 2] yes; 3] weak; 4] strong’ Naturally, this behaviour is not mandatory; and other ODD processors may create documentation in other ways, or ignore those parts of the ODD specifications when creating schemas.

An individual attribute consists of an <rng:attribute> with a *name* attribute derived according to the naming rules described above (23.5.3. *Names and Documentation in Generated Schemas*). In addition, the ODD model supports a <defaultVal>, which is transformed to a *defaultValue* attribute in the namespace <http://relaxng.org/ns/compatibility/annotations/1.0> attribute on the <rng:attribute>. The body of the attribute is taken from the <datatype> child, unless there is a supporting <valList> with a *type* value of closed. In that case an <rng:choice> is created, listing the allowed values. Thus the following attribute definition

```

<attDef ident="full" usage="opt">
  <defaultVal>yes</defaultVal>
  <valList type="closed">
    <valItem ident="yes">
      <desc>the name component is spelled out in full.</desc>
    </valItem>
    <valItem ident="abb">
      <gloss>abbreviated</gloss>
    </valItem>
  </valList>
</attDef>

```

```

    <desc>the name component is given in an abbreviated form.</desc>
  </valItem>
  <valItem ident="init">
    <gloss>initial letter</gloss>
    <desc>the name component is indicated only by one initial.</desc>
  </valItem>
</valList>
</attDef>

```

may generate this RELAX NG code:

```

<rng:define name="att.full">
  <rng:optional>
    <rng:attribute name="full"
      a:defaultValue="yes">
      <rng:choice>
        <rng:value>yes</rng:value>
        <a:documentation> the name component is spelled out in full. </a:documentation>
        <rng:value>abb</rng:value>
        <a:documentation> the name component is given in an abbreviated form.
</a:documentation>
        <rng:value>init</rng:value>
        <a:documentation> the name component is indicated only by one initial.
</a:documentation>
      </rng:choice>
    </rng:attribute>
  </rng:optional>
</rng:define>

```

Note the use of the <http://relaxng.org/ns/compatibility/annotations/1.0> namespace to provide default values and documentation.

### 23.5.4.3 Elements

An `<elementSpec>` produces a RELAX NG specification in two parts; firstly, it must generate an `<rng:define>` pattern by which other elements can refer to it, and then it must generate an `<rng:element>` with the content model and attributes. It may be convenient to make two separate patterns, one for the element's attributes and one for its content model.

The content model is created simply by copying the body of the `<content>` element; the attributes are processed in the same way as those from attribute classes, described above.

### 23.5.5 Making a DTD

Generation of DTDs largely follows the same pattern as RELAX NG generation, with one important exception—*the order of declaration matters*. A DTD may not refer to an entity which has not yet been declared. Since both macros and classes generate DTD parameter entities, the TEI Guidelines are constructed so that they can be declared in the right order. A processor must therefore work in the following order:

1. declare all model classes which have a *predeclare* value of true
2. declare all macros which have a *predeclare* value of true
3. declare all other classes
4. declare the modules (if DTD fragments are being constructed)
5. declare any remaining macros
6. declare the elements and their attributes

Let us consider a complete example, a simple element with no attributes of its own:

```
<elementSpec module="namesdates"
  ident="faith">
  <desc>specifies the faith, religion, or belief set of a person.</desc>
  <classes>
    <memberOf key="model.persStateLike"/>
    <memberOf key="att.editLike"/>
    <memberOf key="att.datable"/>
  </classes>
  <content>
    <rng:ref name="macro.phraseSeq"/>
  </content>
</elementSpec>
```

If DTD fragments are being generated (for use as described in 23.5.7. *Using TEI Parameterized Schema Fragments*), this will result in the following:

```
<!ENTITY % faith 'INCLUDE' >
<![ %faith; [

<!--doc:specifies the faith, religion, or belief set of a person. -->
<!ELEMENT %n.fait; %om.RR; %macro.phraseSeq;>
<!ATTLIST %n.fait; xmlns CDATA "http://www.tei-c.org/ns/1.0">
<!ATTLIST %n.fait;
%att.global.attributes;
%att.editLike.attributes;
%att.datable.attributes; >
]]>
```

Here the whole stanza is contained in a marked section (for use as described in 23.5.7.2. *Inclusion and Exclusion of Elements*), the element name is parameterized (see 23.5.7.3. *Changing the Names of Generic Identifiers*), and the class attributes are entity references derived from the <memberOf> records in <classes>. Note the additional attribute which provides a default *xmlns* declaration for the element; the effect of this is that if the document is processed by a DTD-aware XML processor, the namespace declaration will be present automatically without the document author even being aware of it.

A simpler rendition for a flattened DTD generated from a customization will result in the following, with no containing marked section, and no parameterized name:

```
<!ELEMENT faith %macro.phraseSeq;>
<!ATTLIST faith xmlns CDATA "http://www.tei-c.org/ns/1.0">
<!ATTLIST faith
%att.global.attribute.xmlspace;
%att.global.attribute.xmlid;
%att.global.attribute.n;
%att.global.attribute.xmllang;
%att.global.attribute.rend;
%att.global.attribute.xmlbase;
%att.global.linking.attribute.corresp;
%att.global.linking.attribute.synch;
%att.global.linking.attribute.sameAs;
```

```

%att.global.linking.attribute.copyOf;
%att.global.linking.attribute.next;
%att.global.linking.attribute.prev;
%att.global.linking.attribute.exclude;
%att.global.linking.attribute.select;
%att.editLike.attribute.cert;
%att.editLike.attribute.resp;
%att.editLike.attribute.evidence;
%att.dateable.w3c.attribute.period;
%att.dateable.w3c.attribute.when;
%att.dateable.w3c.attribute.notBefore;
%att.dateable.w3c.attribute.notAfter;
%att.dateable.w3c.attribute.from;
%att.dateable.w3c.attribute.to;>

```

Here the attributes from classes have been expanded into individual entity references.

### 23.5.6 Generating Documentation

In Donald Knuth's literate programming terminology (Knuth (1992)), the previous sections have dealt with the *tangle* process; to generate documentation, we now turn to the *weave* process.

An ODD customization may consist largely of general documentation and examples, requiring no ODD-specific processing. It will normally however also contain a <schemaSpec> element and possibly some <specGrp> fragments.

The generated documentation may be of two forms. On the one hand, we may document the customization itself, that is, only those elements (etc.) which differ in their specification from that provided by the TEI reference documentation. Alternatively, we may generate reference documentation for the complete subset of the TEI which results from applying the customization. The TEI Roma tools take the latter approach, and operate on the result of the first stage processing described in 23.5.1. *Making a Unified ODD*.

Generating reference documentation for <elementSpec>, <classSpec>, and <macroSpec> elements is largely dependent on the design of the preferred output. Some applications may, for example, want to turn all names of objects into hyperlinks, show lists of class members, or present lists of attributes as tables, lists, or inline prose. Another technique implemented in these Guidelines is to show lists of potential 'parents' for each element, by tracing which other elements have them as possible members of their content models.

One model of display on a web page is shown in 29, corresponding to the <faith> element shown in section 23.5.5. *Making a DTD*.

### 23.5.7 Using TEI Parameterized Schema Fragments

The TEI parameterized DTD and RELAX NG fragments make use of parameter entities and patterns for several purposes. In this section we describe their interface for the user. In general we recommend use of ODD instead of this technique.

#### 23.5.7.1 Selection of Modules

Special-purpose parameter entities are used to specify which modules are to be combined into a TEI DTD. They take the form `TEI.xxxxx` where `xxxxx` is the name of the module as given in table the table on p. 2 in 1.1. *TEI Modules*. For example, the parameter entity `TEI.linking` is used to define whether or not to include the module `linking`. All such parameter entities are declared by default with the value `IGNORE`: to select a module, therefore, the encoder declares the appropriate parameter entities with the value `INCLUDE`.

For XML DTD fragments, note that some modules generate two DTD fragments: for example the `analysis` module generates fragments called `analysis-decl` and `analysis`. This is because the declarations they contain are needed at different points in the creation of an XML DTD.

The parameter entity named for the module is used as the keyword controlling a conditional marked section in the DTD fragment generated by the `tei` module. The declarations for each DTD fragment constituting the module are contained within such marked sections. For example, the parameter entity `TEI.linking` appears twice in `tei.dtd`, once for the `linking-decl` schema fragment:

| <b>&lt;faith&gt;</b>   |  | Home   Table of Contents<br>Element catalogue |
|--|--|---|
| <b>&lt;faith&gt;</b> specifies the faith, religion, or belief set of a person. |  |   |
| <b>Module</b>  | namesdates — <a href="#">13 Names, Dates, People, and Places</a>   |   |
| <b>Attributes</b>  | [ <a href="#">att.editLike</a> <a href="#">att.dateable</a> ]  |   |
| <b>Declaration</b>   | <div style="text-align: right;"><a href="#">Compact to XML format</a></div> <pre> element faith {   att.global.attributes,   att.editLike.attributes,   att.dateable.w3c.attributes,   att.dateable.iso.attributes,   macro.phraseSeq } </pre> |   |
| <b>Example</b>   | <code>&lt;faith&gt;protestant&lt;/faith&gt;</code>   |   |
| <b>Contained by</b>  | <a href="#">model.persTraitLike</a>  |   |

Figure 29: Example reference documentation for &lt;faith&gt;

```

<!ENTITY % TEI.linking 'IGNORE' >
<![%TEI.linking;[
<!ENTITY % file.linking-decl PUBLIC '-//TEI P5//ENTITIES Linking, Segmentation, and
Alignment//EN' 'linking-decl.dtd' >
%file.linking-decl;
]] >

```

and once for the linking schema fragment:

```

<![%TEI.linking;[
<!ENTITY % file.linking PUBLIC '-//TEI P5//ELEMENTS Linking, Segmentation, and Align-
ment//EN' 'linking.dtd' >
%file.linking;
]] >

```

If TEI.linking has its default value of IGNORE, neither declaration has any effect. If however it has the value INCLUDE, then the content of each marked section is acted upon: the parameter entities `file.linking` and `file.linking-decl` are referenced, which has the effect of embedding the content of the files they represent at the appropriate point in the DTD.

The RELAX NG schema fragments can be combined in a wrapper schema using the standard mechanism of `<rng:include>` in that language.

### 23.5.7.2 Inclusion and Exclusion of Elements

The TEI DTD fragments also use marked sections and parameter entity references to allow users to exclude the definitions of individual elements, in order either to make the elements illegal in a document or to allow the element to be redefined. The parameter entities used for this purpose have exactly the same name as the generic identifier of the element concerned. The default definition for these parameter entities is INCLUDE but they may be changed to IGNORE in order to exclude the standard element and attribute definition list declarations from the DTD.

The declarations for the element `<p>`, for example, are preceded by a definition for a parameter entity with the name `p` and contained within a marked section whose keyword is given as `%p;`:

```
<!ENTITY % p 'INCLUDE' >
<![ %p; [
<!-- element and attribute list declaration for p here -->
]]
```

These parameter entities are defined immediately preceding the element whose declarations they control; because their names are completely regular, they are not documented further.

To define a DTD in which the element <p> is excluded therefore, the entity `p` needs to be redefined as IGNORE by ensuring that a declaration such as

```
<!ENTITY % p 'IGNORE' >
```

is added earlier in the DTD than the default (see further *23.5.7.4. Embedding Local Modifications (DTD only)*).

Similarly, in the parameterized RELAX NG schemas, every element is defined by a pattern named after the element. To undefine an element therefore all that is necessary is to add a declaration like the following:

```
p = notAllowed
```

### 23.5.7.3 Changing the Names of Generic Identifiers

In the TEI DTD fragments, elements are not referred to directly by their generic identifiers; instead, the DTD fragments refer to parameter entities which expand to the standard generic identifiers. This allows users to rename elements by redefining the appropriate parameter entity. Parameter entities used for this purpose are formed by taking the standard generic identifier of the element and attaching the string `n.` as a prefix. Thus the standard generic identifiers for paragraphs, notes, and quotations, <p>, <note>, and <persName> are defined by declarations of the following form:

```
<!ENTITY % n.p "p">
<!ENTITY % n.note "note">
<!ENTITY % n.persName "persName">
```

Note that since all names are case-sensitive, the specific mix of uppercase and lowercase letters in the standard generic identifier must be preserved in the entity name.

These declarations are generated by an ODD processor when TEI DTD fragments are created.

In the RELAX NG schemas, all elements are normally defined using a pattern with the same name as the element (as described in *23.5.3. Names and Documentation in Generated Schemas*): for example

```
abbr = element abbr { abbr.content, abbr.attributes }
```

The easiest way of renaming the element is thus simply to rewrite the pattern with a different element name; any references use the pattern, not the element, name.

```
abbr = element abbrev { abbr.content, abbr.attributes }
```

More complex revisions, such as redefining the content of the element (defined by the pattern `abbr.content`) or its attributes (defined by the pattern `abbr.attributes`) can be accomplished in a similar way, using the features of the RELAX NG language. The recommended method of carrying out such modifications is however to use the ODD language as further described in section 22. *Documentation Elements*.

#### 23.5.7.4 Embedding Local Modifications (DTD only)

Any local modifications to a DTD (i.e. changes to a schema other than simple inclusion or exclusion of modules) are made by declarations stored in one of two local extension files, one containing modifications to the TEI parameter entities, and the other new or changed declarations of elements and their attributes. Entity declarations must be made which associate the names of these two files with the appropriate parameter entity so that the declarations they contain can be embedded within the TEI DTD at an appropriate point.

The following entities are referred to by the main `tei.dtd` file to embed portions of the TEI DTD fragments or locally developed extensions.

**TEI.extensions.ent** identifies a local file containing extensions to the TEI parameter entities

**TEI.extensions.dtd** identifies a local file containing extensions to the TEI module

For example, if the relevant files are called `project.ent` and `project.dtd`, then declarations like the following would be appropriate:

```
<!ENTITY % TEI.extensions.ent SYSTEM 'project.ent' >
<!ENTITY % TEI.extensions.dtd SYSTEM 'project.dtd' >
```

When an entity is declared more than once, the first declaration is binding and the others are ignored. The local modifications to parameter entities should therefore be handled before the standard parameter entities themselves are declared in `tei.dtd`. The entity `TEI.extensions.ent` is referred to before any TEI declarations are handled, to allow the user's declarations to take priority. If the user does not provide a `TEI.extensions.ent` entity, the entity will be expanded to the empty string.

For example the encoder might wish to add two phrase-level elements `<it>` and `<bd>`, perhaps as synonyms for `<hi rend='italics'>` and `<hi rend='bold'>`. As described in chapter 23.3. *Personalization and Customization*, this involves two distinct steps: one to define the new elements, and the other to ensure that they are placed into the TEI document structure at the right place.

Creating the new declarations is done in the same way for user-defined elements as for any other; the same parameter entities need to be defined so that they may be referenced by other elements. The content models of these new elements may also reference other parameter entities, which is why they need to be declared after other declarations.

The second step involves modifying the element class to which the new elements should be attached. This requires that the parameter entity `macro.phraseSeq` should be modified to include the generic identifiers for the new elements we wish to create. The declaration for each modifiable parameter entity in the DTD includes a reference to an additional parameter entity with the same name prefixed by an `X.`; these entities are declared by default as the null string. However, in the file containing local declarations they may be redeclared to include references to the new class members:

```
<!ENTITY % x.macro.phraseSeq 'it | bd | '>
```

and this declaration will take precedence over the default when the declaration for `macro.phraseSeq` is evaluated.

---

## A Model Classes

---

**model.addressLike** groups elements used to represent a postal or email address. [1. *The TEI Infrastructure*]

*Module* tei – The TEI Infrastructure

*Used by* location model.correspActionPart model.pPart.data

*Members* address affiliation email

---

---

**model.titlepagePart** groups elements which can occur as direct constituents of a title page, such as <docTitle>, <docAuthor>, <docImprint>, or <epigraph>. [4.6. Title Pages]

*Module* tei – The TEI Infrastructure

*Used by* msItem titlePage

*Members* argument binaryObject byline docAuthor docDate docEdition docImprint docTitle epigraph graphic imprimatur titlePart

## B Attribute Classes

**att.ascribed** provides attributes for elements representing speech or action that can be ascribed to a specific individual. [3.3.3. *Quotation 8.3. Elements Unique to Spoken Texts*]

*Module* tei – The TEI Infrastructure

*Members* annotationBlock change incident kinesic move pause q said setting shift sp spGrp stage u vocal writing

*Attributes* Attributes

**@who** indicates the person, or group of people, to whom the element content is ascribed.

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.pointer separated by whitespace

In the following example from Hamlet, speeches (<sp>) in the body of the play are linked to <castItem> elements in the <castList> using the *who* attribute.

```
<castItem type="role">
  <role xml:id="Barnardo">Bernardo</role>
</castItem>
<castItem type="role">
  <role xml:id="Francisco">Francisco</role>
  <roleDesc>a soldier</roleDesc>
</castItem>
<!-- ... -->
<sp who="#Barnardo">
  <speaker>Bernardo</speaker>
  <l n="1">Who's there?</l>
</sp>
<sp who="#Francisco">
  <speaker>Francisco</speaker>
  <l n="2">Nay, answer me: stand, and unfold yourself.</l>
</sp>
```

*Note* For transcribed speech, this will typically identify a participant or participant group; in other contexts, it will point to any identified <person> element.

**att.breaking** provides an attribute to indicate whether or not the element concerned is considered to mark the end of an orthographic token in the same way as whitespace. [3.10.3. *Milestone Elements*]

*Module* tei – The TEI Infrastructure

*Members* cb gb lb milestone pb

*Attributes* Attributes

**@break** indicates whether or not the element bearing this attribute should be considered to mark the end of an orthographic token in the same way as whitespace.

*Status* Recommended

*Datatype* teidata.enumerated

*Sample values include* **yes** the element bearing this attribute is considered to mark the end of any adjacent orthographic token irrespective of the presence of any adjacent whitespace

**no** the element bearing this attribute is considered not to mark the end of any adjacent orthographic token irrespective of the presence of any adjacent whitespace

**maybe** the encoding does not take any position on this issue.

In the following lines from the 'Dream of the Rood', linebreaks occur in the middle of the words *lādost* and *reord-berendum*. <ab> ...epesa tome iu icpæs

```

3eporden p̄ita heardoft .
leodum la<lb break="no"/> ðost ærþan ichim lifes
pe3 rihtne 3erymde reord be<lb break="no"/>
rendum h̄pæt me þa3eþeorðode puldres ealdor ofer...
</ab>

```

---

**att.canonical** provides attributes which can be used to associate a representation such as a name or title with canonical information about the object being named or referenced.

*Module* tei – The TEI Infrastructure

*Members* att.naming[att.personal[addName forename genName name orgName persName placeName roleName surname] affiliation author birth bloc climate collection country death district editor education event geogFeat geogName institution nationality occupation offset origPlace population pubPlace region repository residence rs settlement socecStatus state terrain trait] correspDesc docAuthor docTitle faith funder material meeting objectType principal relation resp respStmt sponsor term title

*Attributes* Attributes

**@key** provides an externally-defined means of identifying the entity (or entities) being named, using a coded value of some kind.

*Status* Optional

*Datatype* teidata.text

```

<author>
  <name key="name 427308"
    type="organisation">[New Zealand Parliament, Legislative
Council]</name>
</author>
<author>
  <name key="Hugo, Victor (1802-1885)"
    ref="http://www.idref.fr/026927608">Victor Hugo</name>
</author>

```

*Note* The value may be a unique identifier from a database, or any other externally-defined string identifying the referent. No particular syntax is proposed for the values of the key attribute, since its form will depend entirely on practice within a given project. For the same reason, this attribute is not recommended in data interchange, since there is no way of ensuring that the values used by one project are distinct from those used by another. In such a situation, a preferable approach for magic tokens which follows standard practice on the Web is to use a *ref* attribute whose value is a tag URI as defined in RFC 4151.

**@ref** (reference) provides an explicit means of locating a full definition or identity for the entity being named by means of one or more URIs.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

```

<name ref="http://viaf.org/viaf/109557338"
  type="person">Seamus Heaney</name>

```

*Note* The value must point directly to one or more XML elements or other resources by means of one or more URIs, separated by whitespace. If more than one is supplied the implication is that the name identifies several distinct entities.

**att.citing** provides attributes for specifying the specific part of a bibliographic item being cited. [1.3.1. Attribute Classes]

*Module* tei – The TEI Infrastructure

*Members* biblScope citedRange

*Attributes* Attributes

**@unit** identifies the unit of information conveyed by the element, e.g. columns, pages, volume.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **volume** the element contains a volume number.

**issue** the element contains an issue number, or volume and issue numbers.

**page** the element contains a page number or page range.

**line** the element contains a line number or line range.

**chapter** the element contains a chapter indication (number and/or title)

**part** the element identifies a part of a book or collection.

**column** the element identifies a column.

**@from** specifies the starting point of the range of units indicated by the *unit* attribute.

*Status* Optional

*Datatype* teidata.word

**@to** specifies the end-point of the range of units indicated by the *unit* attribute.

*Status* Optional

*Datatype* teidata.word

**att.combinable** provides attributes indicating how multiple references to the same object in a schema should be combined

*Module* tagdocs – Documentation Elements

*Members* att.identified[attDef classSpec constraintSpec dataSpec elementSpec macroSpec moduleSpec paramSpec schemaSpec] valDesc valItem valList

*Attributes* att.deprecated (@validUntil)

**@mode** specifies the effect of this declaration on its parent object.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **add** this declaration is added to the current definitions[Default]

**delete** if present already, the whole of the declaration for this object is removed from the current setup

**change** this declaration changes the declaration of the same name in the current definition

**replace** this declaration replaces the declaration of the same name in the current definition

*Note* An ODD processor should handle the values for *mode* as follows:

**add** the object should be created (processing any children in add mode); raise an error if an object with the same identifier already exists

**replace** use this object in preference to any existing object with the same identifier, and ignore any children of that object; process any new children in replace mode

**delete** do not process this object or any existing object with the same identifier; raise an error if any new children supplied

**change** process this object, and process its children, and those of any existing object with the same identifier, in change mode

**att.coordinated** provides attributes which can be used to position their parent element within a two dimensional coordinate system.

*Module* transcr — Representation of Primary Sources

*Members* line surface zone

*Attributes* Attributes

**@start** indicates the element within a transcription of the text containing at least the start of the writing represented by this zone or surface.

*Status* Optional

*Datatype* teidata.pointer

**@ulx** gives the x coordinate value for the upper left corner of a rectangular space.

*Status* Optional

*Datatype* teidata.numeric

**@uly** gives the y coordinate value for the upper left corner of a rectangular space.

*Status* Optional

*Datatype* teidata.numeric

**@lrx** gives the x coordinate value for the lower right corner of a rectangular space.

*Status* Optional

*Datatype* teidata.numeric

**@lry** gives the y coordinate value for the lower right corner of a rectangular space.

*Status* Optional

*Datatype* teidata.numeric

**@points** identifies a two dimensional area within the bounding box specified by the other attributes by means of a series of pairs of numbers, each of which gives the x,y coordinates of a point on a line enclosing the area.

*Status* Optional

*Datatype* 3–∞ occurrences of teidata.point separated by whitespace

---

**att.cReferencing** provides an attribute which may be used to supply a *canonical reference* as a means of identifying the target of a pointer.

*Module* tei — The TEI Infrastructure

*Members* gloss ptr ref term

*Attributes* Attributes

**@cRef** (canonical reference) specifies the destination of the pointer by supplying a canonical reference expressed using the scheme defined in a <refsDecl> element in the TEI header

*Status* Optional

*Datatype* teidata.text

*Note* The value of *cRef* should be constructed so that when the algorithm for the resolution of canonical references (described in section 16.2.5. *Canonical References*) is applied to it the result is a valid URI reference to the intended target. The <refsDecl> to use may be indicated with the *decls* attribute.

Currently these Guidelines only provide for a single canonical reference to be encoded on any given <ptr> element.

---

**att.damaged** provides attributes describing the nature of any physical damage affecting a reading. [11.3.3.1. *Damage, Illegibility, and Supplied Text 1.3.1. Attribute Classes*]

*Module* tei – The TEI Infrastructure

*Members* damage damageSpan

*Attributes* att.dimensions (*@unit*, *@quantity*, *@extent*, *@precision*, *@scope*) (att.ranging (*@atLeast*, *@atMost*, *@min*, *@max*, *@confidence*)) att.written (*@hand*)

**@agent** categorizes the cause of the damage, if it can be identified.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **rubbing** damage results from rubbing of the leaf edges

**mildew** damage results from mildew on the leaf surface

**smoke** damage results from smoke

**@degree** provides a coded representation of the degree of damage, either as a number between 0 (undamaged) and 1 (very extensively damaged), or as one of the codes high, medium, low, or unknown. The <damage> element with the *degree* attribute should only be used where the text may be read with some confidence; text supplied from other sources should be tagged as <supplied>.

*Status* Optional

*Datatype* teidata.probCert

*Note* The <damage> element is appropriate where it is desired to record the fact of damage although this has not affected the readability of the text, for example a weathered inscription. Where the damage has rendered the text more or less illegible either the <unclear> tag (for partial illegibility) or the <gap> tag (for complete illegibility, with no text supplied) should be used, with the information concerning the damage given in the attribute values of these tags. See section 11.3.3.2. *Use of the gap, del, damage, unclear, and supplied Elements in Combination* for discussion of the use of these tags in particular circumstances.

**@group** assigns an arbitrary number to each stretch of damage regarded as forming part of the same physical phenomenon.

*Status* Optional

*Datatype* teidata.count

**att.dateable** provides attributes for normalization of elements that contain dates, times, or dateable events. [3.5.4.

*Dates and Times 13.3.6. Dates and Times]*

*Module* tei – The TEI Infrastructure

*Members* acquisition affiliation age application binding birth bloc change climate country creation custEvent date death district education event faith floruit geogFeat geogName langKnowledge langKnown licence location name nationality occupation offset orgName origDate origPlace origin persName placeName population precision provenance region relation residence resp seal settlement sex socecStatus stamp state terrain time trait

*Attributes* att.dateable.w3c (*@when*, *@notBefore*, *@notAfter*, *@from*, *@to*) att.dateable.iso (*@when-iso*, *@notBefore-iso*, *@notAfter-iso*, *@from-iso*, *@to-iso*) att.dateable.custom (*@when-custom*, *@notBefore-custom*, *@notAfter-custom*, *@from-custom*, *@to-custom*, *@datingPoint*, *@datingMethod*)

**@calendar** indicates the system or calendar to which the date represented by the content of this element belongs.

*Status* Optional

*Datatype* teidata.pointer

*Schematron* <sch:rule context="tei:\*[@calendar]"> <sch:assert test="string-length(.) gt 0">@calendar indicates the system or calendar to which the date represented by the content of this element belongs, but this <sch:name/> element has no textual content.</sch:assert> </sch:rule>

He was born on `<date calendar="#Gregorian">Feb. 22, 1732</date>`  
`(<date calendar="#Julian"`  
`when="1732-02-22"> Feb. 11, 1731/32, O.S.</date>).`

*Note* Note that the *calendar* attribute (unlike *datingMethod* defined in `att.datable.custom`) defines the calendar system of the date in the original material defined by the parent element, *not* the calendar to which the date is normalized.

`@period` supplies a pointer to some location defining a named period of time within which the datable item is understood to have occurred.

*Status* Optional

*Datatype* `teidata.pointer`

*Note* This ‘superclass’ provides attributes that can be used to provide normalized values of temporal information. By default, the attributes from the `att.datable.w3c` class are provided. If the module for names & dates is loaded, this class also provides attributes from the `att.datable.iso` and `att.datable.custom` classes. In general, the possible values of attributes restricted to the W3C datatypes form a subset of those values available via the ISO 8601 standard. However, the greater expressiveness of the ISO datatypes may not be needed, and there exists much greater software support for the W3C datatypes.

---

**att.datable.custom** provides attributes for normalization of elements that contain datable events to a custom dating system (i.e. other than the Gregorian used by W3 and ISO). [*13.3.6. Dates and Times*]

*Module* `namesdates` — Names, Dates, People, and Places

*Members* `att.datable`[`acquisition` `affiliation` `age` `application` `binding` `birth` `bloc` `change` `climate` `country` `creation` `custEvent` `date` `death` `district` `education` `event` `faith` `floruit` `geogFeat` `geogName` `langKnowledge` `langKnown` `licence` `location` `name` `nationality` `occupation` `offset` `orgName` `origDate` `origPlace` `origin` `persName` `placeName` `population` `precision` `provenance` `region` `relation` `residence` `resp` `seal` `settlement` `sex` `socecStatus` `stamp` `state` `terrain` `time` `trait`]

*Attributes* Attributes

`@when-custom` supplies the value of a date or time in some custom standard form.

*Status* Optional

*Datatype*  $1-\infty$  occurrences of `teidata.word` separated by whitespace

The following are examples of custom date or time formats that are *not* valid ISO or W3C format normalizations, normalized to a different dating system `<p>Alhazen died in Cairo on the`

`<date when="1040-03-06"`

`when-custom="431-06-12"> 12th day of Jumada t-Tania, 430 AH`

`</date>.</p>`

`<p>The current world will end at the`

`<date when="2012-12-21"`

`when-custom="13.0.0.0.0">end of B'ak'tun 13</date>.</p>`

`<p>The Battle of Meggidu`

`(<date when-custom="Thutmose_III:23">23rd year of reign of`

`Thutmose III</date>).</p>`

`<p>Esidorus bixit in pace annos LXX plus minus sub`

`<date when-custom="Ind:4-10-11">die XI mensis Octobris`

`indictione IIII</date>`

`</p>Not all custom date formulations will have Gregorian`

`equivalents.The when-custom attribute and other custom dating are`

`not constrained to a datatype by the TEI, but individual projects`

`are recommended to regularize and document their dating formats.`

`@notBefore-custom` specifies the earliest possible date for the event in some custom standard form.

- Status* Optional  
*Datatype* 1-∞ occurrences of teidata.word separated by whitespace
- @notAfter-custom** specifies the latest possible date for the event in some custom standard form.  
*Status* Optional  
*Datatype* 1-∞ occurrences of teidata.word separated by whitespace
- @from-custom** indicates the starting point of the period in some custom standard form.  
*Status* Optional  
*Datatype* 1-∞ occurrences of teidata.word separated by whitespace
- ```
<event xml:id="FIRE1"
  datingMethod="#julian"
  from-custom="1666-09-02"
  to-custom="1666-09-05">
  <head>The Great Fire of London</head>
  <p>The Great Fire of London burned through a large part
    of the city of London.</p>
</event>
```
- @to-custom** indicates the ending point of the period in some custom standard form.  
*Status* Optional  
*Datatype* 1-∞ occurrences of teidata.word separated by whitespace
- @datingPoint** supplies a pointer to some location defining a named point in time with reference to which the datable item is understood to have occurred  
*Status* Optional  
*Datatype* teidata.pointer
- @datingMethod** supplies a pointer to a <calendar> element or other means of interpreting the values of the custom dating attributes.  
*Status* Optional  
*Datatype* teidata.pointer
- Contayning the Originall, Antiquity, Increate, Moderne eftate, and defcription of that Citie, written in the yeare
- ```
<date when-custom="1598"
  calendar="#julian"
  datingMethod="#julian">1598</date>. by Iohn Stow
```
- Citizen of London. In this example, the *calendar* attribute points to a <calendar> element for the Julian calendar, specifying that the text content of the <date> element is a Julian date, and the *datingMethod* attribute also points to the Julian calendar to indicate that the content of the *when-custom* attribute value is Julian too.
- ```
<date when="1382-06-28"
  when-custom="6890-06-20"
  datingMethod="#creationOfWorld"> μὴν Ἰουνίου εἰς <num>κ</num>
  ἔτους <num>ζω</num>
```
- </date> In this example, a date is given in a Mediaeval text measured "from the creation of the world", which is normalised (in *when*) to the Gregorian date, but is also normalized (in *when-custom*) to a machine-actionable, numeric version of the date from the Creation.
- Note* Note that the *datingMethod* attribute (unlike *calendar* defined in att.datable) defines the calendar or dating system to which the date described by the parent element is normalized (i.e. in the *when-custom* or other *X-custom* attributes), *not* the calendar of the original date in the element.

**att.datable.iso** provides attributes for normalization of elements that contain datable events using the ISO 8601 standard. [3.5.4. Dates and Times 13.3.6. Dates and Times]

*Module* namesdates — Names, Dates, People, and Places

*Members* att.datable[acquisition affiliation age application binding birth bloc change climate country creation custEvent date death district education event faith floruit geogFeat geogName langKnowledge langKnown licence location name nationality occupation offset orgName origDate origPlace origin persName placeName population precision provenance region relation residence resp seal settlement sex socecStatus stamp state terrain time trait]

*Attributes* Attributes

**@when-iso** supplies the value of a date or time in a standard form.

*Status* Optional

*Datatype* teidata.temporal.iso

The following are examples of ISO date, time, and date & time formats that are *not* valid W3C format normalizations.

`<date when-iso="1996-09-24T07:25+00">Sept. 24th, 1996 at 3:25 in the morning</date>`

`<date when-iso="1996-09-24T03:25-04">Sept. 24th, 1996 at 3:25 in the morning</date>`

`<time when-iso="1999-01-04T20:42-05">4 Jan 1999 at 8:42 pm</time>`

`<time when-iso="1999-W01-1T20,70-05">4 Jan 1999 at 8:42 pm</time>`

`<date when-iso="2006-05-18T10:03">a few minutes after ten in the morning on Thu 18 May</date>`

`<time when-iso="03:00">3 A.M.</time>`

`<time when-iso="14">around two</time>`

`<time when-iso="15,5">half past three</time>`All of the examples of the *when* attribute in the att.datable.w3c class are also valid with respect to this attribute.

He likes to be punctual. I said `<q>`

`<time when-iso="12">around noon</time>`

`</q>`, and he showed up at `<time when-iso="12:00:00">12`

`0'clock</time>` on the dot. The second occurrence of `<time>` could have been encoded with the *when* attribute, as 12:00:00 is a valid time with respect to the W3C XML Schema Part 2: Datatypes Second Edition specification. The first occurrence could not.

**@notBefore-iso** specifies the earliest possible date for the event in standard form, e.g.

yyyy-mm-dd.

*Status* Optional

*Datatype* teidata.temporal.iso

**@notAfter-iso** specifies the latest possible date for the event in standard form, e.g. yyyy-mm-dd.

*Status* Optional

*Datatype* teidata.temporal.iso

**@from-iso** indicates the starting point of the period in standard form.

*Status* Optional

*Datatype* teidata.temporal.iso

**@to-iso** indicates the ending point of the period in standard form.

*Status* Optional

*Datatype* teidata.temporal.iso

*Note* The value of these attributes should be a normalized representation of the date, time, or combined date & time intended, in any of the standard formats specified by ISO 8601, using the Gregorian calendar.

*Note* If both *when-iso* and *dur-iso* are specified, the values should be interpreted as indicating a span of time by its starting time (or date) and duration. That is,

```
<date when-iso="2007-06-01" dur-iso="P8D"/>
```

indicates the same time period as

```
<date when-iso="2007-06-01/P8D"/>
```

In providing a ‘regularized’ form, no claim is made that the form in the source text is incorrect; the regularized form is simply that chosen as the main form for purposes of unifying variant forms under a single heading.

**att.datable.w3c** provides attributes for normalization of elements that contain datable events conforming to the W3C *XML Schema Part 2: Datatypes Second Edition*. [3.5.4. Dates and Times 13.3.6. Dates and Times]

**@notBefore** specifies the earliest possible date for the event in standard form, e.g. yyyy-mm-dd.

*Status* Optional

*Datatype* teidata.temporal.w3c

**@notAfter** specifies the latest possible date for the event in standard form, e.g. yyyy-mm-dd.

*Status* Optional

*Datatype* teidata.temporal.w3c

**@from** indicates the starting point of the period in standard form, e.g. yyyy-mm-dd.

*Status* Optional

*Datatype* teidata.temporal.w3c

**@to** indicates the ending point of the period in standard form, e.g. yyyy-mm-dd.

*Status* Optional

*Datatype* teidata.temporal.w3c

*Schematron* <sch:rule context="tei:\*[@when]"> <sch:report test="@notBefore|@notAfter|@from|@to" role="nonfatal">The @when attribute cannot be used with any other att.dateable.w3c attributes.</sch:report> </sch:rule>

*Schematron* <sch:rule context="tei:\*[@from]"> <sch:report test="@notBefore" role="nonfatal">The @from and @notBefore attributes cannot be used together.</sch:report> </sch:rule>

*Schematron* <sch:rule context="tei:\*[@to]"> <sch:report test="@notAfter" role="nonfatal">The @to and @notAfter attributes cannot be used together.</sch:report> </sch:rule>

*Example*

```
<date from="1863-05-28" to="1863-06-01">28 May through 1 June 1863</date>
```

*Note* The value of these attributes should be a normalized representation of the date, time, or combined date & time intended, in any of the standard formats specified by *XML Schema Part 2: Datatypes Second Edition*, using the Gregorian calendar. The most commonly-encountered format for the date portion of a temporal attribute is yyyy-mm-dd, but yyyy, --mm, ---dd, yyyy-mm, or --mm-dd may also be used. For the time part, the form hh:mm:ss is used.

Note that this format does not currently permit use of the value 0000 to represent the year 1 BCE; instead the value -0001 should be used.

**att.datcat** provides the *dcr:datcat* and *dcr:ValueDatcat* attributes which are used to align XML elements or attributes with the appropriate Data Categories (DCs) defined by the ISO 12620:2009 standard and stored in the Web repository called ISOCat at <http://www.isocat.org/>. [9.5.2. Lexical View 18.3. Other Atomic Feature Values]

*Module* tei – The TEI Infrastructure

*Members* att.lexicographic[case colloc def entryFree etym form gen gram gramGrp hom hyph iType lang lbl mood number oRef oVar orth pRef pVar per pos pron re sense subc syll tns usg xr] att.segLike[c cl m pc phr s seg w] binary f fs numeric string symbol

*Attributes* Attributes

**@datcat** contains a PID (persistent identifier) that aligns the given element with the appropriate Data Category (or categories) in ISOCat.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

**@valueDatcat** contains a PID (persistent identifier) that aligns the content of the given element or the value of the given attribute with the appropriate simple Data Category (or categories) in ISOCat.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Example* In this example *dcr:datcat* relates the feature name to the data category "partOfSpeech" and

*dcr:valueDatcat* the feature value to the data category "commonNoun". Both these data categories reside in the ISOcat DCR at [www.isocat.org](http://www.isocat.org), which is the DCR used by ISO TC37 and hosted by its registration authority, the MPI for Psycholinguistics in Nijmegen.

```
<fs
  xmlns:dcr="http://www.isocat.org/ns/dcr">
  <f name="POS"
    dcr:datcat="http://www.isocat.org/datcat/DC-1345" fVal="#commonNoun"
    dcr:valueDatcat="http://www.isocat.org/datcat/DC-1256"/>
</fs>
```

*Note* ISO 12620:2009 is a standard describing the data model and procedures for a Data Category Registry (DCR). Data categories are defined as elementary descriptors in a linguistic structure. In the DCR data model each data category gets assigned a unique Persistent Identifier (PID), i.e., an URI. Linguistic resources or preferably their schemas that make use of data categories from a DCR should refer to them using this PID. For XML-based resources, like TEI documents, ISO 12620:2009 normative Annex A gives a small Data Category Reference XML vocabulary (also available online at <http://www.isocat.org/12620/>), which provides two attributes, *dcr:datcat* and *dcr:valueDatcat*.

**att.declarable** provides attributes for those elements in the TEI header which may be independently selected by means of the special purpose *decls* attribute. [15.3. *Associating Contextual Information with a Text*]

*Module* tei – The TEI Infrastructure

*Members* availability bibl biblFull biblStruct broadcast correction correspDesc editorialDecl equipment geoDecl hyphenation interpretation langUsage listApp listBibl listEvent listNym listOrg listPerson listPlace metDecl normalization particDesc projectDesc punctuation quotation recording refsDecl samplingDecl scriptStmnt segmentation settingDesc sourceDesc stdVals styleDefDecl textClass textDesc xenoData

*Attributes* Attributes

**@default** indicates whether or not this element is selected by default when its parent is selected.

*Status* Optional

*Datatype* teidata.truthValue

*Legal values are:* **true** This element is selected if its parent is selected

**false** This element can only be selected explicitly, unless it is the only one of its kind, in which case it is selected if its parent is selected.[Default]

*Note* The rules governing the association of declarable elements with individual parts of a TEI text are fully defined in chapter 15.3. *Associating Contextual Information with a Text*. Only one element of a particular type may have a *default* attribute with a value of true.

**att.declaring** provides attributes for elements which may be independently associated with a particular declarable element within the header, thus overriding the inherited default for that element. [15.3. *Associating Contextual Information with a Text*]

*Module* tei – The TEI Infrastructure

*Members* ab back body div div1 div2 div3 div4 div5 div6 div7 facsimile floatingText front geo gloss graphic group lg media msDesc p ptr ref sourceDoc surface surfaceGrp term text u

*Attributes* Attributes

**@decls** identifies one or more *declarable elements* within the header, which are understood to apply to the element bearing this attribute and its content.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Note* The rules governing the association of declarable elements with individual parts of a TEI text are fully defined in chapter 15.3. *Associating Contextual Information with a Text*.

---

**att.deprecated** provides attributes indicating how a deprecated feature will be treated in future releases.

*Module* tagdocs — Documentation Elements

*Members* att.combinable[att.identified[attDef classSpec constraintSpec dataSpec elementSpec macroSpec moduleSpec paramSpec schemaSpec] valDesc valItem valList]

*Attributes* Attributes

**@validUntil** provides a date before which the construct being defined will not be removed.

*Status* Optional

*Datatype* date

*Schematron* <sch:rule context="tei:\*[@validUntil]"> <sch:assert test="@validUntil cast as xs:date ge current-date()"> <sch:value-of select="if (@ident) then concat('The ',@ident) else concat('This ',local-name()); of ',ancestor::tei:\*[@ident][1]/@ident)"/> construct is outdated (as of <sch:value-of select="@validUntil"/>); ODD processors may ignore it, and its use is no longer supported</sch:assert>  
<sch:assert role="nonfatal" test="@validUntil cast as xs:date ge (current-date() + (60\*xs:dayTimeDuration('P1D')))"> <sch:value-of select="if (@ident) then concat('The ',@ident) else concat('This ',local-name()); of ',ancestor::tei:\*[@ident][1]/@ident)"/> construct becomes outdated on <sch:value-of select="@validUntil"/> </sch:assert> </sch:rule>

*Note* The value of this attribute should represent a date (in standard yyyy-mm-dd format) which is later than the date on which the attribute is added to an ODD. Technically, this attribute asserts only the intent to leave a construct in future releases of the markup language being defined up to at least the specified date, and makes no assertion about what happens past that date. In practice, the expectation is that the construct will be removed from future releases of the markup language being defined sometime shortly after the *validUntil* date. An ODD processor will typically not process a specification element which has a *validUntil* date that is in the past. An ODD processor will typically warn users about constructs which have a *validUntil* date that is in the future. E.g., the documentation for such a construct might include the phrase *warning: deprecated* in red.

---

**att.dimensions** provides attributes for describing the size of physical objects.

    who="#LB"/>
</revisionDesc>
```

---

**att.duration** provides attributes for normalization of elements that contain datable events.

*Module* spoken – Transcriptions of Speech

*Members* att.timed[annotationBlock binaryObject gap incident kinesic media pause u vocal writing] date recording time

*Attributes* att.duration.w3c (@dur) att.duration.iso (@dur-iso)

*Note* This ‘superclass’ provides attributes that can be used to provide normalized values of temporal information. By default, the attributes from the **att.duration.w3c** class are provided. If the module for names & dates is loaded, this class also provides attributes from the **att.duration.iso** class. In general, the possible values of attributes restricted to the W3C datatypes form a subset of those values available via the ISO 8601 standard. However, the greater expressiveness of the ISO datatypes is rarely needed, and there exists much greater software support for the W3C datatypes.

---

**att.duration.iso** provides attributes for recording normalized temporal durations. [3.5.4. Dates and Times  
13.3.6. Dates and Times]

*Module* tei – The TEI Infrastructure

*Members* att.duration[att.timed[annotationBlock binaryObject gap incident kinesic media pause u vocal writing] date recording time]

*Attributes* Attributes

**@dur-iso** (duration) indicates the length of this element in time.

*Status* Optional

*Datatype* teidata.duration.iso

*Note* If both *when* and *dur* or *dur-iso* are specified, the values should be interpreted as indicating a span of time by its starting time (or date) and duration. In order to represent a time range by a duration and its ending time the *when-iso* attribute must be used. In providing a ‘regularized’ form, no claim is made that the form in the source text is incorrect; the regularized form is simply that chosen as the main form for purposes of unifying variant forms under a single heading.

**att.duration.w3c** provides attributes for recording normalized temporal durations. [3.5.4. Dates and Times  
13.3.6. Dates and Times]

*Module* tei – The TEI Infrastructure

*Members* att.duration[att.timed[annotationBlock binaryObject gap incident kinesic media pause u vocal writing] date recording time]

*Attributes* Attributes

**@dur** (duration) indicates the length of this element in time.

*Status* Optional

*Datatype* teidata.duration.w3c

*Note* If both *when* and *dur* are specified, the values should be interpreted as indicating a span of time by its starting time (or date) and duration. In order to represent a time range by a duration and its ending time the *when-iso* attribute must be used. In providing a ‘regularized’ form, no claim is made that the form in the source text is incorrect; the regularized form is simply that chosen as the main form for purposes of unifying variant forms under a single heading.

**att.edition** provides attributes identifying the source edition from which some encoded feature derives.

*Module* tei – The TEI Infrastructure

*Members* cb lb milestone pb refState

*Attributes* Attributes

**@ed** (edition) supplies a sigil or other arbitrary identifier for the source edition in which the associated feature (for example, a page, column, or line break) occurs at this point in the text.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.word separated by whitespace

**@edRef** (edition reference) provides a pointer to the source edition in which the associated feature (for example, a page, column, or line break) occurs at this point in the text.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Example*

```
<l>of Mans First Disobedience,<lb ed="1674"/> and<lb ed="1667"/> the Fruit</l>
<l>of that Forbidden Tree, whose<lb ed="1667 1674"/> mortal tast</l>
```

```
<l>Brought Death into the World,<lb ed="1667"/> and all<lb ed="1674"/> our
woe,</l>
```

Example

```
<listBibl>
  <bibl xml:id="stapledon1937">
    <author>Olaf Stapledon</author>,
    <title>Starmaker</title>, <publisher>Methuen</publisher>, <date>1937</date>
  </bibl>
  <bibl xml:id="stapledon1968">

their ancient culture,
still living their personal lives in zest and endless
novelty of action, ... I saw myself still
preserving, though with increasing difficulty, my lucid
con-<pb n="291" edRef="#stapledon1937"/>sciousness;</p>
```

---

**att.editLike** provides attributes describing the nature of an encoded scholarly intervention or interpretation of any kind. [3.4. Simple Editorial Changes 10.3.1. Origination 13.3.2. The Person Element 11.3.1.1. Core Elements for Transcriptional Work]

Module *tei* – The TEI Infrastructure

Members *att.transcriptional*[add addSpan del delSpan mod redo restore retrace subst substJoin undo] affiliation age am birth climate corr date death education event ex expan faith floruit gap geogFeat geogName langKnowledge langKnown location name nationality occupation offset org orgName origDate origPlace origin persName person place placeName population reg relation residence secl sex socecStatus state supplied surplus terrain time trait unclear

Attributes *att.dimensions* (@unit, @quantity, @extent, @precision, @scope) (*att.ranging* (@atLeast, @atMost, @min, @max, @confidence)) *att.source* (@source)

**@evidence** indicates the nature of the evidence supporting the reliability or accuracy of the intervention or interpretation.

Status Optional

Datatype 1–∞ occurrences of *teidata.enumerated* separated by whitespace

Suggested values include: **internal** there is internal evidence to support the intervention.

**external** there is external evidence to support the intervention.

**conjecture** the intervention or interpretation has been made by the editor, cataloguer, or scholar on the basis of their expertise.

**@instant** indicates whether this is an instant revision or not.

Status Optional

Datatype *teidata.xTruthValue*

Default false

Note The members of this attribute class are typically used to represent any kind of editorial intervention in a text, for example a correction or interpretation, or to date or localize manuscripts etc.

*Note* Each pointer on the *source* (if present) corresponding to a witness or witness group should reference a bibliographic citation such as a <witness>, <msDesc>, or <bibl> element, or another external bibliographic citation, documenting the source concerned.

---

**att.enjamb** (enjambement) provides an attribute which may be used to indicate enjambement of the parent element. [6.2. *Components of the Verse Line*]

*Module* verse – Verse

*Members* 1

*Attributes* Attributes

**@enjamb** (enjambement) indicates that the end of a verse line is marked by enjambement.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **no** the line is end-stopped

**yes** the line in question runs on into the next

**weak** the line is weakly enjambed

**strong** the line is strongly enjambed

*Note* The usual practice will be to give the value ‘yes’ to this attribute when enjambement is being marked, or the values ‘weak’ and ‘strong’ if degrees of enjambement are of interest; if no value is given, however, the attribute does not default to a value of ‘no’; this allows the attribute to be omitted entirely when enjambement is not of particular interest.

---

**att.entryLike** provides an attribute used to distinguish different styles of dictionary entries. [9.1. *Dictionary Body and Overall Structure* 9.2. *The Structure of Dictionary Entries*]

*Module* dictionaries – Dictionaries

*Members* entry entryFree superEntry

*Attributes* Attributes

**@type** indicates type of entry, in dictionaries with multiple types.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **main** a main entry (default).[Default]

**hom** (homograph) groups information relating to one homograph within an entry.

**xref** (cross reference) a reduced entry whose only function is to point to another main entry (e.g. for forms of an irregular verb or for variant spellings: *was* pointing to *be*, or *esthete* to *aesthete*).

**affix** an entry for a prefix, infix, or suffix.

**abbr** (abbreviation) an entry for an abbreviation.

**supplemental** a supplemental entry (for use in dictionaries which issue supplements to their main work in which they include updated information about entries).

**foreign** an entry for a foreign word in a monolingual dictionary.

*Note* The global *n* attribute may be used to encode the homograph numbers attached to entries for homographs.

---

**att.fragmentable** provides an attribute for representing fragmentation of a structural element, typically as a consequence of some overlapping hierarchy.

*Module* tei — The TEI Infrastructure

*Members* att.divLike[div div1 div2 div3 div4 div5 div6 div7 lg] att.segLike[c cl m pc phr s seg w] ab l p

*Attributes* Attributes

**@part** specifies whether or not its parent element is fragmented in some way, typically by some other overlapping structure: for example a speech which is divided between two or more verse stanzas, a paragraph which is split across a page division, a verse line which is divided between two speakers.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* Y (yes) the element is fragmented in some (unspecified) respect

N (no) the element is not fragmented, or no claim is made as to its completeness[Default]

I (initial) this is the initial part of a fragmented element

M (medial) this is a medial part of a fragmented element

F (final) this is the final part of a fragmented element

*Note* The values I, M, or F should be used only where it is clear how the element may be reconstituted.

---

**att.global** provides attributes common to all elements in the TEI encoding scheme. [1.3.1.1. Global Attributes]

*Module* tei — The TEI Infrastructure

*Members* TEI ab abbr abstract accMat acquisition activity actor add addName addSpan additional additions addrLine address adminInfo affiliation age alt altGrp altIdent altIdentifier alternate am analytic anchor annotationBlock app appInfo application arc argument att attDef attList attRef author authority availability back bibl biblFull biblScope biblStruct bicond binary binaryObject binding bindingDesc birth bloc body broadcast byline c cRefPattern caesura calendar calendarDesc camera caption case castGroup castItem castList catDesc catRef catchwords category cb cell change channel char charDecl charName charProp choice cit citedRange cl classCode classDecl classRef classSpec classes climate closer code collation collection colloc colophon cond condition constitution constraint constraintSpec content corr correction correspAction correspContext correspDesc country creation custEvent custodialHist damage damageSpan dataRef dataSpec datatype date dateline death decoDesc decoNote def default defaultVal del delSpan depth derivation desc dictScrap dim dimensions distinct distributor district div div1 div2 div3 div4 div5 div6 div7 divGen docAuthor docDate docEdition docImprint docTitle domain eLeaf eTree edition editionStmnt editor editorialDecl education eg eXML elementRef elementSpec email emph encodingDesc entry entryFree epigraph epilogue equipment equiv etym event ex exemplum expan explicit extent f fDecl fDescr fLib facsimile factuality faith figDesc figure fileDesc filiation finalRubric floatingText floruit foliation foreign forename forest form formula front fs fsConstraints fsDecl fsDescr fsdDecl fsdLink funder fvLib fw g gap gb gen genName geo geoDecl geogFeat geogName gi gloss glyph glyphName gram gramGrp graph graphic group handDesc handNote handNotes handShift head headItem headLabel height heraldry hi history hom hyph hyphenation iNode iType ident idno if iff imprimatur imprint incident incipit index institution interaction interp interpGrp interpretation item join joinGrp keywords kinesic l label lacunaEnd lacunaStart lang langKnowledge langKnown langUsage language layout layoutDesc lb lbl leaf lem lg licence line link linkGrp list listApp listBibl listChange listEvent listForest listNym listOrg listPerson listPlace listPrefixDef listRef listRelation listTranspose listWit localName locale location locus locusGrp m macroRef macroSpec mapping material measure measureGrp media meeting memberOf mentioned metDecl metSym metamark milestone mod model modelGrp modelSequence moduleRef moduleSpec monogr mood move msContents msDesc msFrag msIdentifier msItem msItemStruct msName msPart musicNotation name nameLink namespace nationality node normalization notatedMusic note notesStmnt num number numeric nym oRef oVar objectDesc objectType occupation offset opener org orgName orig origDate origPlace origin orth outputRendition p pRef pVar param paramList paramSpec particDesc pause pb pc per performance persName person personGrp phr

*Attributes* att.global.rendition (*@rend*, *@style*, *@rendition*) att.global.linking (*@corresp*, *@synch*, *@sameAs*, *@copyOf*, *@next*, *@prev*, *@exclude*, *@select*) att.global.analytic (*@ana*) att.global.facs (*@facs*) att.global.change (*@change*) att.global.responsibility (*@cert*, *@resp*)

**@xml:id** (identifier) provides a unique identifier for the element bearing the attribute.

*Status* Optional

*Datatype* ID

*Note* The *xml:id* attribute may be used to specify a canonical reference for an element; see section 3.10. *Reference Systems*.

**@n** (number) gives a number (or other label) for an element, which is not necessarily unique within the document.

*Status* Optional

*Datatype* teidata.text

*Note* The value of this attribute is always understood to be a single token, even if it contains space or other punctuation characters, and need not be composed of numbers only. It is typically used to specify the numbering of chapters, sections, list items, etc.; it may also be used in the specification of a standard reference system for the text.

**@xml:lang** (language) indicates the language of the element content using a 'tag' generated according to BCP 47.

*Status* Optional

*Datatype* teidata.language

**<p>** ... The consequences of this rapid depopulation were the loss of the last **<foreign xml:lang="rap">ariki</foreign>** or chief (Routledge 1920:205,210) and their connections to ancestral territorial organization.**</p>**

*Note* The *xml:lang* value will be inherited from the immediately enclosing element, or from its parent, and so on up the document hierarchy. It is generally good practice to specify *xml:lang* at the highest appropriate level, noticing that a different default may be needed for the *teiHeader* from that needed for the associated resource element or elements, and that a single TEI document may contain texts in many languages. The authoritative list of registered language subtags is maintained by IANA and is available at <http://www.iana.org/assignments/language-subtag-registry>. For a good general overview of the construction of language tags, see <http://www.w3.org/International/articles/language-tags/>, and for a practical step-by-step guide, see <https://www.w3.org/International/questions/qa-choosing-language-tags.en.php>.

The value used must conform with BCP 47. If the value is a private use code (i.e., starts with x- or contains -x-), a <language> element with a matching value for its *ident* attribute should be supplied in the TEI header to document this value. Such documentation may also optionally be supplied for non-private-use codes, though these must remain consistent with their ( IETF) Internet Engineering Task Force definitions.

**@xml:base** provides a base URI reference with which applications can resolve relative URI references into absolute URI references.

*Status* Optional

*Datatype* teidata.pointer

```
<div type="bibl">
  <head>Bibliography</head>
  <listBibl xml:base="http://www.lib.ucdavis.edu/BWRP/Works/">

  </listBibl>
</div>
```

**@xml:space** signals an intention about how white space should be managed by applications.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **default** signals that the application's default white-space processing modes are acceptable

**preserve** indicates the intent that applications preserve all white space

*Note* The XML specification provides further guidance on the use of this attribute. Note that many parsers may not handle xml:space correctly.

---

**att.global.analytic** provides additional global attributes for associating specific analyses or interpretations with appropriate portions of a text. [17.2. *Global Attributes for Simple Analyses* 17.3. *Spans and Interpretations*]

*Module* analysis — Simple Analytic Mechanisms

*Members* att.global[TEI ab abbr abstract accMat acquisition activity actor add addName addSpan additional additions addrLine address adminInfo affiliation age alt altGrp altIdent altIdentifier alternate am analytic anchor annotationBlock app appInfo application arc argument att attDef attList attRef author authority availability back bibl biblFull biblScope biblStruct bicond binary binaryObject binding bindingDesc birth bloc body broadcast byline c cRefPattern caesura calendar calendarDesc camera caption case castGroup castItem castList catDesc catRef catchwords category cb cell change channel char charDecl charName charProp choice cit citedRange cl classCode classDecl classRef classSpec classes climate closer code collation collection colloc colophon cond condition constitution constraint constraintSpec content corr correction correspAction correspContext correspDesc country creation custEvent custodialHist damage damageSpan dataRef dataSpec datatype date dateline death decoDesc decoNote def default defaultVal del delSpan depth derivation desc dictScrap dim dimensions distinct distributor district div div1 div2 div3 div4 div5 div6 div7 divGen docAuthor docDate docEdition docImprint docTitle domain eLeaf eTree edition editionStmnt editor editorialDecl education eg egXML elementRef elementSpec email emph encodingDesc entry entryFree epigraph epilogue equipment equiv etym event ex exemplum expan explicit extent f fDecl fDescr fLib facsimile factuality faith figDesc figure fileDesc filiation finalRubric floatingText floruit foliation foreign forename forest form formula front fs fsConstraints fsDecl fsDescr fsdDecl fsdLink funder fvLib fw g gap gb gen genName geo geoDecl geogFeat geogName gi gloss glyph glyphName gram gramGrp graph graphic group handDesc handNote handNotes handShift head headItem headLabel height heraldry hi history hom hyph hyphenation iNode iType ident idno if iff imprimum imprint incident incipit index institution interaction interp interpGrp interpretation item join joinGrp keywords kinesic l label lacunaEnd lacunaStart lang langKnowledge langKnown langUsage language layout layoutDesc lb lbl leaf lem lg licence line link linkGrp list listApp listBibl listChange listEvent listForest listNym listOrg listPerson listPlace listPrefixDef listRef listRelation listTranspose listWit localName locale location locus locusGrp m macroRef macroSpec mapping material measure measureGrp media meeting memberOf mentioned metDecl metSym metamark milestone mod model modelGrp modelSequence moduleRef moduleSpec monogr mood move msContents msDesc msFrag msIdentifier msItem msItemStruct msName msPart musicNotation name nameLink namespace nationality node normalization notatedMusic note notesStmnt num number numeric nym oRef oVar objectDesc objectType occupation offset opener org orgName orig origDate origPlace origin orth outputRendition p pRef pVar param paramList paramSpec particDesc pause pb pc per performance persName person personGrp phr physDesc place placeName population pos postBox postCode postscript precision prefixDef preparedness principal profileDesc projectDesc prologue pron provenance ptr pubPlace publicationStmnt publisher punctuation purpose q quotation quote rdg rdgGrp re recordHist recording recordingStmnt redo ref refState refsDecl reg region relatedItem relation remarks rendition repository residence resp respStmnt respons restore retrace revisionDesc rhyme role roleDesc roleName root row rs rubric s said salute samplingDecl schemaSpec scriptDesc scriptNote scriptStmnt seal sealDesc secFol secl seg segmentation sense sequence series seriesStmnt set setting settingDesc settlement sex shift sic signatures signed soCalled socecStatus sound source sourceDesc sourceDoc sp spGrp span spanGrp speaker specDesc specGrp specGrpRef specList sponsor stage stamp state stdVals street stress string styleDefDecl subc subst substJoin summary superEntry supplied support supportDesc surface surfaceGrp surname surplus surrogates syll symbol table tag tagUsage tagsDecl taxonomy tech teiCorpus teiHeader term terrain text textClass textDesc textLang textNode then time timeline title titlePage titlePart titleStmnt tns trailer trait transcriptionDesc transpose tree triangle typeDesc typeNote u unclear undo unicodeName usg vAlt vColl vDefault vLabel vMerge vNot vRange val valDesc vallItem vallList value variantEncoding view vocal w watermark when width wit witDetail witEnd witStart witness writing xenoData xr zone]

#### *Attributes* Attributes

**@ana** (analysis) indicates one or more elements containing interpretations of the element on which the *ana* attribute appears.

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.pointer separated by whitespace

*Note* When multiple values are given, they may reflect either multiple divergent interpretations of an ambiguous text, or multiple mutually consistent interpretations of the same passage in different contexts.

**att.global.change** supplies the *change* attribute, allowing its member elements to specify one or more states or revision campaigns with which they are associated.

*Module* transcr — Representation of Primary Sources

*Members* att.global[TEI ab abbr abstract accMat acquisition activity actor add addName addSpan additional additions addrLine address adminInfo affiliation age alt altGrp altIdent altIdentifier alternate am analytic anchor annotationBlock app appInfo application arc argument att attDef attList attRef author authority availability back bibl biblFull biblScope biblStruct bicond binary binaryObject binding bindingDesc birth bloc body broadcast byline c cRefPattern caesura calendar calendarDesc camera caption case castGroup castItem castList catDesc catRef catchwords category cb cell change channel char charDecl charName charProp choice cit citedRange cl classCode classDecl classRef classSpec classes climate closer code collation collection colloc colophon cond condition constitution constraint constraintSpec content corr correction correspAction correspContext correspDesc country creation custEvent custodialHist damage damageSpan dataRef dataSpec datatype date dateline death decoDesc decoNote def default defaultVal del delSpan depth derivation desc dictScrap dim dimensions distinct distributor district div div1 div2 div3 div4 div5 div6 div7 divGen docAuthor docDate docEdition docImprint docTitle domain eLeaf eTree edition editionStmnt editor editorialDecl education eg egXML elementRef elementSpec email emph encodingDesc entry entryFree epigraph epilogue equipment equiv etym event ex exemplum expan explicit extent f fDecl fDesc fLib facsimile factuality faith figDesc figure fileDesc filiation finalRubric floatingText floruit foliation foreign forename forest form formula front fs fsConstraints fsDecl fsDesc fsdDecl fsdLink funder fvLib fw g gap gb gen genName geo geoDecl geogFeat geogName gi gloss glyph glyphName gram gramGrp graph graphic group handDesc handNote handNotes handShift head headItem headLabel height heraldry hi history hom hyph hyphenation iNode iType ident idno if iff imprimum imprint incident incipit index institution interaction interp interpGrp interpretation item join joinGrp keywords kinesic l label lacunaEnd lacunaStart lang langKnowledge langKnown langUsage language layout layoutDesc lb lbl leaf lem lg licence line link linkGrp list listApp listBibl listChange listEvent listForest listNym listOrg listPerson listPlace listPrefixDef listRef listRelation listTranspose listWit localName locale location locus locusGrp m macroRef macroSpec mapping material measure measureGrp media meeting memberOf mentioned metDecl metSym metamark milestone mod model modelGrp modelSequence moduleRef moduleSpec monogr mood move msContents msDesc msFrag msIdentifier msItem msItemStruct msName msPart musicNotation name nameLink namespace nationality node normalization notatedMusic note notesStmnt num number numeric nym oRef oVar objectDesc objectType occupation offset opener org orgName orig origDate origPlace origin orth outputRendition p pRef pVar param paramList paramSpec particDesc pause pb pc per performance persName person personGrp phr physDesc place placeName population pos postBox postCode postscript precision prefixDef preparedness principal profileDesc projectDesc prologue pron provenance ptr pubPlace publicationStmnt publisher punctuation purpose q quotation quote rdg rdgGrp re recordHist recording recordingStmnt redo ref refState refsDecl reg region relatedItem relation remarks rendition repository residence resp respStmnt respons restore retrace revisionDesc rhyme role roleDesc roleName root row rs rubric s said salute samplingDecl schemaSpec scriptDesc scriptNote scriptStmnt seal sealDesc secFol secl seg segmentation sense sequence series seriesStmnt set setting settingDesc settlement sex shift sic signatures signed soCalled socecStatus sound source sourceDesc sourceDoc sp spGrp span spanGrp speaker specDesc specGrp specGrpRef specList sponsor stage stamp state stdVals street stress string styleDefDecl subc subst substJoin summary superEntry supplied support supportDesc surface surfaceGrp surname surplus surrogates syll symbol table tag tagUsage tagsDecl taxonomy tech teiCorpus teiHeader term terrain text textClass textDesc textLang textNode then time timeline title titlePage titlePart titleStmnt tns trailer trait transcriptionDesc transpose tree triangle typeDesc typeNote u unclear undo unicodeName usg vAlt vColl vDefault vLabel vMerge vNot vRange val valDesc valltem valList value variantEncoding view vocal w watermark when width wit witDetail witEnd witStart witness writing xenoData xr zone]

*Attributes* Attributes

**@change** points to one or more <change> elements documenting a state or revision campaign to which the element bearing this attribute and its children have been assigned by the encoder.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

**att.global.facs** provides an attribute used to express correspondence between an element containing transcribed text and all or part of an image representing that text. [11.1. Digital Facsimiles]

Module transcr — Representation of Primary Sources

*Attributes* Attributes

**@corresp** (corresponds) points to elements that correspond to the current element in some way.

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.pointer separated by whitespace

```
<group>
  <text xml:id="t1-g1-t1"
    xml:lang="mi">
    <body xml:id="t1-g1-t1-body1">
      <div type="chapter">
        <head>He Whakamaramatanga mo te Ture Hoko, Riihi hoki, i
nga Whenua Maori, 1876.</head>
        <p>...</p>
      </div>
    </body>
  </text>
  <text xml:id="t1-g1-t2"
    xml:lang="en">
    <body xml:id="t1-g1-t2-body1"
      corresp="#t1-g1-t1-body1">
      <div type="chapter">
        <head>An Act to regulate the Sale, Letting, and Disposal
of Native Lands, 1876.</head>
        <p>...</p>
      </div>
    </body>
  </text>
```

**</group>**In this example a **<group>** contains two **<text>**s, each containing the same document in a different language. The correspondence is indicated using *corresp*. The language is indicated using *xml:lang*, whose value is inherited; both the tag with the *corresp* and the tag pointed to by the *corresp* inherit the value from their immediate parent.

```
<!-- In a placeography --><place xml:id="LOND1"
  corresp="#LOND2 #GENI1">
  <placeName>London</placeName>
  <desc>The city of London...</desc>
</place>
<!-- In a literary personography -->
<person xml:id="LOND2"
  corresp="#LOND1 #GENI1">
  <persName type="lit">London</persName>
  <note>
    <p>Allegorical character representing the city of
<ref target="LOND1.xml">London</ref>.
    </p>
  </note>
</person>
<person xml:id="GENI1"
  corresp="#LOND1 #LOND2">
  <persName type="lit">London's Genius</persName>
  <note>
    <p>Personification of London's genius. Appears as an
allegorical character in mayoral shows.
```

- </p>  
</note>  
</person>In this example, a <place> element containing information about the city of London is linked with two <person> elements in a literary personography. This correspondence represents a slightly looser relationship than the one in the preceding example; there is no sense in which an allegorical character could be substituted for the physical city, or vice versa, but there is obviously a correspondence between them.
- @synch** (synchronous) points to elements that are synchronous with the current element.  
*Status* Optional  
*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace
- @sameAs** points to an element that is the same as the current element.  
*Status* Optional  
*Datatype* teidata.pointer
- @copyOf** points to an element of which the current element is a copy.  
*Status* Optional  
*Datatype* teidata.pointer  
*Note* Any content of the current element should be ignored. Its true content is that of the element being pointed at.
- @next** points to the next element of a virtual aggregate of which the current element is part.  
*Status* Optional  
*Datatype* teidata.pointer
- @prev** (previous) points to the previous element of a virtual aggregate of which the current element is part.  
*Status* Optional  
*Datatype* teidata.pointer
- @exclude** points to elements that are in exclusive alternation with the current element.  
*Status* Optional  
*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace
- @select** selects one or more alternants; if one alternant is selected, the ambiguity or uncertainty is marked as resolved. If more than one alternant is selected, the degree of ambiguity or uncertainty is marked as reduced by the number of alternants not selected.  
*Status* Optional  
*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace  
*Note* This attribute should be placed on an element which is superordinate to all of the alternants from which the selection is being made.

---

**att.global.rendition** provides rendering attributes common to all elements in the TEI encoding scheme.

[1.3.1.1.3. Rendition Indicators]

#### Attributes Attributes

**@rend** (rendition) indicates how the element in question was rendered or presented in the source text.

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.word separated by whitespace

```
<head rend="align(center) case(allcaps)">
  <lb/>To The <lb/>Duchesse <lb/>of <lb/>Newcastle,
  <lb/>On Her <lb/>
  <hi rend="case(mixed)">New Blazing-World</hi>.
</head>
```

*Note* These Guidelines make no binding recommendations for the values of the *rend* attribute; the characteristics of visual presentation vary too much from text to text and the decision to record or ignore individual characteristics varies too much from project to project. Some potentially useful conventions are noted from time to time at appropriate points in the Guidelines. The values of

the *rend* attribute are a set of sequence-indeterminate individual tokens separated by whitespace.

**@style** contains an expression in some formal style definition language which defines the rendering or presentation used for this element in the source text

*Status* Optional

*Datatype* teidata.text

```
<head style="text-align: center; font-variant: small-caps">
  <lb/>To The <lb/>Duchesse <lb/>of <lb/>Newcastle, <lb/>On Her
  <lb/>
  <hi style="font-variant: normal">New Blazing-World</hi>.
</head>
```

*Note* Unlike the attribute values of *rend*, which uses whitespace as a separator, the *style* attribute may contain whitespace. This attribute is intended for recording inline stylistic information concerning the source, not any particular output. The formal language in which values for this attribute are expressed may be specified using the `<styleDefDecl>` element in the TEI header.

**@rendition** points to a description of the rendering or presentation used for this element in the source text.

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.pointer separated by whitespace

```
<head rendition="#ac #sc">
  <lb/>To The <lb/>Duchesse <lb/>of <lb/>Newcastle, <lb/>On Her
  <lb/>
  <hi rendition="#normal">New Blazing-World</hi>.
</head>
<!-- elsewhere... -->
<rendition xml:id="sc"
  scheme="css">font-variant: small-caps</rendition>
<rendition xml:id="normal"
  scheme="css">font-variant: normal</rendition>
<rendition xml:id="ac"
  scheme="css">text-align: center</rendition>
```

*Note* The *rendition* attribute is used in a very similar way to the *class* attribute defined for XHTML but with the important distinction that its function is to describe the appearance of the source text, not necessarily to determine how that text should be presented on screen or paper. Where both *rendition* and *rend* are supplied, the latter is understood to override or complement the former.

Each URI provided should indicate a `<rendition>` element defining the intended rendition in terms of some appropriate style language, as indicated by the *scheme* attribute.

---

**att.global.responsibility** provides attributes indicating the agent responsible for some aspect of the text, the markup or something asserted by the markup, and the degree of certainty associated with it. [3.4. Simple Editorial Changes 11.3.2.2. Hand, Responsibility, and Certainty Attributes 17.3. Spans and Interpretations 13.1.1. Linking Names and Their Referents]

#### Attributes Attributes

**@cert** (certainty) signifies the degree of certainty associated with the intervention or interpretation.

*Status* Optional

*Datatype* teidata.probCert

**@resp** (responsible party) indicates the agency responsible for the intervention or interpretation, for example an editor or transcriber.

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.pointer separated by whitespace

*Note* Note that a simple *resp* pointing to a person or organization is likely to be somewhat ambiguous with regard to the nature of the responsibility. For this reason, we recommend that *resp* be used to point not to an agent (<person> or <org>) but to a <respStmnt>, <author>, <editor> or similar element which clarifies the exact role

played by the agent. Pointing to multiple <respStmt>s allows the encoder to specify clearly each of the roles played in part of a TEI file (creating, transcribing, encoding, editing, proofing etc.).

*Example*

```
Blessed are the
<choice>
  <sic>placemakers</sic>
  <corr resp="#editor" cert="high">peacemakers</corr>
</choice>: for they shall be called the children of God.
```

*Example*

```
<!-- in the <text> ... --><lg>
<!-- ... -->
  <l>Punkes, Panders, bafe extortionizing
    sla<choice>
      <sic>n</sic>
      <corr resp="#JENS1_transcriber">u</corr>
    </choice>es,</l>
<!-- ... -->
</lg>
<!-- in the <teiHeader> ... -->
<!-- ... -->
<respStmt xml:id="JENS1_transcriber">
  <resp when="2014">Transcriber</resp>
  <name>Janelle Jenstad</name>
</respStmt>
```

---

**att.handFeatures** provides attributes describing aspects of the hand in which a manuscript is written.

[11.3.2.1. Document Hands]

*Module* tei – The TEI Infrastructure

*Members* handNote handShift scriptNote typeNote

*Attributes* Attributes

- @scribe** gives a name or other identifier for the scribe believed to be responsible for this hand.  
*Status* Optional  
*Datatype* teidata.name
- @scribeRef** points to a full description of the scribe concerned, typically supplied by a <person> element elsewhere in the description.  
*Status* Optional  
*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace
- @script** characterizes the particular script or writing style used by this hand, for example *secretary, copperplate, Chancery, Italian*, etc.  
*Status* Optional  
*Datatype* 1–∞ occurrences of teidata.name separated by whitespace
- @scriptRef** points to a full description of the script or writing style used by this hand, typically supplied by a <scriptNote> element elsewhere in the description.  
*Status* Optional  
*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace
- @medium** describes the tint or type of ink, e.g. *brown*, or other writing medium, e.g. *pencil*  
*Status* Optional

*Datatype* 1–∞ occurrences of teidata.enumerated separated by whitespace  
**@scope** specifies how widely this hand is used in the manuscript.  
*Status* Optional  
*Datatype* teidata.enumerated  
*Legal values are:* **sole** only this hand is used throughout the manuscript  
**major** this hand is used through most of the manuscript  
**minor** this hand is used occasionally in the manuscript

*Note* Usually either *script* or *scriptRef*, and similarly, either *scribe* or *scribeRef*, will be supplied.

**att.identified** provides the identifying attribute for elements which can be subsequently referenced by means of a *key* attribute.

*Module* tagdocs – Documentation Elements

*Members* attDef classSpec constraintSpec dataSpec elementSpec macroSpec moduleSpec paramSpec schemaSpec

*Attributes* att.combinable (*@mode*) (att.deprecated (*@validUntil*))

**@ident** supplies the identifier by which this element may be referenced.

*Status* Required

*Datatype* teidata.name

**@predeclare** says whether this object should be predeclared in the **tei** infrastructure module.

*Status* Optional

*Datatype* teidata.truthValue

*Default* false

**@module** supplies a name for the module in which this object is to be declared.

*Status* Optional

*Datatype* teidata.xmlName

*Schematron* <s:rule context="tei:elementSpec[@module]|tei:classSpec[@module]|tei:macroSpec[@module]">  
 <s:assert test="(not(ancestor::tei:schemaSpec | ancestor::tei:TEI | ancestor::tei:teiCorpus)) or  
 (not(@module) or (not(//tei:moduleSpec) and not(//tei:moduleRef)) or (//tei:moduleSpec[@ident =  
 current()/@module]) or (//tei:moduleRef[@key = current()/@module]))" > Specification  
 <s:value-of select="@ident"/>: the value of the module attribute ("<s:value-of select="@module"/>")  
 should correspond to an existing module, via a moduleSpec or moduleRef</s:assert> </s:rule>

**att.internetMedia** provides attributes for specifying the type of a computer resource using a standard taxonomy.

*Module* tei – The TEI Infrastructure

*Members* att.media[binaryObject graphic] equiv ptr ref

*Attributes* Attributes

**@mimeType** (MIME media type) specifies the applicable multimedia internet mail extension (MIME) media type

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.word separated by whitespace

*Example* In this example *mimeType* is used to indicate that the URL points to a TEI XML file encoded in UTF-8.

```
<ref mimeType="application/tei+xml; charset=UTF-8"
  target="http://sourceforge.net/p/tei/code/HEAD/tree/trunk/P5/Source/
  guidelines-en.xml"/>
```

*Note* This attribute class provides an attribute for describing a computer resource, typically available over the internet, using a value taken from a standard taxonomy. At present only a single taxonomy is supported, the Multipurpose Internet Mail Extensions (MIME) Media Type system. This typology of media types is defined by the Internet Engineering Task Force in RFC 2046. The list of types is maintained by the Internet Assigned Numbers Authority (IANA). The *mimeType* attribute must have a value taken from this list.

---

**att.interpLike** provides attributes for elements which represent a formal analysis or interpretation. [17.2. *Global Attributes for Simple Analyses*]

*Module* tei – The TEI Infrastructure

*Members* interp interpGrp span spanGrp

*Attributes* att.source (@source)

**@type** indicates what kind of phenomenon is being noted in the passage.

*Status* Recommended

*Datatype* teidata.enumerated

*Sample values include:* **image** identifies an image in the passage.

**character** identifies a character associated with the passage.

**theme** identifies a theme in the passage.

**allusion** identifies an allusion to another text.

**@inst** (instances) points to instances of the analysis or interpretation represented by the current element.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Note* The current element should be an analytic one. The element pointed at should be a textual one.

---

**att.lexicographic** provides a set of attributes common to all elements in the dictionary module. [9.2. *The Structure of Dictionary Entries*]

*Module* dictionaries – Dictionaries

*Members* case colloc def entryFree etym form gen gram gramGrp hom hyph iType lang lbl mood number oRef oVar orth pRef pVar per pos pron re sense subc syll tns usg xr

*Attributes* att.datcat (@datcat, @valueDatcat)

**@expand** gives an expanded form of information presented more concisely in the dictionary

*Status* Optional

*Datatype*

```
<gramGrp>
  <pos>n</pos>
</gramGrp>
```

**@norm** (normalized) gives a normalized form of information given by the source text in a non-normalized form

*Status* Optional

*Datatype* teidata.text

```
<gramGrp>
  <pos norm="noun">n</pos>
</gramGrp>
```

**@split** gives the list of split values for a merged form

*Status* Optional

*Datatype* teidata.text

- @value** gives a value which lacks any realization in the printed source text.  
*Status* Optional  
*Datatype* teidata.text
- @orig** (original) gives the original string or is the empty string when the element does not appear in the source text.  
*Status* Optional  
*Datatype* teidata.text
- @location** indicates an <anchor> element typically elsewhere in the document, but possibly in another document, which is the original location of this component.  
*Status* Optional  
*Datatype* teidata.pointer
- @mergedIn** gives a reference to another element, where the original appears as a merged form.  
*Status* Optional  
*Datatype* teidata.pointer
- @opt** (optional) indicates whether the element is optional or not  
*Status* Optional  
*Datatype* teidata.truthValue  
*Default* false

---

**att.measurement** provides attributes to represent a regularized or normalized measurement.

*Module* tei – The TEI Infrastructure

*Members* measure measureGrp

*Attributes* Attributes

- @unit** indicates the units used for the measurement, usually using the standard symbol for the desired units.  
*Status* Optional  
*Datatype* teidata.enumerated  
*Suggested values include:* **m** (metre) SI base unit of length  
**kg** (kilogram) SI base unit of mass  
**s** (second) SI base unit of time  
**Hz** (hertz) SI unit of frequency  
**Pa** (pascal) SI unit of pressure or stress  
**Ω** (ohm) SI unit of electric resistance  
**L** (litre) 1 dm<sup>3</sup>  
**t** (tonne) 10<sup>3</sup> kg  
**ha** (hectare) 1 hm<sup>2</sup>  
**Å** (ångström) 10<sup>-10</sup> m  
**mL** (millilitre)  
**cm** (centimetre)  
**dB** (decibel) see remarks, below  
**kbit** (kilobit) 10<sup>3</sup> or 1000 bits  
**Kibit** (kibibit) 2<sup>10</sup> or 1024 bits  
**kB** (kilobyte) 10<sup>3</sup> or 1000 bytes  
**KiB** (kibibyte) 2<sup>10</sup> or 1024 bytes  
**MB** (megabyte) 10<sup>6</sup> or 1 000 000 bytes  
**MiB** (mebibyte) 2<sup>20</sup> or 1 048 576 bytes

*Note* If the measurement being represented is not expressed in a particular unit, but rather is a number of discrete items, the unit count should be used, or the *unit* attribute may be left unspecified. Wherever appropriate, a recognized SI unit name should be used (see further <http://www.bipm.org/en/publications/si-brochure/>; <http://physics.nist.gov/cuu/Units/>). The list above is indicative rather than exhaustive.

**@quantity** specifies the number of the specified units that comprise the measurement

*Status* Optional

*Datatype* teidata.numeric

**@commodity** indicates the substance that is being measured

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.word separated by whitespace

*Note* In general, when the commodity is made of discrete entities, the plural form should be used, even when the measurement is of only one of them.

*Note* This attribute class provides a triplet of attributes that may be used either to regularize the values of the measurement being encoded, or to normalize them with respect to a standard measurement system.

```
<|>
<!-- regularization:-->
So weren't you gonna buy <measure quantity="0.5" unit="gal"
  commodity="ice cream">half
  a gallon</measure>, baby
</|>
<|>
<!-- normalization: -->
So won't you go and buy <measure quantity="1.893" unit="L"
  commodity="ice cream">half
  a gallon</measure>, baby?
</|>
```

*Note* The unit should normally be named using the standard abbreviation for an SI unit (see further <http://www.bipm.org/en/publications/si-brochure/>; <http://physics.nist.gov/cuu/Units/>). However, encoders may also specify measurements using informally defined units such as lines or characters.

---

**att.media** provides attributes for specifying display and related properties of external media.

*Module* tei – The TEI Infrastructure

*Members* binaryObject graphic

*Attributes* att.internetMedia (@mimeType)

**@width** Where the media are displayed, indicates the display width

*Status* Optional

*Datatype* teidata.outputMeasurement

**@height** Where the media are displayed, indicates the display height

*Status* Optional

*Datatype* teidata.outputMeasurement

**@scale** Where the media are displayed, indicates a scale factor to be applied when generating the desired display size

*Status* Optional

*Datatype* teidata.numeric

---

**att.metrical** defines a set of attributes which certain elements may use to represent metrical information. [6.4. *Rhyme and Metrical Analysis*]

*Module* verse – Verse

*Members* att.divLike[div div1 div2 div3 div4 div5 div6 div7 lg] att.segLike[c cl m pc phr s seg w] l

*Attributes* Attributes

**@met** (metrical structure, conventional) contains a user-specified encoding for the conventional metrical structure of the element.

*Status* Recommended

*Datatype* token

*Note* The pattern may be specified by means of either a standard term for the kind of metrical unit (e.g. *hexameter*) or an encoded representation for the metrical pattern (e.g. +---+---+). In either case, the notation used should be documented by a <metDecl> element within the <encodingDesc> of the associated header. Where this attribute is not specified, the metrical pattern for the element concerned is understood to be inherited from its parent.

**@real** (metrical structure, realized) contains a user-specified encoding for the actual realization of the conventional metrical structure applicable to the element.

*Status* Optional

*Datatype* token

*Note* The pattern may be specified by means of either a standard term for the kind of metrical unit (e.g. *hexameter*) or an encoded representation for the metrical pattern (e.g. +---+---+). In either case, the notation used should be documented by a <metDecl> element within the <encodingDesc> of the associated header. Where this attribute is not specified, the metrical realization for the element concerned is understood to be identical to that specified or implied for the *met* attribute.

**@rhyme** (rhyme scheme) specifies the rhyme scheme applicable to a group of verse lines.

*Status* Recommended

*Datatype* token

*Note* By default, the rhyme scheme is expressed as a string of alphabetic characters each corresponding with a rhyming line. Any non-rhyming lines should be represented by a hyphen or an X. Alternative notations may be defined as for *met* by use of the <metDecl> element in the TEI header. When the default notation is used, it does not make sense to specify this attribute on any unit smaller than a line. Nor does the default notation provide any way to record internal rhyme, or to specify non-conventional rhyming practice. These extensions would require user-defined alternative notations.

---

**att.milestoneUnit** provides an attribute to indicate the type of section which is changing at a specific milestone. [3.10.3. *Milestone Elements* 2.3.6.3. *Milestone Method* 2.3.6. *The Reference System Declaration*]

*Module* core – Elements Available in All TEI Documents

*Members* milestone refState

*Attributes* Attributes

**@unit** provides a conventional name for the kind of section changing at this milestone.

*Status* Required

*Datatype* teidata.enumerated

*Suggested values include:* **page** physical page breaks (synonymous with the <pb> element).

**column** column breaks.

**line** line breaks (synonymous with the <lb> element).  
**book** any units termed book, liber, etc.  
**poem** individual poems in a collection.  
**canto** cantos or other major sections of a poem.  
**speaker** changes of speaker or narrator.  
**stanza** stanzas within a poem, book, or canto.  
**act** acts within a play.  
**scene** scenes within a play or act.  
**section** sections of any kind.  
**absent** passages not present in the reference edition.  
**unnumbered** passages present in the text, but not to be included as part of the reference.  
**<milestone n="23"**  
    ed="La"  
    unit="Dreissiger"/>  
... **<milestone n="24"**  
    ed="AV"  
    unit="verse"/> ...

*Note* If the milestone marks the beginning of a piece of text not present in the reference edition, the special value *absent* may be used as the value of *unit*. The normal interpretation is that the reference edition does not contain the text which follows, until the next <milestone> tag for the edition in question is encountered. In addition to the values suggested, other terms may be appropriate (e.g. *Stephanus* for the Stephanus numbers in Plato).

---

**att.msExcerpt** (manuscript excerpt) provides attributes used to describe excerpts from a manuscript placed in a description thereof. [10.6. *Intellectual Content*]

*Module* msdescription – Manuscript Description

*Members* explicit incipit msContents msItem msItemStruct quote

*Attributes* Attributes

**@defective** indicates whether the passage being quoted is defective, i.e. incomplete through loss or damage.

*Status* Optional

*Datatype* teidata.xTruthValue

*Default* false

*Note* In the case of an incipit, indicates whether the incipit as given is defective, i.e. the first words of the text as preserved, as opposed to the first words of the work itself. In the case of an explicit, indicates whether the explicit as given is defective, i.e. the final words of the text as preserved, as opposed to what the closing words would have been had the text of the work been whole.

---

**att.namespaceable** provides an attribute indicating the target namespace for an object being created

*Module* tagdocs – Documentation Elements

*Members* elementSpec schemaSpec

*Attributes* Attributes

**@ns** (namespace) specifies the namespace to which this element belongs

*Status* Optional

*Datatype* teidata.namespace  
*Default* http://www.tei-c.org/ns/1.0

---

**att.naming** provides attributes common to elements which refer to named persons, places, organizations etc.

[3.5.1. Referring Strings 13.3.5. Names and Nyms]

*Module* tei – The TEI Infrastructure

*Members* att.personal[addName forename genName name orgName persName placeName roleName surname] affiliation author birth bloc climate collection country death district editor education event geogFeat geogName institution nationality occupation offset origPlace population pubPlace region repository residence rs settlement socecStatus state terrain trait

*Attributes* att.canonical (@key, @ref)

**@role** may be used to specify further information about the entity referenced by this name in the form of a set of whitespace-separated values, for example the occupation of a person, or the status of a place.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.enumerated separated by whitespace

**@nymRef** (reference to the canonical name) provides a means of locating the canonical form (*nym*) of the names associated with the object named by the element bearing it.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Note* The value must point directly to one or more XML elements by means of one or more URIs, separated by whitespace. If more than one is supplied, the implication is that the name is associated with several distinct canonical names.

---

**att.notated** provides an attribute to indicate any specialised notation used for element content.

*Module* tei – The TEI Infrastructure

*Members* formula oRef pRef pVar pron u

*Attributes* Attributes

**@notation** names the notation used for the content of the element.

*Status* Optional

*Datatype* teidata.enumerated

---

**att.patternReplacement** provides attributes for regular-expression matching and replacement. [16.2.3.

Using Abbreviated Pointers 2.3.6.3. Milestone Method 2.3.6. The Reference System Declaration 2.3.6.2. Search-and-Replace Method]

*Module* header – The TEI Header

*Members* cRefPattern prefixDef

*Attributes* Attributes

**@matchPattern** specifies a regular expression against which the values of other attributes can be matched.

*Status* Required

*Datatype* teidata.pattern

*Note* The syntax used should follow that defined by W3C XPath syntax. Note that parenthesized groups are used not only for establishing order of precedence and

atoms for quantification, but also for creating subpatterns to be referenced by the *replacementPattern* attribute.

**@replacementPattern** specifies a ‘replacement pattern’, that is, the skeleton of a relative or absolute URI containing references to groups in the *matchPattern* which, once subpattern substitution has been performed, complete the URI.

*Status* Required

*Datatype* teidata.replacement

*Note* The strings *\$1*, *\$2* etc. are references to the corresponding group in the regular expression specified by *matchPattern* (counting open parenthesis, left to right). Processors are expected to replace them with whatever matched the corresponding group in the regular expression. If a digit preceded by a dollar sign is needed in the actual replacement pattern (as opposed to being used as a back reference), the dollar sign must be written as *%24*.

---

**att.personal** (attributes for components of names usually, but not necessarily, personal names) common attributes for those elements which form part of a name usually, but not necessarily, a personal name. [13.2.1. Personal Names]

*Module* tei – The TEI Infrastructure

*Members* addName forename genName name orgName persName placeName roleName surname

*Attributes* att.naming (@role, @nymRef) (att.canonical (@key, @ref))

**@full** indicates whether the name component is given in full, as an abbreviation or simply as an initial.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **yes** the name component is spelled out in full. [Default]

**abb** (abbreviated) the name component is given in an abbreviated form.

**init** (initial letter) the name component is indicated only by one initial.

**@sort** specifies the sort order of the name component in relation to others within the name.

*Status* Optional

*Datatype* teidata.count

---

**att.placement** provides attributes for describing where on the source page or object a textual element appears. [3.4.3. Additions, Deletions, and Omissions 11.3.1.4. Additions and Deletions]

*Module* tei – The TEI Infrastructure

*Members* add addSpan figure fw label metamark notatedMusic note stage witDetail

*Attributes* Attributes

**@place** specifies where this item is placed.

*Status* Recommended

*Datatype* 1-∞ occurrences of teidata.enumerated separated by whitespace

*Suggested values include:* **below** below the line

**bottom** at the foot of the page

**margin** in the margin (left, right, or both)

**top** at the top of the page

**opposite** on the opposite, i.e. facing, page

**overleaf** on the other side of the leaf

**above** above the line

**end** at the end of e.g. chapter or volume.  
**inline** within the body of the text.  
**inspace** in a predefined space, for example left by an earlier scribe.  
**<add place="margin">**[An addition written in the margin]**</add>**  
**<add place="bottom opposite">**[An addition written at the  
foot of the current page and also on the facing page]**</add>**  
**<note place="bottom">**Ibid, p.7**</note>**

**att.pointing** provides a set of attributes used by all elements which point to other elements by means of one or more URI references. [1.3.1.1.2. *Language Indicators* 3.6. *Simple Links and Cross-References*]

*Module* tei – The TEI Infrastructure

*Members* att.pointing.group[altGrp joinGrp linkGrp] calendar catRef citedRange gloss join licence link locus  
note oRef oVar pRef pVar ptr ref span substJoin term witDetail

*Attributes* Attributes

**@targetLang** specifies the language of the content to be found at the destination referenced by *target*, using a ‘language tag’ generated according to BCP 47.

*Status* Optional

*Datatype* teidata.language

*Schematron* <sch:rule context="tei:\*[not(self::tei:schemaSpec)][@targetLang]">  
<sch:assert test="@target">@targetLang should only be used on <sch:name/> if  
@target is specified.</sch:assert> </sch:rule>

```
<linkGrp xml:id="pol-swh_aln_2.1-linkGrp">
  <ptr xml:id="pol-swh_aln_2.1.1-ptr"
    target="pol/UDHR/text.xml#pol_txt_1-head"
    type="tuv"
    targetLang="pl"/>
  <ptr xml:id="pol-swh_aln_2.1.2-ptr"
    target="sw/UDHR/text.xml#swh_txt_1-head"
    type="tuv"
    targetLang="sw"/>
</linkGrp>
```

In the example above, the <linkGrp> combines pointers at parallel fragments of the *Universal Declaration of Human Rights*: one of them is in Polish, the other in Swahili.

*Note* The value must conform to BCP 47. If the value is a private use code (i.e., starts with x- or contains x-), a <language> element with a matching value for its *ident* attribute should be supplied in the TEI header to document this value. Such documentation may also optionally be supplied for non-private-use codes, though these must remain consistent with their (IETF) Internet Engineering Task Force definitions.

**@target** specifies the destination of the reference by supplying one or more URI References

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Note* One or more syntactically valid URI references, separated by whitespace. Because whitespace is used to separate URIs, no whitespace is permitted inside a single URI. If a whitespace character is required in a URI, it should be escaped with the normal mechanism, e.g. TEI%20Consortium.

**@evaluate** specifies the intended meaning when the target of a pointer is itself a pointer.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **all** if the element pointed to is itself a pointer, then the target of that pointer will be taken, and so on, until an element is found which is not a pointer.

**one** if the element pointed to is itself a pointer, then its target (whether a pointer or not) is taken as the target of this pointer.

**none** no further evaluation of targets is carried out beyond that needed to find the element specified in the pointer's target.

*Note* If no value is given, the application program is responsible for deciding (possibly on the basis of user input) how far to trace a chain of pointers.

---

**att.pointing.group** provides a set of attributes common to all elements which enclose groups of pointer elements. [16. *Linking, Segmentation, and Alignment*]

*Module* tei – The TEI Infrastructure

*Members* altGrp joinGrp linkGrp

*Attributes* att.pointing (@targetLang, @target, @evaluate) att.typed (@type, @subtype)

**@domains** optionally specifies the identifiers of the elements within which all elements indicated by the contents of this element lie.

*Status* Optional

*Datatype* 2–∞ occurrences of teidata.pointer separated by whitespace

*Note* If this attribute is supplied every element specified as a target must be contained within the element or elements named by it. An application may choose whether or not to report failures to satisfy this constraint as errors, but may not access an element of the right identifier but in the wrong context. If this attribute is not supplied, then target elements may appear anywhere within the target document.

**@targFunc** (target function) describes the function of each of the values of the *target* attribute of the enclosed <link>, <join>, or <alt> tags.

*Status* Optional

*Datatype* 2–∞ occurrences of teidata.word separated by whitespace

*Note* The number of separate values must match the number of values in the *target* attribute in the enclosed <link>, <join>, or <alt> tags (an intermediate <ptr> element may be needed to accomplish this). It should also match the number of values in the *domains* attribute, of the current element, if one has been specified.

---

**att.ranging** provides attributes for describing numerical ranges.

*Module* tei – The TEI Infrastructure

*Members* att.dimensions[att.damaged[damage damageSpan] att.editLike[att.transcriptional[add addSpan del delSpan mod redo restore retrace subst substJoin undo] affiliation age am birth climate corr date death education event ex expan faith floruit gap geogFeat geogName langKnowledge langKnown location name nationality occupation offset org orgName origDate origPlace origin persName person place placeName population reg relation residence secl sex soccecStatus state supplied surplus terrain time trait unclear] depth dim dimensions height space width] num precision

*Attributes* Attributes

**@atLeast** gives a minimum estimated value for the approximate measurement.

*Status* Optional

*Datatype* teidata.numeric

**@atMost** gives a maximum estimated value for the approximate measurement.

*Status* Optional

*Datatype* teidata.numeric

- @min** where the measurement summarizes more than one observation or a range, supplies the minimum value observed.  
*Status* Optional  
*Datatype* teidata.numeric
- @max** where the measurement summarizes more than one observation or a range, supplies the maximum value observed.  
*Status* Optional  
*Datatype* teidata.numeric
- @confidence** specifies the degree of statistical confidence (between zero and one) that a value falls within the range specified by *min* and *max*, or the proportion of observed values that fall within that range.  
*Status* Optional  
*Datatype* teidata.probability

*Example*

```
The MS. was lost in transmission by mail from <del rend="overstrike">
  <gap reason="illegible"
    extent="one or two letters" atLeast="1" atMost="2" unit="chars"/>
</del> Philadelphia to the Graphic office, New York.
```

**att.rdgPart** provides attributes to mark the beginning or ending of a fragmentary manuscript or other witness.  
 [12.1.5. Fragmentary Witnesses]

*Module* textcrit – Critical Apparatus

*Members* lacunaEnd lacunaStart wit witEnd witStart

*Attributes* Attributes

- @wit** (witness or witnesses) contains a space-delimited list of one or more sigla indicating the witnesses to this reading beginning or ending at this point.  
*Status* Optional  
*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Note* These elements may appear anywhere within the elements <lem> and <rdg>, and also within any of their constituent elements.

**att.readFrom** provides an attribute used by specification elements which derive components from some external source.

*Module* tei – The TEI Infrastructure

*Members* classRef dataRef elementRef macroRef moduleRef schemaSpec

*Attributes* Attributes

- @SOURCE** specifies the source from which declarations and definitions for the components of the object being defined may be obtained.  
*Status* Optional  
*Datatype* teidata.pointer

*Note* The context indicated must provide a set of TEI-conformant specifications in a form directly usable by an ODD processor. By default, this will be the location of the current release of the TEI Guidelines. The source may be specified in the form of a private URI, for which the form recommended is `tei:x.y.z`, where `x.y.z`

indicates the version number, e.g. `tei:1.5.1` for 1.5.1 release of TEI P5 or (as a special case) `tei:current` for whatever is the latest release.

---

**att.repeatable** supplies attributes for the elements which define component parts of a content model.

*Module* tagdocs – Documentation Elements

*Members* alternate classRef elementRef sequence

*Attributes* Attributes

**@context** supplies an XPath identifying a context within which this component of a content model must be found

*Status* Optional

*Datatype*

**@minOccurs** (minimum number of occurrences) indicates the smallest number of times this component may occur.

*Status* Optional

*Datatype* teidata.count

*Default* 1

**@maxOccurs** (maximum number of occurrences) indicates the largest number of times this component may occur.

*Status* Optional

*Datatype* teidata.unboundedInt

*Default* 1

---

**att.resourced** provides attributes by which a resource (such as an externally held media file) may be located.

*Module* tei – The TEI Infrastructure

*Members* graphic media

*Attributes* Attributes

**@url** (uniform resource locator) specifies the URL from which the media concerned may be obtained.

*Status* Required

*Datatype* teidata.pointer

---

**att.scoping** provides attributes for selecting particular elements within a document.

*Module* tei – The TEI Infrastructure

*Members* certainty precision respons

*Attributes* Attributes

**@target** points at one or several elements or sets of elements by means of one or more data pointers, using the URI syntax.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

```
Elizabeth went to <persName xml:id="ESSEX">Essex</persName>
<certainty target="#ESSEX"
  locus="name"
  degree="0.6" />
```

**@match** supplies an arbitrary XPath expression using the syntax defined in Kay (ed.) (2007) which identifies a set of nodes, selected within the context identified by the *target* attribute if this is supplied, or within the context of the parent element if it is not.

*Status* Optional

*Datatype*

```
<gap reason="cancelled">
  <certainty match="@reason"
    locus="value"
    cert="low"/>
</gap>
```

*Note* The expression of certainty applies to the nodeset identified by the value of the *target* attribute, possibly modified additionally by the value of the *match* attribute. If more than one identifier is given, the implication is that all elements (or nodesets) are intended. The *match* attribute may also be used as a means of identifying groups of elements. If *target* and *match* are present, *target* selects an element and the XPath expression in *match* is evaluated in the context of that element. If neither attribute is present, the expression applies to its parent element. If only *target* is given, the expression refers to the selected element or nodeset. If only *match* is given, the XPath expression is evaluated in the context of the parent element of the bearing element.

*Note* that the value of the *target* attribute may include an XPointer expression including an XPath expression (see 16.2.4. *TEI XPointer Schemes*).

**att.segLike** provides attributes for elements used for arbitrary segmentation. [16.3. *Blocks, Segments, and Anchors* 17.1. *Linguistic Segment Categories*]

*Module* tei – The TEI Infrastructure

*Members* c cl m pc phr s seg w

*Attributes* att.metrical (*@met*, *@real*, *@rhyme*) att.datcat (*@datcat*, *@valueDatcat*) att.fragmentable (*@part*)

**@function** characterizes the function of the segment.

*Status* Optional

*Datatype* teidata.enumerated

*Note* Attribute values will often vary depending on the type of element to which they are attached. For example, a <cl>, may take values such as coordinate, subject, adverbial etc. For a <phr>, such values as subject, predicate etc. may be more appropriate. Such constraints will typically be implemented by a project-defined customization.

**att.sortable** provides attributes for elements in lists or groups that are sortable, but whose sorting key cannot be derived mechanically from the element content. [9.1. *Dictionary Body and Overall Structure*]

*Module* tei – The TEI Infrastructure

*Members* bibl biblFull biblStruct correspAction entry entryFree event idno item list listApp listBibl listChange listEvent listNym listOrg listPerson listPlace listRelation listWit msDesc nym org person personGrp place relation superEntry term witness

*Attributes* Attributes

**@sortKey** supplies the sort key for this element in an index, list or group which contains it.

*Status* Optional

*Datatype* teidata.word

```
David's other principal backer, Josiah
ha-Kohen <index indexName="NAMES">
  <term sortKey="Azarya_Josiah_Kohen">Josiah ha-Kohen b.
Azarya</term>
</index> b. Azarya, son of one of the last gaons of Sura was
David's own first
cousin.
```

*Note* The sort key is used to determine the sequence and grouping of entries in an index. It provides a sequence of characters which, when sorted with the other values, will produced the desired order; specifics of sort key construction are application-dependent. Dictionary order often differs from the collation sequence of machine-readable character sets; in English-language dictionaries, an entry for *4-H* will often appear alphabetized under 'fourh', and *McCoy* may be alphabetized under 'maccoy', while *A1*, *A4*, and *A5* may all appear in numeric order 'alphabetized' between 'a-' and 'AA'. The sort key is required if the orthography of the dictionary entry does not suffice to determine its location.

---

**att.source** provides attributes for pointing to the source of a bibliographic reference. [3.3.3. *Quotation* 8.3.4. *Writing*]

*Module* tei – The TEI Infrastructure

*Members* att.editLike[att.transcriptional[add addSpan del delSpan mod redo restore retrace subst substJoin undo] affiliation age am birth climate corr date death education event ex expan faith floruit gap geogFeat geogName langKnowledge langKnown location name nationality occupation offset org orgName origDate origPlace origin persName person place placeName population reg relation residence secl sex socecStatus state supplied surplus terrain time trait unclear] att.interpLike[interp interpGrp span spanGrp] att.textCritical[lem rdg rdgGrp] abbr abstract egXML handShift note orig provenance q quote respons rs seg sic space witDetail writing

*Attributes* Attributes

**@SOURCE** provides a pointer to the bibliographical source from which a quotation or citation is drawn.

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.pointer separated by whitespace

*Example*

```
<p>
<!-- ... -->
As Willard McCarty (<bibl xml:id="mcc_2012">2012, p.2</bibl>)
tells us, <quote source="#mcc_2012">'Collaboration' is a
  problematic and should be a contested term.</quote>
<!-- ... -->
</p>
```

*Example*

```
<p>
<!-- ... -->
  <quote source="#chicago_15_ed">Grammatical theories
  are in flux, and the more we learn, the less we
  seem to know.</quote>
<!-- ... -->
</p>
```

```

<!-- ... -->
<bibl xml:id="chicago_15_ed">
  <title level="m">The Chicago Manual of Style</title>,
  <edition>15th edition</edition>.
  <pubPlace>Chicago</pubPlace>:
  <publisher>University of Chicago Press</publisher>
  (<date>2003</date>),
  <biblScope unit="page">p.147</biblScope>.

</bibl>

```

**att.spanning** provides attributes for elements which delimit a span of text by pointing mechanisms rather than by enclosing it. [1.3.1. Attribute Classes]

*Module* tei – The TEI Infrastructure

*Members* addSpan cb damageSpan delSpan gb index lb metamark milestone mod pb redo retrace undo

*Attributes* Attributes

**@spanTo** indicates the end of a span initiated by the element bearing this attribute.

*Status* Optional

*Datatype* teidata.pointer

*Schematron* The @spanTo attribute must point to an element following the current element <sch:rule context="tei:\*[@spanTo]"> <sch:assert test="id(substring(@spanTo,2)) and following::\*[@xml:id=substring(current()/@spanTo,2)]">The element indicated by @spanTo (<sch:value-of select="@spanTo"/>) must follow the current element <sch:name/> </sch:assert> </sch:rule>

*Note* The span is defined as running in document order from the start of the content of the pointing element to the end of the content of the element pointed to by the *spanTo* attribute (if any). If no value is supplied for the attribute, the assumption is that the span is coextensive with the pointing element. If no content is present, the assumption is that the starting point of the span is immediately following the element itself.

**att.styleDef** provides attributes to specify the name of a formal definition language used to provide formatting or rendition information.

*Module* tei – The TEI Infrastructure

*Members* rendition styleDefDecl

*Attributes* Attributes

**@scheme** identifies the language used to describe the rendition.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **css** Cascading Stylesheet Language

**xslfo** Extensible Stylesheet Language Formatting Objects

**free** Informal free text description

**other** A user-defined rendition description language

*Note* If no value for the @scheme attribute is provided, then the default assumption should be that CSS is in use.

**@schemeVersion** supplies a version number for the style language provided in *scheme*.

*Status* Optional

*Datatype* teidata.versionNumber

*Schematron* <sch:rule context="tei:\*[@schemeVersion]"> <sch:assert test="@scheme and not(@scheme = 'free')"> @schemeVersion can only be used if @scheme is specified.  
</sch:assert> </sch:rule>

*Note* If *schemeVersion* is used, then *scheme* should also appear, with a value other than free.

---

**att.tableDecoration** provides attributes used to decorate rows or cells of a table. [14. *Tables, Formulæ, Graphics and Notated Music*]

*Module* tei – The TEI Infrastructure

*Members* cell row

*Attributes* Attributes

**@role** indicates the kind of information held in this cell or in each cell of this row.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **label** labelling or descriptive information only.

**data** data values.[Default]

*Note* When this attribute is specified on a row, its value is the default for all cells in this row. When specified on a cell, its value overrides any default specified by the *role* attribute of the parent <row> element.

**@rows** indicates the number of rows occupied by this cell or row.

*Status* Optional

*Datatype* teidata.count

*Default* 1

*Note* A value greater than one indicates that this cell spans several rows. Where several cells span multiple rows, it may be more convenient to use nested tables.

**@cols** (columns) indicates the number of columns occupied by this cell or row.

*Status* Optional

*Datatype* teidata.count

*Default* 1

*Note* A value greater than one indicates that this cell or row spans several columns. Where an initial cell spans an entire row, it may be better treated as a heading.

---

**att.textCritical** defines a set of attributes common to all elements representing variant readings in text critical work. [12.1. *The Apparatus Entry, Readings, and Witnesses*]

*Module* textcrit – Critical Apparatus

*Members* lem rdg rdgGrp

*Attributes* att.source (@source) att.written (@hand)

**@type** classifies the reading according to some useful typology.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **substantive** the reading offers a substantive variant.

**orthographic** the reading differs only orthographically, not in substance, from other readings.

**@cause** classifies the cause for the variant reading, according to any appropriate typology of possible origins.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **homeoteleuton**

**homeoarchy**  
**paleographicConfusion**  
**haplography**  
**dittography**  
**falseEmendation**

**@varSeq** (variant sequence) provides a number indicating the position of this reading in a sequence, when there is reason to presume a sequence to the variants.

*Status* Optional

*Datatype* teidata.count

*Note* Different variant sequences could be coded with distinct number trails: 1-2-3 for one sequence, 5-6-7 for another. More complex variant sequences, with (for example) multiple branchings from single readings, may be expressed through the <join> element.

*Note* This element class defines attributes inherited by <rdg>, <lem>, and <rdgGrp>.

**att.timed** provides attributes common to those elements which have a duration in time, expressed either absolutely or by reference to an alignment map. [8.3.5. *Temporal Information*]

*Module* tei – The TEI Infrastructure

*Members* annotationBlock binaryObject gap incident kinesic media pause u vocal writing

*Attributes* att.duration (att.duration.w3c (@dur)) (att.duration.iso (@dur-iso))

**@start** indicates the location within a temporal alignment at which this element begins.

*Status* Optional

*Datatype* teidata.pointer

*Note* If no value is supplied, the element is assumed to follow the immediately preceding element at the same hierarchic level.

**@end** indicates the location within a temporal alignment at which this element ends.

*Status* Optional

*Datatype* teidata.pointer

*Note* If no value is supplied, the element is assumed to precede the immediately following element at the same hierarchic level.

**att.transcriptional** provides attributes specific to elements encoding authorial or scribal intervention in a text when transcribing manuscript or similar sources. [11.3.1.4. *Additions and Deletions*]

*Module* tei – The TEI Infrastructure

*Members* add addSpan del delSpan mod redo restore retrace subst substJoin undo

*Attributes* att.editLike (@evidence, @instant) (att.dimensions (@unit, @quantity, @extent, @precision, @scope) (att.ranging (@atLeast, @atMost, @min, @max, @confidence))) (att.source (@source)) att.written (@hand)

**@status** indicates the effect of the intervention, for example in the case of a deletion, strikeouts which include too much or too little text, or in the case of an addition, an insertion which duplicates some of the text already present.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **duplicate** all of the text indicated as an addition duplicates some text that is in the original, whether the duplication is word-for-word or less exact.

**duplicate-partial** part of the text indicated as an addition duplicates some text that is in the original

**excessStart** some text at the beginning of the deletion is marked as deleted even though it clearly should not be deleted.

**excessEnd** some text at the end of the deletion is marked as deleted even though it clearly should not be deleted.

**shortStart** some text at the beginning of the deletion is not marked as deleted even though it clearly should be.

**shortEnd** some text at the end of the deletion is not marked as deleted even though it clearly should be.

**partial** some text in the deletion is not marked as deleted even though it clearly should be.

**unremarkable** the deletion is not faulty.[Default]

*Note* Status information on each deletion is needed rather rarely except in critical editions from authorial manuscripts; status information on additions is even less common. Marking a deletion or addition as faulty is inescapably an interpretive act; the usual test applied in practice is the linguistic acceptability of the text with and without the letters or words in question.

**@CAUSE** documents the presumed cause for the intervention.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **fix** repeated for the purpose of fixation

**unclear** repeated to clarify a previously illegible or badly written text or mark

**@SEQ** (sequence) assigns a sequence number related to the order in which the encoded features carrying this attribute are believed to have occurred.

*Status* Optional

*Datatype* teidata.count

---

**att.translatable** provides attributes used to indicate the status of a translatable portion of an ODD document.

*Module* tei – The TEI Infrastructure

*Members* desc exemplum gloss remarks valDesc

*Attributes* Attributes

**@versionDate** specifies the date on which the source text was extracted and sent to the translator

*Status* Optional

*Datatype* teidata.temporal.w3c

*Note* The *versionDate* attribute can be used to determine whether a translation might need to be revisited, by comparing the modification date on the containing file with the *versionDate* value on the translation. If the file has changed, changelogs can be checked to see whether the source text has been modified since the translation was made.

---

**att.typed** provides attributes which can be used to classify or subclassify elements in any way. [1.3.1. Attribute Classes 17.1.1. Words and Above 3.5.1. Referring Strings 3.6. Simple Links and Cross-References 3.5.5. Abbreviations and Their Expansions 3.12.1. Core Tags for Verse 7.2.5. Speech Contents 4.1.1. Un-numbered Divisions 4.1.2. Numbered Divisions 4.2.1. *Attributes* Attributes

**@type** characterizes the element in some sense, using any convenient classification scheme or typology.

*Status* Optional

*Datatype* teidata.enumerated

```
<div type="verse">
  <head>Night in Tarras</head>
  <lg type="stanza">
    <l>At evening tramping on the hot white road</l>
    <l>...</l>
  </lg>
  <lg type="stanza">
    <l>A wind sprang up from nowhere as the sky</l>
    <l>...</l>
  </lg>
</div>
```

*Note* The *type* attribute is present on a number of elements, not all of which are members of att.typed, usually because these elements restrict the possible values for the attribute in a specific way.

**@subtype** provides a sub-categorization of the element, if needed

*Status* Optional

*Datatype* teidata.enumerated

*Note* The *subtype* attribute may be used to provide any sub-classification for the element additional to that provided by its *type* attribute.

*Schematron* <sch:rule context="tei:\*[@subtype]"> <sch:assert test="@type">The <sch:name/> element should not be categorized in detail with @subtype unless also categorized in general with @type</sch:assert> </sch:rule>

*Note* When appropriate, values from an established typology should be used. Alternatively a typology may be defined in the associated TEI header. If values are to be taken from a project-specific list, this should be defined using the <valList> element in the project-specific schema description, as described in 23.3.1.4. *Modification of Attribute and Attribute Value Lists* .

**att.witnessed** supplies the attribute used to identify the witnesses supporting a particular reading in a critical apparatus. [12.1. *The Apparatus Entry, Readings, and Witnesses*]

*Module* textcrit – Critical Apparatus

*Members* lem rdg

*Attributes* Attributes

**@wit** (witness or witnesses) contains a space-delimited list of one or more pointers indicating the witnesses which attest to a given reading.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Note* If the apparatus contains readings only for a single witness, this attribute may be consistently omitted. This attribute may occur both within an apparatus gathering variant readings in the transcription of an individual witness and within an apparatus gathering readings from different witnesses. Additional descriptions or alternative versions of the sigla referenced may be supplied as the content of a child <wit> element.

---

**att.written** provides an attribute to indicate the hand in which the textual content of an element was written in the source being transcribed. [1.3.1. Attribute Classes]

*Module* tei – The TEI Infrastructure

*Members* att.damaged[damage damageSpan] att.textCritical[lem rdg rdgGrp] att.transcriptional[add addSpan del delSpan mod redo restore retrace subst substJoin undo] ab closer div fw head hi label line note opener p salute seg text zone

*Attributes* Attributes

**@hand** points to a <handNote> element describing the hand considered responsible for the textual content of the element concerned.

*Status* Optional

*Datatype* teidata.pointer

## C Elements

**<ab>** (anonymous block) contains any arbitrary component-level unit of text, acting as an anonymous container for phrase or inter level elements analogous to, but without the semantic baggage of, a paragraph. [16.3. *Blocks, Segments, and Anchors*]

*Module* linking — Linking, Segmentation, and Alignment

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.typed (@type, @subtype) att.declaring (@decls) att.fragmentable (@part) att.written (@hand)

|-----------------------------------------------|
| att.written.attributes,<br>macro.paraContent} |
|-----------------------------------------------|

<abbr> (abbreviation) contains an abbreviation of any sort. [3.5.5. Abbreviations and Their Expansions]

*Module* core – Elements Available in All TEI Documents

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.source (@source) att.typed (type, @subtype)

@type allows the encoder to classify the abbreviation according to some convenient typology.

*Derived from* att.typed

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **suspension** the abbreviation provides the first letter(s) of the word or phrase, omitting the remainder.

**contraction** the abbreviation omits some letter(s) in the middle.

**brevigraph** the abbreviation comprises a special symbol or mark.

**superscription** the abbreviation includes writing above the line.

**acronym** the abbreviation comprises the initial letters of the words of a phrase.

**title** the abbreviation is for a title of address (Dr, Ms, Mr, ...)

**organization** the abbreviation is for the name of an organization.

**geographic** the abbreviation is for a geographic name.

*Note* The *type* attribute is provided for the sake of those who wish to classify abbreviations at their point of occurrence; this may be useful in some circumstances, though usually the same abbreviation will have the same type in all occurrences. As the sample values make clear, abbreviations may be classified by the method used to construct them, the method of writing them, or the referent of the term abbreviated; the typology used is up to the encoder and should be carefully planned to meet the needs of the expected use. For a typology of Middle English abbreviations, see Petty (1977)

Note This element is intended only for cases where no abstract is available in the original source. Any abstract already present in the source document should be encoded as a <div> within the <front>, as it should for a born-digital document.

Example

```

<profileDesc>
  <abstract resp="#LB">
    <p>Good database design involves the acquisition and deployment of
      skills which have a wider relevance to the educational process. From
      a set of more or less instinctive rules of thumb a formal discipline
      or "methodology" of database design has evolved. Applying that
      methodology can be of great benefit to a very wide range of academic
      subjects: it requires fundamental skills of abstraction and
      generalisation and it provides a simple mechanism whereby complex
      ideas and information structures can be represented and manipulated,
      even without the use of a computer. </p>
  </abstract>
</profileDesc>

*Note* In a diplomatic edition attempting to represent an original source, the <add> element should not be used for additions to the current TEI electronic edition made by editors or encoders. In these cases, either the <corr> or <supplied> element are recommended. In a TEI edition of a historical text with previous editorial emendations in which such additions or reconstructions are considered part of the source text, the use of <add> may be appropriate, dependent on the editorial philosophy of the project.

*Example*

```
The story I am
going to relate is true as to its main facts, and as to the
consequences <add place="above">of these facts</add> from which
this tale takes its title.

*Note* As with other culturally-constructed traits such as sex, the way in which this concept is described in different cultural contexts may vary. The normalizing attributes are provided as a means of simplifying that variety to Western European norms and should not be used where that is inappropriate. The content of the element may be used to describe the intended concept in more detail, using plain text.

*Example*

```
<age value="2" notAfter="1986">under 20 in the early eighties</age>
```

---

**<alt>** (alternation) identifies an alternation or a set of choices among elements or passages. [16.8. Alternation]

*Module* linking – Linking, Segmentation, and Alignment

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.typed (@type, @subtype) att.pointing (~~target~~, @targetLang, @evaluate)

**@target** specifies the destination of the reference by supplying one or more URI References

*Derived from* att.pointing

*Status* Optional

*Datatype* 2–∞ occurrences of teidata.pointer separated by whitespace

**@mode** states whether the alternations gathered in this collection are exclusive or inclusive.

*Status* Recommended

*Datatype* teidata.enumerated

*Legal values are:* **excl** (exclusive) indicates that the alternation is exclusive, i.e. that at most one of the alternatives occurs.

**incl** (inclusive) indicates that the alternation is not exclusive, i.e. that one or more of the alternatives occur.

**@weights** If *mode* is **excl**, each weight states the probability that the corresponding alternative occurs. If *mode* is **incl** each weight states the probability that the corresponding alternative occurs given that at least one of the other alternatives occurs.

*Status* Optional

*Datatype* 2-∞ occurrences of teidata.probability separated by whitespace

*Note* If *mode* is **excl**, the sum of weights must be 1. If *mode* is **incl**, the sum of weights must be in the range from 0 to the number of alternants.

**<analytic>** (analytic level) contains bibliographic elements describing an item (e.g. an article or poem) published within a monograph or journal and not as an independent publication. [3.11.2.1. *Analytic, Monographic, and Series Levels*]

Module core — Elements Available in All TEI Documents

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

*Contained by*

*core:* biblStruct

*May contain*

*core:* author date editor ptr ref respStmt textLang title

*header:* availability idno

*Note* May contain titles and statements of responsibility (author, editor, or other), in any order. The <analytic> element may only occur within a <biblStruct>, where its use is mandatory for the description of an analytic level bibliographic item.

*Example*

```
<biblStruct>
  <analytic>
    <author>Chesnutt, David</author>
    <title>Historical Editions in the States</title>
  </analytic>
  <monogr>
    <title level="j">Computers and the Humanities</title>
    <imprint>
      <biblScope>25.6</biblScope>
      <date when="1991-12">(December, 1991):</date>
      <biblScope>377-380</biblScope>
    </imprint>
  </monogr>
</biblStruct>
```

*Content model*

}

```

**<app>** (apparatus entry) contains one entry in a critical apparatus, with an optional lemma and usually one or more readings or notes on the relevant passage. [12.1.1. *The Apparatus Entry*]

*Module* textcrit – Critical Apparatus

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))

(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@type** classifies the variation contained in this element according to some convenient typology.

*Status* Optional

*Datatype* teidata.enumerated

**@from** identifies the beginning of the lemma in the base text.

*Status* Optional

*Datatype* teidata.pointer

*Note* This attribute should be used when either the double-end point method of apparatus markup, or the location-referenced method with a URL rather than canonical reference, are used.

**@to** identifies the endpoint of the lemma in the base text.

*Status* Optional

*Datatype* teidata.pointer

*Note* This attribute is only used when the double-end point method of apparatus markup is used, when the encoded apparatus is not embedded *in-line* in the base-text.

**@loc** (location) indicates the location of the variation, when the location-referenced method of apparatus markup is used.

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.word separated by whitespace

*Note* This attribute is used only when the location-referenced encoding method is used. It supplies a string containing a canonical reference for the passage to which the variation applies.

*Member of* model.global.edit

  att.global.change.attributes,
  att.global.responsibility.attributes,
  model.applicationLike+
}

```

**<application>** provides information about an application which has acted upon the document. [2.3.10. *The Application Information Element*]

*Module header* — The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.typed (@type, @subtype) att.dateable (@calendar, @period) (att.dateable.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.dateable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.dateable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod))

**@ident** supplies an identifier for the application, independent of its version number or display name.

*Status* Required

*Datatype* teidata.name

**@version** supplies a version number for the application, independent of its identifier or display name.

*Status* Required

*Datatype* teidata.versionNumber

*Member of* model.applicationLike

*Contained by*

*header:* appInfo

*May contain*

core: desc label p ptr ref

linking: ab

Example

```

<appInfo>
  <application version="1.5"
    ident="ImageMarkupTool1" notAfter="2006-06-01">
    <label>Image Markup Tool</label>
    <ptr target="#P1"/>
    <ptr target="#P2"/>
  </application>
</appInfo>

```

This example shows an appInfo element documenting the fact that version 1.5 of the Image Markup Tool1 application has an interest in two parts of a document which was last saved on June 6 2006. The parts concerned are accessible at the URLs given as target for the two <ptr> elements.

```

<arc> encodes an arc, the connection from one node to another in a graph. [19.1. Graphs and Digraphs]

Module nets — Graphs, Networks, and Trees

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@from** gives the identifier of the node which is adjacent from this arc.

*Status* Required

*Datatype* teidata.pointer

**@to** gives the identifier of the node which is adjacent to this arc.

*Status* Required

*Datatype* teidata.pointer

*Containment* graph

*May contain*

*core:* label

*Note* The <arc> element must be used if the arcs are labeled. Otherwise, arcs can be encoded using the *adj*, *adjTo* and *adjFrom* attributes on the <node> tags in the graph. Both <arc> tags and adjacency attributes can be used, but the resulting encoding would be highly redundant. Zero, one, or two children <label> elements may be present. The first occurrence of <label> provides a label for the arc; the second provides a second label for the arc, and should be used if a transducer is being encoded.

*Example*

```
<arc from="#T3" to="#T3">
  <label>OLD</label>
  <label>VIEUX</label>
</arc>
```

*Content model*

```
<content>
  <sequence minOccurs="0">
    <elementRef key="label"/>
    <elementRef key="label" minOccurs="0"/>
  </sequence>
</content>
```

*Schema Declaration*

```
element arc
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  attribute from { text },
  attribute to { text },
  ( label, label? )?
}
```

<argument> contains a formal list or prose description of the topics addressed by a subdivision of a text. [4.2. Elements Common to All Divisions 4.6. Title Pages]

Module textstructure – Default Text Structure

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

---

**<att>** (attribute) contains the name of an attribute appearing within running text. [22. *Documentation Elements*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@scheme** supplies an identifier for the scheme in which this name is defined.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **TEI** (text encoding initiative) this attribute is part of the TEI scheme.[Default]

**DBK** (docbook) this attribute is part of the Docbook scheme.

**XX** (unknown) this attribute is part of an unknown scheme.

**imaginary** the attribute is from a non-existent scheme, for illustrative purposes only

**XHTML** the attribute is part of the XHTML language

**XML** the attribute is part of the XML language

**XI** the attribute is defined in the xInclude schema

*Member of* model.phrase.xml

*verse:* caesura rhyme

*Note* Particularly where cataloguing is likely to be based on the content of the header, it is advisable to use a generally recognized name authority file to supply the content for this element. The attributes *key* or *ref* may also be used to reference canonical information about the author(s) intended from any appropriate authority, such as a library catalogue or online resource. In the case of a broadcast, use this element for the name of the company or network responsible for making the broadcast.

Where an author is unknown or unspecified, this element may contain text such as *Unknown* or *Anonymous*. When the appropriate TEI modules are in use, it may also contain detailed tagging of the names used for people, organizations or places, in particular where multiple names are given.

*Example*

```
<author>British Broadcasting Corporation</author>
<author>La Fayette, Marie Madeleine Pioche de la Vergne, comtesse de
(1634–1693)</author>
<author>Anonymous</author>
<author>Bill and Melinda Gates Foundation</author>

}
```

<binary> (binary value) represents the value part of a feature-value specification which can contain either of exactly two possible values. [18.2. Elementary Feature Structures and the Binary Feature Value]

Module iso-fs – Feature Structures

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.datcat (@datcat, @valueDatcat)

@value supplies a binary value.

Status Required

Datatype teidata.truthValue

Note This attribute has a datatype of data.truthValue, which may be represented by the values 1 or true, or 0 or false.

Member of model.featureVal.single

Contained by

iso-fs: f fvLib if vAlt vColl vDefault vLabel vMerge vNot vRange

May contain Empty element

*Note* The value attribute may take any value permitted for attributes of the W3C datatype Boolean: this includes for example the strings `true` or `1` which are equivalent.

*Example*

```
<f name="strident">
  <binary value="true"/>
</f>
<f name="exclusive">
  <binary value="false"/>
</f>
```

*Content model* `<content></content>`

*Schema Declaration*

```
element binary
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,

May contain Empty element

Note On this element, the global n attribute indicates the number or other value associated with the column which follows the point of insertion of this <cb> element. Encoders should adopt a clear and consistent policy as to whether the numbers associated with column breaks relate to the physical sequence number of the column in the whole text, or whether columns are numbered within the page. The <cb> element is placed at the head of the column to which it refers.

Example Markup of an early English dictionary printed in two columns:

```
<pb/>
<cb n="1"/>
<entryFree>
  <form>Well</form>, <sense>a Pit to hold Spring-Water</sense>:
  <sense>In the Art of <hi rend="italic">War</hi>, a Depth the Miner
    sinks into the Ground, to find out and disappoint the Enemies Mines,
    or to prepare one</sense>.
</entryFree>
<entryFree>To <form>Welter</form>, <sense>to wallow</sense>, or
<sense>lie groveling</sense>.</entryFree>
<!-- remainder of column -->
<cb n="2"/>
<entryFree>
  <form>Wey</form>, <sense>the greatest Measure for dry Things,
    containing five Chaldron</sense>.
</entryFree>
<entryFree>
  <form>Whale</form>, <sense>the greatest of
    Sea-Fishes</sense>.
</entryFree>
```

Content model <content></content>

```

**<certainty>** indicates the degree of certainty associated with some aspect of the text markup. [21.1.2. *Structured Indications of Uncertainty*]

*Module* certainty – Certainty, Precision, and Responsibility

*Attributes* att.scoping (@target, @match) att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) att.global.rendition (@rend, @style, @rendition) att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) att.global.analytic (@ana) att.global.facs (@facs) att.global.change (@change) att.global.responsibility (~~cert~~, @resp)

**@cert** (certainty) signifies the degree of certainty associated with the object pointed to by the <certainty> element.

*Derived from* att.global.responsibility

*Status* Optional

*Datatype* teidata.certainty

**@locus** indicates more exactly the aspect concerning which certainty is being expressed: specifically, whether the markup is correctly located, whether the correct element or attribute name has been used, or whether the content of the element or attribute is correct, etc.

*Status* Required

*Datatype* teidata.enumerated

*Legal values are:* **name** uncertainty concerns whether the name of the element or attribute used is correctly applied.

**start** uncertainty concerns whether the start of the element is correctly identified.

**end** uncertainty concerns whether the end of the element is correctly identified.

**location** uncertainty concerns both the start and the end of the element.

**value** uncertainty concerns the content (for an element) or the value (for an attribute)

**@assertedValue** provides an alternative value for the aspect of the markup in question—an alternative generic identifier, transcription, or attribute value, or the identifier of an <anchor> element (to indicate an alternative starting or ending location). If an *assertedValue* is given, the confidence level specified by *degree* applies to the alternative markup specified by *assertedValue*; if none is given, it applies to the markup in the text.

*Status* Recommended

*Datatype* teidata.word

**<certainty** target="#ESX"

locus="name"

assertedValue="placeName"

cert="low">

**<desc>**It is unlikely, but possible, that this refers to the place

rather than the person.</desc>

**</certainty>**

*Note* This attribute makes it possible to indicate the degree of confidence in a specific alternative to some aspect of the markup. In the first example above the encoder is expressing the likelihood (.2) that the generic identifier should be <placeName> rather than <persName>, which is the coded element.

**@given** indicates one or more element(s) characterizing the conditions which are assumed in the assignment of a degree of confidence conditions assumed in the assignment of a degree of confidence.

*Status* Recommended

*Datatype* 1-∞ occurrences of teidata.pointer separated by whitespace

*Note* The envisioned typical value of this attribute would be the identifier of another <certainty> element or a list of such identifiers. It may thus be possible to construct probability networks by chaining <certainty> elements together. Such networks would ultimately be grounded in unconditional <certainty> elements (with no value for *given*). The semantics of this chaining would be understood in this way: if a <certainty> element is specified, via a reference, as the assumption, then it is not the attribution of uncertainty that is the assumption, but rather the assertion itself. For instance, in the example above, the first <certainty> element indicates that the confidence in the identification of the new scribe as *msm*. The second indicates the degree of confidence that *Essex* is a personal name, given that the new scribe is *msm*. Note that the given in the second <certainty> element is not the assertion that the likelihood that *msm* is the new scribe is 0.6, but simply the assertion that *msm* is the new scribe; this is a recommended convention to facilitate building networks. The ambitious encoder may wish to attempt complex networks or probability assertions, experimenting with references to other elements or prose assertions, and deploying feature structure connectives such as <alt>, <join>, and <note>. However, we do not believe that the <certainty> element gives, at this time, a comprehensive ambiguity-free system for indicating certainty.

**@degree** indicates the degree of confidence assigned to the aspect of the markup named by the *locus* attribute.

*Status* Optional

*Datatype* teidata.probability

*Member of* model.certLike model.global.meta

*Contained by*

**<channel>** (primary channel) describes the medium or channel by which a text is delivered or experienced. For a written text, this might be print, manuscript, email, etc.; for a spoken one, radio, telephone, face-to-face, etc. [15.2.1. *The Text Description*]

*Module* corpus – Language Corpora

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@mode** specifies the mode of this channel with respect to speech and writing.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* s (spoken)

w (written)

sw (spoken to be written) e.g. dictation

ws (written to be spoken) e.g. a script

m (mixed)

x (unknown or inapplicable) [Default]

att.global.change.attributes,
att.global.responsibility.attributes,
( desc?, ( char | glyph )+ )
}

```

**<charName>** (character name) contains the name of a character, expressed following Unicode conventions.  
[5.2. Markup Constructs for Representation of Characters and Glyphs]

*Module* gaiji – Characters, Glyphs, and Writing Modes

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

*Contained by*

gaiji: char

*May contain* Character data only

*Note* The name must follow Unicode conventions for character naming. Projects working in similar fields are recommended to coordinate and publish their list of <charName>s to facilitate data exchange.

*Example*

```
<charName>CIRCLED IDEOGRAPH 4EBA</charName>
```

*Content model* <content> <textNode/></content>

*Schema Declaration*

```

element charName
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  text
}

```

**<charProp>** (character property) provides a name and value for some property of the parent character or glyph.  
[5.2. Markup Constructs for Representation of Characters and Glyphs]

*Module* gaiji – Characters, Glyphs, and Writing Modes

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.typed (@type, @subtype)

*Contained by*

gaiji: char glyph

*May contain*

*gaiji*: localName unicodeName value

*Note* If the property is a Unicode Normative Property, then its <unicodeName> must be supplied. Otherwise, its name must be specified by means of a <localName>. At a later release, additional constraints will be defined on possible value/name combinations using Schematron rules

*Example*

```
<charProp>
  <unicodeName>character-decomposition-mapping</unicodeName>
  <value>circle</value>
</charProp>
<charProp>
  <localName>daikanwa</localName>
  <value>36</value>
</charProp>
```

*Content model*

```
<content>
  <sequence>
    <alternate>
      <elementRef key="unicodeName"/>
      <elementRef key="localName"/>
    </alternate>
    <elementRef key="value"/>
  </sequence>
</content>
```

*Schema Declaration*

```
element charProp
{
  att.global.attributes,
  att.global.rendition.attributes,

*Note* Because the children of a <choice> element all represent alternative ways of encoding the same sequence, it is natural to think of them as mutually exclusive. However, there may be cases where a full representation of a text requires the alternative encodings to be considered as parallel. Note also that <choice> elements may self-nest.

Where the purpose of an encoding is to record multiple witnesses of a single work, rather than to identify multiple possible encoding decisions at a given point, the <app> element and associated elements discussed in section 12.1. *The Apparatus Entry, Readings, and Witnesses* should be preferred.

*Example* An American encoding of *Gulliver's Travels* which retains the British spelling but also provides a version regularized to American spelling might be encoded as follows.

```
<p>Lastly, That, upon his solemn oath to observe all the above
articles, the said man-mountain shall have a daily allowance of
meat and drink sufficient for the support of <choice>
  <sic>1724</sic>
  <corr>1728</corr>
</choice> of our subjects,
with free access to our royal person, and other marks of our
<choice>
  <orig>favour</orig>
```

```
<reg>favor</reg>
</choice>.</p>
```

  att.global.responsibility.attributes,
  attribute scheme { text },
  macro.phraseSeq.limited}

```

**<classDecl>** (classification declarations) contains one or more taxonomies defining any classificatory codes used elsewhere in the text. [2.3.7. *The Classification Declaration* 2.3. *The Encoding Description*]

*Module header* – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

*Member of* model.encodingDescPart

*Contained by*

header: encodingDesc

May contain

header: taxonomy

Example

```
<classDecl>
  <taxonomy xml:id="LCSH">
    <bibl>Library of Congress Subject Headings</bibl>
  </taxonomy>
</classDecl>
<!-- ... -->
<textClass>
  <keywords scheme="#LCSH">
    <term>Political science</term>
    <term>United States -- Politics and government --
      Revolution, 1775-1783</term>
  </keywords>
</textClass>
```

Content model

```
<content>
  <elementRef key="taxonomy" minOccurs="1"
    maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```
element classDecl
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  taxonomy+
}
```

---

**<classes>** specifies all the classes of which the documented element or class is a member or subclass. [22.5.

*Element Specifications 22.6. Class Specifications]*

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@mode** specifies the effect of this declaration on its parent module.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **change** this declaration changes the declaration of the same name in the current definition

**replace** this declaration replaces the declaration of the same name in the current definition[Default]

*Content model:* classSpec elementSpec

*May contain*

*tagdocs:* memberOf

*Note* An empty <classes> element indicates that the element documented is not a member of any class. This should not generally happen.

*Example*

```
<classes>
  <memberOf key="model.qLike"/>
  <memberOf key="att.declarable"/>
</classes>
```

This <classes> element indicates that the element documented (which may be an element or a class) is a member of two distinct classes: `model.qLike` and `att.declarable`.

*Content model*

```
<content>
  <elementRef key="memberOf" minOccurs="0"
    maxOccurs="unbounded"/>
</content>
```

*Schema Declaration*

```
element classes
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  attribute mode { "change" | "replace" }?,
  memberOf*
}
```

**<classRef>** points to the specification for an attribute or model class which is to be included in a schema [22.6. Class Specifications]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.repeatable (@context, @minOccurs, @maxOccurs) att.readFrom (@source)

**@key** the identifier used for the required class within the source indicated.

*Status* Required

*Datatype* teidata.xmlName

**@expand** indicates how references to this class within a content model should be interpreted.

*Status* Optional

*Legal values are:* **alternate** any one member of the class may appear

**sequence** a single occurrence of all members of the class may appear in sequence

**sequenceOptional** a single occurrence of one or more members of the class may appear in sequence

**sequenceOptionalRepeatable** one or more occurrences of one or more members of the class may appear in sequence.

**sequenceRepeatable** one or more occurrences of all members of the class may appear in sequence

*Note* If the members of the class are a, b and c, then a reference to the class within a content model is understood as being a reference to a|b|c when *expand* has the value *alternation*; to a,b,c when it has the value *sequence*; to (a?,b?,c?) when it has the value *sequenceOptional*; to (a\*,b\*, c\*) when it has the value *sequenceOptionalRepeatable*; or to (a+,b+,c+) when it has the value *sequenceOptionalRepeatable*.

**@include** supplies a list of class members which are to be included in the schema being defined.

*Status* Optional

*Datatype* 0-∞ occurrences of teidata.xmlName separated by whitespace

**@except** supplies a list of class members which are to be excluded from the schema being defined.

*Status* Optional

*Datatype* 0-∞ occurrences of teidata.xmlName separated by whitespace

*Member of* model.contentPart model.oddRef

*Contained by*

*tagdocs:* alternate content schemaSpec sequence specGrp

*May contain* Empty element

*Note* Attribute and model classes are identified by the name supplied as value for the *ident* attribute on the <classSpec> element in which they are declared. All TEI names are unique; attribute class names conventionally begin with the letters **att**.

*Example*

```
<schemaSpec ident="myTEIe" start="TEI">
  <moduleRef key="tei"/>
  <moduleRef key="core"
    include="abbr add core addrLine address author bibl biblScope choice cit
    corr date del desc divGen editor emph expan foreign gap gloss graphic head hi

}?,
( attribute include { list { * } }? | attribute except { list { * } }? ),
empty
}

```

**<classSpec>** (class specification) contains reference information for a TEI element class; that is a group of elements which appear together in content models, or which share some common attribute, or both. [22.3. *Specification Elements 22.6. Class Specifications*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.identified (@ident, @predeclare, @module) (att.combinable (@mode) (att.deprecated (@validUntil)))

**@type** indicates whether this is a model class or an attribute class

*Status* Required

*Datatype* teidata.enumerated

*Legal values are:* **model** (content model) members of this class appear in the same content models

**atts** (attributes) members of this class share common attributes

**@generate** indicates which alternation and sequence instantiations of a model class may be referenced. By default, all variations are permitted.

*Status* Optional

*Datatype* 1–5 occurrences of teidata.enumerated separated by whitespace

*Legal values are:* **alternation** members of the class are alternatives

**sequence** members of the class are to be provided in sequence

**sequenceOptional** members of the class may be provided, in sequence, but are optional

**sequenceOptionalRepeatable** members of the class may be provided one or more times, in sequence, but are optional.

**sequenceRepeatable** members of the class may be provided one or more times, in sequence

```
<condition>
  <p>There are lacunae in three places in this
    manuscript. After 14v two
    leaves has been cut out and narrow strips leaves remains in the spine. After
    68v one gathering is missing and after 101v at least one gathering of 8
    leaves
    has been lost. </p>
  <p>Several leaves are damaged with tears or holes or have a
    irregular shape. Some of the damages do not allow the lines to be of full
    length and they are apparently older than the script. There are tears on
    fol.
    2r-v, 9r-v, 10r-v, 15r-18v, 19r-v, 20r-22v, 23r-v, 24r-28v, 30r-v, 32r-35v,
    37r-v, 38r-v, 40r-43v, 45r-47v, 49r-v, 51r-v, 53r-60v, 67r-v, 68r-v, 70r-v,
    74r-80v, 82r-v, 86r-v, 88r-v, 89r-v, 95r-v, 97r-98v 99r-v, 100r-v. On fol.
    98
    the corner has been torn off. Several leaves are in a bad condition due to
    moist and wear, and have become dark, bleached or
    wrinkled. </p>
  <p>The script has been
    touched up in the 17th century with black ink. The touching up on the
    following
    fols. was done by
    <name>Bishop Brynjólf Sveinsson</name>: 1v, 3r, 4r, 5r,
    6v, 8v,9r, 10r, 14r, 14v, 22r,30v, 36r-52v, 72v, 77r,78r,103r, 104r,. An
    AM-note says according to the lawman
    <name>Sigurður Björnsson</name> that the rest of the
    touching up was done by himself and another lawman
    <name>Sigurður Jónsson</name>.
    <name>Sigurður Björnsson</name> did the touching up
    on the following fols.: 46v, 47r, 48r, 49r-v, 50r, 52r-v.
    <name>Sigurður Jónsson</name> did the rest of the
    touching up in the section 36r-59r containing
    <title>Bretasögur</title>
  </p>
</condition>

```

**<constitution>** describes the internal composition of a text or text sample, for example as fragmentary, complete, etc. [15.2.1. The Text Description]

*Module* corpus – Language Corpora

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@type** specifies how the text was constituted.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **single** a single complete text[Default]

**composite** a text made by combining several smaller items, each individually complete

**frags** (fragments) a text made by combining several smaller, not necessarily complete, items

**unknown** composition unknown or unspecified

*Member of* model.textDescPart

*Contained by*

*corpus:* textDesc

*May contain*

*analysis:* interp interpGrp span spanGrp

*certainty:* certainty precision respons

*core:* abbr address cb choice date distinct email emph expan foreign gap gb gloss hi index lb measure measureGrp mentioned milestone name note num pb ptr ref rs soCalled term time title

*Note* The function of this element seems to overlap with both the *org* attribute on <div> and the <samplingDecl> in the <encodingDesc>.

Example

```
<constitution type="frags">Prologues only.</constitution>
```

Content model

```
<content>
  <macroRef key="macro.phraseSeq.limited"/>
</content>
```

Schema Declaration

```
element constitution
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  attribute type { "single" | "composite" | "frags" | "unknown" }?,
  macro.phraseSeq.limited}

```

**<constraint>** (constraint rules) the formal rules of a constraint [22.5. Element Specifications]

Module tagdocs – Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

Contained by

tagdocs: constraintSpec

May contain Empty element

Example

```
<constraintSpec ident="isoconstraint"
  scheme="isoschematron"
  xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <constraint>
    <s:assert test="tei:fileDesc/tei:titleStmt/tei:title[@type='main']"> a main
    title must be supplied
    </s:assert>
  </constraint>
</constraintSpec>
```

Example

```
<constraintSpec ident="local"
  scheme="private">
  <constraint>
    (output = (ident(title) ident(author) "You must supply a title or an
    author"))
  </constraint>
</constraintSpec>
```

```
</constraint>
</constraintSpec>
```

Content model

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <textNode/>
    <macroRef key="macro.anyXML" />
  </alternate>
</content>
```

Schema Declaration

```
element constraint
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  ( text | macro.anyXML )*
}
```

**<constraintSpec>** (constraint on schema) contains a constraint, expressed in some formal syntax, which cannot be expressed in the structural content model [22.5. *Element Specifications*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.identified (@ident, @predeclare, @module) (att.combinable (@mode)) (att.deprecated (@validUntil)) att.typed (@type, @subtype)

@scheme supplies the name of the language in which the constraints are defined

*Status* Required

*Datatype* teidata.enumerated

*Suggested values include:* **schematron** (Schematron)

**isoschematron** (ISO Schematron)

*Member of* model.oddDecl

*Contained by*

*core:* add corr del desc emph head hi item l meeting note orig p q quote ref reg said sic stage title unclear

*transcr:* damage metamarck mod restore retrace secl supplied surplus

*verse:* rhyme

*May contain*

*core:* desc gloss

*tagdocs:* altIdent constraint equiv

*Example* This constraint uses Schematron to enforce the presence of the *spanTo* attribute (which comes from an attribute class) on the <addSpan> element:

```
<constraintSpec ident="demo-c1"
  scheme="isoschematron"
  xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <desc>Enforce the presence of the <att>spanTo</att> attribute</desc>
  <constraint>
    <sch:assert test="@spanTo">The spanTo= attribute of <sch:name/>
      is required.</sch:assert>
  </constraint>
</constraintSpec>
```

*Example*

```
<constraintSpec ident="demo-c2"
  scheme="isoschematron"
  xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <desc>Implement an accessibility rule which says that pictures should
    have textual explanations</desc>
  <constraint>
    <sch:report test="not(tei:figDesc or tei:head)"> You should
      provide information in a figure from which
      we can construct an alt attribute in HTML </sch:report>
  </constraint>
</constraintSpec>
```

*Example* This constraint uses SPITBOL (a language which is not expressed in XML) to check whether the title and author are identical:

```
<constraintSpec ident="local"
  scheme="SPITBOL">
  <constraint>
    (output = leq(title,author) "title and author cannot be the same")
  </constraint>
</constraintSpec>
```

*Schematron* Relationship between scheme attribute and contents: Schematron 1.x <sch:ns prefix="s" uri="http://www.ascc.net/xml/schematron"/> <sch:report test="tei:constraint/s:\* and @scheme ne 'schematron'">Rules in the Schematron 1.\* language must be inside a constraintSpec with a value of 'schematron' on the scheme attribute</sch:report>

*Schematron* Relationship between scheme attribute and contents: ISO Schematron <sch:ns prefix="sch"

uri="http://purl.oclc.org/dsdl/schematron"/> <sch:report test="tei:constraint/sch:\* and @scheme ne 'isoschematron'">Rules in the ISO Schematron language must be inside a constraintSpec with a value of 'isoschematron' on the scheme attribute</sch:report>

*Schematron* <sch:ns prefix="sch" uri="http://purl.oclc.org/dsdl/schematron"/>

<sch:rule context="tei:macroSpec/tei:constraintSpec[@scheme='isoschematron']/tei:constraint">

<sch:report test="sch:assert|sch:report">An ISO Schematron constraint specification for a macro should not have an 'assert' or 'report' element without a parent 'rule' element</sch:report> </sch:rule>

*Content model*

```
<content>
  <sequence>
    <alternate minOccurs="0"
      maxOccurs="unbounded">
      <classRef key="model.glossLike"/>
      <classRef key="model.descLike"/>
    </alternate>
    <elementRef key="constraint"
      minOccurs="0"/>
  </sequence>
</content>
```

*Schema Declaration*

```
element constraintSpec
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.identified.attributes,
  att.combinable.attributes,
  att.deprecated.attributes,
  att.typed.attributes,
  attribute scheme { "schematron" | "isoschematron" },
  ( ( model.glossLike | model.descLike )*, constraint? )
}
```

---

**<content>** (content model) contains the text of a declaration for the schema documented. [22.5. *Element Specifications*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@autoPrefix** controls whether or not pattern names generated in the corresponding Relax NG schema source are automatically prefixed to avoid potential nameclashes.

*Status* Optional

*Datatype* teidata.truthValue

*Legal values are:* **true** Each name referenced in e.g. a <rng:ref> element within a content model is automatically prefixed by the value of the *prefix* attribute on the current <schemaSpec>[Default]

**false** No prefixes are added: any prefix required by the value of the *prefix* attribute on the current <schemaSpec> must therefore be supplied explicitly, as appropriate.

*Content types:* dataSpec elementSpec macroSpec moduleRef

*May contain*

*tagdocs:* alternate classRef dataRef elementRef macroRef sequence textNode valList

*Note* As the example shows, content models may be expressed using the RELAX NG syntax directly. To avoid ambiguity when schemas using elements from different namespaces are created, the name supplied for an element in a content model will be automatically prefixed by a short string, as specified by the *prefix* attribute on <schemaSpec>. The *autoPrefix* attribute may be used to reverse this behaviour. The macro `macro.schemaPattern` defines which elements may be used to define content models. Alternatively, a content model may be expressed using the TEI <valList> element.

*Example* This <content> element indicates that the element being specified has no content:

```
<content/>
```

*Example* This <content> element defines a content model allowing either a sequence of paragraphs or a series of msItem elements optionally preceded by a summary:

```
<content>
  <alternate>
    <classRef key="model.pLike"
      maxOccurs="unbounded"/>
    <sequence>
      <elementRef key="summary" minOccurs="0"
        maxOccurs="1"/>
      <elementRef key="msItem"
        maxOccurs="unbounded"/>
    </sequence>
  </alternate>
</content>
```

*Example* This content model defines a content model allowing either a sequence of paragraphs or a series of msItem elements optionally preceded by a summary:

```
<content>
  <rng:choice>
    <rng:oneOrMore>
      <rng:ref name="model.pLike"/>
    </rng:oneOrMore>
    <rng:group>
      <rng:optional>
        <rng:ref name="summary"/>
      </rng:optional>
      <rng:oneOrMore>
        <rng:ref name="msItem"/>
      </rng:oneOrMore>
    </rng:group>
  </rng:choice>
</content>
```

*Content model*

```
<alternate maxOccurs="unbounded">
  <macroRef key="macro.anyXML"/>
  <classRef key="model.contentPart"/>
</alternate>
</content>
```

Schema Declaration

```
element content
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,

  macro.paraContent}
```

---

**<correction>** (correction principles) states how and under what circumstances corrections have been made in the text. [2.3.3. *The Editorial Practices Declaration* 15.3.2. *Declarable Elements*]

*Module header* – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.declarable (@default)

**@status** indicates the degree of correction applied to the text.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **high** the text has been thoroughly checked and proofread.

**medium** the text has been checked at least once.

**low** the text has not been checked.

**unknown** the correction status of the text is unknown.[Default]

**@method** indicates the method adopted to indicate corrections within the text.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **silent** corrections have been made silently[Default]

**markup** corrections have been represented using markup

*Member of* model.editorialDeclPart

*Contained by*

*header:* editorialDecl

*May contain*

*core:* p

*linking:* ab

*Note* May be used to note the results of proof reading the text against its original, indicating (for example) whether discrepancies have been silently rectified, or recorded using the editorial tags described in section 3.4. *Simple Editorial Changes*.

Example

```
<correction>
  <p>Errors in transcription controlled by using the WordPerfect spelling
  checker, with a user
  defined dictionary of 500 extra words taken from Chambers Twentieth Century
  Dictionary.</p>
</correction>
```

*Note* The <creation> element may be used to record details of a text's creation, e.g. the date and place it was composed, if these are of interest. It may also contain a more structured account of the various stages or revisions associated with the evolution of a text; this should be encoded using the <listChange> element. It should not be confused with the <publicationStmnt> element, which records date and place of publication.

*Example*

```

<creation>
  <date>Before 1987</date>
</creation>

```

Example

```
<creation>
  <date when="1988-07-10">10 July 1988</date>
</creation>

May contain

core: p

linking: ab

Note The result of the substitution may be either an absolute or a relative URI reference. In the latter case it is combined with the value of *xml:base* in force at the place where the *cRef* attribute occurs to form an absolute URI in the usual manner as prescribed by XML Base.

Example

```
<cRefPattern matchPattern="([1-9A-Za-z]+)\s+([0-9]+):([0-9]+)"
replacementPattern="#xpath(//div[@type='book'][@n='$1']/div[@type='chap']
[@n='$2']/div[@type='verse'][@n='$3'])"/>

verse: metSym rhyme

May contain Empty element

*Note* Both the beginning and ending of the damaged sequence must be marked: the beginning by the <damageSpan> element, the ending by the target of the *spanTo* attribute: if no other element available, the <anchor> element may be used for this purpose. The damaged text must be at least partially legible, in order for the encoder to be able to transcribe it. If it is not legible at all, the <damageSpan> element should not be used. Rather, the <gap> or <unclear> element should be employed, with the value of the *reason* attribute giving the cause. See further sections 11.3.3.1. *Damage, Illegibility, and Supplied Text* and 11.3.3.2. *Use of the gap, del, damage, unclear, and supplied Elements in Combination*.

*Example*

```
<p>Paragraph partially damaged. This is the undamaged
portion <damageSpan spanTo="#a34"/>and this the damaged
portion of the paragraph.</p>
<p>This paragraph is entirely damaged.</p>
<p>Paragraph partially damaged; in the middle of this
```

paragraph the damage ends and the anchor point marks the start of the <anchor xml:id="a34"/> undamaged part of the text. ...</p>

---

**<datatype>** specifies the declared value for an attribute, by referring to any datatype defined by the chosen schema language. [«#DTYPES» 22.5.4. *Attribute List Specification*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@minOccurs** (minimum number of occurrences) indicates the minimum number of times this datatype may occur in the specification of the attribute being defined

*Status* Optional

*Datatype* teidata.count

*Default* 1

**@maxOccurs** (maximum number of occurrences) indicates the maximum number of times this datatype may occur in the specification of the attribute being defined  
*Status* Optional  
*Datatype* teidata.unboundedInt  
*Default* 1

*Content model*: attDef

*May contain*

*tagdocs*: dataRef textNode

*Note* In the TEI scheme, most datatypes are expressed using pre-defined TEI macros, which map a name in the form `data.XXXX` to a RelaxNG or WSD defined datatype.

*Example*

```
<datatype>
  <rng:data type="token"/>
</datatype>
```

*Example*

```
<datatype>
  <rng:ref name="data.enumerated"/>
</datatype>
```

*Example* The encoding in the following example requires that the attribute being defined contain at least two URIs in its value, as is the case for the *target* attribute of <join>.

```
<datatype minOccurs="2"
  maxOccurs="unbounded">
  <rng:ref name="data.pointer"/>
</datatype>
```

*Content model*

```
<content>
  <alternate>
    <elementRef key="textNode"/>
    <elementRef key="dataRef"/>
    <macroRef key="macro.schemaPattern"/>
  </alternate>
</content>
```

*Schema Declaration*

```
element datatype
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  attribute minOccurs { text }?,
  attribute maxOccurs { text }?,
```

```
( textNode | dataRef | macro.schemaPattern )
}
```

**<default>** (default feature value) represents the value part of a feature-value specification which contains a defaulted value. [18.9. Default Values]

Module iso-fs – Feature Structures

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

Member of model.featureVal.single

Contained by

iso-fs: f fvLib if vAlt vColl vDefault vLabel vMerge vNot vRange

May contain Empty element

Example

```
<f name="gender">
  <default/>
</f>
```

Content model `<content></content>`

Schema Declaration

```
element default
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  empty
}

```

**<defaultVal>** (default value) specifies the default declared value for an attribute. [22.5.4. *Attribute List Specification*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

*Contained by*

*tagdocs:* attDef

*May contain* Character data only

*Note* any legal declared value or TEI-defined keyword

*Example*

```
<defaultVal>#IMPLIED</defaultVal>
```

*Content model* `<content> <textNode/></content>`

*Schema Declaration*

```
element defaultVal
{
  att.global.attributes,
  att.global.rendition.attributes,

*verse:* caesura rhyme

*Note* This element should be used for deletion of shorter sequences of text, typically single words or phrases. The <delSpan> element should be used for longer sequences of text, for those containing structural subdivisions, and for those containing overlapping additions and deletions. The text deleted must be at least partially legible in order for the encoder to be able to transcribe it (unless it is restored in a <supplied> tag). Illegible or lost text within a deletion may be marked using the <gap> tag to signal that text is present but has not been transcribed, or is no longer visible. Attributes on the <gap> element may be used to indicate how much text is omitted, the reason for omitting it, etc. If text is not fully legible, the

<unclear> element (available when using the additional tagset for transcription of primary sources) should be used to signal the areas of text which cannot be read with confidence in a similar way. Degrees of uncertainty over what can still be read, or whether a deletion was intended may be indicated by use of the <certainty> element (see 21. *Certainty, Precision, and Responsibility*). There is a clear distinction in the TEI between <del> and <surplus> on the one hand and <gap> or <unclear> on the other. <del> indicates a deletion present in the source being transcribed, which states the author's or a later scribe's intent to cancel or remove text. <surplus> indicates material present in the source being transcribed which should have been so deleted, but which is not in fact. <gap> or <unclear>, by contrast, signal an editor's or encoder's decision to omit something or their inability to read the source text. See sections 11.3.1.7. *Text Omitted from or Supplied in the Transcription* and 11.3.3.2. *Use of the gap, del, damage, unclear, and supplied Elements in Combination* for the relationship between these and other related elements used in detailed transcription.

### Example

```
<l>
  <del rend="overtyped">Mein</del> Frisch
  <del rend="overstrike" type="primary">schwebt</del>
  weht der Wind
</l>
```

### Example

```
<del rend="overstrike">
  <gap reason="illegible" quantity="5"
    unit="character"/>
</del>
```

### Content model

*verse:* metSym rhyme

*May contain* Empty element

*Note* Both the beginning and ending of the deleted sequence must be marked: the beginning by the <delSpan> element, the ending by the target of the *spanTo* attribute. The text deleted must be at least partially legible, in order for the encoder to be able to transcribe it. If it is not legible at all, the <delSpan> tag should not be used. Rather, the <gap> tag should be employed to signal that text cannot be transcribed, with the value of the *reason* attribute giving the cause for the omission from the transcription as deletion. If it is not fully legible, the <unclear> element should be used to signal the areas of text which cannot be read

with confidence. See further sections 11.3.1.7. *Text Omitted from or Supplied in the Transcription* and, for the close association of the <delSpan> tag with the <gap>, <damage>, <unclear> and <supplied> elements, 11.3.3.2. *Use of the gap, del, damage, unclear, and supplied Elements in Combination*. The <delSpan> tag should not be used for deletions made by editors or encoders. In these cases, either the <corr> tag or the <gap> tag should be used.

*Example*

```
<p>Paragraph partially deleted. This is the undeleted
portion <delSpan spanTo="#a23"/>and this the deleted
portion of the paragraph.</p>
<p>Paragraph deleted together with adjacent material.</p>
<p>Second fully deleted paragraph.</p>
<p>Paragraph partially deleted; in the middle of this
paragraph the deletion ends and the anchor point marks
the resumption <anchor xml:id="a23"/> of the text. ...</p>
```

  att.global.responsibility.attributes,
  att.typed.attributes,
  att.dimensions.attributes,
  att.ranging.attributes,
  macro.xtext}

```

**<dimensions>** contains a dimensional specification. [10.3.4. Dimensions]

*Module* msdescription – Manuscript Description

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.dimensions (@unit, @quantity, @extent, @precision, @scope) (att.ranging (@atLeast, @atMost, @min, @max, @confidence))

**@type** indicates which aspect of the object is being measured.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **leaves** dimensions relate to one or more leaves (e.g. a single leaf, a gathering, or a separately bound part)

**ruled** dimensions relate to the area of a leaf which has been ruled in preparation for writing.

**pricked** dimensions relate to the area of a leaf which has been pricked out in preparation for ruling (used where this differs significantly from the ruled area, or where the ruling is not measurable).

**written** dimensions relate to the area of a leaf which has been written, with the height measured from the top of the minims on the top line of writing, to the bottom of the minims on the bottom line of writing.

**miniatures** dimensions relate to the miniatures within the manuscript

**binding** dimensions relate to the binding in which the codex or manuscript is contained

**box** dimensions relate to the box or other container in which the manuscript is stored.

*textstructure:* byline closer dateline docAuthor docDate docEdition docImprint imprimatur opener salute signed titlePart trailer

*transcr:* damage fw metamark mod restore retrace secl supplied surplus

*verse:* metSym rhyme

*May contain*

*msdescription:* depth dim height width

*Note* Contains no more than one of each of the specialized elements used to express a three-dimensional object's height, width, and depth, combined with any number of other kinds of dimensional specification.

*Example*

```
<dimensions type="leaves">
  <height scope="range">157-160</height>
  <width>105</width>
</dimensions>
<dimensions type="ruled">
  <height scope="most">90</height>
  <width scope="most">48</width>
</dimensions>
<dimensions unit="in">
  <height>12</height>
  <width>10</width>
</dimensions>
```

*Example* This element may be used to record the dimensions of any text-bearing object, not necessarily a codex. For example:

```
<dimensions type="panels">
  <height scope="all">7004</height>
  <width scope="all">1803</width>
  <dim type="relief" unit="mm">345</dim>
</dimensions>
```

This might be used to show that the inscribed panels on some (imaginary) monument are all the same size (7004 by 1803 cm) and stand out from the rest of the monument by 345 mm.

*Example* When simple numeric quantities are involved, they may be expressed on the *quantity* attribute of any or all of the child elements, as in the following example:

```
<dimensions type="leaves">
  <height scope="range">157-160</height>
  <width quantity="105"/>
</dimensions>
<dimensions type="ruled">
  <height unit="cm" scope="most"
    quantity="90"/>
  <width unit="cm" scope="most" quantity="48"/>
</dimensions>
<dimensions unit="in">
  <height quantity="12"/>
  <width quantity="10"/>
</dimensions>
```

*Schematron* <s:report test="count(tei:width)> 1">The element <s:name/> may appear once only </s:report>  
<s:report test="count(tei:height)> 1">The element <s:name/> may appear once only </s:report>

  )
}

```

---

**<divGen>** (automatically generated text division) indicates the location at which a textual division generated automatically by a text-processing application is to appear. [3.8.2. *Index Entries*]

*Module* core – Elements Available in All TEI Documents

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@type** specifies what type of generated text division (e.g. index, table of contents, etc.) is to appear.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **index** an index is to be generated and inserted at this point.

**toc** a table of contents

**figlist** a list of figures

**tablist** a list of tables

*Note* Valid values are application-dependent; those shown are of obvious utility in document production, but are by no means exhaustive.

*Member of* model.divGenLike model.frontPart

*Contained by*

*textstructure:* back body div div1 div2 div3 div4 div5 div6 front

*May contain*

*core:* head

*Note* This element is intended primarily for use in document production or manipulation, rather than in the transcription of pre-existing materials; it makes it easier to specify the location of indices, tables of contents, etc., to be generated by text preparation or word processing software.

*Example* One use for this element is to allow document preparation software to generate an index and insert it in the appropriate place in the output. The example below assumes that the *indexName* attribute on <index> elements in the text has been used to specify index entries for the two generated indexes, named NAMES and THINGS:

```
<back>
  <div1 type="backmat">
    <head>Bibliography</head>
<!-- ... -->
  </div1>
  <div1 type="backmat">
    <head>Indices</head>
    <divGen n="Index Nominum" type="NAMES"/>
    <divGen n="Index Rerum" type="THINGS"/>
  </div1>
</back>
```

*Example* Another use for <divGen> is to specify the location of an automatically produced table of contents:

```
<front>
<!--<titlePage>...</titlePage>-->
  <divGen type="toc"/>
  <div>
    <head>Preface</head>
    <p> ... </p>
  </div>
</front>
```

*Content model*

```
<content>
  <classRef key="model.headLike"
    minOccurs="0" maxOccurs="unbounded"/>
</content>
```

*Schema Declaration*

```
element divGen
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
```

```

att.global.facs.attributes,
att.global.change.attributes,
att.global.responsibility.attributes,
attribute type { text }?,
model.headLike*
}

```

**<docAuthor>** (document author) contains the name of the author of the document, as given on the title page (often but not always contained in a byline). [4.6. Title Pages]

*Module* textstructure – Default Text Structure

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.canonical (@key, @ref)

*textcrit:* app witDetail

*transcr:* addSpan am damage damageSpan delSpan ex fw handShift listTranspose metamark mod redo restore retrace secl space subst substJoin supplied surplus undo

*verse:* caesura rhyme

*Note* The document author's name often occurs within a byline, but the <docAuthor> element may be used whether the <byline> element is used or not. It should be used only for the author(s) of the entire document, not for author(s) of any subset or part of it. (Attributions of authorship of a subset or part of

the document, for example of a chapter in a textbook or an article in a newspaper, may be encoded with <byline> without <docAuthor>.)

Example

```
<titlePage>
  <docTitle>
    <titlePart>Travels into Several Remote Nations of the World, in Four
      Parts.</titlePart>
  </docTitle>
  <byline> By <docAuthor>Lemuel Gulliver</docAuthor>, First a Surgeon,
    and then a Captain of several Ships</byline>
</titlePage>
```

Content model

```
<content>

  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.canonical.attributes,
  macro.phraseSeq}
```

---

**<docDate>** (document date) contains the date of a document, as given on a title page or in a dateline. [4.6. *Title Pages*]

*Module* textstructure – Default Text Structure

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@when** gives the value of the date in standard form, i.e. YYYY-MM-DD.

*Status* Optional

*Datatype* teidata.temporal.w3c

*Note* For simple dates, the *when* attribute should give the Gregorian or proleptic Gregorian date in one of the formats specified in *XML Schema Part 2: Datatypes Second Edition*.

*Member of* model.divWrapper model.pLike.front model.titlepagePart

*Contained by*

*core:* lg list

*drama:* castList epilogue performance prologue

*figures:* figure table

*msdescription:* msItem

*textstructure:* back body dateline div div1 div2 div3 div4 div5 div6 div7 docImprint front group titlePage

*May contain*

*analysis:* c cl interp interpGrp m pc phr s span spanGrp w

*Note* If the example contains material in XML markup, either it must be enclosed within a CDATA marked

section, or character entity references must be used to represent the markup delimiters. If the example contains well-formed XML, it should be marked using the more specific `<egXML>` element.

### Example

```
<p>The
<gi>term</gi> element is declared using the following syntax:
<eg><![CDATA[<!ELEMENT term (%phrase.content;)>]]</eg>
</p>
```

### Content model

```
<content>
  <macroRef key="macro.phraseSeq" />
</content>
```

### Schema Declaration

```
element eg
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  macro.phraseSeq}
```

---

**<egXML>** (example of XML) contains a single well-formed XML fragment demonstrating the use of some XML element or attribute, in which the `<egXML>` element itself functions as the root element. [22.1.1. *Phrase Level Terms*]

*Namespace* `http://www.tei-c.org/ns/Examples`

*Module* tagdocs – Documentation Elements

*Attributes* `att.global` (`@xml:id`, `@n`, `@xml:lang`, `@xml:base`, `@xml:space`) (`att.global.rendition` (`@rend`, `@style`, `@rendition`)) (`att.global.linking` (`@corresp`, `@synch`, `@sameAs`, `@copyOf`, `@next`, `@prev`, `@exclude`, `@select`)) (`att.global.analytic` (`@ana`)) (`att.global.facs` (`@facs`)) (`att.global.change` (`@change`)) (`att.global.responsibility` (`@cert`, `@resp`)) `att.source` (`@source`)

**@valid** indicates the intended validity of the example with respect to a schema.

*Status* Optional

*Datatype* `teidata.enumerated`

*Legal values are:* **true** the example is intended to be fully valid, assuming that its root element, or a provided root element, could have been used as a possible root element in the schema concerned.[Default]

**feasible** the example could be transformed into a valid document by inserting any number of valid attributes and child elements anywhere within it; or it is valid against a version of the schema concerned in which the provision of character data, list, element, or attribute values has been made optional.

**false** the example is not intended to be valid, and contains deliberate errors.

 May contain Empty element

*Note* In the source of the TEI Guidelines, this element declares itself and its content as belonging to the namespace <http://www.tei-c.org/ns/Examples>. This enables the content of the element to be validated independently against the TEI scheme. Where this element is used outside this context, a different namespace or none at all may be preferable. The content must however be a well-formed XML fragment or document: where this is not the case, the more general <eg> element should be used in preference. In a TEI context use of the *rend* attribute in the TEI namespace, as opposed to the TEI Examples namespace, enables recording of rendition information.

*Example*

```
<egXML><div>
  <head>A slide about <gi>egXML</gi>
</head>
  <list>
    <item>
      <gi>egXML</gi> can be used to give XML examples in the TEI
      Examples namespace</item>
    <item>Attributes values for <att>valid</att>:
    <list rend="collapsed">
      <item>
        <val rend="green">>true</val>: intended to be fully
        valid</item>
      <item>
        <val rend="amber">feasible</val>: valid if missing nodes
        provided</item>
      <item>
        <val rend="red">>false</val>: not intended to be valid</item>
    </list>
    </item>
    <item>The <att>rend</att> attribute in the TEI namespace can be
      used for recording how parts of the example was rendered.</item>
  </list>
</div>
</egXML>
```

*Example*

```

<egXML valid="feasible"><text>
  <front>
    <!-- front matter for the whole group -->
    </front>
    <group>
      <text>
        <!-- first text -->
        </text>
      <text>
        <!-- second text -->
        </text>
      </group>
    </text>
    <!-- This example is not valid TEI, but could be made so by
    adding missing components -->
  </egXML>

```

*Example*

```

<egXML xmlns="http://www.tei-c.org/ns/Examples" valid="false">
  <para xml:lang="en">Doubloons are a pirate's best friend</para>
</egXML>

```

*Content model*

```

<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <textNode/>
    <macroRef key="macro.anyXML"/>
  </alternate>
</content>

```

*Schema Declaration*

```

element egXML
{
  att.global.attributes,
  att.global.rendition.attributes,

  att.global.responsibility.attributes,
  att.source.attributes,
  attribute valid { "true" | "feasible" | "false" }?,
  ( text | macro.anyXML )*
}

```

---

**<eLeaf>** (leaf or terminal node of an embedding tree) provides explicitly for a leaf of an embedding tree, which may also be encoded with the eTree element. [19.3. Another Tree Notation]

Module nets — Graphs, Networks, and Trees

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.typed (@type, @subtype)

**@value** indicates the value of an embedding leaf, which is a feature structure or other analytic element.

*Status* Optional

*Datatype* teidata.pointer

*Content model* eTree triangle

*May contain*

*core:* label ptr ref

*Note* The <eTree> tag may be used if the encoder does not wish to distinguish by name between nonleaf and leaf nodes in embedding trees; they are distinguished by their arrangement.

*Example*

```
<eLeaf value="http://an.fsurl.tei/#FSWITH">
  <label>with</label>
</eLeaf>
```

*Content model*

```
<content>
  <sequence>
    <elementRef key="label" minOccurs="0"/>
    <classRef key="model.ptrLike"
      minOccurs="0"/>
  </sequence>
</content>
```

*Schema Declaration*

```
element eLeaf
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.typed.attributes,
  attribute value { text }?,
  ( label?, model.ptrLike? )
}
```

---

**<elementRef>** points to the specification for some element which is to be included in a schema [22.2. *Modules and Schemas*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))

(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.repeatable (@context, @minOccurs, @maxOccurs) att.readFrom (@source)  
**@key** the identifier used for the required element within the source indicated.

*Status* Required

*Datatype* teidata.xmlName

*Member of* model.contentPart model.oddRef

*Contained by*

*tagdocs:* alternate content schemaSpec sequence specGrp

*May contain* Empty element

*Note* Elements are identified by the name supplied as value for the *ident* attribute on the <elementSpec> element in which they are declared. TEI element names are unique.

*Example*

```
<elementRef key="p" />
```

Include in the schema an element named <p> available from the current default source.

*Example*

```
<elementRef key="p" source="tei:1.2.1"/>
```

Include in the schema an element named <p> available from the TEI P5 1.2.1 release.

*Content model* `<content></content>`

*Schema Declaration*

```
element elementRef
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.repeatable.attributes,
  att.readFrom.attributes,
  attribute key { text },
  empty
}
```

---

**<elementSpec>** (element specification) documents the structure, content, and purpose of a single element type. [22.5. Element Specifications 22. Documentation Elements]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.identified (@ident, @predeclare, @module) (att.combinable (@mode)) (att.deprecated (@validUntil)) att.namespaceable (@ns)

**@prefix** specifies a default prefix which will be prepended to all patterns relating to the element, unless otherwise stated.

*Status* Optional

*Datatype* 0–1 occurrences of teidata.xmlName separated by whitespace

*Note* Colons, although permitted inside the value, will cause an invalid schema to be generated.

*Member of* model.oddDecl

*linking:* alt altGrp anchor join joinGrp link linkGrp timeline

*spoken:* incident kinesic pause shift vocal writing

*textcrit:* app witDetail

*transcr:* addSpan damageSpan delSpan fw listTranspose metamark space substJoin

*Note* Like all elements, <entry> inherits an *xml:id* attribute from the class *global*. No restrictions are placed on the method used to construct *xml:ids*; one convenient method is to use the orthographic form of the headword, appending a disambiguating number where necessary. Identification codes are sometimes included on machine-readable tapes of dictionaries for in-house use. It is recommended to use the <sense> element even for an entry that has only one sense to group together all parts of the definition relating to the word sense since this leads to more consistent encoding across entries.

*Example*

```
<entry>
  <form>
    <orth>disproof</orth>
    <pron>dIs"pru:f</pron>
  </form>
  <gramGrp>
    <pos>n</pos>
  </gramGrp>
  <sense n="1">
    <def>facts that disprove something.</def>
  </sense>
  <sense n="2">
    <def>the act of disproving.</def>
  </sense>
</entry>
```

*Content model*

**<equipment>** provides technical details of the equipment and media used for an audio or video recording used as the source for a spoken text. [8.2. Documenting the Source of Transcribed Speech 15.3.2. Declarable Elements]

Module spoken — Transcriptions of Speech

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.declarable (@default)

Member of model.recordingPart

Contained by

spoken: recording

May contain

core: p

linking: ab

Example

```
<equipment>
  <p>"Hi-8" 8 mm NTSC camcorder with integral directional
    microphone and windshield and stereo digital sound
    recording channel.
  </p>
</equipment>
```

Example

```
<equipment>
  <p>8-track analogue transfer mixed down to 19 cm/sec audio
    tape for cassette mastering</p>
</equipment>
```

Content model

```
<content>
  <classRef key="model.pLike" minOccurs="1"
    maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```
element equipment
{

  att.global.facs.attributes,
```

```

att.global.change.attributes,
att.global.responsibility.attributes,
att.declarable.attributes,
model.pLike+
}

```

**<equiv>** (equivalent) specifies a component which is considered equivalent to the parent element, either by co-reference, or by external link. [3.3.4. Terms, Glosses, Equivalents, and Descriptions 22.4.1. Description of Components]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.internetMedia (@mimeType)

**@name** a single word which follows the rules defining a legal XML name (see <http://www.w3.org/TR/REC-xml/#dt-name>), naming the underlying concept of which the parent is a representation.

*Status* Optional

*Datatype* teidata.name

**@uri** (uniform resource identifier) references the underlying concept of which the parent is a representation by means of some external identifier

*Status* Optional

*Datatype* teidata.pointer

**@filter** references an external script which contains a method to transform instances of this element to canonical TEI

*Status* Optional

*Datatype* teidata.pointer

*Member of* model.glossLike

*Contained by*

*header:* category taxonomy

*linking:* joinGrp

*tagdocs:* attDef classSpec constraintSpec dataSpec elementSpec macroSpec model modelGrp modelSequence moduleSpec paramSpec schemaSpec valltem

*May contain* Empty element

*Note* The *mimeType* attribute should be used to supply the MIME media type of the filter script specified by the *filter* attribute.

*Example* The following example declares that the <bo> element is conceptually equivalent to the markup construct <hi rend='bold'>, and that an external definition of this concept is available from the URI indicated

```

<elementSpec ident="hi" mode="change">
  <equiv name="BOLD"/>
  <desc>bold typography</desc>
  <attList>
    <attDef ident="rend" mode="change">
      <valList>
        <valItem ident="bold"/>
      </valList>
    </attDef>
  </attList>
</elementSpec>

```

```

</attList>
</elementSpec>
<elementSpec ident="bo" mode="add">
  <equiv name="BOLD"
    uri="http://www.example.com/typesetting/bold"/>
</elementSpec>

```

Content model `<content></content>`

Schema Declaration

---

<f> (feature) represents a *feature value specification*, that is, the association of a name with a value of any of several different types. [18.2. Elementary Feature Structures and the Binary Feature Value]

*Module* iso-fs — Feature Structures

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.datcat (@datcat, @valueDatcat)

**@name** a single word which follows the rules defining a legal XML name (see <http://www.w3.org/TR/REC-xml/#dt-name>), providing a name for the feature.

*Status* Required

*Datatype* teidata.name

**@fVal** (feature value) references any element which can be used to represent the value of a feature.

Status Optional

Datatype teidata.pointer

Note If this attribute is supplied as well as content, the value referenced is to be unified with that contained.

Contains: bicond cond fLib fs if

May contain

gaiji: g

iso-fs: binary default fs numeric string symbol vAlt vColl vLabel vMerge vNot

Note If the element is empty then a value must be supplied for the fVal attribute. The content of <f> may also be textual, with the assumption that the data type of the feature value is determined by the schema—this is the approach used in many language-technology-oriented projects and recommendations.

Example

```
<f name="gender">
  <symbol value="feminine"/>
</f>
```

Example

```
<fs>
  <f name="voice">active</f>
  <f name="tense">SimPre</f>
</fs>
```

Schematron <sch:report test="tei:\* and text()[normalize-space(.) ne '"]">A feature value cannot contain both text and element content</sch:report>

Schematron <sch:report test="count(tei:\*) gt 1">A feature value can contain only one child element</sch:report>

Content model

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.gLike"/>
    <classRef key="model.featureVal"/>
  </alternate>
</content>
```

Schema Declaration

```
element f
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,

}
```

<factuality> describes the extent to which the text may be regarded as imaginative or non-imaginative, that is, as describing a fictional or a non-fictional world. [15.2.1. The Text Description]

*Module* corpus – Language Corpora

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@type** categorizes the factuality of the text.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **fiction** the text is to be regarded as entirely imaginative

**fact** the text is to be regarded as entirely informative or factual

**mixed** the text contains a mixture of fact and fiction

**inapplicable** the fiction/fact distinction is not regarded as helpful or appropriate to this text

*Member of* model.textDescPart

*Contained by*

*corpus:* textDesc

*May contain*

*analysis:* interp interpGrp span spanGrp

*certainty:* certainty precision respons

*core:* abbr address cb choice date distinct email emph expan foreign gap gb gloss hi index lb measure measureGrp mentioned milestone name note num pb ptr ref rs soCalled term time title

*spoken*: incident kinesic pause shift vocal writing

*tagdocs*: att code gi ident tag val

*textcrit*: app witDetail

*transcr*: addSpan am damageSpan delSpan ex fw listTranspose metamark space subst substJoin

*Note* Usually empty, unless some further clarification of the type attribute is needed, in which case it may contain running prose. For many literary texts, a simple binary opposition between ‘fiction’ and ‘fact’ is naïve in the extreme; this parameter is not intended for purposes of subtle literary analysis, but as a simple means of characterizing the claimed fictiveness of a given text. No claim is made that works characterized as ‘fact’ are in any sense ‘true’.

*Example*

```
<factuality type="fiction"/>
```

*Example*

```
<factuality type="mixed">contains a mixture of gossip and speculation about real people and events</factuality>
```

*Content model*

**<fDecl>** (feature declaration) declares a single feature, specifying its name, organization, range of allowed values, and optionally its default value. [18.11. Feature System Declaration]

*Module* iso-fs – Feature Structures

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@name** a single word which follows the rules defining a legal XML name (see <http://www.w3.org/TR/REC-xml/#dt-name>), indicating the name of the feature being declared; matches the *name* attribute of <f> elements in the text.

*Status* Required

*Datatype* teidata.name

**@optional** indicates whether or not the value of this feature may be present.

*Status* Optional

*Datatype* teidata.truthValue

*Default* true

*Note* If a feature is marked as optional, it is possible for it to be omitted from a feature structure. If an obligatory feature is omitted, then it is understood to have a default value, either explicitly declared, or, if no default is supplied, the special value any. If an optional feature is omitted, then it is understood to be missing and any possible value (including the default) is ignored.

*Contained by:* fsDecl

*May contain*

*iso-fs:* fDescr vDefault vRange

*Example*

```

<fDecl name="INV">
  <fDescr>inverted sentence</fDescr>
  <vRange>
    <vAlt>
      <binary value="true"/>
      <binary value="false"/>
    </vAlt>
  </vRange>
  <vDefault>
    <binary value="false"/>
  </vDefault>
</fDecl>

```

```
</vDefault>
</fDecl>
```

Content model

```
<content>
  <sequence>
    <elementRef key="fDescr" minOccurs="0"/>
    <elementRef key="vRange"/>
    <elementRef key="vDefault" minOccurs="0"/>

In this example, the reference to ‘Dujchev N17’ includes a link to some other manuscript description which has the identifier DN17.

*Example*

```
<msItem>
  <title>Guan-ben</title>
  <filiation>
    <p>The "Guan-ben" was widely current among mathematicians in the
      Qing dynasty, and "Zhao Qimei version" was also read. It is
      therefore difficult to know the correct filiation path to follow.
      The study of this era is much indebted to Li Di. We explain the
      outline of his conclusion here. Kong Guangsen
      (1752-1786)(17) was from the same town as Dai Zhen, so he obtained
      "Guan-ben" from him and studied it(18). Li Huang (d. 1811)
      (19) took part in editing Si Ku Quan Shu, so he must have had
      "Guan-ben". Then Zhang Dunren (1754-1834) obtained this version,
      and studied "Da Yan Zong Shu Shu" (The General Dayan
      Computation). He wrote Jiu Yi Suan Shu (Mathematics
      Searching for One, 1803) based on this version of Shu Xue Jiu
      Zhang (20).</p>
    <p>One of the most important persons in restoring our knowledge
      concerning the filiation of these books was Li Rui (1768(21)
      -1817)(see his biography). ... only two volumes remain of this
      manuscript, as far as chapter 6 (chapter 3 part 2) p.13, that is,
      question 2 of "Huan Tian San Ji" (square of three loops),
      which later has been lost.</p>
  </filiation>
</msItem>

*Note* The global *xml:lang* attribute should be supplied for this element to identify the language of the word or phrase marked. As elsewhere, its value should be a language tag as defined in *vi.1 Language Identification*. This element is intended for use only where no other element is available to mark the phrase or words concerned. The global *xml:lang* attribute should be used in preference to this element where it is intended to mark the language of the whole of some text element. The *<distinct>* element may be used to identify phrases belonging to sublanguages or registers not generally regarded as true languages.

*Example*

```
This is
heathen Greek to you still? Your <foreign xml:lang="la">lapis
philosophicus</foreign>?

**<form>** (form information group) groups all the information on the written and spoken forms of one headword.  
 [9.3.1. Information on Written and Spoken Forms]

*Module* dictionaries – Dictionaries

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.lexicographic (@expand, @norm, @split, @value, @orig, @location, @mergedIn, @opt) (att.datcat (@datcat, @valueDatcat))

**@type** classifies form as simple, compound, etc.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **simple** single free lexical item

**lemma** the headword itself

**variant** a variant form

**compound** word formed from simple lexical items

**derivative** word derived from headword

**inflected** word in other than usual dictionary form

**phrase** multiple-word lexical item

    <quote>Nam Sibyllam quidem Cumis ego ipse oculis meis vidi in ampulla
      pendere, et cum illi pueri dicerent: <q xml:lang="gr">Σίβυλλα τί
        θέλεις</q>; respondebat illa: <q xml:lang="gr">ἀποθανεῖν θέλω.</q>
    </quote>
  </epigraph>
  <div type="dedication">
    <p>For Ezra Pound <q xml:lang="it">il miglior fabbro.</q>
    </p>
  </div>
</front>
```

*Example*

```
<front>
  <div type="dedication">
    <p>To our three selves</p>
  </div>
  <div type="preface">
    <head>Author's Note</head>
    <p>All the characters in this book are purely imaginary, and if the
      author has used names that may suggest a reference to living persons
      she has done so inadvertently. ...</p>
  </div>
</front>
```

```
</div>  
</front>
```

Example

```
<front>  
  <div type="abstract">  
    <div>  
      <head> BACKGROUND:</head>  
      <p>Food insecurity can put children at greater risk of obesity because  
        of altered food choices and nonuniform consumption patterns.</p>  
    </div>  
    <div>  
      <head> OBJECTIVE:</head>  
      <p>We examined the association between obesity and both child-level  
        food insecurity and personal food insecurity in US children.</p>  
    </div>  
    <div>  
      <head> DESIGN:</head>  
      <p>Data from 9,701 participants in the National Health and Nutrition  
        Examination Survey, 2001-2010, aged 2 to 11 years were analyzed.  
        Child-level food insecurity was assessed with the US Department of  
        Agriculture's Food Security Survey Module based on eight  
        child-specific questions. Personal food insecurity was assessed with  
        five additional questions. Obesity was defined, using physical  
        measurements, as body mass index (calculated as kg/m2) greater than  
        or equal to the age- and sex-specific 95th percentile of the Centers  
        for Disease Control and Prevention growth charts. Logistic  
        regressions adjusted for sex, race/ethnic group, poverty level, and  
        survey year were conducted to describe associations between obesity  
        and food insecurity.</p>  
    </div>  
    <div>  
      <head> RESULTS:</head>  
      <p>Obesity was significantly associated with personal food insecurity  
        for children aged 6 to 11 years (odds ratio=1.81; 95% CI 1.33 to  
        2.48), but not in children aged 2 to 5 years (odds ratio=0.88; 95%  
        CI 0.51 to 1.51). Child-level food insecurity was not associated  
        with obesity among 2- to 5-year-olds or 6- to 11-year-olds.</p>  
    </div>  
    <div>  
      <head> CONCLUSIONS:</head>  
      <p>Personal food insecurity is associated with an increased risk of  
        obesity only in children aged 6 to 11 years. Personal  
        food-insecurity measures may give different results than aggregate  
        food-insecurity measures in children.</p>  
    </div>  
  </div>

---

**<fsDecl>** (feature structure declaration) declares one type of feature structure. [18.11. Feature System Declaration]

Module iso-fs — Feature Structures

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))

(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

@type gives a name for the type of feature structure being declared.

Status Required

Datatype teidata.enumerated

@baseTypes gives the name of one or more typed feature structures from which this type inherits feature specifications and constraints; if this type includes a feature specification with the same name as that of any of those specified by this attribute, or if more than one specification of the same name is inherited, then the set of possible values is defined by unification. Similarly, the set of constraints applicable is derived by combining those specified explicitly within this element with those implied by the baseTypes attribute. When no baseTypes attribute is specified, no feature specification or constraint is inherited.

Status Optional

Datatype 1-∞ occurrences of teidata.name separated by whitespace

Note Inheritance is defined here as a monotonous relation. The process of combining constraints may result in a contradiction, for example if two specifications for the same feature specify disjoint ranges of values, and at least one such specification is mandatory. In such a case, there is no valid representative for the type being defined.

Contains: fsDecl

May contain

iso-fs: fDecl fsConstraints fsDescr

Example

```
<fsDecl type="SomeName">
  <fsDescr>Describes what this type of fs represents</fsDescr>
  <fDecl name="featureOne">

}

```

<fw> (forme work) contains a running head (e.g. a header, footer), catchword, or similar material appearing on the current page. [11.6. Headers, Footers, and Similar Matter]

*Module* transcr – Representation of Primary Sources

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.placement (@place) att.written (@hand)

**@type** classifies the material encoded according to some useful typology.

*Status* Recommended

*Datatype* teidata.enumerated

*Sample values include:* **header** a running title at the top of the page

**footer** a running title at the bottom of the page

**pageNum** (page number) a page number or foliation symbol

**lineNum** (line number) a line number, either of prose or poetry

**sig** (signature) a signature or gathering symbol

**catch** (catchword) a catch-word

*Note* Where running heads are consistent throughout a chapter or section, it is usually more convenient to relate them to the chapter or section, e.g. by use of the *rend* attribute. The `<fw>` element is intended for cases where the running head changes from page to page, or where details of page layout and the internal structure of the running heads are of paramount importance.

### Example

```
<fw type="sig" place="bottom">C3</fw>
```

### Content model

```
<content>  
<macroRef key="macro.phraseSeq"/>
```

&lt;/content&gt;

*Schema Declaration*

```

element fw
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,

*verse*: rhyme

*May contain* Character data only

*Note* The name **g** is short for *gaiji*, which is the Japanese term for a non-standardized character or glyph.

*Example*

```
<g ref="#ctlig">ct</g>
```

This example points to a `<glyph>` element with the identifier `ctlig` like the following:

```
<glyph xml:id="ctlig">
<!-- here we describe the particular ct-ligature intended -->
</glyph>
```

*Example*

```
<g ref="#per-glyph">per</g>
```

The medieval brevigraph `per` could similarly be considered as an individual glyph, defined in a `<glyph>` element with the identifier `per` like the following:

```
<glyph xml:id="per-glyph">
<!-- ... -->
</glyph>
```

---

**<gap>** indicates a point where material has been omitted in a transcription, whether for editorial reasons described in the TEI header, as part of sampling practice, or because the material is illegible, invisible, or inaudible. [3.4.3. Additions, Deletions, and Omissions]

*Module* core — Elements Available in All TEI Documents

*Attributes* `att.global` (`@xml:id`, `@n`, `@xml:lang`, `@xml:base`, `@xml:space`) (`att.global.rendition` (`@rend`, `@style`, `@rendition`)) (`att.global.linking` (`@corresp`, `@synch`, `@sameAs`, `@copyOf`, `@next`, `@prev`, `@exclude`, `@select`))

(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.timed (@start, @end) (att.duration (att.duration.w3c (@dur)) (att.duration.iso (@dur-iso))) att.editLike (@evidence, @instant) (att.dimensions (@unit, @quantity, @extent, @precision, @scope)) (att.ranging (@atLeast, @atMost, @min, @max, @confidence))) (att.source (@source))

**@reason** gives the reason for omission. Sample values include sampling, inaudible, irrelevant, cancelled.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.word separated by whitespace

**@hand** in the case of text omitted from the transcription because of deliberate deletion by an identifiable hand, indicates the hand which made the deletion.

*Deprecated* will be removed on 2017-08-01

*Status* Optional

*Datatype* teidata.pointer

**@agent** in the case of text omitted because of damage, categorizes the cause of the damage, if it can be identified.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **rubbing** damage results from rubbing of the leaf edges

**mildew** damage results from mildew on the leaf surface

**smoke** damage results from smoke

*Note* The <gap>, <unclear>, and <del> core tag elements may be closely allied in use with the <damage> and <supplied> elements, available when using the additional tagset for transcription of primary sources. See section 11.3.3.2. *Use of the gap, del, damage, unclear, and supplied Elements in Combination* for discussion of which element is appropriate for which circumstance. The <gap> tag simply signals the editors decision to omit or inability to transcribe a span of text. Other information, such as the interpretation that text was deliberately erased or covered, should be indicated using the relevant tags, such as <del> in the case of deliberate deletion.

*Example*

```
<gap quantity="4" unit="chars"
  reason="illegible"/>
```

*Example*

```
<gap quantity="1" unit="essay"
  reason="sampling"/>
```

*Example*

```
<del>
  <gap atLeast="4" atMost="8" unit="chars"
    reason="illegible"/>
</del>
```

*Example*

```
<gap extent="unknown" unit="lines"
  reason="lost"/>
```

}

```

**<geoDecl>** (geographic coordinates declaration) documents the notation and the datum used for geographic coordinates expressed as content of the <geo> element elsewhere within the document. [2.3.8. *The Geographic Coordinates Declaration*]

Module header – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.declarable (@default)

**@datum** supplies a commonly used code name for the datum employed.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **WGS84** (World Geodetic System) a pair of numbers to be interpreted as latitude followed by longitude according to the World Geodetic System.[Default]

**MGRS** (Military Grid Reference System) the values supplied are geospatial entity object codes, based on

**OSGB36** (ordnance survey great britain) the value supplied is to be interpreted as a British National Grid Reference.

**ED50** (European Datum coordinate system) the value supplied is to be interpreted as latitude followed by longitude according to the European Datum coordinate system.

**<glyphName>** (character glyph name) contains the name of a glyph, expressed following Unicode conventions for character names. [5.2. Markup Constructs for Representation of Characters and Glyphs]

Module gaiji – Characters, Glyphs, and Writing Modes

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

Contained by

*gaiji*: glyph

May contain Character data only

*Note* For characters of non-ideographic scripts, a name following the conventions for Unicode names should be chosen. For ideographic scripts, an *Ideographic Description Sequence* (IDS) as described in Chapter 10.1 of the Unicode Standard is recommended where possible. Projects working in similar fields are recommended to coordinate and publish their list of <glyphName>s to facilitate data exchange.

*Example*

```
<glyphName>CIRCLED IDEOGRAPH 4EBA</glyphName>
```

Content model `<content> <textNode/></content>`

Schema Declaration

```

element glyphName
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  text
}

```

---

**<gram>** (grammatical information) within an entry in a dictionary or a terminological data file, contains grammatical information relating to a term, word, or form. [9.3.2. *Grammatical Information*]

*Module* dictionaries – Dictionaries

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.lexicographic (@expand, @norm, @split, @value, @orig, @location, @mergedIn, @opt) (att.datcat (@datcat, @valueDatcat))

**@type** classifies the grammatical information given according to some convenient typology—in the case of terminological information, preferably the dictionary of data element types specified in ISO 12620.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **pos** (part of speech) any of the word classes to which a word may be assigned in a given language, based on form, meaning, or a combination of features, e.g. noun, verb, adjective, etc.

**gen** (gender) formal classification by which nouns and pronouns, and often accompanying modifiers, are grouped and inflected, or changed in form, so as to control certain syntactic relationships

**num** (number) grammatical number, e.g. singular, plural, dual, ...

**animate** animate or inanimate

**proper** proper noun or common noun

*Note* A much fuller list of values for the *type* attribute may be generated from the data category registry accessible from <http://www.isocat.org> and maintained by ISO technical committee 37.

---

**<graph>** encodes a graph, which is a collection of nodes, and arcs which connect the nodes. [19.1. *Graphs and Digraphs*]

*Module* nets — Graphs, Networks, and Trees

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@type** describes the type of graph.

*Status* Recommended

*Datatype* teidata.enumerated

*Suggested values include:* **undirected** undirected graph

**directed** directed graph

**transitionNetwork** a directed graph with distinguished initial and final nodes

**transducer** a transition network with up to two labels on each arc

*Note* If *type* is specified as undirected, then the distinction between the *to* and *from* attributes of the <arc> tag is neutralized. Also, the *adj* attribute, rather than the *adjFrom* and *adjTo* attributes, should be used to encode pointers to the ends of the arcs. If *type* is specified as directed (or any other value which implies directionality), then the *adjFrom* and *adjTo* attributes should be used, instead of the *adj* attribute.

**@order** states the order of the graph, i.e., the number of its nodes.

*Status* Optional

*Datatype* teidata.count

**@size** states the size of the graph, i.e., the number of its arcs.

*Status* Optional

*Datatype* teidata.count

*Member of* model.divPart

*Note* The *contentType* attribute should be used to supply the MIME media type of the image specified by the *url* attribute. Within the body of a text, a <graphic> element indicates the presence of a graphic component in the source itself. Within the context of a <facsimile> or <sourceDoc> element, however, a <graphic> element provides an additional digital representation of some part of the source being encoded.

*Example*

```
<figure>
  <graphic url="fig1.png"/>
  <head>Figure One: The View from the Bridge</head>
  <figDesc>A Whistleresque view showing four or five sailing boats in the
  foreground, and a
    series of buoys strung out between them.</figDesc>
</figure>

*verse:* caesura rhyme

*Note* The <head> element is used for headings at all levels; software which treats (e.g.) chapter headings, section headings, and list titles differently must determine the proper processing of a <head> element based on its structural position. A <head> occurring as the first element of a list is the title of that list; one occurring as the first element of a <div1> is the title of that chapter or section.

*Example* The most common use for the <head> element is to mark the headings of sections. In older writings, the headings or *incipits* may be rather longer than usual in modern works. If a section has an explicit ending as well as a heading, it should be marked as a <trailer>, as in this example:

```

<div1 n="I" type="book">
  <head>In the name of Christ here begins the first book of the ecclesiastical
  history of
    Georgius Florentinus, known as Gregory, Bishop of Tours.</head>
  <div2 type="section">
    <head>In the name of Christ here begins Book I of the history.</head>
    <p>Proposing as I do ...</p>
    <p>From the Passion of our Lord until the death of Saint Martin four hundred
    and twelve
      years passed.</p>
    <trailer>Here ends the first Book, which covers five thousand, five hundred
    and ninety-six
      years from the beginning of the world down to the death of Saint
    Martin.</trailer>
  </div2>
</div1>

```

*Example* The <head> element is also used to mark headings of other units, such as lists:

```

With a few exceptions, connectives are equally
useful in all kinds of discourse: description, narration, exposition, argument.
<list rend="bulleted">
  <head>Connectives</head>
  <item>above</item>
  <item>accordingly</item>
  <item>across from</item>
  <item>adjacent to</item>
  <item>again</item>
  <item>
<!-- ... -->
</item>
</list>

```

**<hyphenation>** summarizes the way in which hyphenation in a source text has been treated in an encoded version of it. [2.3.3. *The Editorial Practices Declaration* 15.3.2. *Declarable Elements*]

*Module* header – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.declarable (@default)

@eol (end-of-line) indicates whether or not end-of-line hyphenation has been retained in a text.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **all** all end-of-line hyphenation has been retained, even though the lineation of the original may not have been.

**some** end-of-line hyphenation has been retained in some cases.[Default]

**hard** all soft end-of-line hyphenation has been removed: any remaining end-of-line hyphenation should be retained.

**none** all end-of-line hyphenation has been removed: any remaining hyphenation occurred within the line.

verse: metSym rhyme

May contain

gaiji: g

header: idno

*Note* <idno> should be used for labels which identify an object or concept in a formal cataloguing system such as a database or an RDF store, or in a distributed system such as the World Wide Web. Some suggested values for *type* on <idno> are ISBN, ISSN, DOI, and URI.

*Example*

```
<idno type="ISBN">978-1-906964-22-1</idno>
<idno type="ISSN">0143-3385</idno>
<idno type="DOI">10.1000/123</idno>
<idno type="URI">http://www.worldcat.org/oclc/185922478</idno>
<idno type="URI">http://authority.nzetc.org/463/</idno>
<idno type="LT">Thomason Tract E.537(17)</idno>
<idno type="Wing">C695</idno>
<idno type="oldCat">
  <g ref="#sym"/>345
</idno>
```

In the last case, the identifier includes a non-Unicode character which is defined elsewhere by means of a <glyph> or <char> element referenced here as #sym.

*Content model*

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">

  att.global.responsibility.attributes,
  att.sortable.attributes,
  attribute type { text }?,
  ( text | model.gLike | idno )*
}
```

---

<if> defines a conditional default value for a feature; the condition is specified as a feature structure, and is met if it subsumes the feature structure in the text for which a default value is sought. [18.11. Feature System Declaration]

*Module* iso-fs — Feature Structures

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

Contained by

iso-fs: vDefault

May contain

iso-fs: binary default f fs numeric string symbol then vAlt vColl vLabel vMerge vNot

Note May contain a feature structure, followed by a feature value; the two are separated by a <then> element.

Example

```
<vDefault>
  <if>
    <fs>
      <f name="VFORM">
        <symbol value="INF"/>
      </f>
      <f name="SUBJ">
        <binary value="true"/>
      </f>
    </fs>
    <then/>
    <symbol value="for"/>
  </if>
</vDefault>
```

Content model

```
<content>
  <sequence>
    <alternate>
      <elementRef key="fs"/>
      <elementRef key="f"/>
    </alternate>
    <elementRef key="then"/>
    <classRef key="model.featureVal"/>
  </sequence>
</content>
```

Schema Declaration

```
element if
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  ( ( fs | f ), then, model.featureVal )
}
```

**<iff>** (if and only if) separates the condition from the consequence in a bicond element. [18.11. Feature System Declaration]

*Module* iso-fs – Feature Structures

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

*Contained by*

iso-fs: bicond

*May contain* Empty element

*Note* This element is provided primarily to enhance the human readability of the feature-system declaration.

*Example*

```
<bicond>
  <fs>
    <f name="F00">
      <symbol value="42"/>
    </f>
  </fs>
  <iff/>
  <fs>
    <f name="BAR">
      <binary value="true"/>
    </f>
  </fs>
</bicond>
```

*Content model* `<content></content>`

*Schema Declaration*

```
element iff
{
  att.global.attributes,

  ( term, index? )*
}
```

**<iNode>** (intermediate (or internal) node) represents an intermediate (or internal) node of a tree. [19.2. Trees]

Module nets – Graphs, Networks, and Trees

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

@value indicates an intermediate node, which is a feature structure or other analytic element.

Status Optional

Datatype teidata.pointer

@children provides a list of identifiers of the elements which are the children of the intermediate node.

Status Required

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

@parent provides the identifier of the element which is the parent of this node.

*Status* Optional

*Datatype* teidata.pointer

**@ord** (ordered) indicates whether or not the internal node is ordered.

*Status* Optional

*Datatype* teidata.xTruthValue

*Note* The value true indicates that the children of the intermediate node are ordered, whereas false indicates they are unordered. Use if and only if *ord* is specified as partial on the <tree> element and the intermediate node has more than one child.

**@follow** provides the identifier of an element which this node follows.

*Status* Optional

*Datatype* teidata.pointer

*Note* If the tree is unordered or partially ordered, this attribute has the property of fixing the relative order of the intermediate node and the element which is the value of the attribute.

**@outDegree** gives the out degree of an intermediate node, the number of its children.

*Status* Optional

*Datatype* teidata.count

*Note* The in degree of an intermediate node is always 1.

*Content model* tree

*May contain*

*core:* label

*Example*

```
<iNode xml:id="pt1" children="#GD-UP1"
parent="#GD-VB1" follow="#GD-PN1" outDegree="1">

  macro.xtext}
```

**<interaction>** describes the extent, cardinality and nature of any interaction among those producing and experiencing the text, for example in the form of response or interjection, commentary, etc. [15.2.1. The Text Description]

Module corpus – Language Corpora

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

@type specifies the degree of interaction between active and passive participants in the text.

Status Optional

*Datatype* teidata.enumerated

*Legal values are:* **none** no interaction of any kind, e.g. a monologue

**partial** some degree of interaction, e.g. a monologue with set responses

**complete** complete interaction, e.g. a face to face conversation

**inapplicable** this parameter is inappropriate or inapplicable in this case

**@active** specifies the number of active participants (or *addressors*) producing parts of the text.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **singular** a single addressor

**plural** many addressors

**corporate** a corporate addressor

**unknown** number of addressors unknown or unspecifiable

**@passive** specifies the number of passive participants (or *addressees*) to whom a text is directed or in whose presence it is created or performed.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **self** text is addressed to the originator e.g. a diary

**single** text is addressed to one other person e.g. a personal letter

**many** text is addressed to a countable number of others e.g. a conversation in which all participants are identified

**group** text is addressed to an undefined but fixed number of participants e.g. a lecture

**world** text is addressed to an undefined and indeterminately large number e.g. a published book

*Note* Generally, each <interp> element carries an *xml:id* attribute. This permits the encoder to explicitly associate the interpretation represented by the content of an <interp> with any textual element through its *ana* attribute. Alternatively (or, in addition) an <interp> may carry an *inst* attribute which points to one or more textual elements to which the analysis represented by the content of the <interp> applies.

*Example*

```
<interp type="structuralunit"
  xml:id="ana_am">aftermath</interp>
```

*Content model*

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">

*Note* May contain simple prose or a sequence of chunks. Whatever string of characters is used to label a list item in the copy text may be used as the value of the global *n* attribute, but it is not required that numbering be recorded explicitly. In ordered lists, the *n* attribute on the <item> element is by definition synonymous with the use of the <label> element to record the enumerator of the list item. In glossary lists, however, the term being defined should be given with the <label> element, not *n*.

*Example*

```

<list rend="numbered">
  <head>Here begin the chapter headings of Book IV</head>
  <item n="4.1">The death of Queen Clotild.</item>
  <item n="4.2">How King Lothar wanted to appropriate one third of the Church
revenues.</item>
  <item n="4.3">The wives and children of Lothar.</item>
  <item n="4.4">The Counts of the Bretons.</item>
  <item n="4.5">Saint Gall the Bishop.</item>
  <item n="4.6">The priest Cato.</item>
  <item> ...</item>
</list>

```

**<join>** identifies a possibly fragmented segment of text, by pointing at the possibly discontinuous elements which compose it. [16.7. Aggregation]

*Module* linking – Linking, Segmentation, and Alignment

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.pointing (@targetLang, @target, @evaluate) att.typed (@type, @subtype)

**@result** specifies the name of an element which this aggregation may be understood to represent.

*Status* Optional

*Datatype* teidata.name

**@scope** indicates whether the targets to be joined include the entire element indicated (the entire subtree including its root), or just the children of the target (the branches of the subtree).

*Status* Recommended

*Datatype* teidata.enumerated

*Legal values are:* **root** the rooted subtrees indicated by the *target* attribute are joined, each subtree become a child of the virtual element created by the join[Default]  
**branches** the children of the subtrees indicated by the *target* attribute become the children of the virtual element (i.e. the roots of the subtrees are discarded)

*May contain*

*certainty:* certainty precision respons

*core:* desc

*Example* The following example is discussed in section 16.7. *Aggregation:*

```
<sp>
  <speaker>Hughie</speaker>
  <p>How does it go? <q>
    <l xml:id="frog_x1">da-da-da</l>
    <l xml:id="frog_l2">gets a new frog</l>
    <l>...</l>
  </q>
</p>
</sp>
```

```

<sp>
  <speaker>Louie</speaker>
  <p>
    <q>
      <l xml:id="frog_l1">When the old pond</l>
      <l>...</l>
    </q>
  </p>
</sp>
<sp>
  <speaker>Dewey</speaker>
  <p>
    <q>... <l xml:id="frog_l3">It's a new pond.</l>
    </q>
  </p>
  <join target="#frog_l1 #frog_l2 #frog_l3"
        result="lg" scope="root"/>
</sp>

```

The <join> element here identifies a linegroup (<lg>) comprising the three lines indicated by the *target* attribute. The value `root` for the *scope* attribute indicates that the resulting virtual element contains the three <l> elements linked to at #frog\_l1 #frog\_l2 #frog\_l3, rather than their character data content.

*Example* In this example, the attribute *scope* is specified with the value of `branches` to indicate that the virtual list being constructed is to be made by taking the lists indicated by the *target* attribute of the <join> element, discarding the <list> tags which enclose them, and combining the items contained within the lists into a single virtual list:

```

<p>Southern dialect (my own variety, at least) has only <list xml:id="LP1">
  <item>
    <s>I done gone</s>
  </item>
  <item>
    <s>I done went</s>
  </item>
</list> whereas Negro Non-Standard basilect has both these and
<list xml:id="LP2">
  <item>
    <s>I done go</s>
  </item>
</list>.</p>
<p>White Southern dialect also has <list xml:id="LP3">
  <item>
    <s>I've done gone</s>
  </item>
  <item>
    <s>I've done went</s>
  </item>
</list> which, when they occur in Negro dialect, should probably be considered
as borrowings from other varieties of English.</p>
<join result="list" xml:id="LST1"
      target="#LP1 #LP2 #LP3" scope="branches">
  <desc>Sample sentences in Southern speech</desc>
</join>

```

*Schematron* <s:assert test="contains(@target, ')">You must supply at least two values for @target on <s:name/>  
</s:assert>

*Content model*

```

<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <classRef key="model.descLike"/>
    <classRef key="model.certLike"/>
  </alternate>
</content>

```

Schema Declaration

```

*Example* Labels are commonly used for the headwords in glossary lists; note the use of the global *xml:lang* attribute to set the default language of the glossary list to Middle English, and identify the glosses and headings as modern English or Latin:

```

<list type="gloss" xml:lang="enm">
  <head xml:lang="en">Vocabulary</head>
  <headLabel xml:lang="en">Middle English</headLabel>
  <headItem xml:lang="en">New English</headItem>
  <label>nu</label>
  <item xml:lang="en">now</item>
  <label>lhude</label>
  <item xml:lang="en">loudly</item>
  <label>bloweth</label>
  <item xml:lang="en">blooms</item>
  <label>med</label>
  <item xml:lang="en">meadow</item>
  <label>wude</label>
  <item xml:lang="en">wood</item>
  <label>awe</label>
  <item xml:lang="en">ewe</item>
  <label>lhouth</label>
  <item xml:lang="en">lows</item>
  <label>sterteth</label>
  <item xml:lang="en">bounds, frisks (cf. <cit>
    <ref>Chaucer, K.T.644</ref>
    <quote>a courser, <term>sterting</term>as the fyr</quote>
    </cit>
  </item>
  <label>verteth</label>
  <item xml:lang="la">pedit</item>
  <label>murie</label>
  <item xml:lang="en">merrily</item>
  <label>swik</label>
  <item xml:lang="en">cease</item>
  <label>naver</label>
  <item xml:lang="en">never</item>
</list>

```

*Example* Labels may also be used to record explicitly the numbers or letters which mark list items in ordered lists, as in this extract from Gibbon's *Autobiography*. In this usage the <label> element is synonymous with the *n* attribute on the <item> element:

```

I will add two facts, which have seldom occurred
in the composition of six, or at least of five quartos.
<list rend="runon" type="ordered">
  <label>(1)</label>
  <item>My first rough manuscript, without any intermediate copy, has been sent
to the press.</item>
  <label>(2) </label>
  <item>Not a sheet has been seen by any human eyes, excepting those of the
author and the
  printer: the faults and the merits are exclusively my own.</item>
</list>

```

*Example* Labels may also be used for other structured list items, as in this extract from the journal of Edward Gibbon:

```

<list type="gloss">
  <label>March 1757.</label>
  <item>I wrote some critical observations upon Plautus.</item>
  <label>March 8th.</label>

```

```

<item>I wrote a long dissertation upon some lines of Virgil.</item>
<label>June.</label>
<item>I saw Mademoiselle Curchod – <quote xml:lang="la">Omnia vincit amor, et
nos cedamus
    amori.</quote>
</item>
<label>August.</label>
<item>I went to Crassy, and staid two days.</item>
</list>

```

Note that the <label> might also appear within the <item> rather than as its sibling. Though syntactically valid, this usage is not recommended TEI practice.

*Example* Labels may also be used to represent a label or heading attached to a paragraph or sequence of paragraphs not treated as a structural division, or to a group of verse lines. Note that, in this case, the <label> element appears *within* the <p> or <lg> element, rather than as a preceding sibling of it.

```

<p>[...]
<lb/>& n'entrer en mauvais & mal-heu-
<lb/>r  mefnage. Or des que le confente-
<lb/>ment des parties y eft le mariage eft
<lb/> arreft , quoy que de fait il ne foit
<label place="margin">Puiffance maritale
    entre les Romains.</label>
<lb/> conform . Depuis la conforma-
<lb/>tion du mariage la femme eft fous
<lb/> la puiffance du mary, s'il n'eft efcla-
<lb/>ue ou enfant de famille : car en ce
<lb/> cas, la femme, qui a  pouf  vn en-
<lb/>fant de famille, eft fous la puiffance
[...]</p>

```

In this example the text of the label appears in the right hand margin of the original source, next to the paragraph it describes, but approximately in the middle of it. If so desired the *type* attribute may be used to distinguish different categories of label.

*Content model*

```

```

**<langKnown>** (language known) summarizes the state of a person's linguistic competence, i.e., knowledge of a single language. [15.2.2. *The Participant Description*]

*Module* namesdates — Names, Dates, People, and Places

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))

(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.datable (@calendar, @period) (att.datable.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.datable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.datable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod)) att.editLike (@evidence, @instant) (att.dimensions (@unit, @quantity, @extent, @precision, @scope) (att.ranging (@atLeast, @atMost, @min, @max, @confidence))) (att.source (@source))

**@tag** supplies a valid language tag for the language concerned.

*Status* Required

*Datatype* teidata.language

*Note* The value for this attribute should be a language ‘tag’ as defined in BCP 47.

**@level** a code indicating the person’s level of knowledge for this language

*Status* Optional

*Datatype* teidata.word

*Contained by* ~~dates~~: langKnowledge

*May contain*

*analysis*: interp interpGrp span spanGrp

**<language>** characterizes a single language or sublanguage used within a text. [2.4.2. Language Usage]

*Module header* – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@ident** (identifier) Supplies a language code constructed as defined in BCP 47 which is used to identify the language documented by this element, and which is referenced by the global *xml:lang* attribute.

*Status* Required

*Datatype* teidata.language

**@usage** specifies the approximate percentage (by volume) of the text which uses this language.

*Status* Optional

*Datatype* nonNegativeInteger

*Contained by*: langUsage

*May contain*

*analysis*: interp interpGrp span spanGrp

*certainty*: certainty precision respons

*core*: abbr address cb choice date distinct email emph expan foreign gap gb gloss hi index lb measure measureGrp mentioned milestone name note num pb ptr ref rs soCalled term time title

*May contain* Empty element

*Note* By convention, <lb> elements should appear at the point in the text where a new line starts. The *n* attribute, if used, indicates the number or other value associated with the text between this point and the next <lb> element, typically the sequence number of the line within the page, or other appropriate unit. This element is intended to be used for marking actual line breaks on a manuscript or printed page, at the point where they occur; it should not be used to tag structural units such as lines of verse (for which the <l> element is available) except in circumstances where structural units cannot otherwise be marked. The *type* attribute may be used to characterize the line break in any respect. The more specialized attributes *break*, *ed*, or *edRef* should be preferred when the intent is to indicate whether or not the line break is word-breaking, or to note the source from which it derives.

*Example* This example shows typographical line breaks within metrical lines, where they occur at different places in different editions:

```
<l>Of Mans First Disobedience,<lb ed="1674"/> and<lb ed="1667"/> the Fruit</l>
<l>Of that Forbidden Tree, whose<lb ed="1667 1674"/> mortal tast</l>
<l>Brought Death into the World,<lb ed="1667"/> and all<lb ed="1674"/> our
woe,</l>
```

*Example* This example encodes typographical line breaks as a means of preserving the visual appearance of a title page. The *break* attribute is used to show that the line break does not (as elsewhere) mark the start of a new word.

```
<titlePart>
  <lb/>With Additions, ne- <lb break="no"/>ver before Printed.
</titlePart>
```

**<leaf>** encodes the leaves (terminal nodes) of a tree. [19.2. Trees]

*Module* nets — Graphs, Networks, and Trees

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@value** provides a pointer to a feature structure or other analytic element.

*Status* Optional

*Datatype* teidata.pointer

**@parent** provides the identifier of parent of a leaf.

*Status* Optional

*Datatype* teidata.pointer

**@follow** provides an identifier of an element which this leaf follows.

*Status* Optional

*Datatype* teidata.pointer

*Note* If the tree is unordered or partially ordered, this attribute has the property of fixing the relative order of the leaf and the element which is the value of the attribute.

*Contained by* tree

*May contain*

*core:* label

*Note* The in degree of a leaf is always 1, its out degree always 0.

*Example*

```
<leaf xml:id="peril" parent="#n1">
  <label>periscope</label>
</leaf>
```

*Content model*

```
<content>
  <elementRef key="label" minOccurs="0"/>

*May contain*

*core:* ptr

*linking:* link

*Note* May contain one or more <link> elements only, optionally with interspersed pointer elements. A web or link group is an administrative convenience, which should be used to collect a set of links together for any purpose, not simply to supply a default value for the *type* attribute.

*Example*

```
<linkGrp type="translation">
  <link target="#CCS1 #SW1"/>
  <link target="#CCS2 #SW2"/>
  <link target="#CCS #SW"/>
</linkGrp>
<div type="volume" xml:id="CCS"
  xml:lang="fr">
  <p>
    <s xml:id="CCS1">Longtemps, je me suis couché de bonne heure.</s>
    <s xml:id="CCS2">Parfois, à peine ma bougie éteinte, mes yeux se fermaient
    si vite que je n'avais pas le temps de me dire : "Je m'endors."</s>
  </p>
  <!-- ... -->
</div>
<div type="volume" xml:id="SW" xml:lang="en">
```

```

<p>
  <s xml:id="SW1">For a long time I used to go to bed early.</s>
  <s xml:id="SW2">Sometimes, when I had put out my candle, my eyes would close
so quickly that I had not even time to say "I'm going to sleep."</s>
</p>
<!-- ... -->
</div>

```

```

<list> contains any sequence of items organized as a list. [3.7. Lists]

Module core – Elements Available in All TEI Documents

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.sortable (@sortKey) att.typed (type, @subtype)

@type describes the nature of the items in the list.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Suggested values include: gloss each list item glosses some term or concept, which is given by a label element preceding the list item.

index each list item is an entry in an index such as the alphabetical topical index at the back of a print volume.

instructions each list item is a step in a sequence of instructions, as in a recipe.

**litany** each list item is one of a sequence of petitions, supplications or invocations, typically in a religious ritual.

**syllogism** each list item is part of an argument consisting of two or more propositions and a final conclusion derived from them.

*Note* Previous versions of these Guidelines recommended the use of *type* on <list> to encode the rendering or appearance of a list (whether it was bulleted, numbered, etc.). The current recommendation is to use the *rend* or *style* attributes for these aspects of a list, while using *type* for the more appropriate task of characterizing the nature of the content of a list.

*Note* The formal syntax of the element declarations allows <label> tags to be omitted from lists tagged <list type="gloss">; this is however a semantic error.

*Note* May contain an optional heading followed by a series of items, or a series of label and item pairs, the latter being optionally preceded by one or two specialized headings.

*Example*

```
<list rend="numbered">
  <item>a butcher</item>
```

```
<item>a baker</item>
<item>a candlestick maker, with
<list rend="bulleted">
  <item>rings on his fingers</item>
  <item>bells on his toes</item>
</list>
</item>
</list>
```

Example

```
<list type="syllogism" rend="bulleted">
  <item>All Cretans are liars.</item>
  <item>Epimenides is a Cretan.</item>
  <item>ERGO Epimenides is a liar.</item>
</list>
```

Example

```
<list type="litany" rend="simple">
  <item>God save us from drought.</item>
  <item>God save us from pestilence.</item>
  <item>God save us from wickedness in high places.</item>
  <item>Praise be to God.</item>
</list>
```

Example The following example treats the short numbered clauses of Anglo-Saxon legal codes as lists of items. The text is from an ordinance of King Athelstan (924–939):

```
<div1 type="section">
  <head>Athelstan's Ordinance</head>
  <list rend="numbered">
    <item n="1">Concerning thieves. First, that no thief is to be spared who is
    caught with
      the stolen goods, [if he is] over twelve years and [if the value of the
    goods is] over
      eightpence.
    <list rend="numbered">
      <item n="1.1">And if anyone does spare one, he is to pay for the thief
    with his
      wergild – and the thief is to be no nearer a settlement on that
    account – or to
      clear himself by an oath of that amount.</item>
      <item n="1.2">If, however, he [the thief] wishes to defend himself or to
    escape, he is
      not to be spared [whether younger or older than twelve].</item>
      <item n="1.3">If a thief is put into prison, he is to be in prison 40
    days, and he may
      then be redeemed with 120 shillings; and the kindred are to stand
    surety for him
      that he will desist for ever.</item>
      <item n="1.4">And if he steals after that, they are to pay for him with
    his wergild,
      or to bring him back there.</item>
      <item n="1.5">And if he steals after that, they are to pay for him with
    his wergild,
      whether to the king or to him to whom it rightly belongs; and
```

```

everyone of those who
    supported him is to pay 120 shillings to the king as a
fine.</item>
  </list>
</item>
  <item n="2">Concerning lordless men. And we pronounced about these lordless
men, from whom
    no justice can be obtained, that one should order their kindred to fetch
back such a
    person to justice and to find him a lord in public meeting.
  <list rend="numbered">
    <item n="2.1">And if they then will not, or cannot, produce him on that
appointed day,
    he is then to be a fugitive afterwards, and he who encounters him
is to strike him
    down as a thief.</item>
    <item n="2.2">And he who harbours him after that, is to pay for him with
his wergild
    or to clear himself by an oath of that amount.</item>
  </list>
</item>
  <item n="3">Concerning the refusal of justice. The lord who refuses justice
and upholds
    his guilty man, so that the king is appealed to, is to repay the value
of the goods and
    120 shillings to the king; and he who appeals to the king before he
demands justice as
    often as he ought, is to pay the same fine as the other would have done,
if he had
    refused him justice.
  <list rend="numbered">
    <item n="3.1">And the lord who is an accessory to a theft by his slave,
and it becomes
    known about him, is to forfeit the slave and be liable to his
wergild on the first
    occasionp if he does it more often, he is to be liable to pay all
that he owns.</item>
    <item n="3.2">And likewise any of the king's treasurers or of our
reeves, who has been
    an accessory of thieves who have committed theft, is to liable to
the same.</item>
  </list>
</item>
  <item n="4">Concerning treachery to a lord. And we have pronounced
concerning treachery to
    a lord, that he [who is accused] is to forfeit his life if he cannot
deny it or is
    afterwards convicted at the three-fold ordeal.</item>
</list>
</div1>

```

Note that nested lists have been used so the tagging mirrors the structure indicated by the two-level numbering of the clauses. The clauses could have been treated as a one-level list with irregular numbering, if desired.

*Example*

```
<p>These decrees, most blessed Pope Hadrian, we propounded in the public council
... and they
confirmed them in our hand in your stead with the sign of the Holy Cross, and
afterwards
inscribed with a careful pen on the paper of this page, affixing thus the sign
of the Holy
Cross.
<list rend="simple">
  <item>I, Eanbald, by the grace of God archbishop of the holy church of York,
have
  subscribed to the pious and catholic validity of this document with the
sign of the Holy
  Cross.</item>
  <item>I, Ælfwold, king of the people across the Humber, consenting have
subscribed with
  the sign of the Holy Cross.</item>
  <item>I, Tilberht, prelate of the church of Hexham, rejoicing have
subscribed with the
  sign of the Holy Cross.</item>
  <item>I, Higbald, bishop of the church of Lindisfarne, obeying have
subscribed with the
  sign of the Holy Cross.</item>
  <item>I, Ethelbert, bishop of Candida Casa, suppliant, have subscribed with
thefsign of
  the Holy Cross.</item>
  <item>I, Ealdwulf, bishop of the church of Mayo, have subscribed with devout
will.</item>
  <item>I, Æthelwine, bishop, have subscribed through delegates.</item>
  <item>I, Sicga, patrician, have subscribed with serene mind with the sign of
the Holy
  Cross.</item>
</list>
</p>
```

<listEvent>
  <head>Battles of the American Civil War: Kentucky</head>
  <event xml:id="event01" when="1861-09-19">
    <label>Barbourville</label>
    <desc>The Battle of Barbourville was one of the early engagements of
      the American Civil War. It occurred September 19, 1861, in Knox
      County, Kentucky during the campaign known as the Kentucky Confederate
      Offensive. The battle is considered the first Confederate victory in
      the commonwealth, and threw a scare into Federal commanders, who
      rushed troops to central Kentucky in an effort to repel the invasion,
      which was finally thwarted at the <ref target="#event02">Battle of
      Camp Wildcat</ref> in October.</desc>
  </event>
  <event xml:id="event02" when="1861-10-21">
    <label>Camp Wild Cat</label>
    <desc>The Battle of Camp Wildcat (also known as Wildcat Mountain and Camp
      Wild Cat) was one of the early engagements of the American Civil
      War. It occurred October 21, 1861, in northern Laurel County, Kentucky
      during the campaign known as the Kentucky Confederate Offensive. The
      battle is considered one of the very first Union victories, and marked
      the first engagement of troops in the commonwealth of Kentucky.</desc>
  </event>
  <event xml:id="event03" from="1864-06-11"
    to="1864-06-12">
    <label>Cynthiana</label>
    <desc>The Battle of Cynthiana (or Kellar's Bridge) was an engagement
      during the American Civil War that was fought on June 11 and 12, 1864,
      in Harrison County, Kentucky, near the town of Cynthiana. A part of
      Confederate Brigadier General John Hunt Morgan's 1864 Raid into
      Kentucky, the battle resulted in a victory by Union forces over the
      raiders and saved the town from capture.</desc>

**<listPrefixDef>** (list of prefix definitions) contains a list of definitions of prefixing schemes used in `data.pointer` values, showing how abbreviated URIs using each scheme may be expanded into full URIs. [16.2.3. Using Abbreviated Pointers]

*Module header* – The TEI Header

*Attributes* `att.global` (`@xml:id`, `@n`, `@xml:lang`, `@xml:base`, `@xml:space`) (`att.global.rendition` (`@rend`, `@style`, `@rendition`)) (`att.global.linking` (`@corresp`, `@synch`, `@sameAs`, `@copyOf`, `@next`, `@prev`, `@exclude`, `@select`)) (`att.global.analytic` (`@ana`)) (`att.global.facs` (`@facs`)) (`att.global.change` (`@change`)) (`att.global.responsibility` (`@cert`, `@resp`))

*Member of* `model.encodingDescPart`

*Contained by*

*header:* `encodingDesc listPrefixDef`

*May contain*

*header:* `listPrefixDef prefixDef`

*Example* In this example, two private URI scheme prefixes are defined and patterns are provided for dereferencing them. Each prefix is also supplied with a human-readable explanation in a `<p>` element.

```

<listPrefixDef>
  <prefixDef ident="psn"
    matchPattern="[A-Z]+"
    replacementPattern="personography.xml#$1">
    <p> Private URIs using the <code>psn</code>
      prefix are pointers to <gi>person</gi>
      elements in the personography.xml file.
      For example, <code>psn:MDH</code>
      dereferences to <code>personography.xml#MDH</code>.
    </p>
  </prefixDef>
  <prefixDef ident="bibl"
    matchPattern="[a-z]+[a-z0-9]*"
    replacementPattern="http://www.example.com/getBibl.xql?id=$1">
    <p> Private URIs using the <code>bibl</code> prefix can be
      expanded to form URIs which retrieve the relevant
      bibliographical reference from www.example.com.
    </p>
  </prefixDef>
</listPrefixDef>

```

*Content model*

}
```

---

**<listRelation>** provides information about relationships identified amongst people, places, and organizations, either informally as prose or as formally expressed relation links. [13.3.2.3. *Personal Relationships*]

*Module* namesdates — Names, Dates, People, and Places

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.typed (@type, @subtype) att.sortable (@sortKey)

*Member of* model.biblPart

*Contained by*

*core:* bibl listBibl

*namesdates:* listEvent listNym listOrg listPerson listPlace listRelation

*May contain*

*core:* head p

*linking:* ab

*namesdates:* listRelation relation

*Note* May contain a prose description organized as paragraphs, or a sequence of <relation> elements.

*Example*

```
<listPerson>
  <person xml:id="pp1">
<!-- data about person pp1 -->
  </person>
  <person xml:id="pp2">
<!-- data about person pp1 -->
```

```
</person>
<!-- more person (pp3, pp4) elements here -->
</listPerson>
<listRelation type="personal">
  <relation name="parent" active="#pp1 #pp2"
    passive="#pp3 #pp4"/>
  <relation name="spouse" mutual="#pp1 #pp2"/>
</listRelation>
<listRelation type="social">
  <relation name="employer" active="#pp1"
    passive="#pp3 #pp5 #pp6 #pp7"/>
</listRelation>
```

The persons with identifiers pp1 and p2 are the parents of pp3 and pp4; they are also married to each other; pp1 is the employer of pp3, pp5, pp6, and pp7.

*Example*

```
<listRelation>
  <p>All speakers are members of the Ceruli family, born in Naples.</p>
</listRelation>
```

*Content model*

```
<content>
  <sequence>
    <classRef key="model.headLike"
      minOccurs="0" maxOccurs="unbounded"/>
    <alternate>
      <classRef key="model.pLike"/>
      <alternate minOccurs="1"
        maxOccurs="unbounded">
        <elementRef key="relation"/>
        <elementRef key="listRelation"/>
      </alternate>
    </alternate>
  </sequence>
</content>
```

*Schema Declaration*

```
element listRelation
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.typed.attributes,
  att.sortable.attributes,
  ( model.headLike*, ( model.pLike | ( relation | listRelation )+ ) )
}
```

**<listTranspose>** supplies a list of transpositions, each of which is indicated at some point in a document typically by means of metamarks. [11.3.4.5. *Transpositions*]

*Module* transcr — Representation of Primary Sources

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

*textstructure:* argument back body div div1 div2 div3 div4 div5 div6 div7 docEdition epigraph imprimatur postscript salute signed titlePart trailer

*transcr:* damage metamark mod restore retrace secl supplied surplus

*verse:* rhyme

*May contain*

*core:* head

*textcrit:* listWit witness

*Note* May contain a series of <witness> or <listWit> elements. The provision of a <listWit> element simplifies the automatic processing of the apparatus, e.g. the reconstruction of the readings for all witnesses from an exhaustive apparatus.

Situations commonly arise where there are many more or less fragmentary witnesses, such that there may be quite distinct groups of witnesses for different parts of a text or collection of texts. Such groups may be given separately, or nested within a single <listWit> element at the beginning of the file listing all the witnesses, partial and complete, for the text, with the attestation of fragmentary witnesses indicated within the apparatus by use of the <witStart> and <witEnd> elements described in section 12.1.5.

*Fragmentary Witnesses.*

Note however that a given witness can only be defined once, and can therefore only appear within a single <listWit> element.

*Example*

```
<listWit>
  <witness xml:id="HL26">Ellesmere, Huntingdon Library 26.C.9</witness>
  <witness xml:id="PN392">Hengwrt, National Library of Wales,
    Aberystwyth, Peniarth 392D</witness>
  <witness xml:id="RP149">Bodleian Library Rawlinson Poetic 149
    (see further <ptr target="#MSRP149"/>)</witness>
</listWit>
```

*Content model*

*May contain*

*gaiji:* g

*Note* The *target* attribute should only be used to point to elements that contain or indicate a transcription of the locus being described, as in the first example above. To associate a <locus> element with a page image or other comparable representation, the global *fac*s attribute should be used instead, as shown in the second example. Use of the *target* attribute to indicate an image is strongly deprecated. The *fac*s attribute may be used to indicate one or more image files, as above, or alternatively it may point to one or more appropriate XML elements, such as the <surface>, <zone> element, <graphic>, or <binaryObject> elements.

*Note* When the location being defined consists of a single page, use the *from* and *to* attributes with an identical value. When no clear endpoint is given the *from* attribute should be used without *to*. For example, if the manuscript description being transcribed has 'p. 3ff' as the locus.

*Example*

```
<!-- within ms description --><msItem n="1">
  <locus target="#F1r #F1v #F2r" from="1r"
    to="2r">ff. 1r-2r</locus>
  <author>Ben Jonson</author>
  <title>Ode to himself</title>
  <rubric rend="italics"> An Ode<lb/> to him selfe.</rubric>
  <incipit>Com leaue the loathed stage</incipit>
  <explicit>And see his chariot triumph ore his wayne.</explicit>
  <bibl>
    <name>Beal</name>, <title>Index 1450-1625</title>, JnB 380</bibl>
</msItem>
<!-- within transcription ... -->
<pb xml:id="F1r"/>
<!-- ... -->
<pb xml:id="F1v"/>
<!-- ... -->
<pb xml:id="F2r"/>
<!-- ... -->
```

*Example* The *fac*s attribute is available globally when the **transcr** module is included in a schema. It may be used to point directly to an image file, as in the following example:

```
<msItem>
  <locus facs="images/08v.jpg images/09r.jpg images/09v.jpg images/10r.jpg
  images/10v.jpg">fols. 8v-10v</locus>
  <title>Birds Praise of Love</title>
  <bibl>
    <title>IMEV</title>
    <biblScope>1506</biblScope>
  </bibl>
</msItem>
```

*Content model* `<content> <macroRef key="macro.xtext"/></content>`

*Schema Declaration*

```
element locus
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,

*Note* The *type* attribute may be used to indicate the type of morpheme, taking values such as clitic, prefix, stem,  
 etc. as appropriate.

#### Example

```

<w type="adjective">
  <w type="noun">
    <m type="prefix" baseForm="con">com</m>
    <m type="root">fort</m>
  </w>
  <m type="suffix">able</m>
</w>

```

#### Content model

```

<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.gLike"/>
    <classRef key="model.hiLike"/>
    <elementRef key="seg"/>
  </alternate>
</content>

```

```

<elementRef key="m"/>
<elementRef key="c"/>
<classRef key="model.global"/>
</alternate>
</content>

```

*Schema Declaration*

```

element m
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.segLike.attributes,
  att.metrical.attributes,
  att.datcat.attributes,
  att.fragmentable.attributes,
  att.typed.attributes,
  attribute baseForm { text }?,
  ( text | model.gLike | model.hiLike | seg | m | c | model.global )*
}

```

**<macroRef>** points to the specification for some pattern which is to be included in a schema [22.7. Macro Specifications]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.readFrom (@source)

**@key** the identifier used for the required pattern within the source indicated.

*Status* Required

*Datatype* teidata.xmlName

*Member of* model.contentPart model.oddRef

*Contained by*

*tagdocs:* alternate content schemaSpec sequence specGrp

*May contain* Empty element

*Note* Patterns or macros are identified by the name supplied as value for the *ident* attribute on the <macroSpec> element in which they are declared. All TEI macro names are unique.

*Example*

```

<schemaSpec ident="myTEI"
  source="http://www.tei-c.org/Vault/P5/current/xml/tei/odd/p5subset.xml">
<!-- ... -->
  <macroRef key="data.text"
    source="tei:1.5.0"/>

```

```
<!-- ... -->
</schemaSpec>
```

Content model `<content></content>`

Schema Declaration

```
element macroRef
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.readFrom.attributes,
  attribute key { text },
  empty
}
```

**<macroSpec>** (macro specification) documents the function and implementation of a pattern. [22.3. Specification Elements 22.7. Macro Specifications]

Module tagdocs – Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.identified (@ident, @predeclare, @module) (att.combinable (@mode) (att.deprecated (@validUntil)))

**@type** indicates which type of entity should be generated, when an ODD processor is generating a module using XML DTD syntax.

Status Optional

Datatype teidata.enumerated

Legal values are: **pe** (parameter entity)

**dt** (datatype entity)

**<memberOf>** specifies class membership of the documented element or class. [22.4.3. Classification of Components]

Module tagdocs – Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

@key specifies the identifier for a class of which the documented element or class is a member or subclass

Status Optional

Datatype teidata.name

@mode specifies the effect of this declaration on its parent module.

Status Optional

Datatype teidata.enumerated

Legal values are: **add** this declaration is added to the current definitions[Default]

**delete** this declaration and all of its children are removed from the current setup

@max supplies the maximum number of times the element can occur in elements which use this model class in their content model

Status Optional

Datatype teidata.numeric

@min supplies the minimum number of times the element must occur in elements which use this model class in their content model

Status Optional

Datatype teidata.numeric

Content model: classes

May contain

gaji: g

Note Elements or classes which are members of multiple (unrelated) classes will have more than one <memberOf> element, grouped by a <classes> element. If an element is a member of a class C1, which is itself a subclass of a class C2, there is no need to state this, other than in the documentation for class C1. Any additional comment or explanation of the class membership may be provided as content for this element.

Example

```
<memberOf key="model.divLike"/>
<memberOf key="att.identified"/>
```

This element will appear in any content model which references model.divLike, and will have attributes defined in att.identified (in addition to any defined explicitly for this element).

Content model <content> <macroRef key="macro.xtext"/></content>

Schema Declaration

```
element memberOf

**<metDecl>** (metrical notation declaration) documents the notation employed to represent a metrical pattern when this is specified as the value of a *met*, *real*, or *rhyme* attribute on any structural element of a metrical text (e.g. <lg>, <l>, or <seg>). [6.6. *Metrical Notation Declaration* 6.4. *Rhyme and Metrical Analysis*]

*Module* verse — Verse

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))

(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.declarable (@default)

**@type** indicates whether the notation conveys the abstract metrical form, its actual prosodic realization, or the rhyme scheme, or some combination thereof.

*Status* Optional

*Datatype* 1–3 occurrences of teidata.enumerated separated by whitespace

*Legal values are:* **met** (met attribute) declaration applies to the abstract metrical form recorded on the *met* attribute

**real** (real attribute) declaration applies to the actual realization of the conventional metrical structure recorded on the *real* attribute

**rhyme** declaration applies to the rhyme scheme recorded on the *rhyme* attribute

*Note* By default, the <metDecl> element documents the notation used for metrical pattern and realization. It may also be used to document the notation used for rhyme scheme information; if not otherwise documented, the rhyme scheme notation defaults to the traditional ‘abab’ notation.

**@pattern** (regular expression pattern) specifies a regular expression defining any value that is legal for this notation.

*Status* Optional

*Datatype* teidata.pattern

*Note* The value must be a valid regular expression per the World Wide Web Consortium's *XML Schema Part 2: Datatypes Second Edition*, Appendix F

*Member of* model.encodingDescPart

*Contained by*

*header:* encodingDesc

*May contain*

*core:* note p

*linking:* ab

*textcrit:* witDetail

*verse:* metSym

*Note* The encoder may choose whether to define the notation formally or informally. However, the two methods may not be mixed. That is, <metDecl> may contain either a sequence of <metSym> elements or, alternately, a series of paragraphs or other components. If the *pattern* attribute is specified and <metSym> elements are used, then all the codes appearing within the *pattern* attribute should be documented. Only usable within the header if the verse module is used.

*Example*

```
<metDecl xml:id="ip" type="met"
  pattern="((SU|US)USUSUSUS/)">
  <metSym value="S">stressed syllable</metSym>
  <metSym value="U">unstressed syllable</metSym>
  <metSym value="/">metrical line boundary</metSym>
</metDecl>
```

This example is intended for the far more restricted case typified by the Shakespearean iambic pentameter. Only metrical patterns containing exactly ten syllables, alternately stressed and unstressed, (except for the first two which may be in either order) to each metrical line can be expressed using this notation.

*Content model*

    }
  }?,
  attribute pattern { text }?,
  ( ( model.pLike | model.noteLike )+ | metSym+ )
}

```

<metSym> (metrical notation symbol) documents the intended significance of a particular character or character sequence within a metrical notation, either explicitly or in terms of other symbol elements in the same metDecl. [6.6. Metrical Notation Declaration]

Module verse – Verse

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

@value specifies the character or character sequence being documented.

Status Required

Datatype 1-∞ occurrences of teidata.word separated by whitespace

@terminal specifies whether the symbol is defined in terms of other symbols (terminal is set to false) or in prose (terminal is set to true).

Status Optional

Datatype teidata.truthValue

Default true

*Note* The value true indicates that the element contains a prose definition of its meaning; the value false indicates that the element contains a definition of its meaning given using symbols defined elsewhere in the same <metDecl> element.

```

**<model>** describes the processing intended for a specified element. [22.5.5.1. *The TEI processing model*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@behaviour** names the process or function which this processing model uses in order to produce output.

*Status* Required

*Datatype* teidata.enumerated

*Suggested values include:* **alternate (default,alternate)** support display of alternative visualisations, for example by displaying the preferred content, by displaying both in parallel, or by toggling between the two.

**anchor (id)** create an identifiable anchor point in the output

**block (content)** create a block structure

**body (content)** create the body of a document.

**break (type,label)** create a line, column, or page break according to the value of *type*

**cell (content)** create a table cell

**cit (content,source)** show the content, with an indication of the source

**document (content)** start a new output document

**figure (title)** make a figure with the *title* as caption

**glyph (uri)** show a character by looking up reference to a chardesc at the given URI

**graphic (url,width,height,scale,title)** if *url* is present, uses it to display graphic, else display a placeholder image.

**heading (content,level)** creates a heading.

**index (type)** generate list according to *type*

**inline (content,label)** creates inline element out of *content*

**link (content,uri)** create hyperlink

**list (content)** create a list  
**listItem (content)** create a list item  
**metadata (content)** create metadata section  
**note (content,place,label)** create a note, often out of line, depending on the value of *place*; could be margin, footnote, endnote, inline  
**omit** do nothing, do not process children  
**paragraph (content)** create a paragraph out of *content*.  
**row (content)** create a table row  
**section (content)** create a new section of the output document  
**table (content)** create a table  
**text (content)** create literal text  
**title (content)** create document title

**@predicate** the condition under which this model applies, given as an XPath predicate expression.

*Status* Optional

*Datatype* teidata.xpath

**@useSourceRendition** whether to obey any rendition attribute which is present.

*Status* Optional

*Datatype* teidata.truthValue

*Note* If the *useSourceRendition* attribute is not specified, or has the value false, any renditional information specified in the source document should be ignored.

**@output** the intended output.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **web** the output is intended for presentation in a web format

**print** the output is intended for presentation in a print format

**plain** the output is intended for presentation in a plain text format

*Note* If the *output* attribute is not specified, this model is assumed to apply for all forms of output.

**@cssClass** the name of a CSS class which should be associated with this element

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.name separated by whitespace

*Content models:* elementSpec modelGrp modelSequence

*May contain*

*core:* desc gloss

*tagdocs:* altIdent equiv outputRendition param

*Note* The intended output to be generated for a particular behaviour of a processing model may be documented in one or all of the three following ways. Firstly, the *cssClass* attribute may be used to specify the name of a CSS style in some associated CSS stylesheet which is to be applied to each occurrence of a specified element found (in a given context, for a specified output). Secondly, the attribute *useSourceRendition* may be used to indicate that the default rendition for occurrences of this element, as defined by a <rendition> element in the document header, should be applied. Thirdly, the styling to be applied may be specified explicitly as content of a child <outputRendition> element. When more than one of these options is used, they are understood to be combined in accordance with the rules for multiple declaration of the styling language used.

*Example*

```
<model behaviour="inline"/>
```

*Example*

```
<elementSpec mode="change" ident="quote">
  <model predicate="ancestor::p"
    behaviour="inline">
    <desc versionDate="2015-08-21"
      xml:lang="en">If it's inside a paragraph then it's
        inline</desc>
    </model>
  <model predicate="not(ancestor::p)"
    behaviour="block">
    <desc versionDate="2015-08-21"
      xml:lang="en">If it's not inside a paragraph then it is
        block level</desc>
    </model>
  </elementSpec>
```

*Example*

```
<model predicate="parent::person"
  behaviour="inline">
  <desc versionDate="2015-08-21"
    xml:lang="en">If it is a child of a person element, treat as
      inline</desc>
</model>
```

*Example*

```
<model behaviour="inline">
  <outputRendition>font-weight:bold</outputRendition>
</model>
```

*Example*

```
<model behaviour="inline" output="print"/>
```

*Example*

```
<model predicate="ancestor::p"
  behaviour="inline">
  <param name="content" value="@n"/>
</model>
```

*Example*

```
<elementSpec mode="change" ident="date">
  <model output="print" predicate="text()"
    behaviour="inline"/>
  <model output="print"
    predicate="@when and not(text())" behaviour="inline">
    <param name="content" value="@when"/>
  </model>
  <model predicate="@when" output="web"
    behaviour="alternate">
    <param name="alternate" value="@when"/>
  </model>
</elementSpec>
```

```

</model>
</elementSpec>

```

*Example*

```

<elementSpec mode="change" ident="choice">
  <model predicate="sic and corr"
    behaviour="alternate">
    <param name="default" value="corr"/>
    <param name="alternate" value="sic"/>
  </model>
  <model predicate="abbr and expan"
    behaviour="alternate">
    <param name="default" value="expan"/>
    <param name="alternate" value="abbr"/>
  </model>
  <model predicate="orig and reg"
    behaviour="alternate">
    <param name="default" value="reg"/>
    <param name="alternate" value="orig"/>
  </model>
</elementSpec>

```

```

**<modelGrp>** any grouping of model or modelSequence elements with a common output method [22.5.5.4. *Model Contexts and Outputs*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@useSourceRendition** whether to obey any rendition attribute which is present  
*Status* Optional

*Datatype* teidata.truthValue

**@output** the intended output method  
*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **web** the output is intended for presentation in a web format  
**print** the output is intended for presentation in a print format  
**plaintext** the output is intended for presentation in a plain text format

*Content model:* elementSpec

*May contain*

*core:* desc gloss

*tagdocs:* altIdent equiv model modelSequence outputRendition

*Note* The child <model> elements of a <modelGrp> are always processed independently.

Example

```
<elementSpec mode="change" ident="abbr">
  <modelGrp output="web">
    <model predicate="parent::choice"
      behaviour="omit"/>
    <model predicate="ancestor::front"
      behaviour="inline">
      <outputRendition>font-style:italic;</outputRendition>
    </model>
    <model predicate="not(parent::choice)"
      behaviour="inline">
      <outputRendition scope="before">content: ' ('</outputRendition>
      <outputRendition scope="after">content: ') '</outputRendition>
    </model>
  </modelGrp>
  <modelGrp output="print">
    <model predicate="parent::choice"
      behaviour="omit"/>
    <model predicate="not(parent::choice)"
      behaviour="note">
      <param name="place" value="'foot'"/>
    </model>
  </modelGrp>
</elementSpec>
```

Example

```
<modelGrp output="print">
  <modelSequence>
    <model behaviour="inline">
      <param name="content" value="@n"/>
    </model>
    <model behaviour="note">
      <param name="place" value="'foot'"/>
    </model>
  </modelSequence>
</modelGrp>
```

      maxOccurs="unbounded">
      <elementRef key="modelSequence"/>
      <elementRef key="model"/>
    </alternate>
  </sequence>
</content>
```

Schema Declaration

```

element modelGrp
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  attribute useSourceRendition { text }?,
  attribute output { "web" | "print" | "plaintext" }?,
  (
    ( model.glossLike | model.descLike )*,
    outputRendition?,
    ( modelSequence | model )+
  )
}

```

**<modelSequence>** any sequence of model or modelSequence elements which is to be processed as a single set of actions [22.5.5.7. Model sequence]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@predicate** the condition under which this model applies given as an XPath Predicate Expression

*Status* Optional

*Datatype* teidata.xpath

**@useSourceRendition** whether to obey any rendition attribute which is present

*Status* Optional

*Datatype* teidata.truthValue

**@output** the intended output method

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **web** the output is intended for presentation in a web format

**print** the output is intended for presentation in a print format

**plaintext** the output is intended for presentation in a plain text format

*Content model* tagdocs: elementSpec modelGrp

*May contain*

*core:* desc gloss

*tagdocs:* altIdent equiv model

*Note* All of the child elements of a <modelSequence> element are to be processed together, for example in sequence, rather than independently of one another.

*Example*

```

<modelGrp output="print">
  <modelSequence>

```

```
<model behaviour="inline">
  <param name="content" value="@n"/>
</model>
<model behaviour="footnote">
  <param name="place" value="'foot'"/>
</model>
</modelSequence>
</modelGrp>
```

Content model

```
<content>
<sequence>
  <alternate minOccurs="0"

    <classRef key="model.glossLike"/>
    <classRef key="model.descLike"/>
  </alternate>
  <elementRef key="model"
    maxOccurs="unbounded"/>
</sequence>
</content>
```

Schema Declaration

```
element modelSequence
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  attribute predicate { text }?,
  attribute useSourceRendition { text }?,
  attribute output { "web" | "print" | "plaintext" }?,
  ( ( model.glossLike | model.descLike )*, model+ )
}
```

---

**<moduleRef>** (module reference) references a module which is to be incorporated into a schema. [22.2.

*Modules and Schemas*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.readFrom (@source)

@prefix specifies a default prefix which will be prepended to all patterns from the imported module

Status Optional

Datatype 0–1 occurrences of teidata.xmlName separated by whitespace

*Schematron* <s:rule context="tei:moduleRef"> <s:report test="//\*[ not( generate-id(.) eq generate-id( current() ) ) ]/@prefix = @prefix">The prefix attribute of <s:name/> should not match that of any other element (it would defeat the purpose)</s:report></s:rule>

*Note* Use of this attribute avoids name collisions (and thus invalid schemas) when the external schema being mixed in with TEI uses a name the TEI or some other included external schema already uses for a pattern.

**@include** supplies a list of the elements which are to be copied from the specified module into the schema being defined.

*Status* Optional

*Datatype* 0–∞ occurrences of teidata.xmlName separated by whitespace

**@except** supplies a list of the elements which are not to be copied from the specified module into the schema being defined.

*Status* Optional

*Datatype* 0–∞ occurrences of teidata.xmlName separated by whitespace

**@key** the name of a TEI module

*Status* Optional

*Datatype* teidata.xmlName

**@url** (uniform resource locator) refers to a non-TEI module of RELAX NG code by external location

*Status* Optional

*Datatype* teidata.pointer

*Member of* model.oddRef

*Contained by*

*tagdocs:* schemaSpec specGrp

*May contain*

*tagdocs:* content

*Note* If neither *include* nor *exclude* is supplied, the effect of this element is to make all the declarations contained by the referenced module available to the schema being compiled. If both attributes are supplied, an ODD processor should signal an error. A TEI module is identified by the name supplied as value for the *ident* attribute on a <moduleSpec> element. The *source* attribute may be used to specify an online source from which the specification of that module may be read. A URI may alternatively be supplied in the case of a non-TEI module, and this is expected to be written as a RELAX NG schema.

*Example*

```
<moduleRef key="linking"/>
```

This includes all objects available from the linking module.

*Example*

```
<moduleRef key="linking"
  except="linkGrp link"/>
```

This includes all elements available from the linking module except for the <link> and <linkGrp> elements.

*Example*

```
<moduleRef key="linking"
  include="linkGrp link"/>
```

This includes only the <link> and <linkGrp> elements from the linking module.

*Schematron* <s:rule context="tei:moduleRef"> <s:report test="\*" and @key">Child elements of <s:name/> are only allowed when an external module is being loaded </s:report> </s:rule>

*Content model*

```
<content>
  <elementRef key="content" minOccurs="0"/>
</content>
```

*Schema Declaration*

```
element moduleRef
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,

**<monogr>** (monographic level) contains bibliographic elements describing an item (e.g. a book or journal) published as an independent item (i.e. as a separate physical object). [3.11.2.1. *Analytic, Monographic, and Series Levels*]

*Module* core – Elements Available in All TEI Documents

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

*Contained by*

*core:* biblStruct

*May contain*

*core:* author biblScope editor imprint meeting note ptr ref respStmt textLang title

*header:* authority availability edition extent funder idno sponsor

*textcrit:* witDetail

*Note* May contain specialized bibliographic elements, in a prescribed order. The <monogr> element may only occur only within a <biblStruct>, where its use is mandatory for the description of a monographic-level bibliographic item.

*Example*

```
<biblStruct>
  <analytic>
    <author>Chesnutt, David</author>
    <title>Historical Editions in the States</title>
  </analytic>
  <monogr>
    <title level="j">Computers and the Humanities</title>
    <imprint>
      <date when="1991-12">(December, 1991):</date>
    </imprint>
    <biblScope>25.6</biblScope>
    <biblScope unit="page" from="377" to="380">377–380</biblScope>
  </monogr>
</biblStruct>
```

*Example*

```
<biblStruct type="book">
  <monogr>
    <author>
      <persName>
        <forename>Leo Joachim</forename>
        <surname>Frachtenberg</surname>
      </persName>
    </author>
    <title type="main" level="m">Lower Umpqua Texts</title>
    <imprint>
      <pubPlace>New York</pubPlace>

**<move>** (movement) marks the actual entrance or exit of one or more characters on stage. [7.2.4. Stage Directions]

Module drama – Performance Texts

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.ascribed (@who)

@type characterizes the movement, for example as an entrance or exit.

Status Optional

Datatype teidata.enumerated

Suggested values include: **entrance** character is entering the stage.

**exit** character is exiting the stage.

**onStage** character moves on stage

**@where** specifies the direction of a stage movement.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.enumerated separated by whitespace

*Sample values include:* **L** (left) stage left

**R** (right) stage right

**C** (center) centre stage

*Note* Full blocking information will normally require combinations of values, (for example ‘UL’ for ‘upper stage left’) and may also require more detailed encoding of speed, direction etc. Full documentation of any coding system used should be provided in the header.

**@perf** (performance) identifies the performance or performances in which this movement occurred as specified by pointing to one or more <performance> elements.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Member of* model.stageLike

*Contained by*

*core:* add corr del desc emph head hi item l lg meeting note orig p q quote ref reg said sic sp stage title unclear

```

<msContents> (manuscript contents) describes the intellectual content of a manuscript or manuscript part, either as a series of paragraphs or as a series of structured manuscript items. [10.6. Intellectual Content]

Module msdescription – Manuscript Description

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.msExcerpt (@defective)

@Class identifies the text types or classifications applicable to this object by pointing to other elements or resources defining the classification concerned.

Status Optional

Datatype 1-∞ occurrences of teidata.pointer separated by whitespace

Content model: msDesc msFrag msPart

May contain

core: p textLang

linking: ab

msdescription: msItem msItemStruct summary

textstructure: titlePage

Note Unless it contains a simple prose description, this element should contain at least one of the elements <summary>, <msItem>, or <msItemStruct>. This constraint is not currently enforced by the schema.

Example

```

<msContents class="#sermons">
  <p>A collection of Lollard sermons</p>
</msContents>

```

Example

```

<msContents>

  att.global.responsibility.attributes,
  att.typed.attributes,
  macro.xtext}
```

**<msPart>** (manuscript part) contains information about an originally distinct manuscript or part of a manuscript, which is now part of a composite manuscript. [10.10. Manuscript Parts]

Module msdescription – Manuscript Description

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

Contained by

msdescription: msDesc msPart

May contain

core: head p

linking: ab

msdescription: additional altIdentifier history msContents msIdentifier msPart physDesc

Note As this last example shows, for compatibility reasons the identifier of a manuscript part may be supplied as a simple <altIdentifier> rather than using the more structured <msIdentifier> element. This usage is however deprecated.

Example

```
<msPart>
  <msIdentifier>
    <idno>A</idno>
    <altIdentifier type="catalog">
      <collection>Becker</collection>
      <idno>48, Nr. 145</idno>
    </altIdentifier>
    <altIdentifier type="catalog">
      <collection>Wiener Liste</collection>
      <idno>4o5</idno>
    </altIdentifier>
  </msIdentifier>
  <head>
    <title xml:lang="la">Gregorius: Homiliae in Ezechielem</title>
    <origPlace key="tgn_7008085">Weissenburg (?)</origPlace>
```

```

    <origDate notBefore="0801"
      notAfter="0815">IX. Jh., Anfang</origDate>
  </head>
</msPart>

```

*Example*

```

<msDesc>
  <msIdentifier>
    <settlement>Amiens</settlement>
    <repository>Bibliothèque Municipale</repository>
    <idno>MS 3</idno>

**<node>** encodes a node, a possibly labeled point in a graph. [19.1. Graphs and Digraphs]

*Module* nets – Graphs, Networks, and Trees

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@value** provides the value of a node, which is a feature structure or other analytic element.

*Status* Optional

*Datatype* teidata.pointer

**@type** provides a type for a node.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **initial** initial node in a transition network

**final** final node in a transition network

```
<graph>  
  <node xml:id="gnex11"  
    adjTo="#gnex12"  
    adj="#gnex13"  
    type="initial">  
    <label>1</label>  
  </node>  
  <node xml:id="gnex12"  
    adjFrom="#gnex11"  
    adjTo="#gnex13">  
    <label>2</label>  
  </node>  
  <node xml:id="gnex13"  
    adjFrom="#gnex12"  
    adj="#gnex11"  
    type="final">  
    <label>3</label>  
  </node>  
</graph>
```

**@adjTo** (adjacent to) gives the identifiers of the nodes which are adjacent to the current node.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

```
<graph>
  <node xml:id="gnex21"
    adjTo="#gnex22"
    adj="#gnex23"
    type="initial">
    <label>1</label>
  </node>
  <node xml:id="gnex22"
    adjTo="#gnex23">
    <label>2</label>
  </node>
  <node xml:id="gnex23"
    type="final">
    <label>3</label>
  </node>
</graph>
```

@adjFrom (adjacent from) gives the identifiers of the nodes which are adjacent from the current node.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

```
<graph>
  <node xml:id="gnex31"
    type="initial">
    <label>1</label>
  </node>
  <node xml:id="gnex32"
    adjFrom="#gnex31">
    <label>2</label>
  </node>
  <node xml:id="gnex33"
    adjFrom="#gnex32"
    adj="#gnex31"
    type="final">
    <label>3</label>
  </node>
</graph>
```

@adj (adjacent) gives the identifiers of the nodes which are both adjacent to and adjacent from the current node.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

```
<graph>
  <node xml:id="gnex41"
    adj="#gnex42 #gnex43"
    type="initial">
    <label>1</label>
  </node>
  <node xml:id="gnex42"
    adj="#gnex41 #gnex43">
    <label>2</label>
  </node>
  <node xml:id="gnex43"
    adj="#gnex42 #gnex41"
    type="final">
    <label>3</label>
```

```
</node>  
</graph>
```

*Note* Use this attribute instead of the *adjTo* and *adjFrom* attributes when the graph is undirected and vice versa if the graph is directed.

**@inDegree** gives the in degree of the node, the number of nodes which are adjacent from the given node.

*Status* Optional

*Datatype* teidata.count

```
<graph>  
  <node xml:id="gnex51"  
    adjTo="#gnex52"  
    adj="#gnex53"  
    inDegree="1"  
    type="initial">  
    <label>1</label>  
  </node>  
  <node xml:id="gnex52"  
    adjFrom="#gnex51"  
    adjTo="#gnex53"  
    inDegree="2">  
    <label>2</label>  
  </node>  
  <node xml:id="gnex53"  
    adjFrom="#gnex52"  
    adj="#gnex51"  
    inDegree="2"  
    type="final">  
    <label>3</label>  
  </node>  
</graph>
```

**@outDegree** gives the out degree of the node, the number of nodes which are adjacent to the given node.

*Status* Optional

*Datatype* teidata.count

```
<graph>  
  <node xml:id="gnex61"  
    adjTo="#gnex62"  
    adj="#gnex63"  
    outDegree="2"  
    type="initial">  
    <label>1</label>  
  </node>  
  <node xml:id="gnex62"  
    adjFrom="#gnex61"  
    adjTo="#gnex63"  
    outDegree="1">  
    <label>2</label>  
  </node>  
  <node xml:id="gnex63"  
    adjFrom="#gnex62"  
    adj="#gnex61"  
    outDegree="2"  
    type="final">  
    <label>3</label>  
  </node>  
</graph>
```

**@degree** gives the degree of the node, the number of arcs with which the node is incident.

*Status* Optional

*Datatype* teidata.count

```

<graph>
  <node xml:id="gnex71"
    adjTo="#gnex72"
    adj="#gnex73"
    outDegree="1"
    inDegree="0"
    degree="1"
    type="initial">
    <label>1</label>
  </node>
  <node xml:id="gnex72"
    adjFrom="#gnex71"
    adjTo="#gnex73"
    outDegree="1"
    inDegree="1"
    degree="0">
    <label>2</label>
  </node>
  <node xml:id="gnex73"
    adjFrom="#gnex72"
    adj="#gnex71"
    outDegree="0"
    inDegree="1"
    degree="1"
    type="final">
    <label>3</label>
  </node>
</graph>

```

*Note* Use this attribute instead of the *inDegree* and *outDegree* attributes when the graph is undirected and vice versa if the graph is directed.

*Contained by* graph

*May contain*

*core:* label

*Note* Zero, one, or two children <label> elements may be present. The first occurrence of <label> provides a label for the arc; the second provides a second label for the arc, and should be used if a transducer is being encoded whose actions are associated with nodes rather than with arcs.

*Example*

```

<node xml:id="t6" type="final" inDegree="2"
  outDegree="0">
  <label>6</label>
</node>

```

*Content model*

*Note* It is possible to describe the content of the notation using elements from the `model.labelLike` class and it is possible to point to an external representation using elements from `model.ptrLike`. It is possible to specify the location of digital objects representing the notated music in other media such as images or audio-visual files. The encoder's interpretation of the correspondence between the notated music and these digital objects is not encoded explicitly. We recommend the use of `graphic` and `binaryObject` mainly as a fallback mechanism when the notated music format is not displayable by the application using the encoding. The alignment of encoded notated music, images carrying the notation, and audio files is a complex matter for which we refer the encoder to other formats and specifications such as MPEG-SMR.

*Example*

```
<notatedMusic>
  <ptr target="bar1.xml"/>
  <graphic url="bar1.jpg"/>
  <desc>First bar of Chopin's Scherzo No.3 Op.39</desc>
</notatedMusic>
```

**<note>** contains a note or annotation. [3.8.1. Notes and Simple Annotation 2.2.6. The Notes Statement 3.11.2.8. Notes and Statement of Language 9.3.5.4. Notes within Entries]

*Module* core – Elements Available in All TEI Documents

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.placement (@place) att.pointing (@targetLang, @target, @evaluate) att.source (@source) att.typed (@type, @subtype) att.written (@hand)

@anchored indicates whether the copy text shows the exact place of reference for the note.

*Status* Optional

*Datatype* teidata.truthValue

*Default* true

*Note* In modern texts, notes are usually anchored by means of explicit footnote or endnote symbols. An explicit indication of the phrase or line annotated may however be used instead (e.g. ‘page 218, lines 3–4’). The *anchored* attribute indicates whether any explicit location is given, whether by symbol or by prose cross-reference. The value true indicates that such an explicit location is indicated in the copy text; the value false indicates that the copy text does not indicate a specific place of attachment for the note. If the specific symbols used in the copy text at the location the note is anchored are to be recorded, use the *n* attribute.

@targetEnd points to the end of the span to which the note is attached, if the note is not embedded in the text at that point.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Note* This attribute is retained for backwards compatibility; it may be removed at a subsequent release of the Guidelines. The recommended way of pointing to a span of elements is by means of the **range** function of XPointer, as further described in 16.2.4.6. *range()*.

*Example* In the following example, the translator has supplied a footnote containing an explanation of the term translated as "painterly":

```
And yet it is not only
in the great line of Italian renaissance art, but even in the
painterly <note place="bottom" type="gloss"
  resp="#MDMH">
  <term xml:lang="de">Malerisch</term>. This word has, in the German, two
distinct meanings, one objective, a quality residing in the object,
the other subjective, a mode of apprehension and creation. To avoid
confusion, they have been distinguished in English as
<mentioned>picturesque</mentioned> and
<mentioned>painterly</mentioned> respectively.
</note> style of the
Dutch genre painters of the seventeenth century that drapery has this
psychological significance.
```

For this example to be valid, the code **MDMH** must be defined elsewhere, for example by means of a responsibility statement in the associated TEI header:

```
<respStmt xml:id="MDMH">
  <resp>translation from German to English</resp>
  <name>Hottinger, Marie Donald Mackie</name>
</respStmt>
```

*Example* The global *n* attribute may be used to supply the symbol or number used to mark the note's point of attachment in the source text, as in the following example:

```
Mevorakh b. Saadya's mother, the matriarch of the
family during the second half of the eleventh century,
<note n="126" anchored="true"> The
alleged mention of Judah Nagid's mother in a letter from 1071 is, in fact, a
reference to
Judah's children; cf. above, nn. 111 and 54. </note> is well known from Geniza
documents
published by Jacob Mann.
```

However, if notes are numbered in sequence and their numbering can be reconstructed automatically by processing software, it may well be considered unnecessary to record the note numbers.

*Content model*

**<num>** (number) contains a number, written in any form. [3.5.3. Numbers and Measures]

*Module* core – Elements Available in All TEI Documents

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.ranging (@atLeast, @atMost, @min, @max, @confidence)

**@type** indicates the type of numeric value.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **cardinal** absolute number, e.g. 21, 21.5

**ordinal** ordinal number, e.g. 21st

**fraction** fraction, e.g. one half or three-quarters

**percentage** a percentage

*Note* If a different typology is desired, other values can be used for this attribute.

**@value** supplies the value of the number in standard form.

*Status* Optional

*Datatype* teidata.numeric

*Values* a numeric value.

*Note* The standard form used is defined by the TEI datatype data.numeric.

*Member of* model.measureLike

---

**<numeric>** (numeric value) represents the value part of a feature-value specification which contains a numeric value or range. [18.3. Other Atomic Feature Values]

Module iso-fs — Feature Structures

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.datcat (@datcat, @valueDatcat)

**@value** supplies a lower bound for the numeric value represented, and also (if *max* is not supplied) its upper bound.

*Status* Required

*Datatype* teidata.numeric

**@max** supplies an upper bound for the numeric value represented.

*Status* Optional

*Datatype* teidata.numeric

**@trunc** specifies whether the value represented should be truncated to give an integer value.

*Status* Optional

*Datatype* teidata.truthValue

*Member of* model.featureVal.single

*Contained by*

*iso-fs:* f fvLib if vAlt vColl vDefault vLabel vMerge vNot vRange

*May contain* Empty element

*Note* It is an error to supply the *max* attribute in the absence of a value for the *value* attribute.

*Example*

```
<numeric value="42" />
```

This represents the numeric value 42.

*Example*

```
<numeric value="42.45" max="50" trunc="true" />
```

This represents any of the nine possible integer values between 42 and 50 inclusive. If the *trunc* attribute had the value FALSE, this example would represent any of the infinite number of numeric values between 42.45 and 50.0

*Content model* `<content></content>`

*Schema Declaration*

```
element numeric
{
  att.global.attributes,

```

**<objectDesc>** contains a description of the physical components making up the object which is being described. [10.7.1. *Object Description*]

*Module* msdescription – Manuscript Description

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@form** a short project-specific name identifying the physical form of the carrier, for example as a codex, roll, fragment, partial leaf, cutting etc.

*Status* Optional

*Datatype* teidata.enumerated

*Note* Definitions for the terms used may typically be provided by a <valList> element in the project schema specification.

*Member of* model.physDescPart

*Contained by*

*msdescription:* physDesc

*May contain*

*core:* p

*linking:* ab

*msdescription:* layoutDesc supportDesc

*Example*

```
<objectDesc form="codex">
  <supportDesc material="mixed">
    <p>Early modern
    <material>parchment</material> and

**<oRef>** (orthographic-form reference) in a dictionary example, indicates a reference to the orthographic form(s) of the headword. [9.4. Headword and Pronunciation References]

Module dictionaries – Dictionaries

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.lexicographic (@expand, @norm, @split, @value, @orig, @location, @mergedIn, @opt)

(att.datcat (@datcat, @valueDatcat)) att.pointing (@targetLang, @target, @evaluate) att.notated (@notation)

@type indicates the kind of typographic modification made to the headword in the reference.

Status Optional

Datatype teidata.enumerated

Sample values include: cap (capital) indicates first letter is given as capital

noHyph (no hyphen) indicates that the headword, though a prefix or suffix, loses its hyphen

**<org>** (organization) provides information about an identifiable organization such as a business, a tribe, or any other grouping of people. [13.2.2. Organizational Names]

*Module* namesdates — Names, Dates, People, and Places

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.typed (@type, @subtype) att.editLike (@evidence, @instant) (att.dimensions (@unit, @quantity, @extent, @precision, @scope) (att.ranging (@atLeast, @atMost, @min, @max, @confidence)) (att.source (@source)) att.sortable (@sortKey))

**@role** specifies a primary role or classification for the organization.

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.word separated by whitespace

*Note* Values for this attribute may be locally defined by a project, using arbitrary keywords such as artist, employer, family group, or political party, each of which should be associated with a definition. Such local definitions will typically be provided by a <valList> element in the project schema specification.

```

**<outputRendition>** describes the rendering or appearance intended for all occurrences of an element in a specified context for a specified type of output.

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@SCOPE** provides a way of defining ‘pseudo-elements’, that is, styling rules applicable to specific sub-portions of an element.

*Status* Optional

*Datatype*

*Sample values include:* **first-line** styling applies to the first line of the target element.

**first-letter** styling applies to the first character of the target element.

**before** styling should be applied immediately before the content of the target element.

**after** styling should be applied immediately after the content of the target element.

*May contain* Character data only

*Note* This component of an element specification describes the rendering or appearance intended for all occurrences of the element in a specified context for a specified type of output. The <rendition> element, by contrast, describes the actual rendering or appearance of all occurrences of the specified element in a source document. The *useSourceRendition* attribute may however be used to indicate that formatting information provided by a <rendition> element is to be combined with any provided by an <outputRendition> element. It is strongly recommended that the W3C Cascading Stylesheet language (CSS2 or later) be used to express the required formatting information.

*Example*

```
<model predicate="ancestor::p"
  behaviour="inline">
  <outputRendition>font-style: italic;</outputRendition>
</model>
```

```
<model behaviour="block">
  <outputRendition>left-margin: 2em;</outputRendition>
</model>
```

Content model `<content> <textNode/></content>`

Schema Declaration

```
element outputRendition
{

  att.global.responsibility.attributes,
  att.declaring.attributes,
  att.fragmentable.attributes,
```

att.written.attributes,  
macro.paraContent}

**<param>** provides a parameter for a model behaviour by supplying its name and an XPath expression identifying the location of its content. [22.5.5.5. Behaviours and their parameters]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@name** a name for the parameter being supplied

*Status* Required

*Datatype* teidata.xpath

*Suggested values include:* **alternate** when used with behaviour **alternate**, a parameter of this name supplies one of the pair of possible values; for example the regularized form rather than the original form within a <choice> element.

**default** when used with behaviour **alternate**, a parameter of this name supplies one of the pair of possible values; for example the original form rather than the regularized form within a <choice> element.

**height** when used with behaviour **graphic**, a parameter of this name supplies a value for the height of the graphic e.g. "300px", "50%".

**id** a parameter of this name should supply a unique identifier for the element being processed; as for example with the **anchor** behaviour

**label** a parameter of this name should supply an expression to be used to label something, for example `concat('Page ', @n)` for a page break or `@n` for a footnote reference; typically used with the **note** or **break** behaviours

**level** when used with the **heading** behaviour, a parameter of this name supplies a positive integer indicating the hierarchic level of a heading.

**link** when used with the **link** behaviour, a parameter of this name should supply a URL to be used as the target of a link.

**place** when used with the **note** behaviour, a parameter of this name should provide a string which describes the intended placement of some text; typical values include "margin", "footnote", "endnote", "inline", "bottom"

**type** a parameter of this name can be used to categorize the specified behaviour in any way; for example the kind of break (when used with the **break** behaviour) or the kind of index to be generated (if used with the **index** behaviour) etc.

**url** when used with behaviour **graphic**, a parameter of this name supplies a URL indicating the graphic intended.

**width** when used with behaviour **graphic**, a parameter of this name supplies a value for the width of the graphic e.g. "400px", "70%".

**@value** supplies an XPath expression which when evaluated provides the value for the parameter

*Status* Required

*Datatype* teidata.xpath

*Content type:* model

*May contain* Empty element

*Note* An implementation may require parameters other than those listed here, and is not required to follow this partial specification. The names and datatypes of the expected parameters should be documented in the

corresponding customization using a <paramSpec> element. Literal strings provided in an XPath expression should be quoted.

*Example* In this example, which will be processed for a <choice> element which has both <sic> and <corr> child elements, the **default** parameter will provide the value of the child <corr> element, and the **alternate** parameter will provide that of the child <sic> elements. If neither <param> element was supplied, both elements would still be available to an application, but the application would need to distinguish them for itself.

```
<elementSpec ident="choice">
  <model predicate="sic and corr"
    behaviour="alternate">
    <param name="default" value="corr"/>
    <param name="alternate" value="sic"/>
  </model>
</elementSpec>
```

*Example*

```
<elementSpec ident="graphic" mode="change">
  <model behaviour="graphic">
    <param name="url" value="@url"/>
    <param name="width" value="@width"/>
    <param name="width" value="@height"/>
  </model>
</elementSpec>
```

<paramList> list of parameter specifications

Module tagdocs – Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

Contained by

tagdocs: valItem

May contain

tagdocs: paramSpec

Note The <paramList> element provides a mechanism to document parameter specifications using child <paramSpec> elements.

Example

```
<valItem ident="alternate">
  <desc versionDate="2015-08-21"
    xml:lang="en">create a specialized display of alternating elements for
    displaying the preferred version and an alternative, both at once or by some
    method of toggling between the two.</desc>
  <paramList>
    <paramSpec ident="default">
      <desc>preferred content</desc>
    </paramSpec>
    <paramSpec ident="alternate">
      <desc>alternate content</desc>
    </paramSpec>
  </paramList>
</valItem>
```

Content model

```
<content>
  <elementRef minOccurs="0"
    maxOccurs="unbounded" key="paramSpec"/>
</content>
```

Schema Declaration

```
element paramList
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  paramSpec*
}
```

<paramSpec> supplies specification for one parameter of a model behaviour [22.5.5.8. Defining a processing model]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.identified (@ident, @predeclare, @module) (att.combinable (@mode) (att.deprecated (@validUntil)))

*Contained by*

*tagdocs:* paramList

*May contain*

*core:* desc gloss

*tagdocs:* altIdent equiv

*Note* Where a model behaviour uses more than one parameter, individual <paramSpec> elements should be grouped together using a <paramList> element, as above. Parameter specifications are provided within the <valItem> used to define a particular behaviour, which forms part of the specification of a <model> element's *behaviour* attribute. In the example above, the behaviour `link` has two parameters: `content` and `link`. Using a <desc> attribute within a <paramSpec> is optional but recommended practice.

*Example*

```
<valItem ident="link">
  <desc>create a hyperlink</desc>
  <paramList>
    <paramSpec ident="content">
      <desc>supplies the location of some content describing the link</desc>
    </paramSpec>
    <paramSpec ident="link">
      <desc>supplies the location of the intended URL</desc>
    </paramSpec>
  </paramList>
</valItem>
```

*Content model*

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <classRef key="model.glossLike"/>
    <classRef key="model.descLike"/>
  </alternate>
</content>
```

*Schema Declaration*

```
element paramSpec
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.identified.attributes,
  att.combinable.attributes,
  att.deprecated.attributes,
```

```
( model.glossLike | model.descLike )*
}
```

**<particDesc>** (participation description) describes the identifiable speakers, voices, or other participants in any kind of text or other persons named or otherwise referred to in a text, edition, or metadata. [15.2. Contextual Information]

*Module* corpus – Language Corpora

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.declarable (@default)

*Member of* model.profileDescPart

*Contained by*

*header:* profileDesc

*May contain*

*core:* p

*linking:* ab

*namesdates:* listOrg listPerson org person personGrp

*Note* May contain a prose description organized as paragraphs, or a structured list of persons and person groups, with an optional formal specification of any relationships amongst them.

*Example*

```
<particDesc>
  <listPerson>
    <person xml:id="P-1234" sex="2" age="mid">
      <p>Female informant, well-educated, born in
        Shropshire UK, 12 Jan 1950, of unknown occupation. Speaks French
        fluently.
          Socio-Economic status B2.</p>
    </person>
    <person xml:id="P-4332" sex="1">
      <persName>
        <surname>Hancock</surname>
        <forename>Antony</forename>
        <forename>Aloysius</forename>
        <forename>St John</forename>
      </persName>
      <residence notAfter="1959">
        <address>
          <street>Railway Cuttings</street>
          <settlement>East Cheam</settlement>
        </address>
      </residence>
      <occupation>comedian</occupation>
    </person>
    <listRelation>
      <relation type="personal" name="spouse"
        mutual="#P-1234 #P-4332"/>
    </listRelation>
  </listPerson>
</particDesc>
```

This example shows both a very simple person description, and a very detailed one, using some of the more specialized elements from the module for Names and Dates.

*Content model*

May contain Empty element

*Note* A <pb> element should appear at the start of the page which it identifies. The global *n* attribute indicates the number or other value associated with this page. This will normally be the page number or signature printed on it, since the physical sequence number is implicit in the presence of the <pb> element itself. The *type* attribute may be used to characterize the page break in any respect, for example as word-breaking or not.

*Example* Page numbers may vary in different editions of a text.

```
<p> ... <pb n="145" ed="ed2"/>
<!-- Page 145 in edition "ed2" starts here --> ... <pb n="283" ed="ed1"/>
<!-- Page 283 in edition "ed1" starts here--> ... </p>
```

*Example* A page break may be associated with a facsimile image of the page it introduces by means of the *fac* attribute

```

<body>
  <pb n="1" facs="page1.png"/>
  <!-- page1.png contains an image of the page;
  the text it contains is encoded here -->
  <p>
  <!-- ... -->
  </p>
  <pb n="2" facs="page2.png"/>
  <!-- similarly, for page 2 -->
  <p>
  <!-- ... -->
  </p>
</body>

```

Content model `<content></content>`

Schema Declaration

**<pc>** (punctuation character) contains a character or string of characters regarded as constituting a single punctuation mark. [17.1. Linguistic Segment Categories]

Module analysis – Simple Analytic Mechanisms

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.segLike (@function) (att.metrical (@met, @real, @rhyme)) (att.datcat (@datcat, @valueDatcat)) (att.fragmentable (@part)) att.typed (@type, @subtype)

@force indicates the extent to which this punctuation mark conventionally separates words or phrases

Status Optional

Datatype teidata.enumerated

Legal values are: **strong** the punctuation mark is a word separator

**weak** the punctuation mark is not a word separator

**inter** the punctuation mark may or may not be a word separator

@unit provides a name for the kind of unit delimited by this punctuation mark.

Status Optional

Datatype teidata.enumerated

@pre indicates whether this punctuation mark precedes or follows the unit it delimits.

**<person>** provides information about an identifiable individual, for example a participant in a language interaction, or a person referred to in a historical source. [13.3.2. *The Person Element* 15.2.2. *The Participant Description*]

*Module* namesdates – Names, Dates, People, and Places

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.editLike (@evidence, @instant) (att.dimensions (@unit, @quantity, @extent, @precision, @scope) (att.ranging (@atLeast, @atMost, @min, @max, @confidence)) ) (att.source (@source)) att.sortable (@sortKey)

**@role** specifies a primary role or classification for the person.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.enumerated separated by whitespace

*Note* Values for this attribute may be locally defined by a project, using arbitrary keywords such as artist, employer, author, relative, or servant, each of which should be associated with a definition. Such local definitions will typically be provided by a <valList> element in the project schema specification.

**@sex** specifies the sex of the person.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.sex separated by whitespace

*Note* Values for this attribute may be locally defined by a project, or may refer to an external standard, such as vCard's sex property <http://microformats.org/wiki/gender-formats> (in which M indicates male, F female, O other, N none or not applicable, U unknown), or the often used ISO 5218:2004 *Representation of Human Sexes* [http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266\\_ISO\\_IEC\\_5218\\_2004\(E\\_F\).zip](http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266_ISO_IEC_5218_2004(E_F).zip) (in which 0 indicates unknown; 1 male; 2 female; and 9 not applicable, although the ISO standard is widely considered inadequate); cf. CETH's *Recommendations for Inclusive Data Collection of Trans People* <http://transhealth.ucsf.edu/trans?page=lib-data-collection>.

**@age** specifies an age group for the person.

*Status* Optional

*Datatype* teidata.enumerated

*Note* Values for this attribute may be locally defined by a project, using arbitrary keywords such as infant, child, teen, adult, or senior, each of which should be associated with a definition. Such local definitions will typically be provided by a <valList> element in the project schema specification.

```

**<personGrp>** (personal group) describes a group of individuals treated as a single person for analytic purposes. [15.2.2. The Participant Description]

*Module* namesdates – Names, Dates, People, and Places

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.sortable (@sortKey)

**@role** specifies the role of this group of participants in the interaction.

*Status* Optional

*Datatype* teidata.enumerated

*Note* Values for this attribute may be locally defined by a project, using arbitrary keywords such as movement, employers, relatives, or servants, each of which should be associated with a definition. Such local definitions will typically be provided by a <valList> element in the project schema specification.

**@SEX** specifies the sex of the participant group.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.sex separated by whitespace

*Note* Values for this attribute may be locally defined by a project, or may refer to an external standard, such as vCard's sex property <http://microformats.org/wiki/gender-formats> (in which M indicates male, F female, O other, N none or not applicable, U unknown), or the often used ISO 5218:2004 *Representation of Human Sexes* [http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266\\_ISO\\_IEC\\_5218\\_2004\(E\\_F\).zip](http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266_ISO_IEC_5218_2004(E_F).zip) (in which 0 indicates unknown; 1 male; 2 female; and 9 not applicable, although the ISO standard is widely considered inadequate); cf. CETH's *Recommendations for Inclusive Data Collection of Trans People* <http://transhealth.ucsf.edu/trans?page=lib-data-collection>. For a mixed group, a value such as "mixed" may also be supplied.

**@age** specifies the age group of the participants.

*Status* Optional

*Datatype* teidata.enumerated

*Note* Values for this attribute may be locally defined by a project, using arbitrary keywords such as infant, child, teen, adult, or senior, each of which should be associated with a definition. Such local definitions will typically be provided by a <valList> element in the project schema specification.

**@Size** describes informally the size or approximate size of the group for example by means of a number and an indication of accuracy e.g. approx 200.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.word separated by whitespace

*Member of* model.personLike

*Contained by*

*corpus:* particDesc

*namesdates:* listPerson org

*May contain*

*Module* header – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.patternReplacement (@matchPattern, @replacementPattern)

**@ident** supplies a name which functions as the prefix for an abbreviated pointing scheme such as a private URI scheme. The prefix constitutes the text preceding the first colon.

*Status* Required

*Datatype* teidata.name

*Content model:* listPrefixDef

*May contain*

*core:* p

*linking:* ab

*Note* The abbreviated pointer may be dereferenced to produce either an absolute or a relative URI reference. In the latter case it is combined with the value of *xml:base* in force at the place where the pointing attribute occurs to form an absolute URI in the usual manner as prescribed by XML Base.

*Example*

```
<prefixDef ident="ref"
  matchPattern="[a-z]+"
  replacementPattern="../../references/references.xml#$1">
  <p> In the context of this project, private URIs with
    the prefix "ref" point to <gi>div</gi> elements in
    the project's global references.xml file.
  </p>
</prefixDef>
```

*Content model*

```
<content>
  <classRef key="model.pLike" minOccurs="0"
    maxOccurs="unbounded"/>
</content>
```

*Schema Declaration*

```
element prefixDef
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.patternReplacement.attributes,
  attribute ident { text },
  model.pLike*
}
```

---

**<preparedness>** describes the extent to which a text may be regarded as prepared or spontaneous. [15.2.1. The Text Description]

*Module* corpus – Language Corpora

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@type** a keyword characterizing the type of preparedness.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* none spontaneous or unprepared

**scripted** follows a script  
**formulaic** follows a predefined set of conventions  
**revised** polished or revised before presentation

*Member of* model.textDescPart

```

**<profileDesc>** (text-profile description) provides a detailed description of non-bibliographic aspects of a text, specifically the languages and sublanguages used, the situation in which it was produced, the participants and their setting. [2.4. The Profile Description 2.1.1. The TEI Header and Its Components]

*Module header* — The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

*Member of* model.teiHeaderPart

*Contained by*

*header:* teiHeader

*May contain*

*corpus:* particDesc settingDesc textDesc

*header:* abstract calendarDesc correspDesc creation langUsage textClass

*transcr:* handNotes listTranspose

*Note* Although the content model permits it, it is rarely meaningful to supply multiple occurrences for any of the child elements of <profileDesc> unless these are documenting multiple texts. In earlier versions of these Guidelines, it was required that the <creation> element appear first.

*Example*

```
<profileDesc>
  <langUsage>
    <language ident="fr">French</language>
  </langUsage>
  <textDesc n="novel">
    <channel mode="w">print; part issues</channel>
    <constitution type="single"/>
    <derivation type="original"/>
    <domain type="art"/>
    <factuality type="fiction"/>
    <interaction type="none"/>
    <preparedness type="prepared"/>
    <purpose type="entertain" degree="high"/>
    <purpose type="inform" degree="medium"/>
  </textDesc>
  <settingDesc>
    <setting>
      <name>Paris, France</name>
      <time>Late 19th century</time>
    </setting>
  </settingDesc>
</profileDesc>
```

*Content model*

```

**<publicationStmt>** (publication statement) groups information concerning the publication or distribution of an electronic or other text. [2.2.4. *Publication, Distribution, Licensing, etc.* 2.2. *The File Description*]

*Module header* – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

*Contained by*

*header:* biblFull fileDesc

*May contain*

*core:* address date p pubPlace publisher

*header:* authority availability distributor idno

*linking:* ab

*Note* Where a publication statement contains several members of the model.publicationStmtPart classes rather than one or more paragraphs or anonymous blocks, care should be taken to ensure that the repeated elements are presented in a meaningful order. It is a conformance requirement that elements supplying information about publication place, address, identifier, availability, and date be given following the name of the publisher, distributor, or authority concerned, and preferably in that order.

*Example*

```
<publicationStmt>
  <publisher>C. Muquardt </publisher>
  <pubPlace>Bruxelles & Leipzig</pubPlace>
```

```
<date when="1846"/>
</publicationStmt>
```

*Example*

```
<publicationStmt>
  <publisher>Chadwyck Healey</publisher>
  <pubPlace>Cambridge</pubPlace>
  <availability>
    <p>Available under licence only</p>
  </availability>
  <date when="1992">1992</date>
</publicationStmt>
```

*Content model*

```
<content>
  <alternate>

```

---

**<purpose>** characterizes a single purpose or communicative function of the text. [15.2.1. *The Text Description*]

*Module* corpus – Language Corpora

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@type** specifies a particular kind of purpose.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **persuade** didactic, advertising, propaganda, etc.

**express** self expression, confessional, etc.

**inform** convey information, educate, etc.

**entertain** amuse, entertain, etc.

**@degree** specifies the extent to which this purpose predominates.

*Status* Optional

*Datatype* teidata.certainty

*Note* Values should be interpreted as follows.

**high** this purpose is predominant

**medium** this purpose is intermediate

**low** this purpose is weak

**unknown** extent unknown

*Contained by:* textDesc

*May contain*

*verse:* caesura rhyme

*Note* May contain character data mixed with any other elements defined in the dictionary tag set. Identical in sub-elements to an <entry> tag, and used where a dictionary has embedded information inside one entry which could have formed a separate entry. Some authorities distinguish related entries, run-on entries, and various other types of degenerate entries; no such typology is attempted here.

*Example* The following example from *Webster's New Collegiate Dictionary* (Springfield, Mass.: G. & C. Merriam Company, 1975) shows a single related entry for which no definition is given, since its meaning is held to be readily derivable from the root entry:

```

<entry>
  <form>
    <orth>neu·ral</orth>
    <pron>'n(y)ūr-əl</pron>
  </form>
  <gramGrp>
    <pos>adj</pos>
  </gramGrp>
  <sense n="1">
    <def>of, relating to, or affecting a nerve or the nervous system</def>
  </sense>
  <sense n="2"> ... </sense>
  <re>
    <form>
      <orth>neurally</orth>
      <pron extent="suffix">-ə-lē</pron>
    </form>
    <gramGrp>
      <pos>adv</pos>
    </gramGrp>
  </re>
</entry>
  
```

*Example* The following example from *Diccionario de la Universidad de Chicago Inglés-Español y Español-Inglés / The University of Chicago Spanish Dictionary, Fourth Edition, compiled by Carlos Castillo and Otto F. Bond* (Chicago: University of Chicago Press, 1987) shows a number of related entries embedded in the main entry. The original entry resembles the following:

**abeja** [a·bé·xa]f. bee;**abejera** [a·be·xé·ra]f. beehive;**abejón** [a·be·xóon]m. drone;  
 bumblebee;**abejorro** [a·be·xó·rro]m. bumble bee.

One encoding for this entry would be:

```

<entry>
  <form>
    <orth>abeja</orth>
  </form>
  <gramGrp>
    <gen>f. </gen>
  </gramGrp>
  <sense n="1.">
    <usg type="domain"> (ento.) </usg>
    <def> bee </def>. </sense>
  <sense n="2.">
    <def> busy bee, hard worker </def>. </sense>
  <sense n="3.">
    <usg orig="A." type="domain"> (astron.) </usg>, <def> Musca </def> –
  </sense>
  <re>
    <form>
      <orth orig="a. albanila"> abeja albanila </orth>, </form>
      <sense>
        <def>mason bee</def>;</sense>
    </re>
    <re>
      <form>
        <orth orig="a. carpintera"> abeja carpintera </orth>, </form>
        <sense>
          <def>carpenter bee </def>;</sense>
        </re>
      <re>
        <form>
          <orth xml:id="re-o3"
            orig="a. reina or maestra"> abeja reina </orth>
          <orth mergedIn="#re-o4"> abeja maestra </orth>
        </form>
        <sense>
          <def> queen bee </def>;</sense>
        </re>
      <re>
        <form>
          <orth xml:id="re-o4"
            orig="a. neutra or obrera"> abeja neutra </orth>
          <orth mergedIn="#re-o3"> abeja obrera </orth>
        </form>
        <sense>
          <def>worker bee</def>.</sense>
        </re>
      </entry>

```

*Example* In the much larger Simon & Schuster Spanish-English dictionary (*Tana de Gámez, ed., Simon and Schuster's International Dictionary* (New York: Simon and Schuster, 1973).) these derived forms of *abeja* are treated as separate main entries, but there are other embedded phrases shown as <re>s in its main entry for *abeja*:

abeja, f. 1. (ento.) bee. 2. busy bee, hard worker. 3. (astron.) A., Musca. — a. albanila, mason bee; a. carpintera, carpenter bee; a. reina or maestra, queen bee; a. neutra or obrera, worker bee.

This entry may be encoded thus:

```

<entry>
  <form>
    <orth>abeja</orth>
  </form>
  <gramGrp>
    <gen>f.</gen>
  </gramGrp>
  <sense n="1.">
    <usg type="domain">(ento.)</usg>
    <def>bee</def>. </sense>
  <sense n="2.">
    <def>busy bee, hard worker</def>. </sense>
  <sense n="3.">
    <usg orig="A." type="domain">(astron.)</usg>, <def>Musca</def> – </sense>
  <re>
    <form>
      <orth orig="a. albanila">abeja albanila</orth>, </form>
    <sense>
      <def>mason bee</def>; </sense>
  </re>
  <re>
    <form>
      <orth orig="a. carpintera">abeja carpintera</orth>, </form>
    <sense>
      <def>carpenter bee</def>; </sense>
  </re>
  <re>
    <form>
      <orth xml:id="re-o1"
        orig="a. reina or maestra">abeja reina</orth>
      <orth mergedIn="#re-o1">abeja maestra</orth>
    </form>
    <sense>
      <def>queen bee</def>; </sense>
  </re>
  <re>
    <form>
      <orth xml:id="re-o2"
        orig="a. neutra or obrera">abeja neutra</orth>
      <orth mergedIn="#re-o2">abeja obrera</orth>
    </form>
    <sense>
      <def>worker bee</def>. </sense>
  </re>
</entry>

*Example*

```
<line>
  <redo hand="#g_t" target="#redo-1"
    cause="fix"/>
  <mod xml:id="redo-1" rend="strikethrough"
    spanTo="#anchor-1" hand="#g_bl"/>Ihr hagren, triften,
krummgezog<mod rend="strikethrough">nen</mod>ener Nacken
</line>
<line>Wenn ihr nur piepfet ift die Welt fchon matt.<anchor xml:id="anchor-1"/>
</line>
```

This encoding represents the following sequence of events:

- "Ihr hagren, tristen, krummgezog nenener Nacken/ Wenn ihr nur piepset ist die Welt schon matt." is written
- the redundant letters "nen" in "nenener" are deleted
- the whole passage is deleted by hand **g\_bl** using **strikethrough**
- the deletion is reasserted by another hand (identified here as **g\_t**)

*Example*

```
See especially <ref target="http://www.natcorp.ox.ac.uk/Texts/A02.xml#s2">the
second
sentence</ref>
```

*Example*

```
See also <ref target="#locution">s.v. <term>locution</term>
</ref>.
```

*Schematron* <s:report test="@target and @cRef">Only one of the attributes '@target' and '@cRef' may be supplied on <s:name/> </s:report>

*Content model*

```
<content>
  <macroRef key="macro.paraContent" />
</content>
```

*Schema Declaration*

```
element ref
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.pointing.attributes,
  att.internetMedia.attributes,
  att.typed.attributes,
  att.declaring.attributes,
  att.cReferencing.attributes,
  macro.paraContent}
```

<refsDecl> (references declaration) specifies how canonical references are constructed for this text. [2.3.6.3.

Milestone Method 2.3. The Encoding Description 2.3.6. The Reference System Declaration]

Module header – The TEI Header

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.declarable (@default)

Member of model.encodingDescPart

Contained by

header: encodingDesc

May contain

core: p

header: cRefPattern refState

linking: ab

Example

```
<refsDecl>
  <cRefPattern matchPattern="([A-Za-z0-9]+) ([0-9]+):([0-9]+)"
    replacementPattern="#xpath(//body/div[@n='$1']/div[$2]/div3[$3])"/>
</refsDecl>
```

This example is a formal representation for the referencing scheme described informally in the following example.

Example

```
<refsDecl>
  <p>References are made up by concatenating the value for the
  <att>n</att> attribute on the highest level <gi>div</gi>
  element, followed by a space, followed by the sequential
  number of the next level <gi>div</gi> followed by a colon
  followed by the sequential number of the next (and lowest)
  level <gi>div</gi>.</p>
</refsDecl>
```

Content model

```
<content>
  <alternate>
    <classRef key="model.pLike" minOccurs="1"
      maxOccurs="unbounded"/>
    <elementRef key="cRefPattern"
      minOccurs="1" maxOccurs="unbounded"/>
    <elementRef key="refState" minOccurs="1"
      maxOccurs="unbounded"/>
  </alternate>
</content>
```

Schema Declaration

```
element refsDecl
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
```

```

att.global.facs.attributes,
att.global.change.attributes,
att.global.responsibility.attributes,
att.declarable.attributes,
( model.pLike+ | cRefPattern+ | refState+ )
}

```

**<refState>** (reference state) specifies one component of a canonical reference defined by the milestone method.  
 [2.3.6.3. Milestone Method 2.3.6. The Reference System Declaration]

*Module header* – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.milestoneUnit (@unit) att.edition (@ed, @edRef)

**@length** specifies the fixed length of the reference component.

*Status* Optional

*Datatype* teidata.count

*Note* When constructing a reference, if the reference component found is of numeric type, the length is made up by inserting leading zeros; if it is not, by inserting trailing blanks. In either case, reference components are truncated if necessary at the right hand side. When seeking a reference, the length indicates the number of characters which should be compared. Values longer than this will be regarded as matching, if they start correctly. If no value is provided, the length is unlimited and goes to the next delimiter or to the end of the value.

**@delim** (delimiter) supplies a delimiting string following the reference component.

*Status* Optional

*Datatype* teidata.text

*Content model*: refsDecl

*May contain* Empty element

*Example*

```

<refState unit="book" delim=":"/>
<refState unit="line" length="4"/>

```

*Content model* <content></content>

*Schema Declaration*

```

element refState
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.milestoneUnit.attributes,
  att.edition.attributes,
  attribute length { text }?,
  attribute delim { text }?,
}

```

|            |

  att.global.responsibility.attributes,
  att.typed.attributes,
  attribute target { text }?,
  ( model.biblLike | model.ptrLike )?
}

```

**<relation>** (relationship) describes any kind of relationship or linkage amongst a specified group of places, events, persons, objects or other items. [13.3.2.3. *Personal Relationships*]

*Module* namesdates — Names, Dates, People, and Places

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.dateable (@calendar, @period) (att.dateable.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.dateable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.dateable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod)) att.editLike (@evidence, @instant) (att.dimensions (@unit, @quantity, @extent, @precision, @scope) (att.ranging (@atLeast, @atMost, @min, @max, @confidence))) (att.source (@source)) att.canonical (@key, @ref) att.sortable (@sortKey) att.typed (@type, @subtype)

@name supplies a name for the kind of relationship of which this is an instance.

*Status* Optional

- Datatype* teidata.enumerated
- @active** identifies the 'active' participants in a non-mutual relationship, or all the participants in a mutual one.  
*Status* Optional  
*Datatype* 1-∞ occurrences of teidata.pointer separated by whitespace
- @mutual** supplies a list of participants amongst all of whom the relationship holds equally.  
*Status* Optional  
*Datatype* 1-∞ occurrences of teidata.pointer separated by whitespace
- @passive** identifies the 'passive' participants in a non-mutual relationship.  
*Status* Optional  
*Datatype* 1-∞ occurrences of teidata.pointer separated by whitespace

*Contained by* listBibl

*namespaces:* listEvent listNym listOrg listPerson listPlace listRelation

*May contain*

*core:* desc

*Note* Only one of the attributes *active* and *mutual* may be supplied; the attribute *passive* may be supplied only if the attribute *active* is supplied. Not all of these constraints can be enforced in all schema languages.

*Example*

```
<relation type="social" name="supervisor"
  active="#p1" passive="#p2 #p3 #p4"/>
```

This indicates that the person with identifier p1 is supervisor of persons p2, p3, and p4.

*Example*

```
<relation type="personal" name="friends"
  mutual="#p2 #p3 #p4"/>
```

This indicates that p2, p3, and p4 are all friends.

*Example*

```
<relation type="CRM"
  name="P89_falls_within"
  active="http://id.clarosnet.org/places/metamorphoses/place/italy-orvieto"
  passive="http://id.clarosnet.org/places/metamorphoses/country/IT"/>
```

This indicates that there is a relation, defined by CIDOC CRM, between two resources identified by URLs.

*Example*

```
<relation resp="http://viaf.org/viaf/44335536/"
  ref="http://purl.org/saws/ontology#isVariantOf"
  active="http://www.ancientwisdoms.ac.uk/cts/
urn:cts:greekLit:tlg3017.Syno298.sawsGrc01:divedition.divsection1.o14.a107"
  passive="http://data.perseus.org/citations/
urn:cts:greekLit:tlg0031.tlg002.perseus-grc1:9.35"/>
```

This example records a relationship, defined by the SAWS ontology, between a passage of text identified by a CTS URN, and a variant passage of text in the Perseus Digital Library, and assigns the identification of the relationship to a particular editor (all using resolvable URIs).

*Schematron* <s:assert test="@ref or @key or @name">One of the attributes 'name', 'ref' or 'key' must be supplied</s:assert>

*Schematron* <s:report test="@active and @mutual">Only one of the attributes @active and @mutual may be supplied</s:report>

*Schematron* <s:report test="@passive and not(@active)">the attribute 'passive' may be supplied only if the attribute 'active' is supplied</s:report>

*Content model*

```
<content>
  <elementRef key="desc" minOccurs="0"/>
</content>
```

*Schema Declaration*

```

**<rendition>** supplies information about the rendition or appearance of one or more elements in the source text. [2.3.4. The Tagging Declaration]

*Module header* – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.styleDef (@scheme, @schemeVersion)

**@scope** where CSS is used, provides a way of defining ‘pseudo-elements’, that is, styling rules applicable to specific sub-portions of an element.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **first-line** styling applies to the first line of the target element

**first-letter** styling applies to the first letter of the target element

**before** styling should be applied immediately before the content of the target element

**after** styling should be applied immediately after the content of the target element

**@selector** contains a selector or series of selectors specifying the elements to which the contained style description applies, expressed in the language specified in the *scheme* attribute.

*Status* Optional

*Datatype* teidata.text

```
<rendition scheme="css"
  selector="text, front, back, body, div, p, ab">
```

```

display: block;
</rendition>
<rendition scheme="css"
  selector="*[rend*=italic]"> font-style: italic;
</rendition>

```

*Note* Since the default value of the *scheme* attribute is assumed to be CSS, the default expectation for this attribute, in the absence of *scheme*, is that CSS selector syntax will be used.

*Note* While *rendition* is used to point from an element in the transcribed source to a <rendition> element in the header which describes how it appears, the *selector* attribute allows the encoder to point in the other direction: from a <rendition> in the header to a collection of elements which all share the same renditional features. In both cases, the intention is to record the appearance of the source text, not to prescribe any particular output rendering.

*certainty:* certainty precision respons

*core:* desc

*Note* The <respons> element is designed for cases in which fine-grained information about specific aspects of the markup of a text is desirable for whatever reason. Global responsibility for certain aspects of markup is usually more simply indicated in the TEI header, using the <respStmnt> element within the title statement, edition statement, or change log.

*Example*

```
<respons target="#p1" locus="name location"
  resp="#encoder1"/>
<respons target="#p2" match="@rend"
  locus="value" resp="#encoder2"/>
<list type="encoders">
  <item xml:id="encoder1"/>
  <item xml:id="encoder2"/>
</list>
```

*Example* In this (partially fictional) example the entire document was transcribed and encoded by a single encoder, except for one passage which was transcribed and encoded by the proofreader.

```
<!-- in the <teiHeader>: --><respStmnt xml:id="enc01">
  <name>C. Colin Backslash</name>
  <resp>transcription</resp>
  <resp>encoding</resp>
</respStmnt>
<respStmnt xml:id="prf01">
  <name>Erin Spelling</name>
  <resp>proofreading</resp>
</respStmnt>
<!-- in the <text>: -->
<p>θερινή τροπή
<lb/>
  <foreign xml:lang="heb" xml:id="mp0a8"> □
  <supplied reason="undefined">□□</supplied>
  <unclear/>□<unclear>
    □ □□□
  </foreign>
</p>
<!-- elsewhere: -->
<respons target="#mp0a8" locus="name value"
  resp="#prf01"/>
```

*Example* In this (partially fictional) example an initial encoder ('across.dta') encoded most of the document; a later encoder ('rcapolung.ewo') encoded a particular passage; and a third encoder ('sbauman.emt') fixed some of that encoding.

```
<!-- in the <teiHeader>: --><respStmnt xml:id="enc03">
  <persName ref="../../../contextual/persons.xml#across.dta"/>
  <resp>encoding</resp>
```

```

</respStmt>
<!-- in the <text>: -->

*verse*: caesura rhyme  
*Note* Multiple retraces are indicated by nesting one <retrace> within another. In principle, a retrace differs from a substitution in that second and subsequent rewrites do not materially alter the content of an element. Where minor changes have been made during the retracing action however these may be marked up using <del>, <add>, etc. with an appropriate value for the *change* attribute.

### Content model

**<revisionDesc>** (revision description) summarizes the revision history for a file. [2.6. *The Revision Description* 2.1.1. *The TEI Header and Its Components*]

*Module header* – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.docStatus (@status)

*Contained by*

*header:* teiHeader

*May contain*

*core:* list

*header:* change listChange

*Note* If present on this element, the *status* attribute should indicate the current status of the document. The same attribute may appear on any <change> to record the status at the time of that change. Conventionally change elements should be given in reverse date order, with the most recent change at the start of the list.

*Example*

```

<revisionDesc status="embargoed">
  <change when="1991-11-11" who="#LB"> deleted chapter 10 </change>
</revisionDesc>

```

*Content model*

```

<content>
  <alternate>
    <elementRef key="list"/>
    <elementRef key="listChange"/>
    <elementRef key="change" minOccurs="1"
      maxOccurs="unbounded"/>
  </alternate>
</content>

```

*Schema Declaration*

```

element revisionDesc
{

```

att.global.linking.attributes,
att.global.analytic.attributes,
att.global.facs.attributes,
att.global.change.attributes,
att.global.responsibility.attributes,
att.docStatus.attributes,
( list | listChange | change+ )
}

```

**<rhyme>** marks the rhyming part of a metrical line. [6.5. *Rhyme*]

*Module* verse – Verse

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.typed (@type, @subtype)

**@label** provides a label (usually a single letter) to identify which part of a rhyme scheme this rhyming string instantiates.

*Status* Recommended

*Datatype* teidata.word

*Note* Within a particular scope, all <rhyme> elements with the same value for their *label* attribute are assumed to rhyme with each other. The scope is defined by the nearest ancestor element for which the *rhyme* attribute has been supplied.

  att.typed.attributes,
  macro.phraseSeq}
```

---

**<root>** (root node) represents the root node of a tree. [19.2. Trees]

*Module* nets – Graphs, Networks, and Trees

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@value** identifies the root node of the network by pointing to a feature structure or other analytic element.

*Status* Optional

*Datatype* teidata.pointer

**@children** identifies the elements which are the children of the root node.

*Status* Required

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Note* If the root has no children (i.e., the tree is ‘trivial’), then the *children* attribute should be omitted.

**@ord** (ordered) indicates whether or not the root is ordered.

*Status* Optional

*Datatype* teidata.xTruthValue

*Note* The value true indicates that the children of the root are ordered, whereas false indicates they are unordered. Use if and only if *ord* is specified as partial on the <tree> element and the root has more than one child.

**@outDegree** gives the out degree of the root, the number of its children.

*Status* Optional

*Datatype* teidata.count

Note The in degree of the root is always 0.

Contained by tree

May contain

core: label

Example

```

<root xml:id="vp1" children="#vb1 #pn1"
  outDegree="2">
  <label>VP</label>
</root>
<leaf xml:id="vb1"/>
<leaf xml:id="pn1"/>

**<said>** (speech or thought) indicates passages thought or spoken aloud, whether explicitly indicated in the source or not, whether directly or indirectly reported, whether by real people or fictional characters. [3.3.3. Quotation]

*Module* core – Elements Available in All TEI Documents

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.ascribed (@who)

**@aloud** may be used to indicate whether the quoted matter is regarded as having been vocalized or signed.

*Status* Optional

*Datatype* teidata.xTruthValue

*Default* unknown

```
<p> Celia thought privately, <said aloud="false">Dorothea quite despises Sir James Chettam;
  I believe she would not accept him.</said> Celia felt that this was a pity.
```

```
<!-- ... -->
```

```
</p>
```

*Note* The value true indicates the encoded passage was expressed outwardly (whether spoken, signed, sung, screamed, chanted, etc.); the value false indicates that the encoded passage was thought, but not outwardly expressed.

**@direct** may be used to indicate whether the quoted matter is regarded as direct or indirect speech.

*Status* Optional

*Datatype* teidata.xTruthValue

*Default* true

```
<!-- in the header --><editorialDecl>
  <quotation marks="none"/>
</editorialDecl>
<!-- ... -->
<p> Tantripp had brought a card, and said that there was a
gentleman waiting in the lobby.
The courier had told him that <saïd direct="false">only Mrs.
Casaubon was at home</saïd>,
but he said <saïd direct="false">he was a relation of Mr.
Casaubon's: would she see him?</saïd>
</p>
```

*Note* The value true indicates the speech or thought is represented directly; the value false that speech or thought is represented indirectly, e.g. by use of a marked verbal aspect.

  model.pLike+
}
```

---

**<schemaSpec>** (schema specification) generates a TEI-conformant schema and documentation for it. [2.3. *The Encoding Description 22.2. Modules and Schemas 23.5.1. Making a Unified ODD*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.identified (@ident, @predeclare, @module) (att.combinable (@mode)) (att.deprecated (@validUntil)) att.namespaceable (@ns) att.readFrom (@source) att.docStatus (@status)

**@start** specifies entry points to the schema, i.e. which patterns may be used as the root of documents conforming to it.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.name separated by whitespace

*Default* TEI

**@prefix** specifies a default prefix which will be prepended to all patterns relating to TEI elements, unless otherwise stated.

*Status* Optional

*Datatype* 0–1 occurrences of teidata.xmlName separated by whitespace

*Note* Use of this attribute allows an external schema which has an element with the same local name as a TEI element to be mixed in.

**@targetLang** (target language) specifies which language to use when creating the objects in a schema if names for elements or attributes are available in more than one language

*Status* Optional

*Datatype* teidata.language

**@docLang** (documentation language) specifies which languages to use when creating documentation if the description for an element, attribute, class or macro is available in more than one language

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.language separated by whitespace

*Member of* model.divPart model.encodingDescPart

*Contained by*

*core:* item note q quote said stage

*drama:* castList epilogue performance prologue set view

*figures:* cell figure

*header:* change encodingDesc handNote licence scriptNote typeNote

*msdescription:* accMat acquisition additions collation condition custEvent decoNote filiation foliation layout musicNotation origin provenance signatures source summary support surrogates

*tagdocs:* specGrp

*textcrit:* lem rdg

*textstructure:* argument body div div1 div2 div3 div4 div5 div6 div7 epigraph postscript

*transcr:* metamark

*May contain*

*core:* desc gloss

*tagdocs:* altIdent classRef classSpec constraintSpec dataRef dataSpec elementRef elementSpec equiv listRef macroRef macroSpec moduleRef moduleSpec outputRendition specGrp specGrpRef

*Note* A <schemaSpec> combines references to modules, individual element or macro declarations, and specification groups together to form a unified schema. The processing of the <schemaSpec> element must resolve any conflicts amongst the declarations it contains or references. Different ODD processors may generate schemas and documentation using different concrete syntaxes.

*Example*

```
<schemaSpec prefix="TEI_" ident="testsvg"
  start="TEI svg">
  <moduleRef source="tei:current"
    key="header"/>
  <moduleRef key="core"/>
  <moduleRef key="drama"/>
  <moduleRef url="svg11.rng"/>
</schemaSpec>
```

This schema combines elements from the current versions of the drama and core modules, the current release version of the header module, and elements from an existing RELAXNG schema available from the URL indicated.

*Content model*

```
<content>
  <sequence>
    <alternate minOccurs="0"
      maxOccurs="unbounded">

<seal> contains a description of one seal or similar attachment applied to a manuscript. [10.7.3.2. Seals]

Module msdescription – Manuscript Description

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.typed (@type, @subtype) att.dateable (@calendar, @period) (att.dateable.w3c (@when,

*@notBefore*, *@notAfter*, *@from*, *@to*) (att.datable.iso (*@when-iso*, *@notBefore-iso*, *@notAfter-iso*, *@from-iso*, *@to-iso*) (att.datable.custom (*@when-custom*, *@notBefore-custom*, *@notAfter-custom*, *@from-custom*, *@to-custom*, *@datingPoint*, *@datingMethod*))

**@contemporary** specifies whether or not the seal is contemporary with the item to which it is affixed  
*Status* Optional  
*Datatype* teidata.xTruthValue

*Content model description:* sealDesc

*May contain*

*core:* p

*linking:* ab

*msdescription:* decoNote

*Example*

```
<seal n="2" type="pendant"
  subtype="cauda_duplex">
  <p>The seal of <name>Jens Olufsen</name> in black wax.
  (<ref>DAS 1061</ref>). Legend: <q>S IOHANNES OLAVI</q>.
  Parchment tag on which is written: <q>Woldorp Iohanne G</q>.</p>
</seal>
```

*Content model*

```
<content>
  <alternate minOccurs="1"
    maxOccurs="unbounded">
    <classRef key="model.pLike"/>
    <elementRef key="decoNote"/>
  </alternate>
</content>
```

*Schema Declaration*

```
element seal
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.typed.attributes,
  att.datable.attributes,
  att.datable.w3c.attributes,
  att.datable.iso.attributes,
  att.datable.custom.attributes,
  attribute contemporary { text }?,
  ( model.pLike | decoNote )+
}
```

**<sealDesc>** (seal description) describes the seals or other external items attached to a manuscript, either as a series of paragraphs or as a series of distinct <seal> elements, possibly with additional <decoNote>s.  
[10.7.3.2. Seals]

Module msdescription – Manuscript Description

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

*Note* The <seg> element may be used at the encoder's discretion to mark any segments of the text of interest for processing. One use of the element is to mark text features for which no appropriate markup is otherwise defined. Another use is to provide an identifier for some segment which is to be pointed at by some other element—i.e. to provide a target, or a part of a target, for a <ptr> or other similar element.

*Example*

```
<seg>When are you leaving?</seg>
<seg>Tomorrow.</seg>
```

*Example*

```
<s>
  <seg rend="caps" type="initial-cap">So father's only</seg> glory was the
  ballfield.
</s>
```

*Example*

```
<seg type="preamble">
  <seg>Sigmund, <seg type="patronym">the son of Volsung</seg>, was a king in
  Frankish country.</seg>
  <seg>Sinfiotli was the eldest of his sons ...</seg>
  <seg>Borghild, Sigmund's wife, had a brother ... </seg>
</seg>
```

*Content model*

```

*Note* As with other culturally-constructed traits such as age, the way in which this concept is described in different cultural contexts may vary. The normalizing attributes are provided only as an optional means of simplifying that variety to one or more external standards for purposes of interoperability, or project-internal taxonomies for consistency, and should not be used where that is inappropriate or unhelpful. The content of the element may be used to describe the intended concept in more detail, using plain text.

*Example*

```
<sex value="M">male</sex>
```

*Example*

```
<sex value="2">female</sex>
```

<**shift**> marks the point at which some paralinguistic feature of a series of utterances by any one speaker changes.  
[8.3.6. Shifts]

*Module* spoken — Transcriptions of Speech

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.ascribed (@who)

**@feature** a paralinguistic feature.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **tempo** speed of utterance.

**loud** loudness.

**pitch** pitch range.

**tension** tension or stress pattern.

**rhythm** rhythmic qualities.

**voice** voice quality.

**@new** specifies the new state of the paralinguistic feature specified.

*Status* Recommended

*Datatype* teidata.enumerated

*Default* normal

*Note* Some possible values for this attribute are provided in section 8.4.2. *Synchronization and Overlap*. The special value normal should be used to indicate that the feature concerned ceases to be remarkable at this point. In earlier versions of these Guidelines, a null value for this attribute was understood to have the same effect: this practice is now deprecated and will be removed at a future release.

*Example*

```
for his nose was as sharp as  
a pen, and <sic>a Table</sic> of green fields.
```

*Example* If all that is desired is to call attention to the apparent problem in the copy text, <sic> may be used alone:

```
I don't know, Juan. It's so far in the past now  
– how <sic>we can</sic> prove or disprove anyone's theories?
```

*Example* It is also possible, using the <choice> and <corr> elements, to provide a corrected reading:

```
I don't know, Juan. It's so far in the past now  
– how <choice>  
  <sic>we can</sic>  
  <corr>can we</corr>  
</choice> prove or disprove anyone's theories?
```

*Example*

```
for his nose was as sharp as  
a pen, and <choice>  
  <sic>a Table</sic>  
  <corr>a' babbl'd</corr>  
</choice> of green fields.
```

**<sound>** describes a sound effect or musical sequence specified within a screen play or radio script. [7.3.1. Technical Information 7.3. Other Types of Performance Text]

*Module* drama – Performance Texts

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@type** categorizes the sound in some respect, e.g. as music, special effect, etc.

*Status* Optional

*Datatype* teidata.enumerated

**@discrete** indicates whether the sound overlaps the surrounding speeches or interrupts them.

*Status* Optional

*Datatype* teidata.xTruthValue

*Default* unknown

*Note* The value true indicates that the sound is heard between the surrounding speeches; the value false indicates that the sound overlaps one or more of the surrounding speeches.

*transcr:* addSpan damageSpan delSpan fw listTranspose metamark space substJoin surface surfaceGrp

*Note* This element may be used as an alternative to <facsimile> for TEI documents containing only page images, or for documents containing both images and transcriptions. Transcriptions may be provided within the <surface> elements making up a source document, in parallel with them as part of a <text> element, or in both places if the encoder wishes to distinguish these two modes of transcription.

*Example*

```
<sourceDoc>
  <surfaceGrp n="leaf1">
    <surface facs="page1.png">
      <zone>All the writing on page 1</zone>
    </surface>
    <surface>
      <graphic url="page2-highRes.png"/>
      <graphic url="page2-lowRes.png"/>
      <zone>
        <line>A line of writing on page 2</line>
        <line>Another line of writing on page 2</line>
      </zone>
    </surface>
  </surfaceGrp>

<space> indicates the location of a significant space in the text. [11.5.1. Space]

*Module* `transcr` – Representation of Primary Sources

*Attributes* `att.typed` (`@type`, `@subtype`) `att.dimensions` (`@unit`, `@quantity`, `@extent`, `@precision`, `@scope`) (`att.ranging` (`@atLeast`, `@atMost`, `@min`, `@max`, `@confidence`)) `att.source` (`@source`) `att.global` (`@xml:id`, `@n`, `@xml:lang`, `@xml:base`, `@xml:space`) `att.global.rendition` (`@rend`, `@style`, `@rendition`) `att.global.linking` (`@corresp`, `@synch`, `@sameAs`, `@copyOf`, `@next`, `@prev`, `@exclude`, `@select`) `att.global.analytic` (`@ana`) `att.global.facs` (`@facs`) `att.global.change` (`@change`) `att.global.responsibility` (`@resp`, `@cert`)

**@resp** (responsible party) (responsible party) indicates the individual responsible for identifying and measuring the space

*Derived from* `att.global.responsibility`

*Status* Optional

*Datatype* 1–∞ occurrences of `teidata.pointer` separated by whitespace

**@dim** (dimension) indicates whether the space is horizontal or vertical.

*Status* Recommended

*Datatype* `teidata.enumerated`

*Legal values are:* **horizontal** the space is horizontal.

**vertical** the space is vertical.

*Note* For irregular shapes in two dimensions, the value for this attribute should reflect the more important of the two dimensions. In conventional left-right scripts, a space with both vertical and horizontal components should be classed as vertical.

*Member of* `model.global.edit`

*tagdocs:* classRef classSpec constraintSpec dataRef dataSpec elementRef elementSpec listRef macroRef  
 macroSpec moduleRef moduleSpec outputRendition schemaSpec specGrp specGrpRef

*Note* A specification group is referenced by means of its *xml:id* attribute. The declarations it contains may be included in a <schemaSpec> or <moduleSpec> element only by reference (using a <specGrpRef> element); it may not be nested within a <moduleSpec> element. Different ODD processors may generate representations of the specifications contained by a <specGrp> in different concrete syntaxes.

*Example*

```
<specGrp xml:id="xDAILC">
  <elementSpec ident="s">
<!-- ... -->
  </elementSpec>
  <elementSpec ident="cl">
<!-- ... -->
  </elementSpec>
  <elementSpec ident="w">
<!-- ... -->
  </elementSpec>
  <elementSpec ident="m">
<!-- ... -->
  </elementSpec>
  <elementSpec ident="c">
<!-- ... -->
  </elementSpec>
</specGrp>
```

This specification group with identifier xDAILC contains specifications for the elements <s>,<cl>,<w>,<!-- ... -->, etc.

Content model

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <classRef key="model.oddDecl"/>
    <classRef key="model.oddRef"/>
    <classRef key="model.divPart"/>
  </alternate>
</content>
```

Schema Declaration

```
element specGrp
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  ( model.oddDecl | model.oddRef | model.divPart )*
}
```

**<specGrpRef>** (reference to a specification group) indicates that the declarations contained by the <specGrp> referenced should be inserted at this point. [22.2. Modules and Schemas]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@target** points at the specification group which logically belongs here.

*Status* Required

*Datatype* teidata.pointer

*Member of* model.oddDecl

*Contained by*

*core:* add corr del desc emph head hi item l meeting note orig p q quote ref reg said sic stage title unclear

*verse:* rhyme

*May contain* Empty element

*Note* In ODD documentation processing, a <specGrpRef> usually produces a comment indicating that a set of declarations printed in another section will be inserted at this point in the <specGrp> being discussed. In schema processing, the contents of the specified <specGrp> are made available for inclusion in the generated schema. The specification group identified by the *target* attribute will normally be part of the current ODD document.

*Example*

```
<p>This part of the module contains declarations for names of persons, places,
and
organisations: <specGrpRef target="#names.pers"/>
  <specGrpRef target="#names.place"/>
  <specGrpRef target="#names.org"/>
</p>
<!-- elsewhere -->
<specGrp xml:id="names.pers">
<!--... -->
</specGrp>
<!-- elsewhere -->
<specGrp xml:id="names.place">
<!--... -->
</specGrp>
<!-- elsewhere -->
<specGrp xml:id="names.org">
<!--... -->
</specGrp>
```

*Content model* <content></content>

*Schema Declaration*

```
element specGrpRef
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  attribute target { text },
  empty
}
```

---

**<specList>** (specification list) marks where a list of descriptions is to be inserted into the prose documentation. [22.1.2. Element and Attribute Descriptions]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))

(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**<stage>** (stage direction) contains any kind of stage direction within a dramatic text or fragment. [3.12.2. *Core Tags for Drama* 3.12. *Passages of Verse or Drama* 7.2.4. *Stage Directions*]

*Module* core – Elements Available in All TEI Documents

*Attributes* att.ascribed (@who) att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.placement (@place)

@type indicates the kind of stage direction.

*Status* Recommended

*Datatype* 0–∞ occurrences of teidata.enumerated separated by whitespace

*Suggested values include:* **setting** describes a setting.

**entrance** describes an entrance.

**exit** describes an exit.

**business** describes stage business.

**novelistic** is a narrative, motivating stage direction.

**delivery** describes how a character speaks.

**modifier** gives some detail about a character.

**location** describes a location.

**mixed** more than one of the above

*Note* If the value **mixed** is used, it must be the only value. Multiple values may however be supplied if a single stage direction performs multiple functions, for example is both an entrance and a modifier.

textcrit: witDetail

*Note* Where there is confusion between <trait> and <state> the more general purpose element <state> should be used even for unchanging characteristics. If you wish to distinguish between characteristics that are generally perceived to be time-bound states and those assumed to be fixed traits, then <trait> is available for the more static of these. The <state> element encodes characteristics which are sometimes assumed to change, often at specific times or over a date range, whereas the <trait> elements are used to record characteristics, such as eye-colour, which are less subject to change. Traits are typically, but not necessarily, independent of the volition or action of the holder.

*Example*

```
<state ref="#SCHOL" type="status">
  <label>scholar</label>
</state>
```

*Example*

```
<org>
  <orgName notAfter="1960">The Silver Beetles</orgName>

**<surface>** defines a written surface as a two-dimensional coordinate space, optionally grouping one or more graphic representations of that space, zones of interest within that space, and transcriptions of the writing within them. [11.1. Digital Facsimiles 11.2.2. Embedded Transcription]

*Module* transcr — Representation of Primary Sources

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.coordinated (@start, @ulx, @uly, @lrx, @lry, @points) att.declaring (@decls) att.typed (@type, @subtype)

**@attachment** describes the method by which this surface is or was connected to the main surface

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **glued** glued in place

**pinned** pinned or stapled in place

**sewn** sewn in place

**@flipping** indicates whether the surface is attached and folded in such a way as to provide two writing surfaces

*Status* Optional

*Datatype* teidata.truthValue

*Content model:* facsimile sourceDoc surface surfaceGrp zone

*May contain*

*analysis:* interp interpGrp span spanGrp

*certainty:* certainty precision respons

transcr: addSpan damageSpan delSpan fw line listTranspose metamark space substJoin surface surfaceGrp zone

Note The <surface> element represents any two-dimensional space on some physical surface forming part of the source material, such as a piece of paper, a face of a monument, a billboard, a scroll, a leaf etc. The coordinate space defined by this element may be thought of as a grid *lr*x - *ul*x units wide and *uly* - *lry* units high.

The <surface> element may contain graphic representations or transcriptions of written zones, or both. The coordinate values used by every <zone> element contained by this element are to be understood with reference to the same grid.

Where it is useful or meaningful to do so, any grouping of multiple <surface> elements may be indicated using the <surfaceGrp> elements.

Example

```
<facsimile>
  <surface ulx="0" uly="0" lrx="200" lry="300">
    <graphic url="Bovelles-49r.png"/>
  </surface>
</facsimile>

**<tag>** contains text of a complete start- or end-tag, possibly including attribute specifications, but excluding the opening and closing markup delimiter characters. [22. *Documentation Elements*]

*Module* tagdocs – Documentation Elements

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@type** indicates the type of XML tag intended

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **start** a start-tag, with delimiters < and > is intended

**end** an end-tag, with delimiters </ and > is intended

**empty** a empty tag, with delimiters < and /> is intended

**pi** a pi (processing instruction), with delimiters <? and ?> is intended

**comment** a comment, with delimiters <!-- and --> is intended

**ms** a marked-section, with delimiters <[CDATA[ and ]]> is intended

**@scheme** supplies the name of the schema in which this tag is defined.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **TEI** (text encoding initiative) This tag is defined as part of the TEI scheme.[Default]

**DBK** (docbook) this tag is part of the Docbook scheme.

**XX** (unknown) this tag is part of an unknown scheme.

**<tagsDecl>** (tagging declaration) provides detailed information about the tagging applied to a document. [2.3.4. The Tagging Declaration 2.3. The Encoding Description]

*Module header* – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@partial** indicates whether the element types listed exhaustively include all those found within <text>, or represent only a subset.

*Status* Recommended

*Datatype* teidata.truthValue

*Note* TEI recommended practice is to specify this attribute. When the <tagUsage> elements inside <tagsDecl> are used to list each of the element types in the associated <text>, the value should be given as false. When the <tagUsage> elements inside <tagsDecl> are used to provide usage information or default renditions for only a subset of the elements types within the associated <text>, the value should be true.

*Member of* model.encodingDescPart

*Contained by*

*header:* encodingDesc

*May contain*

*header:* namespace rendition

*Example*

```
<tagsDecl>
  <rendition xml:id="rend-it">to be rendered in italic font</rendition>
  <namespace name="http://www.tei-c.org/ns/1.0">
    <tagUsage gi="hi" occurs="467"
      render="#rend-it"/>

( rendition*, namespace* )
}

```

**<tagUsage>** documents the usage of a specific element within a specified document. [2.3.4. *The Tagging Declaration*]

*Module header* – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@gi** (generic identifier) specifies the name (generic identifier) of the element indicated by the tag, within the namespace indicated by the parent <namespace> element.

*Status* Required

*Datatype* teidata.name

**@OCCURS** specifies the number of occurrences of this element within the text.

*Status* Recommended

*Datatype* teidata.count

**@withId** (with unique identifier) specifies the number of occurrences of this element within the text which bear a distinct value for the global *xml:id* attribute.

*Status* Recommended

*Datatype* teidata.count

**@render** specifies the identifier of a <rendition> element which defines how this element was rendered in the source text.

*Deprecated* will be removed on 2017-01-01

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Note* The recommended way of specifying a default rendition for a set of elements is to use the *selector* attribute on the <rendition> element.

*Contained by:* namespace

---

**<tech>** (technical stage direction) describes a special-purpose stage direction that is not meant for the actors.  
 [7.3.1. *Technical Information*]

*Module* drama – Performance Texts

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@type** categorizes the technical stage direction.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **light** a lighting cue

**sound** a sound cue

**prop** a prop cue

**block** a blocking instruction

**@perf** (performance) points to one or more <performance> elements documenting the performance or performances to which this technical direction applies.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.pointer separated by whitespace

*Member of* model.stageLike

*Contained by*

*core:* add corr del desc emph head hi item l lg meeting note orig p q quote ref reg said sic sp stage title unclear

**<TEI>** (TEI document) contains a single TEI-conformant document, combining a single TEI header with one or more members of the model.resourceLike class. Multiple TEI elements may be combined to form a <teiCorpus> element. [4. Default Text Structure 15.1. Varieties of Composite Text]

*Module* textstructure — Default Text Structure

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.typed (@type, @subtype)

**@version** specifies the major version number of the TEI Guidelines against which this document is valid.

*Status* Optional

*Datatype* teidata.version

*Note* The major version number is historically prefixed by a P (for Proposal), and is distinct from the version number used for individual releases of the Guidelines, as used by (for example) the *source* of the <schemaSpec> element. The current version is P5.

*Contained by* teiCorpus

*May contain*

*header:* teiHeader

*iso-fs:* fsdDecl

*textstructure:* text

*transcr:* facsimile sourceDoc

*Note* This element is required. It is customary to specify the TEI namespace <http://www.tei-c.org/ns/1.0> on it, using the *xmlns* attribute.

*Example*

```

<TEI version="5.0" xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <fileDesc>
      <titleStmt>
        <title>The shortest TEI Document Imaginable</title>
      </titleStmt>
      <publicationStmt>
        <p>First published as part of TEI P2, this is the P5
          version using a name space.</p>
      </publicationStmt>
    </fileDesc>
  </teiHeader>
</TEI>

```

```

    <sourceDesc>
      <p>No source: this is an original work.</p>
    </sourceDesc>
  </fileDesc>
</teiHeader>
<text>
  <body>
    <p>This is about the shortest TEI document imaginable.</p>
  </body>
</text>
</TEI>

```

*Example*

```

<TEI version="5.0" xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <fileDesc>
      <titleStmt>
        <title>A TEI Document containing four page images </title>
      </titleStmt>
      <publicationStmt>
        <p>Unpublished demonstration file.</p>
      </publicationStmt>
      <sourceDesc>
        <p>No source: this is an original work.</p>
      </sourceDesc>
    </fileDesc>

}

```

**<teiCorpus>** contains the whole of a TEI encoded corpus, comprising a single corpus header and one or more TEI elements, each containing a single text header and a text. [4. *Default Text Structure 15.1. Varieties of Composite Text*]

*Module* core — Elements Available in All TEI Documents

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@version** The version of the TEI scheme

*Status* Optional

*Datatype* teidata.version

*Default* 5.0

*Contained by* teiCorpus

*May contain*

*core:* teiCorpus

*header:* teiHeader

*iso-fs:* fsdDecl

*textstructure:* TEI text

*transcr:* facsimile sourceDoc

*Note* Must contain one TEI header for the corpus, and a series of <TEI> elements, one for each text. This element is mandatory when applicable.

*Example*

```

<teiCorpus version="5.2" xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <!-- header for corpus -->
  </teiHeader>
  <TEI>
    <teiHeader>
    <!-- header for first text -->
  </teiHeader>
    <text>
    <!-- content of first text -->
  </text>
  </TEI>
  <TEI>
    <teiHeader>
    <!-- header for second text -->
  </teiHeader>
    <text>

```

```
<!-- content of second text -->
  </text>
</TEI>
<!-- more TEI elements here -->
</teiCorpus>
```

Content model

```

  )
}
```

---

**<teiHeader>** (TEI header) supplies descriptive and declarative metadata associated with a digital resource or set of resources. [2.1.1. *The TEI Header and Its Components* 15.1. *Varieties of Composite Text*]

Module header – The TEI Header

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))

(att.global.analytic (*@ana*)) (att.global.facs (*@facs*)) (att.global.change (*@change*)) (att.global.responsibility (*@cert, @resp*))

**@type** specifies the kind of document to which the header is attached, for example whether it is a corpus or individual text.

*Deprecated* will be removed on 2016-11-18

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **text** the header is attached to a single text.[Default]

**corpus** the header is attached to a corpus.

*Contained by* **teiCorpus**

*textstructure:* TEI

*May contain*

*header:* encodingDesc fileDesc profileDesc revisionDesc xenoData

*Note* One of the few elements unconditionally required in any TEI document.

*Example*

```
<teiHeader>
  <fileDesc>

*Note* When this element appears within an <index> element, it is understood to supply the form under which an index entry is to be made for that location. Elsewhere, it is understood simply to indicate that its content is to be regarded as a technical or specialised term. It may be associated with a <gloss> element by means of its *ref* attribute; alternatively a <gloss> element may point to a <term> element by means of its *target* attribute. In formal terminological work, there is frequently discussion over whether terms must be atomic or may include multi-word lexical items, symbolic designations, or phraseological units. The <term> element may be used to mark any of these. No position is taken on the philosophical issue of what a term can be; the looser definition simply allows the <term> element to be used by practitioners of any persuasion.

As with other members of the `att.canonical` class, instances of this element occurring in a text may be associated with a canonical definition, either by means of a URI (using the *ref* attribute), or by means of some system-specific code value (using the *key* attribute). Because the mutually exclusive *target* and *cRef* attributes overlap with the function of the *ref* attribute, they are deprecated and may be removed at a subsequent release.

*Example*

```
A computational device that infers structure
from grammatical strings of words is known as a <term>parser</term>, and much of
the history
of NLP over the last 20 years has been occupied with the design of parsers.
```

*Example*

```
We may define <term xml:id="TDPV1" rend="sc">discoursal point of view</term>
as
<gloss target="#TDPV1">the relationship, expressed
through discourse structure, between the implied author or some other addresser,
```

and the  
fiction.</gloss>

*Example*

We may define <term ref="#TDPV2" rend="sc">discoursal point of view</term> as  
<gloss xml:id="TDPV2">the relationship, expressed  
through discourse structure, between the implied author or some other addresser,  
and the  
fiction.</gloss>

*Example*

We discuss Leech's concept of  
<term ref="myGlossary.xml#TDPV2" rend="sc">discoursal point of view</term>  
below.

*Note* This element should not be used to represent a text which is inserted at an arbitrary point within the structure of another, for example as in an embedded or quoted narrative; the <floatingText> is provided for this purpose.

*Example*

```
<text>
  <front>
    <docTitle>
      <titlePart>Autumn Haze</titlePart>
    </docTitle>
  </front>
  <body>
    <l>Is it a dragonfly or a maple leaf</l>
    <l>That settles softly down upon the water?</l>
  </body>
</text>
```

*Example* The body of a text may be replaced by a group of nested texts, as in the following schematic:

```
<text>
  <front>
    <!-- front matter for the whole group -->
  </front>
  <group>
    <text>
    <!-- first text -->
    </text>
    <text>
    <!-- second text -->
  </group>
```

```

</text>
</group>
</text>

```

    purpose+  
  )  
}
```

**<textLang>** (text language) describes the languages and writing systems identified within the bibliographic work being described, rather than its description. [3.11.2.4. *Imprint, Size of a Document, and Reprint Information 10.6.6. Languages and Writing Systems*]

*Module* core – Elements Available in All TEI Documents

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@mainLang** (main language) supplies a code which identifies the chief language used in the bibliographic work.

*Status* Optional

*Datatype* teidata.language

**@otherLangs** (other languages) one or more codes identifying any other languages used in the bibliographic work.

*Status* Optional

*Datatype* 0–∞ occurrences of teidata.language separated by whitespace

*Member of* model.biblPart model.msItemPart

*Contained by*

*core:* analytic bibl monogr series

*Note* This element should not be used to document the languages or writing systems used for the bibliographic or manuscript description itself: as for all other TEI elements, such information should be provided by means of the global *xml:lang* attribute attached to the element containing the description. In all cases, languages should be identified by means of a standardized ‘language tag’ generated according to BCP 47. Additional documentation for the language may be provided by a <language> element in the TEI Header.

*Example*

```
<textLang mainLang="en" otherLangs="la"> Predominantly in English with Latin glosses</textLang>
```

*Content model*

```
<content>
  <macroRef key="macro.phraseSeq"/>

}

```

**<timeline>** provides a set of ordered points in time which can be linked to elements of a spoken text to create a temporal alignment of that text. [16.5.2. *Placing Synchronous Events in Time*]

*Module* linking – Linking, Segmentation, and Alignment

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@origin** designates the origin of the timeline, i.e. the time at which it begins.

*Status* Optional

*Datatype* teidata.pointer

*Note* If this attribute is not supplied, the implication is that the time of origin is not known. If it is supplied, it must point either to one of the <when> elements in its content, or to another <timeline> element.

**@unit** specifies the unit of time corresponding to the *interval* value of the timeline or of its constituent points in time.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **d** (days)

**h** (hours)

**min** (minutes)

**s** (seconds)

**ms** (milliseconds)

**@interval** specifies a time interval either as a positive integral value or using one of a set of predefined codes.

*Status* Optional

*Datatype* teidata.interval

*Note* The value irregular indicates uncertainty about all the intervals in the timeline; the value regular indicates that all the intervals are evenly spaced, but the size of the intervals is not known; numeric values indicate evenly spaced values of the size specified. If individual points in time in the timeline are given different values for the *interval* attribute, those values locally override the value given in the timeline.

**<title>** contains a title for any kind of work. [3.11.2.2. *Titles, Authors, and Editors* 2.2.1. *The Title Statement* 2.2.5. *The Series Statement*]

*Module* core – Elements Available in All TEI Documents

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.canonical (@key, @ref) att.typed (~~type~~, @subtype)

**@type** classifies the title according to some convenient typology.

*Derived from* att.typed

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **main** main title

**sub** (subordinate) subtitle, title of part

**alt** (alternate) alternate title, often in another language, by which the work is also known

**short** abbreviated form of title

**desc** (descriptive) descriptive paraphrase of the work functioning as a title

*Note* This attribute is provided for convenience in analysing titles and processing them according to their type; where such specialized processing is not necessary, there is no need for such analysis, and the entire title, including subtitles and any parallel titles, may be enclosed within a single <title> element.

**@level** indicates the bibliographic level for a title, that is, whether it identifies an article, book, journal, series, or unpublished material.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **a** (analytic) the title applies to an analytic item, such as an article, poem, or other work published as part of a larger item.

- m** (monographic) the title applies to a monograph such as a book or other item considered to be a distinct publication, including single volumes of multi-volume works
- j** (journal) the title applies to any serial or periodical publication such as a journal, magazine, or newspaper
- s** (series) the title applies to a series of otherwise distinct publications such as a collection
- u** (unpublished) the title applies to any unpublished material (including theses and dissertations unless published by a commercial press)

*Note* The level of a title is sometimes implied by its context: for example, a title appearing directly within an <analytic> element is *ipso facto* of level ‘a’, and one appearing within a <series> element of level ‘s’. For this reason, the *level* attribute is not required in contexts where its value can be unambiguously inferred. Where it is supplied in such contexts, its value should not contradict the value implied by its parent element.

*Note* The attributes *key* and *ref*, inherited from the class `att.canonical` may be used to indicate the canonical form for the title; the former, by supplying (for example) the identifier of a record in some external library system; the latter by pointing to an XML element somewhere containing the canonical form of the title.

*Example*

```
<title>Information Technology and the Research Process: Proceedings of
a conference held at Cranfield Institute of Technology, UK,
18–21 July 1989</title>
```

*Example*

```
<title>Hardy's Tess of the D'Urbervilles: a machine readable
edition</title>
```

*Example*

```
<title type="full">
  <title type="main">Synthèse</title>
  <title type="sub">an international journal for
    epistemology, methodology and history of
    science</title>
</title>
```

*Content model*

  macro.paraContent}

```

**<titlePage>** (title page) contains the title page of a text, appearing within the front or back matter. [4.6. Title Pages]

Module textstructure – Default Text Structure

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

@type classifies the title page according to any convenient typology.

Status Optional

Datatype teidata.enumerated

Note This attribute allows the same element to be used for volume title pages, series title pages, etc., as well as for the ‘main’ title page of a work.

*Note* Where there is confusion between <trait> and <state> the more general purpose element <state> should be used even for unchanging characteristics. If you wish to distinguish between characteristics that are generally perceived to be time-bound states and those assumed to be fixed traits, then <trait> is available for the more static of these. The <state> element encodes characteristics which are sometimes assumed to change, often at specific times or over a date range, whereas the <trait> elements are used to record characteristics, such as eye-colour, which are less subject to change. Traits are typically, but not necessarily, independent of the volition or action of the holder.

*Example*

```
<trait type="physical">
  <label>Eye colour</label>
  <desc>Blue</desc>
</trait>
```

}
```

**<transcriptionDesc>** describes the set of transcription conventions used, particularly for spoken material.  
[8.2. Documenting the Source of Transcribed Speech]

*Module* spoken – Transcriptions of Speech

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@ident** supplies an identifier for the encoding convention, independent of any version number.

*Status* Required

*Datatype* teidata.name

**@version** supplies a version number for the encoding conventions used, if any.

*Status* Optional

*Datatype* teidata.versionNumber

*Member of* model.encodingDescPart

*Contained by*

*header:* encodingDesc

*May contain*

*core:* desc label p ptr ref

*linking:* ab

*Example*

```
<transcriptionDesc ident="HIAT"  
  version="2004"/>
```

*Content model*

```
<content>  
  <alternate minOccurs="0"  
    maxOccurs="unbounded">  
    <classRef key="model.labelLike"/>  
    <classRef key="model.ptrLike"/>  
    <classRef key="model.pLike"/>  
  </alternate>  
</content>
```

*Schema Declaration*

```

element transcriptionDesc
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  attribute ident { text },
  attribute version { text }?,
  ( model.labelLike | model.ptrLike | model.pLike )*
}

```

**<transpose>** describes a single textual transposition as an ordered list of at least two pointers specifying the order in which the elements indicated should be re-combined. [11.3.4.5. *Transpositions*]

*Module* transcr – Representation of Primary Sources

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

*Contained by*

transcr: listTranspose

*May contain*

core: ptr

*Note* Transposition is usually indicated in a document by a metamark such as a wavy line or numbering. The order in which <ptr> elements appear within a <transpose> element should correspond with the desired order, as indicated by the metamark.

*Example*

```

<transpose>
  <ptr target="#ib02"/>
  <ptr target="#ib01"/>
</transpose>

```

The transposition recorded here indicates that the content of the element with identifier **ib02** should appear before the content of the element with identifier **ib01**.

*Content model*

att.global.change.attributes,  
att.global.responsibility.attributes,  
( ptr, ptr+ )  
}
```

<tree> encodes a tree, which is made up of a root, internal nodes, leaves, and arcs from root to leaves. [19.2. Trees]

Module nets — Graphs, Networks, and Trees

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

@arity gives the maximum number of children of the root and internal nodes of the tree.

Status Optional

Datatype teidata.count

@ord (ordered) indicates whether or not the tree is ordered, or if it is partially ordered.

Status Required

Datatype teidata.enumerated

Legal values are: **true** indicates that all of the branching nodes of the tree are ordered.

**partial** indicates that some of the branching nodes of the tree are ordered and some are unordered.

**false** indicates that all of the branching nodes of the tree are unordered.

@order gives the order of the tree, i.e., the number of its nodes.

Status Optional

Datatype teidata.count

Note The size of a tree is always one less than its order, hence there is no need for both a size and order attribute.

}

```

<triangle> (underspecified embedding tree, so called because of its characteristic shape when drawn) provides for an underspecified eTree, that is, an eTree with information left out. [19.3. Another Tree Notation]

Module nets – Graphs, Networks, and Trees

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

@value supplies a value for the triangle, in the form of the identifier of a feature structure or other analytic element.

Status Optional

Datatype teidata.pointer

Contained by eTree forest triangle

May contain

core: label

nets: eLeaf eTree triangle

Note An optional label followed by zero or more embedding trees, triangles, or embedding leaves.

Example

```

<triangle>
  <label>NP</label>
  <eLeaf>
    <label>the periscope</label>
  </eLeaf>
</triangle>

```

*Content model*

```
( text | model.gLike | model.phrase | model.global )*
```

**<unclear>** contains a word, phrase, or passage which cannot be transcribed with certainty because it is illegible or inaudible in the source. [11.3.3.1. *Damage, Illegibility, and Supplied Text* 3.4.3. *Additions, Deletions, and Omissions*]

*Module* core — Elements Available in All TEI Documents

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.editLike (@evidence, @instant) (att.dimensions (@unit, @quantity, @extent, @precision, @scope) (att.ranging (@atLeast, @atMost, @min, @max, @confidence))) (att.source (@source))

**@reason** indicates why the material is hard to transcribe.

*Status* Optional

*Datatype* 1-∞ occurrences of teidata.word separated by whitespace

```
<div>
  <head>Rx</head>
  <p>500 mg <unclear reason="illegible">placebo</unclear>
</p>
</div>
```

*Note* One or more words may be used to describe the reason; usually each word will refer to a single cause. Typical examples might thus include *faded*, *illegible*, *eccentric\_ductus background\_noise*, *passing\_truck*, etc.

**@hand** Where the difficulty in transcription arises from action (partial deletion, etc.) assignable to an identifiable hand, signifies the hand responsible for the action.

*Deprecated* will be removed on 2017-08-01

*Status* Optional

*Datatype* teidata.pointer

**@agent** Where the difficulty in transcription arises from damage, categorizes the cause of the damage, if it can be identified.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **rubbing** damage results from rubbing of the leaf edges

**mildew** damage results from mildew on the leaf surface

**smoke** damage results from smoke

*Note* The same element is used for all cases of uncertainty in the transcription of element content, whether for written or spoken material. For other aspects of certainty, uncertainty, and reliability of tagging and transcription, see chapter 21. *Certainty, Precision, and Responsibility*. The <damage>, <gap>, <del>, <unclear> and <supplied> elements may be closely allied in use. See section 11.3.3.2. *Use of the gap, del, damage, unclear, and supplied Elements in Combination* for discussion of which element is appropriate for which circumstance.

The *hand* attribute points to a definition of the hand concerned, as further discussed in section 11.3.2.1. *Document Hands*.

*Example*

<u> ...and then <unclear reason="background-noise">Nathalie</unclear> said ...  
</u>

May contain Empty element

Example

```
<line>This is <del change="#s2" rend="overstrike">
  <seg xml:id="undo-a">just some</seg>
  sample <seg xml:id="undo-b">text</seg>,
  we need</del>
  <add change="#s2">not</add>
a real example.</line>
<undo target="#undo-a #undo-b"
rend="dotted" change="#s3"/>
```

This encoding represents the following sequence of events:

- "This is just some sample text, we need a real example" is written
- At stage s2, "just some sample text, we need" is deleted by overstriking, and "not" is added
- At stage s3, parts of the deletion are cancelled by underdotted, thus reinstating the words "just some" and "text".

```

**<usg>** (usage) contains usage information in a dictionary entry. [9.3.5.2. Usage Information and Other Labels]

*Module* dictionaries – Dictionaries

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.lexicographic (@expand, @norm, @split, @value, @orig, @location, @mergedIn, @opt) (att.datcat (@datcat, @valueDatcat))

**@type** classifies the usage information using any convenient typology.

*Status* Optional

*Datatype* teidata.enumerated

*Sample values include:* **geo** (geographic) geographic area

**time** temporal, historical era (archaic, old, etc.)

**dom** (domain) domain or subject matter (e.g. scientific, literary etc.)

**register**

**style** style (figurative, literal, etc.)

**plev** (preference level) preference level (chiefly, usually, etc.)

**lang** (language) name of a language mentioned in etymological or other linguistic discussion.

**gram** (grammatical) grammatical usage

**syn** (synonym) synonym given to show use

**hyper** (hypernym) hypernym given to show usage

**colloc** (collocation) typical collocates of the headword.

**comp** (complement) typical complement

**obj** (object) typical object

**subj** (subject) typical subject

**verb** typical verb

**hint** unclassifiable piece of information to guide sense choice

}
```

---

**<valList>** (value list) contains one or more <valItem> elements defining possible values. [22.5.4. Attribute List Specification]

Module tagdocs – Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.combinable (@mode) att.deprecated (@validUntil)

@type specifies the extensibility of the list of values specified.

Status Optional

Datatype teidata.enumerated

Legal values are: closed only the values specified are permitted.

semi (semi-open) all the values specified should be supported, but other values are legal and software should have appropriate fallback processing for them.

open the values specified are sample values only.[Default]

Member of model.contentPart

Contained by

tagdocs: alternate attDef content dataSpec elementSpec macroSpec sequence

May contain

tagdocs: valItem

Example

```
<valList type="closed">
  <valItem ident="req">

  att.global.responsibility.attributes,
  ( model.featureVal, model.featureVal+ )
}
```

**<value>** contains a single value for some property, attribute, or other analysis. [5.2.1. Character Properties]

Module gaiji — Characters, Glyphs, and Writing Modes

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))

(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

Contained by

gaiji: charProp

May contain

gaiji: g

Example

```
<value>unknown</value>
```

Content model `<content> <macroRef key="macro.xtext"/></content>`

Schema Declaration

```
element value
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  macro.xtext}
```

**<variantEncoding>** declares the method used to encode text-critical variants. [12.1.1. The Apparatus Entry]

Module textcrit – Critical Apparatus

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

@method indicates which method is used to encode the apparatus of variants.

Status Required

Datatype teidata.enumerated

Legal values are: **location-referenced** apparatus uses line numbers or other canonical reference scheme referenced in a base text.

**double-end-point** apparatus indicates the precise locations of the beginning and ending of each lemma relative to a base text.

**parallel-segmentation** alternate readings of a passage are given in parallel in the text; no notion of a base text is necessary.

Note The value 'parallel-segmentation' requires in-line encoding of the apparatus.

@location indicates whether the apparatus appears within the running text or external to it.

Status Required

Datatype teidata.enumerated

Schematron `<sch:rule context="tei:variantEncoding"> <sch:assert test="(@location != 'external') or (@method != 'parallel-segmentation')"> The @location value "external" is inconsistent with the parallel-segmentation method of apparatus markup.</sch:assert> </sch:rule>`

Legal values are: **internal** apparatus appears within the running text.

**external** apparatus appears outside the base text.

*Note* The value ‘external’ is inconsistent with the parallel-segmentation method of apparatus markup.

Member of model.encodingDescPart

    " "
    "" The @location value "external" is inconsistent with the parallel-segmentation me
  ],
  empty
}
```

---

**<vColl>** (collection of values) represents the value part of a feature-value specification which contains multiple values organized as a set, bag, or list. [18.7. Collections as Complex Feature Values]

*Module* iso-fs – Feature Structures

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@org** (organization) indicates organization of given value or values as set, bag or list.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **set** indicates that the given values are organized as a set.

**bag** indicates that the given values are organized as a bag (multiset).

**list** indicates that the given values are organized as a list.

Member of model.featureVal.complex

Contained by

iso-fs: f fvLib if vAlt vDefault vLabel vMerge vNot vRange

May contain

  att.global.responsibility.attributes,
  attribute org { "set" | "bag" | "list" }?,
  ( fs | model.featureVal.single )*
}

```

**<vDefault>** (value default) declares the default value to be supplied when a feature structure does not contain an instance of <f> for this name; if unconditional, it is specified as one (or, depending on the value of the *org* attribute of the enclosing <fDecl>) more <fs> elements or primitive values; if conditional, it is specified as one or more <if> elements; if no default is specified, or no condition matches, the value none is assumed. [18.11. Feature System Declaration]

Module iso-fs – Feature Structures

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

Contained by

iso-fs: fDecl

May contain

iso-fs: binary default fs if numeric string symbol vAlt vColl vLabel vMerge vNot

Note May contain a legal feature value, or a series of <if> elements.

Example

```

<fDecl name="INV">
  <fDescr>inverted sentence</fDescr>
  <vRange>
    <vAlt>
      <binary value="true"/>
      <binary value="false"/>
    </vAlt>
  </vRange>
  <vDefault>
    <binary value="false"/>
  </vDefault>
</fDecl>

```

Content model

```

<content>
  <alternate>
    <classRef key="model.featureVal"
      minOccurs="1" maxOccurs="unbounded"/>
    <elementRef key="if" minOccurs="1"
      maxOccurs="unbounded"/>
  </alternate>

```

</content>

Schema Declaration

```

element vDefault
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  ( model.featureVal+ | if+ )
}

```

<view> describes the visual context of some part of a screen play in terms of what the spectator sees, generally independent of any dialogue. [7.3.1. Technical Information 7.3. Other Types of Performance Text]

Module drama – Performance Texts

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

  att.global.responsibility.attributes,
  attribute name { text },
  model.featureVal?
}

```

---

**<vMerge>** (merged collection of values) represents a feature value which is the result of merging together the feature values contained by its children, using the organization specified by the *org* attribute. [18.8.3. Collection of Values]

Module iso-fs – Feature Structures

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@org** indicates the organization of the resulting merged values as set, bag or list.

*Status* Optional

*Datatype* teidata.enumerated

*Legal values are:* **set** indicates that the resulting values are organized as a set.

**bag** indicates that the resulting values are organized as a bag (multiset).

**list** indicates that the resulting values are organized as a list.

*Member of* model.featureVal.complex

*Contained by*

*iso-fs:* f fvLib if vAlt vDefault vLabel vMerge vNot vRange

*May contain*

iso-fs: binary default fs numeric string symbol vAlt vColl vLabel vMerge vNot

Example

```
<vMerge org="list">
  <vColl org="set">
    <symbol value="masculine"/>
    <symbol value="neuter"/>
    <symbol value="feminine"/>
  </vColl>
  <symbol value="indeterminate"/>
</vMerge>
```

This example returns a list, concatenating the indeterminate value with the set of values masculine, neuter and feminine.

Content model

```
<content>
  <classRef key="model.featureVal"
    minOccurs="1" maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```
element vMerge
{

```

**<when>** indicates a point in time either relative to other elements in the same timeline tag, or absolutely. [16.5.2. *Placing Synchronous Events in Time*]

*Module* linking – Linking, Segmentation, and Alignment

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))

**@absolute** supplies an absolute value for the time.

*Status* Optional

*Datatype* teidata.temporal.w3c

*Note* This attribute should always be specified on a <when> element which serves as the target for the *origin* attribute of a <timeLine>.

**@unit** specifies the unit of time in which the *interval* value is expressed, if this is not inherited from the parent <timeline>.

*Status* Optional

*Datatype* teidata.enumerated

*Suggested values include:* **d** (days)

**h** (hours)

**min** (minutes)

**s** (seconds)

**ms** (milliseconds)

**@interval** specifies a time interval either as a number or as one of the keywords defined by the datatype data.interval

*Status* Optional

*Datatype* teidata.interval

**@since** identifies the reference point for determining the time of the current <when> element, which is obtained by adding the interval to the time of the reference point.

*Status* Optional

*Datatype* teidata.pointer

*Note* This attribute should point to another <when> element in the same <timeline>. If no value is supplied, and the *absolute* attribute is also unspecified, then the reference point is understood to be the origin of the enclosing <timeline> tag.

*Content model*: timeline

*May contain* Empty element

*Note* On this element, the global *xml:id* attribute must be supplied to specify an identifier for this point in time. The value used may be chosen freely provided that it is unique within the document and is a syntactically valid name. There is no requirement for values containing numbers to be in sequence.

*Example*

```
<when xml:id="TW3" interval="20" since="#w2"/>
```

*Content model* `<content></content>`

*Schema Declaration*

```
element when
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
```

```

att.global.facs.attributes,
att.global.change.attributes,
att.global.responsibility.attributes,
attribute absolute { text }?,
attribute unit { "d" | "h" | "min" | "s" | "ms" }?,
attribute interval { text }?,
attribute since { text }?,
empty
}

```

**<width>** contains a measurement measured along the axis parallel to the bottom of the written surface, i.e. perpendicular to the spine of a book or codex. [10.3.4. Dimensions]

*Module* msdescription – Manuscript Description

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.dimensions (@unit, @quantity, @extent, @precision, @scope) (att.ranging (@atLeast, @atMost, @min, @max, @confidence))

*verse*: caesura rhyme

*Note* The <witDetail> element should be regarded as a specialized type of <note> element; it is synonymous with <note type='witnessDetail'>, but differs in the omission of some attributes seldom applicable to notes within critical apparatus, and in the provision of the *wit* attribute, which permits an application to extract all annotation concerning a particular witness or witnesses from the apparatus. It also differs in that the location of a <witDetail> element is not significant and may not be used to imply the point of attachment for the annotation; this must be explicitly given by means of the *target* attribute.

*Example*

```
<app type="substantive">
  <rdgGrp type="subvariants">
    <lem xml:id="W026x" wit="#E1 #HG">Experience</lem>
    <rdg wit="#Ha4">Experiens</rdg>

}

```

**<writing>** contains a passage of written text revealed to participants in the course of a spoken text. [8.3.4.

Writing]

Module spoken — Transcriptions of Speech

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.ascribed (@who) att.typed (@type, @subtype) att.timed (@start, @end) (att.duration (att.duration.w3c (@dur)) (att.duration.iso (@dur-iso))) att.source (@source)

@gradual indicates whether the writing is revealed all at once or gradually.

Status Optional

Datatype teidata.xTruthValue

Note The value true indicates the writing is revealed gradually; the value false that the writing is revealed all at once.

**<xenodata>** (outside metadata) provides a container element into which metadata in non-TEI formats may be placed. [2.5. Non-TEI Metadata]

*Module header* – The TEI Header

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.declarable (@default) att.typed (@type, @subtype)

*Member of* model.teiHeaderPart

*Contained by*

*header:* teiHeader

*May contain* Empty element

*Example* This example presumes that the prefix `dc` has been bound to the namespace `http://purl.org/dc/elements/1.1/` and the prefix `rdf` is bound to the namespace `http://www.w3.org/1999/02/22-rdf-syntax-ns#`. Note: The *about* attribute on the `rdf:Description` in this example gives a URI indicating the resource to which the metadata contained therein refer. The `rdf:Description` in the second `<xenoData>` block has a blank *about*, meaning it is pointing at the *current* document, so the RDF is about the document within which it is contained, i.e. the TEI document containing the `<xenoData>` block. Similarly, any kind of relative URI may be used, including fragment identifiers (see *v.5.2 Identifiers and Indicators*). Do note, however, that if the contents of the `<xenoData>` block are to be extracted and used elsewhere, any relative URIs will have to be resolved accordingly.

```
<xenoData
  xmlns:dc="http://purl.org/dc/elements/1.1/"
  xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
  <rdf:RDF>
    <rdf:Description rdf:about="http://www.worldcat.org/oclc/606621663">
      <dc:title>The description of a new world, called the
blazing-world</dc:title>
      <dc:creator>The Duchess of Newcastle</dc:creator>
      <dc:date>1667</dc:date>
      <dc:identifier>British Library, 8407.h.10</dc:identifier>
      <dc:subject>utopian fiction</dc:subject>
    </rdf:Description>
  </rdf:RDF>
</xenoData>
<xenoData>
  <rdf:RDF>
    <rdf:Description rdf:about="">

```

<XΓ> (cross-reference phrase) contains a phrase, sentence, or icon referring the reader to some other location in this or another text. [9.3.5.3. *Cross-References to Other Entries*]

*Module* dictionaries – Dictionaries

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.lexicographic (@expand, @norm, @split, @value, @orig, @location, @mergedIn, @opt) (att.datcat (@datcat, @valueDatcat))

@type indicates the type of cross reference, using any convenient typology.

*Status* Recommended

*Datatype* teidata.enumerated

*Sample values include:* **syn** (synonym) cross reference for synonym information

**etym** (etymological) etymological information

**cf** (compare or consult) related or similar term

**illus** (illustration) illustration of an object

*Member of* model.entryPart model.entryPart.top

  (
    text
    | model.gLike      | model.phrase      | model.inter      | usg      | lbl      | model.global
  )
}

```

**<zone>** defines any two-dimensional area within a <surface> element. [11.1. Digital Facsimiles 11.2.2. Embedded Transcription]

*Module* transcr — Representation of Primary Sources

*Attributes* att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) att.coordinated (@start, @ulx, @uly, @lrx, @lry, @points) att.typed (@type, @subtype) att.written (@hand)

**@rotate** indicates the amount by which this zone has been rotated clockwise, with respect to the normal orientation of the parent <surface> element as implied by the dimensions given in the <msDesc> element or by the coordinates of the <surface> itself. The orientation is expressed in arc degrees.

*Status* Optional

*Datatype* teidata.count

*Default* 0

*Member of* model.linePart

*Contained by*

*transcr:* line surface zone

*May contain*

*analysis:* c cl interp interpGrp m pc phr s span spanGrp w

*certainty:* certainty precision respons

*core:* add binaryObject cb choice corr del gap gb graphic hi index lb media milestone note orig pb reg sic unclear

*figures:* figure formula notatedMusic

*iso-fs:* fLib fs fvLib

*linking:* alt altGrp anchor join joinGrp link linkGrp seg timeline

*spoken:* incident kinesic pause shift vocal writing

*textcrit:* app witDetail

*transcr:* addSpan damage damageSpan delSpan fw handShift line listTranspose metamark mod redo restore retrace secl space substJoin supplied surface surplus undo zone

*Note* The position of every zone for a given surface is always defined by reference to the coordinate system defined for that surface. A graphic element contained by a zone represents the whole of the zone. A zone may be of any shape. The attribute *points* may be used to define a polygonal zone, using the coordinate system defined by its parent surface.

*Example*

```
<surface ulx="14.54" uly="16.14" lrx="0"
  lry="0">
  <graphic url="stone.jpg"/>
  <zone points="4.6,6.3 5.25,5.85 6.2,6.6 8.19222,7.4125 9.89222,6.5875
10.9422,6.1375 11.4422,6.7125 8.21722,8.3125 6.2,7.65"/>
</surface>
```

This example defines a non-rectangular zone: see the illustration in section 11.4. *Advanced Uses of surface and zone.*

*Example*

```
<facsimile>
  <surface ulx="50" uly="20" lrx="400"
    lry="280">
    <zone ulx="0" uly="0" lrx="500" lry="321">
      <graphic url="graphic.png"/>
    </zone>
  </surface>
</facsimile>
```

This example defines a zone which has been defined as larger than its parent surface in order to match the dimensions of the graphic it contains.

*Content model*

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.graphicLike"/>
    <classRef key="model.global"/>
    <elementRef key="surface"/>
    <classRef key="model.linePart"/>
  </alternate>
</content>
```

*Schema Declaration*

```

| writtenLines       | layout                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| xml:base           | att.global                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| xml:id             | att.global                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| xml:lang           | att.global                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| xml:space          | att.global                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## E Datatypes and Other Macros

---

**data.certainty** defines the range of attribute values expressing a degree of certainty.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration* `data.certainty = "high" | "medium" | "low" | "unknown"`

*Note* Certainty may be expressed by one of the predefined symbolic values high, medium, or low. The value unknown should be used in cases where the encoder does not wish to assert an opinion about the matter. For more precise indication, `data.probability` may be used instead or in addition.

---

**data.count** defines the range of attribute values used for a non-negative integer value used as a count.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration* `data.count = xsd:nonNegativeInteger`

*Note* Only positive integer values (including zero) are permitted

---

**data.duration.iso** defines the range of attribute values available for representation of a duration in time using ISO 8601 standard formats

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration*

`data.duration.iso = token { pattern = "[0-9.,DHMPRSTWYZ/:\+\\-]+" }`

*Example*

```
<time dur-iso="PT0,75H">three-quarters of an hour</time>
```

*Example*

```
<date dur-iso="P1,5D">a day and a half</date>
```

*Example*

```
<date dur-iso="P14D">a fortnight</date>
```

*Example*

```
<time dur-iso="PT0.02S">20 ms</time>
```

*Note* A duration is expressed as a sequence of number-letter pairs, preceded by the letter P; the letter gives the unit and may be Y (year), M (month), D (day), H (hour), M (minute), or S (second), in that order. The numbers are all unsigned integers, except for the last, which may have a decimal component (using either . or , as the decimal point; the latter is preferred). If any number is 0, then that number-letter pair may be omitted. If any of the H (hour), M (minute), or S (second) number-letter pairs are present, then the separator T must precede the first 'time' number-letter pair. For complete details, see ISO 8601 *Data elements and interchange formats – Information interchange – Representation of dates and times*.

**data.duration.w3c** defines the range of attribute values available for representation of a duration in time using W3C datatypes.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration* `data.duration.w3c = xsd:duration`

*Example*

```
<time dur="PT45M">forty-five minutes</time>
```

*Example*

```
<date dur="P1DT12H">a day and a half</date>
```

*Example*

```
<date dur="P7D">a week</date>
```

*Example*

```
<time dur="PT0.02S">20 ms</time>
```

*Note* A duration is expressed as a sequence of number-letter pairs, preceded by the letter P; the letter gives the unit and may be Y (year), M (month), D (day), H (hour), M (minute), or S (second), in that order. The numbers are all unsigned integers, except for the S number, which may have a decimal component (using . as the decimal point). If any number is 0, then that number-letter pair may be omitted. If any of the H (hour), M (minute), or S (second) number-letter pairs are present, then the separator T must precede the first 'time' number-letter pair. For complete details, see the W3C specification.

---

**data.enumerated** defines the range of attribute values expressed as a single XML name taken from a list of documented possibilities.

*Module* tei – The TEI Infrastructure

*Used by* Element:

- outputRendition/@scope

*Declaration* `data.enumerated = data.word`

*Note* Attributes using this datatype must contain a single word matching the pattern defined for this datatype: for example it cannot include whitespace but may begin with digits. Typically, the list of documented possibilities will be provided (or exemplified) by a value list in the associated attribute specification, expressed with a <valList> element.

---

**data.interval** defines attribute values used to express an interval value.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration*

```
data.interval =  
  xsd:float { minExclusive = "0" } | "regular" | "irregular" | "unknown"
```

*Note* Any value greater than zero or any one of the values regular, irregular, unknown.

**data.language** defines the range of attribute values used to identify a particular combination of human language and writing system. [*vi.1 Language Identification*]

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration* `data.language = xsd:language | ""`

*Note* The values for this attribute are language ‘tags’ as defined in BCP 47. Currently BCP 47 comprises RFC 5646 and RFC 4647; over time, other IETF documents may succeed these as the best current practice. A ‘language tag’, per BCP 47, is assembled from a sequence of components or *subtags* separated by the hyphen character (-, U+002D). The tag is made of the following subtags, in the following order. Every subtag except the first is optional. If present, each occurs only once, except the fourth and fifth components (variant and extension), which are repeatable.

**language** The IANA-registered code for the language. This is almost always the same as the ISO 639 2-letter language code if there is one. The list of available registered language subtags can be found at <http://www.iana.org/assignments/language-subtag-registry>. It is recommended that this code be written in lower case.

**script** The ISO 15924 code for the script. These codes consist of 4 letters, and it is recommended they be written with an initial capital, the other three letters in lower case. The canonical list of codes is maintained by the Unicode Consortium, and is available at <http://unicode.org/iso15924/iso15924-codes.html>. The IETF recommends this code be omitted unless it is necessary to make a distinction you need.

**region** Either an ISO 3166 country code or a UN M.49 region code that is registered with IANA (not all such codes are registered, e.g. UN codes for economic groupings or codes for countries for which there is already an ISO 3166 2-letter code are not registered). The former consist of 2 letters, and it is recommended they be written in upper case; the list of codes can be searched or browsed at <https://www.iso.org/obp/ui/#search/code/>. The latter consist of 3 digits; the list of codes can be found at <http://unstats.un.org/unsd/methods/m49/m49.htm>.

**variant** An IANA-registered variation. These codes ‘are used to indicate additional, well-recognized variations that define a language or its dialects that are not covered by other available subtags’.

**extension** An extension has the format of a single letter followed by a hyphen followed by additional subtags. These exist to allow for future extension to BCP 47, but as of this writing no such extensions are in use.

**private use** An extension that uses the initial subtag of the single letter *x* (i.e., starts with *x-*) has no meaning except as negotiated among the parties involved. These should be used with great care, since they interfere with the interoperability that use of RFC 4646 is intended to promote. In order for a document that makes use of these subtags to be TEI-conformant, a corresponding <language> element must be present in the TEI header.

There are two exceptions to the above format. First, there are language tags in the IANA registry that do not match the above syntax, but are present because they have been ‘grandfathered’ from previous specifications.

Second, an entire language tag can consist of only a private use subtag. These tags start with *x-*, and do not need to follow any further rules established by the IETF and endorsed by these Guidelines. Like all language tags that make use of private use subtags, the language in question must be documented in a corresponding <language> element in the TEI header.

Examples include

**sn** Shona

**zh-TW** Taiwanese

**zh-Hant-HK** Chinese written in traditional script as used in Hong Kong

**en-SL** English as spoken in Sierra Leone

**pl** Polish

**es-MX** Spanish as spoken in Mexico

**es-419** Spanish as spoken in Latin America

The W3C Internationalization Activity has published a useful introduction to BCP 47, Language tags in HTML and XML.

---

**data.name** defines the range of attribute values expressed as an XML Name.

*Module* tei – The TEI Infrastructure

*Used by* att gi

*Declaration* `data.name = xsd:Name`

*Note* Attributes using this datatype must contain a single word which follows the rules defining a legal XML name (see <http://www.w3.org/TR/REC-xml/#dt-name>): for example they cannot include whitespace or begin with digits.

---

**data.namespace** defines the range of attribute values used to indicate XML namespaces as defined by the W3C Namespaces in XML Technical Recommendation.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration* `data.namespace = xsd:anyURI`

*Note* The range of syntactically valid values is defined by RFC 3986 *Uniform Resource Identifier (URI): Generic Syntax*

---

**data.numeric** defines the range of attribute values used for numeric values.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration*

```
data.numeric =  
  xsd:double | token { pattern = "(\\-?[\\d]+/\\-?[\\d]+)" } | xsd:decimal
```

*Note* Any numeric value, represented as a decimal number, in floating point format, or as a ratio. To represent a floating point number, expressed in scientific notation, 'E notation', a variant of 'exponential notation', may be used. In this format, the value is expressed as two numbers separated by the letter E. The first number, the significand (sometimes called the mantissa) is given in decimal format, while the second is an integer. The value is obtained by multiplying the mantissa by 10 the number of times indicated by the integer. Thus the value represented in decimal notation as 1000.0 might be represented in scientific notation as 10E3.

A value expressed as a ratio is represented by two integer values separated by a solidus (/) character. Thus, the value represented in decimal notation as 0.5 might be represented as a ratio by the string 1/2.

**data.outputMeasurement** defines a range of values for use in specifying the size of an object that is intended for display.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration*

```
data.outputMeasurement =
  token
  {
    pattern = "[\ -+]?\\d+(\\.\\d+)?(%|cm|mm|in|pt|pc|px|em|ex|gd|rem|vw|vh|vm)"
  }
```

*Example*

```
<figure>
  <head>The TEI Logo</head>
  <figDesc>Stylized yellow angle brackets with the letters
  <mentioned>TEI</mentioned> in
    between and <mentioned>text encoding initiative</mentioned> underneath, all
    on a white
    background.</figDesc>
  <graphic height="600px" width="600px"
    url="http://www.tei-c.org/logos/TEI-600.jpg"/>
</figure>
```

*Note* These values map directly onto the values used by XSL-FO and CSS. For definitions of the units see those specifications; at the time of this writing the most complete list is in the CSS3 working draft.

**data.pattern** (regular expression pattern) defines attribute values which are expressed as a regular expression.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration* data.pattern = token

*Note* A regular expression, often called a *pattern*, is an expression that describes a set of strings. They are usually used to give a concise description of a set, without having to list all elements. For example, the set containing the three strings *Handel*, *Händel*, and *Haendel* can be described by the pattern `H(ä|ae?)ndel` (or alternatively, it is said that the pattern `H(ä|ae?)ndel` *matches* each of the three strings)Wikipedia

**data.percentage** defines attribute values used to express a percentage value.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration*

```
data.percentage = xsd:nonNegativeInteger { maxInclusive = "100" }
```

*Note* Any non-negative integer value less than 100.

**data.point** defines the data type used to express a point in cartesian space.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration*

```
data.point = token { pattern = "(\\-?[0-9]+\\.?[0-9]*,\\-?[0-9]+\\.?[0-9]*)" }
```

*Example*

```
<facsimile>
  <surface ulx="0" uly="0" lrx="400" lry="280">
    <zone points="220,100 300,210 170,250 123,234">
      <graphic url="handwriting.png" />
    </zone>
  </surface>
</facsimile>
```

*Note* A point is defined by two numeric values, which may be expressed in any notation permitted.

---

**data.pointer** defines the range of attribute values used to provide a single URI, absolute or relative, pointing to some other resource, either within the current document or elsewhere.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration* `data.pointer = xsd:anyURI`

*Note* The range of syntactically valid values is defined by RFC 3986 *Uniform Resource Identifier (URI): Generic Syntax*. Note that the values themselves are encoded using RFC 3987 *Internationalized Resource Identifiers (IRIs) mapping to URIs*. For example, <https://secure.wikimedia.org/wikipedia/en/wiki/%> is encoded as <https://secure.wikimedia.org/wikipedia/en/wiki/%25> while <http://www.وزارة-الاتصالات.مصر> is encoded as <http://xn--4gbrim.xn----rmckbbajlc6dj7bxne2c.xn--wgbh1c/>

---

**data.probability** defines the range of attribute values expressing a probability.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration*

```
data.probability = xsd:double { minInclusive = "0" maxInclusive = "1" }
```

*Note* Probability is expressed as a real number between 0 and 1; 0 representing *certainly false* and 1 representing *certainly true*.

---

**data.replacement** defines attribute values which contain a replacement template.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration* `data.replacement = text`

---

**data.sex** defines the range of attribute values used to identify human or animal sex.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration* `data.sex = data.word`

*Note* Values for attributes using this datatype may be locally defined by a project, or may refer to an external standard, such as vCard's sex property <http://microformats.org/wiki/gender-formats> (in which M indicates male, F female, O other, N none or not applicable, U unknown), or the often used ISO 5218:2004 *Representation of Human Sexes* [http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266\\_ISO\\_IEC\\_5218\\_2004\(E\\_F\).zip](http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266_ISO_IEC_5218_2004(E_F).zip) (in which 0 indicates unknown; 1 male; 2 female; and 9 not applicable, although the ISO standard is widely considered inadequate); cf. CETH's *Recommendations for Inclusive Data Collection of Trans People* <http://transhealth.ucsf.edu/trans?page=lib-data-collection>.

**data.temporal.iso** defines the range of attribute values expressing a temporal expression such as a date, a time, or a combination of them, that conform to the international standard *Data elements and interchange formats – Information interchange – Representation of dates and times*.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration*

```
data.temporal.iso =
  xsd:date
  | xsd:gYear
  | xsd:gMonth
  | xsd:gDay
  | xsd:gYearMonth
  | xsd:gMonthDay
  | xsd:time
  | xsd:dateTime
  | token { pattern = "[0-9.,DHMPRTWYZ/:\-]+" }
```

*Note* If it is likely that the value used is to be compared with another, then a time zone indicator should always be included, and only the dateTime representation should be used. For all representations for which ISO 8601 describes both a *basic* and an *extended* format, these Guidelines recommend use of the extended format.

While ISO 8601 permits the use of both `00:00` and `24:00` to represent midnight, these Guidelines strongly recommend against the use of `24:00`.

**data.temporal.w3c** defines the range of attribute values expressing a temporal expression such as a date, a time, or a combination of them, that conform to the W3C *XML Schema Part 2: Datatypes Second Edition* specification.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration*

```
data.temporal.w3c =
  xsd:date
  | xsd:gYear
  | xsd:gMonth
  | xsd:gDay
```

```
| xsd:gYearMonth
| xsd:gMonthDay
| xsd:time
| xsd:dateTime
```

*Note* If it is likely that the value used is to be compared with another, then a time zone indicator should always be included, and only the `dateTime` representation should be used.

---

**data.text** defines the range of attribute values used to express some kind of identifying string as a single sequence of unicode characters possibly including whitespace.

*Module* `tei` – The TEI Infrastructure

*Used by*

*Declaration* `data.text = string`

*Note* Attributes using this datatype must contain a single ‘token’ in which whitespace and other punctuation characters are permitted.

---

**data.truthValue** defines the range of attribute values used to express a truth value.

*Module* `tei` – The TEI Infrastructure

*Used by*

*Declaration* `data.truthValue = xsd:boolean`

*Note* The possible values of this datatype are 1 or true, or 0 or false. This datatype applies only for cases where uncertainty is inappropriate; if the attribute concerned may have a value other than true or false, e.g. unknown, or inapplicable, it should have the extended version of this datatype: `data.xTruthValue`.

---

**data.version** defines the range of attribute values which may be used to specify a TEI or Unicode version number.

*Module* `tei` – The TEI Infrastructure

*Used by*

*Declaration* `data.version = token { pattern = "[\d]+(\.[\d]+){0,2}" }`

*Note* The value of this attribute follows the pattern specified by the Unicode consortium for its version number (<http://unicode.org/versions/>). A version number contains digits and fullstop characters only. The first number supplied identifies the major version number. A second and third number, for minor and sub-minor version numbers, may also be supplied.

---

**data.versionNumber** defines the range of attribute values used for version numbers.

*Module* `tei` – The TEI Infrastructure

*Used by*

*Declaration*

```
data.versionNumber =
  token { pattern = "[\d]+[a-z]*[\d]*(\.[\d]+[a-z]*[\d]*){0,3}" }
```

---

**data.word** defines the range of attribute values expressed as a single word or token.

*Module* tei – The TEI Infrastructure

*Used by* data.enumerated data.sex

*Declaration*

```
data.word = token { pattern = "(\\p{L}|\\p{N}|\\p{P}|\\p{S})+" }
```

*Note* Attributes using this datatype must contain a single ‘word’ which contains only letters, digits, punctuation characters, or symbols: thus it cannot include whitespace.

**data.xmlName** defines attribute values which contain an XML name.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration* `data.xmlName = xsd:NCName`

*Note* The rules defining an XML name form a part of the XML Specification.

**data.xpath** defines attribute values which contain an XPath expression.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration* `data.xpath = text`

*Note* Any XPath expression using the syntax defined in Kay (ed.) (2007)

**data.xTruthValue** (extended truth value) defines the range of attribute values used to express a truth value which may be unknown.

*Module* tei – The TEI Infrastructure

*Used by*

*Declaration*

```
data.xTruthValue = xsd:boolean | "unknown" | "inapplicable"
```

*Note* In cases where where uncertainty is inappropriate, use the datatype `data.TruthValue`.

**macro.anyXML** defines a content model within which any XML elements are permitted

*Module* tei – The TEI Infrastructure

*Used by* constraint content egXML macro.anyXML macro.schemaPattern xenoData

*Declaration*

```
macro.anyXML =
  element * - (tei:* | teix:egXML)
  {
    attribute * { text }*,
    ( text | macro.anyXML )*
  }
```

**macro.limitedContent** (paragraph content) defines the content of prose elements that are not used for transcription of extant materials. [1.3. *The TEI Class System*]

*Module* tei – The TEI Infrastructure

*Used by* desc fDescr figDesc fsDescr meeting rendition tagUsage witness

*Content model*

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.limitedPhrase"/>
    <classRef key="model.inter"/>
  </alternate>
</content>
```

*Declaration*

```
macro.limitedContent = ( text | model.limitedPhrase | model.inter )*
```

**macro.paraContent** (paragraph content) defines the content of paragraphs and similar elements. [1.3. *The TEI Class System*]

*Module* tei – The TEI Infrastructure

    <classRef key="model.global"/>
  </alternate>
</content>
```

*Declaration*

```
macro.phraseSeq.limited = ( text | model.limitedPhrase | model.global )*
```

**macro.schemaPattern** provides a pattern to match elements from the chosen schema language

*Module* tagdocs – Documentation Elements

*Used by* datatype

*Content model* `<content> <macroRef key="macro.anyXML"/></content>`

*Declaration* `macro.schemaPattern = macro.anyXML`

---

**macro.specialPara** ('special' paragraph content) defines the content model of elements such as notes or list items, which either contain a series of component-level elements or else have the same structure as a paragraph, containing a series of phrase-level and inter-level elements. [1.3. The TEI Class System]

*Module* tei – The TEI Infrastructure

*Used by* accMat acquisition additions cell change collation condition custEvent decoNote filiation foliation handNote item layout licence metamark musicNotation note origin provenance q quote said scriptNote signatures source stage summary support surrogates typeNote view

*Content model*

```
<content>
<alternate minOccurs="0"
  maxOccurs="unbounded">
  <textNode/>
  <classRef key="model.gLike"/>
  <classRef key="model.phrase"/>
  <classRef key="model.inter"/>
  <classRef key="model.divPart"/>
  <classRef key="model.global"/>
</alternate>
</content>
```

*Declaration*

```
macro.specialPara =
(
  text
  | model.gLike   | model.phrase   | model.inter   | model.divPart | model.global
```

---

**macro.xtext** (extended text) defines a sequence of character data and gaiji elements.

*Module* tei – The TEI Infrastructure

*Used by* c collection depth dim ex height institution locus mapping memberOf msName repository string value width

*Content model*

```
<content>
<alternate minOccurs="0"
  maxOccurs="unbounded">
  <textNode/>
  <classRef key="model.gLike"/>
</alternate>
</content>
```

*Declaration* `macro.xtext = ( text | model.gLike )*`

---

**teidata.certainty** defines the range of attribute values expressing a degree of certainty.

*Module* tei – The TEI Infrastructure

*Used by* teidata.probCertElement:

- certainty/@cert
- precision/@precision
- purpose/@degree

*Content model*

```
<content>
<valList type="closed">
  <valItem ident="high"/>
  <valItem ident="medium"/>
  <valItem ident="low"/>
  <valItem ident="unknown"/>
</valList>
</content>
```

*Declaration* `teidata.certainty = "high" | "medium" | "low" | "unknown"`

*Note* Certainty may be expressed by one of the predefined symbolic values high, medium, or low. The value unknown should be used in cases where the encoder does not wish to assert an opinion about the matter. For more precise indication, `data.probability` may be used instead or in addition.

---

**teidata.count** defines the range of attribute values used for a non-negative integer value used as a count.

*Module* tei – The TEI Infrastructure

*Used by* Element:

- age/@value
- datatype/@minOccurs
- graph/@order
- graph/@size
- handDesc/@hands
- iNode/@outDegree
- layout/@columns
- layout/@ruledLines
- layout/@writtenLines
- node/@inDegree
- node/@outDegree
- node/@degree
- refState/@length
- root/@outDegree
- sense/@level
- table/@rows
- table/@cols

- tagUsage/@occurs
- tagUsage/@withId
- tree/@arity
- tree/@order
- zone/@rotate

*Content model*

```
<content>
  <dataRef name="nonNegativeInteger"/>
</content>
```

*Declaration* `teidata.count = xsd:nonNegativeInteger`

*Note* Only positive integer values (including zero) are permitted

---

**teidata.duration.iso** defines the range of attribute values available for representation of a duration in time using ISO 8601 standard formats

*Module* tei – The TEI Infrastructure

*Used by*

*Content model*

```
<content>
  <dataRef name="token"
    restriction="[0-9.,DHMPRSTWYZ/:\- ]+"/>
</content>
```

*Declaration*

```
teidata.duration.iso = token { pattern = "[0-9.,DHMPRSTWYZ/:\- ]+" }
```

*Example*

```
<time dur-iso="PT0,75H">three-quarters of an hour</time>
```

*Example*

```
<date dur-iso="P1,5D">a day and a half</date>
```

*Example*

```
<date dur-iso="P14D">a fortnight</date>
```

*Example*

```
<time dur-iso="PT0.02S">20 ms</time>
```

*Note* A duration is expressed as a sequence of number-letter pairs, preceded by the letter P; the letter gives the unit and may be Y (year), M (month), D (day), H (hour), M (minute), or S (second), in that order. The numbers are all unsigned integers, except for the last, which may have a decimal component (using either . or , as the decimal point; the latter is preferred). If any number is 0, then that number-letter pair may be omitted. If any of the H (hour), M (minute), or S (second) number-letter pairs are present, then the

separator T must precede the first ‘time’ number-letter pair. For complete details, see ISO 8601 *Data elements and interchange formats — Information interchange — Representation of dates and times*.

**teidata.duration.w3c** defines the range of attribute values available for representation of a duration in time using W3C datatypes.

*Module* tei — The TEI Infrastructure

*Used by*

*Content model* `<content> <dataRef name="duration"/></content>`

*Declaration* `teidata.duration.w3c = xsd:duration`

*Example*

```
<time dur="PT45M">forty-five minutes</time>
```

*Example*

```
<date dur="P1DT12H">a day and a half</date>
```

*Example*

```
<date dur="P7D">a week</date>
```

*Example*

```
<time dur="PT0.02S">20 ms</time>
```

*Note* A duration is expressed as a sequence of number-letter pairs, preceded by the letter P; the letter gives the unit and may be Y (year), M (month), D (day), H (hour), M (minute), or S (second), in that order. The numbers are all unsigned integers, except for the S number, which may have a decimal component (using . as the decimal point). If any number is 0, then that number-letter pair may be omitted. If any of the H (hour), M (minute), or S (second) number-letter pairs are present, then the separator T must precede the first ‘time’ number-letter pair. For complete details, see the W3C specification.

**teidata.enumerated** defines the range of attribute values expressed as a single XML name taken from a list of documented possibilities.

*Module* tei — The TEI Infrastructure

*Used by* Element:

*Content model* `<content> <dataRef key="teidata.word"/></content>`

*Declaration* `teidata.enumerated = teidata.word`

*Note* Attributes using this datatype must contain a single word matching the pattern defined for this datatype: for example it cannot include whitespace but may begin with digits. Typically, the list of documented possibilities will be provided (or exemplified) by a value list in the associated attribute specification, expressed with a `<valList>` element.

---

**teidata.interval** defines attribute values used to express an interval value.

*Module* tei – The TEI Infrastructure

*Used by* Element:

- timeline/@interval
- when/@interval

*Content model*

```
<content>
  <alternate>
    <dataRef name="float"/>
    <valList>
      <valItem ident="regular"/>
      <valItem ident="irregular"/>
      <valItem ident="unknown"/>
    </valList>
  </alternate>
</content>
```

*Declaration*

```
teidata.interval = xsd:float | ( "regular" | "irregular" | "unknown" )
```

*Note* Any value greater than zero or any one of the values regular, irregular, unknown.

**teidata.language** defines the range of attribute values used to identify a particular combination of human language and writing system. [*vi.1 Language Identification*]

*Module* tei – The TEI Infrastructure

*Used by Element:*

- langKnowledge/@tags
- langKnown/@tag
- language/@ident
- schemaSpec/@targetLang
- schemaSpec/@docLang
- textLang/@mainLang
- textLang/@otherLangs

*Content model*

```
<content>
  <alternate>
    <dataRef name="language"/>
    <valList>
      <valItem ident=""/>
    </valList>
  </alternate>
</content>
```

*Declaration* `teidata.language = xsd:language | ( "" )`

*Note* The values for this attribute are language ‘tags’ as defined in BCP 47. Currently BCP 47 comprises RFC 5646 and RFC 4647; over time, other IETF documents may succeed these as the best current practice. A ‘language tag’, per BCP 47, is assembled from a sequence of components or *subtags* separated by the hyphen character (-, U+002D). The tag is made of the following subtags, in the following order. Every subtag except the first is optional. If present, each occurs only once, except the fourth and fifth components (variant and extension), which are repeatable.

**language** The IANA-registered code for the language. This is almost always the same as the ISO 639 2-letter language code if there is one. The list of available registered language subtags can be found at <http://www.iana.org/assignments/language-subtag-registry>. It is recommended that this code be written in lower case.

**script** The ISO 15924 code for the script. These codes consist of 4 letters, and it is recommended they be written with an initial capital, the other three letters in lower case. The canonical list of codes is maintained by the Unicode Consortium, and is available at <http://unicode.org/iso15924/iso15924-codes.html>. The IETF recommends this code be omitted unless it is necessary to make a distinction you need.

**region** Either an ISO 3166 country code or a UN M.49 region code that is registered with IANA (not all such codes are registered, e.g. UN codes for economic groupings or codes for countries for which there is already an ISO 3166 2-letter code are not registered). The former consist of 2 letters, and it is recommended they be written in upper case; the list of codes can be searched or browsed at

<https://www.iso.org/obp/ui/#search/code/>. The latter consist of 3 digits; the list of codes can be found at <http://unstats.un.org/unsd/methods/m49/m49.htm>.

**variant** An IANA-registered variation. These codes ‘are used to indicate additional, well-recognized variations that define a language or its dialects that are not covered by other available subtags’.

**extension** An extension has the format of a single letter followed by a hyphen followed by additional subtags. These exist to allow for future extension to BCP 47, but as of this writing no such extensions are in use.

**private use** An extension that uses the initial subtag of the single letter *x* (i.e., starts with *x-*) has no meaning except as negotiated among the parties involved. These should be used with great care, since they interfere with the interoperability that use of RFC 4646 is intended to promote. In order for a document that makes use of these subtags to be TEI-conformant, a corresponding `<language>` element must be present in the TEI header.

There are two exceptions to the above format. First, there are language tags in the IANA registry that do not match the above syntax, but are present because they have been ‘grandfathered’ from previous specifications.

Second, an entire language tag can consist of only a private use subtag. These tags start with *x-*, and do not need to follow any further rules established by the IETF and endorsed by these Guidelines. Like all language tags that make use of private use subtags, the language in question must be documented in a corresponding `<language>` element in the TEI header.

Examples include

**sn** Shona

**zh-TW** Taiwanese

**zh-Hant-HK** Chinese written in traditional script as used in Hong Kong

**en-SL** English as spoken in Sierra Leone

**pl** Polish

**es-MX** Spanish as spoken in Mexico

**es-419** Spanish as spoken in Latin America

The W3C Internationalization Activity has published a useful introduction to BCP 47, Language tags in HTML and XML.

---

**teidata.name** defines the range of attribute values expressed as an XML Name.

*Module* `tei` – The TEI Infrastructure

*Used by* Element:

- `application/@ident`
- `equiv/@name`
- `f/@name`
- `fDecl/@name`
- `fsDecl/@baseTypes`
- `index/@indexName`
- `join/@result`
- `joinGrp/@result`
- `memberOf/@key`
- `model/@cssClass`

- prefixDef/@ident
- schemaSpec/@start
- specDesc/@key
- specDesc/@atts
- tagUsage/@gi
- transcriptionDesc/@ident

*Content model* `<content> <dataRef name="Name"/></content>`

*Declaration* `teidata.name = xsd:Name`

*Note* Attributes using this datatype must contain a single word which follows the rules defining a legal XML name (see <http://www.w3.org/TR/REC-xml/#dt-name>): for example they cannot include whitespace or begin with digits.

---

**teidata.namespace** defines the range of attribute values used to indicate XML namespaces as defined by the W3C Namespaces in XML Technical Recommendation.

*Module* tei – The TEI Infrastructure

*Used by Element:*

- attDef/@ns
- namespace/@name

*Content model* `<content> <dataRef name="anyURI"/></content>`

*Declaration* `teidata.namespace = xsd:anyURI`

*Note* The range of syntactically valid values is defined by RFC 3986 *Uniform Resource Identifier (URI): Generic Syntax*

---

**teidata.nullOrName** defines attribute values which contain either the null string or an XML name.

*Module* tei – The TEI Infrastructure

*Used by*

*Content model*

```
<content>
  <alternate>
    <valList>
      <valItem ident="" />
    </valList>
    <dataRef name="NCName" />
  </alternate>
</content>
```

*Declaration* `teidata.nullOrName = ( "" ) | xsd:NCName`

*Note* The rules defining an XML name form a part of the XML Specification.

---

**teidata.numeric** defines the range of attribute values used for numeric values.

*Module* tei – The TEI Infrastructure

Used by Element:

- memberOf/@max
- memberOf/@min
- num/@value
- numeric/@value
- numeric/@max
- precision/@stdDeviation

Content model

```
<content>
  <alternate>
    <dataRef name="double"/>
    <dataRef name="token"
      restriction="(\-?[\d]+\-?[\d]+)"/>
    <dataRef name="decimal"/>
  </alternate>
</content>
```

Declaration

```
teidata.numeric =
  xsd:double | token { pattern = "(\-?[\d]+\-?[\d]+)" } | xsd:decimal
```

*Note* Any numeric value, represented as a decimal number, in floating point format, or as a ratio. To represent a floating point number, expressed in scientific notation, 'E notation', a variant of 'exponential notation', may be used. In this format, the value is expressed as two numbers separated by the letter E. The first number, the significand (sometimes called the mantissa) is given in decimal format, while the second is an integer. The value is obtained by multiplying the mantissa by 10 the number of times indicated by the integer. Thus the value represented in decimal notation as 1000.0 might be represented in scientific notation as 10E3.

A value expressed as a ratio is represented by two integer values separated by a solidus (/) character. Thus, the value represented in decimal notation as 0.5 might be represented as a ratio by the string 1/2.

---

**teidata.outputMeasurement** defines a range of values for use in specifying the size of an object that is intended for display.

*Module* tei – The TEI Infrastructure

*Used by*

*Content model*

```
<content>
  <dataRef name="token"
    restriction="[\-+]?[d+(\.\d+)?(%|cm|mm|in|pt|pc|px|em|ex|gd|rem|vw|vh|vm)"/>
</content>
```

*Declaration*

```
teidata.outputMeasurement =
  token
  {
```

```

} pattern = "[\ -+]?[d+(\.d+)?(%|cm|mm|in|pt|pc|px|em|ex|gd|rem|vw|vh|vm)]"

```

*Example*

```

<figure>
  <head>The TEI Logo</head>
  <figDesc>Stylized yellow angle brackets with the letters
<mentioned>TEI</mentioned> in
  between and <mentioned>text encoding initiative</mentioned> underneath, all
  on a white
  background.</figDesc>
  <graphic height="600px" width="600px"
  url="http://www.tei-c.org/logos/TEI-600.jpg"/>
</figure>

```

*Note* These values map directly onto the values used by XSL-FO and CSS. For definitions of the units see those specifications; at the time of this writing the most complete list is in the CSS3 working draft.

**teidata.pattern** defines attribute values which are expressed as a regular expression.

*Module* tei – The TEI Infrastructure

*Used by* Element:

- dataRef/@restriction
- metDecl/@pattern

*Content model* <content> <dataRef name="token"/></content>

*Declaration* teidata.pattern = token

*Note* A regular expression, often called a *pattern*, is an expression that describes a set of strings. They are usually used to give a concise description of a set, without having to list all elements. For example, the set containing the three strings *Handel*, *Händel*, and *Haendel* can be described by the pattern `H(ä|æ?)ndel` (or alternatively, it is said that the pattern `H(ä|æ?)ndel` *matches* each of the three strings)Wikipedia

This TEI datatype is mapped to the XSD token datatype, and may therefore contain any string of characters. However, it is recommended that the value used conform to the particular flavour of regular expression syntax supported by XSD Schema.

**teidata.percentage** defines attribute values used to express a percentage value.

*Module* tei – The TEI Infrastructure

*Used by*

*Content model*

```

<content>
  <dataRef name="nonNegativeInteger"/>
</content>

```

*Declaration* teidata.percentage = xsd:nonNegativeInteger

*Note* Any non-negative integer value less than 100.

**teidata.point** defines the data type used to express a point in cartesian space.

*Module* tei — The TEI Infrastructure

*Used by*

*Content model*

```
<content>
  <dataRef name="token"
    restriction="(\-?[0-9]+\.\?[0-9]*,\-?[0-9]+\.\?[0-9]*)"/>
</content>
```

*Declaration*

```
teidata.point = token { pattern = "(\\-?[0-9]+\\.?[0-9]*,\\-?[0-9]+\\.?[0-9]*)" }
```

*Example*

```
<facsimile>
  <surface ulx="0" uly="0" lrx="400" lry="280">
    <zone points="220,100 300,210 170,250 123,234">
      <graphic url="handwriting.png "/>
    </zone>
  </surface>
</facsimile>
```

*Note* A point is defined by two numeric values, which may be expressed in any notation permitted.

---

**teidata.pointer** defines the range of attribute values used to provide a single URI, absolute or relative, pointing to some other resource, either within the current document or elsewhere.

*Module* tei — The TEI Infrastructure

*Used by* Element:

- alt/@target
- app/@from
- app/@to
- arc/@from
- arc/@to
- catRef/@scheme
- certainty/@given
- change/@target
- classCode/@scheme
- eLeaf/@value
- eTree/@value
- equiv/@uri
- equiv/@filter
- event/@where
- f/@fVal

- fs/@feats
- fsdLink/@target
- g/@ref
- gap/@hand
- handShift/@new
- iNode/@value
- iNode/@children
- iNode/@parent
- iNode/@follow

- msItemStruct/@class
- node/@value
- node/@adjTo
- node/@adjFrom
- node/@adj
- normalization/@source
- note/@targetEnd
- nym/@parts
- occupation/@scheme
- occupation/@code
- redo/@target
- relatedItem/@target
- relation/@active
- relation/@mutual
- relation/@passive
- root/@value
- root/@children
- socecStatus/@scheme
- socecStatus/@code
- space/@resp

- span/@from
- span/@to
- specGrpRef/@target
- tagUsage/@render
- tech/@perf
- timeline/@origin
- triangle/@value
- unclear/@hand
- undo/@target
- w/@lemmaRef
- when/@since
- witDetail/@wit

*Content model* `<content> <dataRef name="anyURI" /></content>`

*Declaration* `teidata.pointer = xsd:anyURI`

*Note* The range of syntactically valid values is defined by RFC 3986 *Uniform Resource Identifier (URI): Generic Syntax*. Note that the values themselves are encoded using RFC 3987 *Internationalized Resource Identifiers (IRIs) mapping to URIs*. For example, <https://secure.wikimedia.org/wikipedia/en/wiki/%> is encoded as <https://secure.wikimedia.org/wikipedia/en/wiki/%25> while <http://www.وزارة-الاتصالات.مصر.xn--rmckbbajlc6dj7bxne2c.xn--wgbh1c/>

---

**teidata.probability** defines the range of attribute values expressing a probability.

*Module* tei – The TEI Infrastructure

*Used by* teidata.probCertElement:

- alt/@weights
- certainty/@degree

*Content model* `<content> <dataRef name="double" /></content>`

*Declaration* `teidata.probability = xsd:double`

*Note* Probability is expressed as a real number between 0 and 1; 0 representing *certainly false* and 1 representing *certainly true*.

---

**teidata.probCert** defines a range of attribute values which can be expressed either as a numeric probability or as a coded certainty value.

*Module* tei – The TEI Infrastructure

*Used by*

*Content model*

```
<content>
  <alternate>
    <dataRef key="teidata.probability"/>
    <dataRef key="teidata.certainty"/>
  </alternate>
```

```
</content>
```

*Declaration*

```
teidata.probCert = teidata.probability | teidata.certainty
```

---

**teidata.replacement** defines attribute values which contain a replacement template.

*Module* tei – The TEI Infrastructure

*Used by*

*Content model* `<content> <textNode/></content>`

*Declaration* `teidata.replacement = text`

---

**teidata.sex** defines the range of attribute values used to identify human or animal sex.

*Module* tei – The TEI Infrastructure

*Used by* Element:

- person/@sex
- personGrp/@sex
- sex/@value

*Content model* `<content> <dataRef key="teidata.word"/></content>`

*Declaration* `teidata.sex = teidata.word`

*Note* Values for attributes using this datatype may be locally defined by a project, or may refer to an external standard, such as vCard's sex property <http://microformats.org/wiki/gender-formats> (in which M indicates male, F female, O other, N none or not applicable, U unknown), or the often used ISO 5218:2004 *Representation of Human Sexes* [http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266\\_ISO\\_IEC\\_5218\\_2004\(E\\_F\).zip](http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266_ISO_IEC_5218_2004(E_F).zip) (in which 0 indicates unknown; 1 male; 2 female; and 9 not applicable, although the ISO standard is widely considered inadequate); cf. CETH's *Recommendations for Inclusive Data Collection of Trans People* <http://transhealth.ucsf.edu/trans?page=lib-data-collection>.

---

**teidata.temporal.iso** defines the range of attribute values expressing a temporal expression such as a date, a time, or a combination of them, that conform to the international standard *Data elements and interchange formats – Information interchange – Representation of dates and times*.

*Module* tei – The TEI Infrastructure

*Used by*

*Content model*

```
<content>
  <alternate>
    <dataRef name="date"/>
    <dataRef name="gYear"/>
    <dataRef name="gMonth"/>
    <dataRef name="gDay"/>
    <dataRef name="gYearMonth"/>
```

```
<dataRef name="gMonthDay"/>
<dataRef name="time"/>
<dataRef name="dateTime"/>
<dataRef name="token"
  restriction="[0-9.,DHMPRSTWYZ/:\-]+" />
</alternate>
</content>
```

### Declaration

```
teidata.temporal.iso =
  xsd:date
  | xsd:gYear
  | xsd:gMonth
  | xsd:gDay
  | xsd:gYearMonth
  | xsd:gMonthDay
  | xsd:time
  | xsd:dateTime
  | token { pattern = "[0-9.,DHMPRSTWYZ/:\-]+" }
```

*Note* If it is likely that the value used is to be compared with another, then a time zone indicator should always be included, and only the `dateTime` representation should be used. For all representations for which ISO 8601 describes both a *basic* and an *extended* format, these Guidelines recommend use of the extended format.

While ISO 8601 permits the use of both `00:00` and `24:00` to represent midnight, these Guidelines strongly recommend against the use of `24:00`.

---

**teidata.temporal.w3c** defines the range of attribute values expressing a temporal expression such as a date, a time, or a combination of them, that conform to the *W3C XML Schema Part 2: Datatypes Second Edition* specification.

*Module* `tei` – The TEI Infrastructure

*Used by Element:*

- `docDate/@when`
- `when/@absolute`

*Content model*

```
<content>
  <alternate>
    <dataRef name="date"/>
    <dataRef name="gYear"/>
    <dataRef name="gMonth"/>
    <dataRef name="gDay"/>
    <dataRef name="gYearMonth"/>
    <dataRef name="gMonthDay"/>
    <dataRef name="time"/>
    <dataRef name="dateTime"/>
  </alternate>
</content>
```

### Declaration

```
teidata.temporal.w3c =
  xsd:date
  | xsd:gYear
  | xsd:gMonth
  | xsd:gDay
  | xsd:gYearMonth
  | xsd:gMonthDay
  | xsd:time
  | xsd:dateTime
```

*Note* If it is likely that the value used is to be compared with another, then a time zone indicator should always be included, and only the dateTime representation should be used.

**teidata.text** defines the range of attribute values used to express some kind of identifying string as a single sequence of unicode characters possibly including whitespace.

*Module* tei – The TEI Infrastructure

*Used by* Element:

- attRef/@name
- distinct/@time
- distinct/@space
- distinct/@social
- refState/@delim
- rendition/@selector
- valItem/@ident
- w/@lemma

*Content model* `<content> <dataRef name="string"/></content>`

*Declaration* `teidata.text = string`

*Note* Attributes using this datatype must contain a single ‘token’ in which whitespace and other punctuation characters are permitted.

**teidata.truthValue** defines the range of attribute values used to express a truth value.

*Module* tei – The TEI Infrastructure

*Used by* Element:

- binary/@value
- content/@autoPrefix
- fDecl/@optional
- listChange/@ordered
- metSym/@terminal
- model/@useSourceRendition
- modelGrp/@useSourceRendition
- modelSequence/@useSourceRendition
- note/@anchored

- numeric/@trunc
- pc/@pre
- sequence/@preserveOrder
- surface/@flipping
- tagsDecl/@partial

*Content model* `<content> <dataRef name="boolean"/></content>`

*Declaration* `teidata.truthValue = xsd:boolean`

*Note* The possible values of this datatype are 1 or true, or 0 or false. This datatype applies only for cases where uncertainty is inappropriate; if the attribute concerned may have a value other than true or false, e.g. unknown, or inapplicable, it should have the extended version of this datatype: `data.xTruthValue`.

---

**teidata.unboundedInt** defines an attribute value which can be either any non-negative integer or the string "unbounded".

*Module* tei – The TEI Infrastructure

*Used by Element:*

- datatype/@maxOccurs

*Content model*

```
<content> <alternate>
  <dataRef name="nonNegativeInteger"/>
  <valList type="closed">
    <valItem ident="unbounded"/>
  </valList>
</alternate>
</content>
```

*Declaration*

```
teidata.unboundedInt = xsd:nonNegativeInteger | ( "unbounded" )
```

---

**teidata.version** defines the range of attribute values which may be used to specify a TEI or Unicode version number.

*Module* tei – The TEI Infrastructure

*Used by Element:*

- TEI/@version
- teiCorpus/@version
- unicodeName/@version

*Content model*

```
<content>
  <dataRef name="token"
    restriction="[\d]+(\.[\d]+){0,2}"/>
</content>
```

*Declaration*

```
teidata.version = token { pattern = "[\d]+(\.[\d+]{0,2}" }
```

*Note* The value of this attribute follows the pattern specified by the Unicode consortium for its version number (<http://unicode.org/versions/>). A version number contains digits and fullstop characters only. The first number supplied identifies the major version number. A second and third number, for minor and sub-minor version numbers, may also be supplied.

**teidata.versionNumber** defines the range of attribute values used for version numbers.

*Module* tei – The TEI Infrastructure

*Used by Element:*

- application/@version
- transcriptionDesc/@version

*Content model*

```
<content>
  <dataRef name="token"
    restriction="[\d]+[a-z]*[\d]*(\.[\d]+[a-z]*[\d]*){0,3}" />
</content>
```

*Declaration*

```
teidata.versionNumber =
  token { pattern = "[\d]+[a-z]*[\d]*(\.[\d]+[a-z]*[\d]*){0,3}" }
```

**teidata.word** defines the range of attribute values expressed as a single word or token.

*Module* tei – The TEI Infrastructure

*Used by* teidata.enumerated teidata.sexElement:

- app/@loc
- attRef/@class
- binaryObject/@encoding
- certainty/@assertedValue
- code/@lang
- gap/@reason
- langKnown/@level
- locus/@from
- locus/@to
- m/@baseForm
- media/@mimeType
- metSym/@value
- metamark/@function
- org/@role
- personGrp/@size

- rhyme/@label
- secl/@reason
- supplied/@reason
- surplus/@reason
- symbol/@value
- unclear/@reason
- vLabel/@name

### Content model

```
<content>
  <dataRef name="token"
    restriction="(\p{L}|\p{N}|\p{P}|\p{S})+"/>
</content>
```

### Declaration

```
teidata.word = token { pattern = "(\p{L}|\p{N}|\p{P}|\p{S})+" }
```

*Note* Attributes using this datatype must contain a single ‘word’ which contains only letters, digits, punctuation characters, or symbols: thus it cannot include whitespace.

---

**teidata.xmlName** defines attribute values which contain an XML name.

*Module* tei – The TEI Infrastructure

*Used by Element:*

- classRef/@key
- classRef/@include
- classRef/@except
- dataRef/@key
- dataRef/@name
- dataRef/@ref
- elementRef/@key
- elementSpec/@prefix
- macroRef/@key
- moduleRef/@prefix
- moduleRef/@include
- moduleRef/@except
- moduleRef/@key
- schemaSpec/@prefix

*Content model* `<content> <dataRef name="NCName"/></content>`

*Declaration* `teidata.xmlName = xsd:NCName`

*Note* The rules defining an XML name form a part of the XML Specification.

**teidata.xpath** defines attribute values which contain an XPath expression.

*Module* tei – The TEI Infrastructure

*Used by Element:*

- model/@predicate
- modelSequence/@predicate
- param/@name
- param/@value

*Content model* `<content> <textNode/></content>`

*Declaration* `teidata.xpath = text`

*Note* Any XPath expression using the syntax defined in Kay (ed.) (2007)

**teidata.xTruthValue** (extended truth value) defines the range of attribute values used to express a truth value which may be unknown.

*Module* tei – The TEI Infrastructure

*Used by Element:*

- binding/@contemporary
- iNode/@ord
- kinesic/@iterated
- root/@ord
- said/@aloud
- said/@direct
- seal/@contemporary
- sound/@discrete
- vocal/@iterated
- writing/@gradual

*Content model*

```
<content>
  <alternate>
    <dataRef name="boolean"/>
    <valList>
      <valItem ident="unknown"/>
      <valItem ident="inapplicable"/>
    </valList>
  </alternate>
</content>
```

*Declaration*

```
teidata.xTruthValue = xsd:boolean | ( "unknown" | "inapplicable" )
```

*Note* In cases where where uncertainty is inappropriate, use the datatype `data.TruthValue`.

## F.3 Reading List

The following lists of readings in markup theory and the TEI derive from work originally prepared by Susan Schreibman and Kevin Hawkins for the TEI Education Special Interest Group, recoded in TEI P5 by Sabine Krott and Eva Radermacher. They should be regarded only as a snapshot of work in progress, to which further contributions and corrections are welcomed (see further [http://www.tei-c.org/Support/Learn/tei\\_bibliography.xml](http://www.tei-c.org/Support/Learn/tei_bibliography.xml)).

### Theory of Markup and XML

## G Prefatory Notes

This Appendix contains (in reverse chronological order) the ‘Introductory Notes’ prefixed to each revision of the TEI Guidelines since its first publication in 1994.

### G.1 Prefatory Note (March 2002)

The primary goal of this revision has been to make available a new and corrected version of the TEI Guidelines which:

- is expressed in XML and conforms to a TEI-conformant XML DTD;
- generates a set of DTD fragments that can be combined together to form either SGML or XML document type definitions;
- corrects blatant errors, typographical mishaps, and other egregious editorial oversights;
- can be processed and maintained using readily available XML tools instead of the special-purpose ad hoc software originally used for TEI P3.

A second major design goal of this revision has been to ensure that the DTD fragments generated would not break existing documents: in other words, that any document conforming to the original TEI P3 SGML DTD would also conform to the new XML version of it. Although full backwards compatibility cannot be guaranteed, we believe our implementation is consistent with that goal.

In most respects, the TEI Guidelines have stood the test of time remarkably well. The present edition makes no substantial attempt to rewrite those few parts of them which have now been rendered obsolete by changes since their first publication, though an indication is given in the text of where such rewriting is now considered necessary. Neither does the present version attempt to address any of the many possible new areas of digital activity in which the TEI approach to standardization may have something to offer. Both these tasks require the existence of an informed and active TEI Council to direct and validate such extension and maintenance work, in response to the changing needs and priorities of the TEI user community.

Two exceptions to the above principles may be cited: firstly, the chapter which originally provided a ‘Gentle Introduction’ to SGML has been completely rewritten to provide a similarly gentle introduction to XML; secondly the chapter on character sets has been completely revised in light of the close connexion between Unicode and XML. The editors gratefully acknowledge the assistance of the *ad hoc* workgroup chaired by Christian Wittern, which undertook to provide expert advice and correction at very short notice, in the latter task.

The preparation of this new version relied extensively on preliminary work carried out by the former North American editor of the TEI Guidelines, C.M. Sperberg-McQueen. In a TEI working paper written in 1999<sup>132</sup> he sketched out a precise blueprint for the conversion of the TEI from SGML to XML, which we have implemented, with only slight modification.

The Editors would also like to express thanks to the team of volunteers from the TEI community who helped us with the task of proofreading the first draft during the summer of 2001; and to Sebastian Rahtz of Oxford University Computing Services, without whose skill and enthusiasm this new edition would not have been possible.

A substantial proportion of the work of preparing this new edition was funded with the assistance of a grant from the US National Endowment for the Humanities, whose continued support of the TEI has also been crucial to the effort of setting up the TEI Consortium.

Finally, we would like to thank all our colleagues on the interim management board of the TEI Consortium, in particular its Chairman John Unsworth, for their continued support of the TEI’s work, and their willingness to devote effort to the difficult task of overseeing its transition to a new organizational infrastructure.

Summary details of the changes made in the present and previous editions are given in their Prefatory Notes, all of which are now reproduced in an Appendix to the present edition: see *Appendix G Prefatory Notes*.

Lou Burnard and Syd Bauman (TEI Editors)  
Oxford and Providence, March 2002.

### G.2 Introductory Note (November 2001)

To complete the work started in June of this year, the TEI Editors asked for volunteers from the TEI community to proofread the preliminary XML version. 24 volunteers responded to this call during August, and gave invaluable

---

<sup>132</sup> *TEI ED W69*, available from the TEI web site at <http://www.tei-c.org/Vault/ED/edw69.htm>.

help both by identifying a number of previously un-noticed errors, and by suggesting areas in which more substantial revision should be undertaken in the future. The Editors gratefully acknowledge the assistance of the following individuals during this exercise:

Jimmy Adair, Syd Bauman, Michael Beddow, Steven Bird, Lisa Charlong, Matthew Driscoll, Patrick Durusau, Tomaz Erjavec, Nick Finke, Tim Finney, Julia Flanders, Mike Fraser, Pankaj Kamthan, François Lachance, Terry Langendoen, Anne Mahoney, Gregory Murphy, Daniel Pitti, Rafal Prinke, Laurent Romary, Stewart Russell, Gary Simons, Elisabeth Solopova, Christian Wittern, Martin Wynne.

In addition to error correction, and clear delineation of those sections in which substantial revision is yet to be undertaken for TEI P5, the present draft differs from earlier ones in the following respects:

- Formal Public Identifiers have been introduced as a means of constructing TEI DTDs and an SGML Open Catalog is now included with the standard release;
- Some systematic errors and omissions in the reference section have been removed; the format of this section has been substantially changed, we hope for the better;
- The chapters on obtaining the TEI DTDs and WSDs have been brought up to date; the chapter on modification has been expanded to include a discussion of the TEI Lite customization;
- All examples and cited markup has been checked for XML validity against the published DTDs, and corrected where faulty; examples have been formatted in a (more or less) consistent style.

Lou Burnard and Syd Bauman (Editors)  
Oxford and Providence, November 2001.

## G.3 Introductory Note (June 2001)

This is a preliminary version of a revised and fully XML-compliant edition of the TEI Guidelines. Although work on revising and correcting the text of the document is incomplete, by making available this preliminary version we hope to facilitate testing of the XML document type declarations which it describes by as wide a range of TEI users as possible.

The primary goal of this revision is to make available the corrected (May 1999) edition of the Guidelines in a new version which:

- is expressed in XML and itself conforms to a TEI-conformant XML DTD;
- generates a set of XML DTD fragments that can be combined together in the same way as the existing TEI (P3) SGML DTD fragments to form true TEI XML DTD fragments without loss of functionality;
- can be processed and maintained using readily available XML tools instead of the special-purpose ad hoc software originally used for TEI P3.

As noted elsewhere, a number of errors were corrected in the May 1999 edition. A (much) smaller number of errors have also been corrected in this edition, but no new material has been added. We expect the expansion and modification of the Guidelines to become a real possibility in the context of the newly formed TEI Consortium, which has funded the preparation of this present edition.

A major design goal of both this and the previous revision has been to ensure that the DTD fragments generated would not break existing documents: in other words, that any document conforming to the original TEI P3 SGML DTD would also conform to the new XML version of it. Although full backwards compatibility cannot be guaranteed, we believe our implementation is consistent with that goal.

In making this new version, we relied extensively on preliminary work carried out by the outgoing North American editor of the TEI Guidelines, Michael Sperberg-McQueen. In a TEI working paper written in 1999, TEI ED W69, Michael sketched out a precise blueprint for the conversion of the TEI from SGML to XML, which we have implemented, with only slight modification. The current TEI editors wish to express here our admiration for the detailed care put into that paper, without which our task would have been forbiddingly difficult, if not impossible. We would also like to express our thanks to Sebastian Rahtz of Oxford University Computing Services, for his invaluable assistance in preparing this new edition.

We list here in summary form all the changes made in the present edition. Full technical details are provided in documents TEI EDW69 and TEI EDW70, available from the TEI web site.

1. A new keyword `TEI.XML` has been added. By setting its value to `INCLUDE`, rather than the default `IGNORE`, the user can request generation of an XML rather than an SGML DTD;
2. The content models of all elements have been checked, and, where necessary, changed so that they are equally valid as SGML or as XML;
3. The declared value for all attributes has been changed to a form which is equally valid as SGML or as XML;
4. All the examples have been checked for conformance and converted to use XML syntax, where possible. (This process is currently incomplete.)
5. Some errors and duplications in the class membership of elements from the names and dates tagsets have been corrected.

To implement the first of these, we have parameterized the *tag omissibility* indicators ‘- o’ and ‘- -’ used within element declarations in the DTD. When XML is to be generated, the parameter entities concerned are redeclared with the null string as their value.

The second change was achieved by removing SGML-specific features (ampersand connectors, inclusion and exclusion exceptions, various types of attribute content) from the DTD and revising the syntax of the DTD to conform to XML requirements (specifically in the representation of mixed-content models, and by removing redundant parentheses). In making these changes, we took care to ensure that the resulting content model would continue to accept existing valid documents, though in the nature of things it could not be guaranteed to reject the same set of documents. As further discussed in EDW69 and EDW70, some constraints (exclusion exceptions, for example) which could be carried out by a generic SGML parser using TEI P3 will have to be implemented by a special purpose TEI validator using TEI P4.

Much work remains to be done, firstly in testing the new DTD fragments against as wide a range of TEI materials as possible, secondly in revising the discussion of markup theory and practice within the text to reflect current thinking. A few sections of the current text (the Gentle Introduction to SGML and the discussion of Extended Pointer syntax are two examples) will need substantial rewriting. For the most part, however, we think the Guidelines have stood the test of time well and can be recommended to a new generation of text encoders scarcely born at the time they were first formulated.

Lou Burnard and Steve De Rose (Editors)  
Oxford and Providence, May 2001.

### G.4 Introductory Note (May 1999)

No work of the size and complexity of the TEI *Guidelines* could reasonably be expected to be error-free on publication, nor to remain long uncorrected. It has however taken rather longer than might have been anticipated to complete production of the present corrected reprint of the first edition, for which we present our apologies, both to the many individuals and institutions whose enthusiastic adoption and promotion of the TEI encoding scheme have ensured its continued survival in the rapidly changing world of digital scholarship, and also to the many helpfully critical users whose assiduous uncovering and reporting of our errors have made possible the present revision.

At its first meeting in Bergen, in June 1996, the TEI Technical Review Committee (TRC) approved the setting up of a small working committee to oversee the production of a revised edition of the TEI *Guidelines*, to include corrections of as many as possible of the ‘corrigible errors’ notified to the editors since publication of the first edition in May 1994, the bulk of which are summarized in a TEI working paper (TEI EDW67, available from the TEI web site).

During the spring of 1997, this TRC Core Subcommittee reviewed nearly 200 comments and proposals which the editors had collected from public debate and discussion over the preceding two years, and provided invaluable technical guidance in disposition of them. We are glad to take this opportunity of expressing our thanks to this subcommittee, whose members were Elli Mylonas, Dominic Dunlop, and David T. Barnard.

The work of making the corrections and regenerating the text proceeded rather fitfully during 1998 and 1999, largely because of increasing demands on the editors’ time from their other responsibilities. With the establishment of the new TEI Consortium, it is to be hoped that maintenance of the Guidelines will be placed on a more secure footing. Some specific areas in which we anticipate future revisions being carried out are listed below.

#### Typographic Corrections Made

- examples of TEI markup throughout the text were all checked against the relevant DTD fragment and an embarrassingly large number of tagging errors corrected;

- various minor typographic and spelling errors were corrected;
- the ‘corrigible errors’ listed in working paper TEI EDW67 were all corrected: some of these required specific changes to the DTD which are listed in the next section.

## Specific Changes in the DTD

A major goal of this revision was to avoid changes which might invalidate existing data, even where existing constructs seemed erroneous in retrospect. To that end, wherever changes have been made in content models for existing elements, they have as far as possible been made so that the DTD will now accept a superset of what was previously legal. Only one new element (`<ab>`) has been added.

Where possible, a few content models have been changed in such a way as to facilitate conversion to XML, but XML compatibility is *not* a goal of this revision.

Brief details of all changes made in the DTD follow:

- Several changes were made in class membership, in order to correct unreachability problems. Specifically:
  - elements `<geogName>`, `<persName>`, `<placeName>` were added to the `m.data` class;
  - `<geogName>` and `<placeName>` were removed from the `m.placepart` class;
  - the elements `<addSpan>`, `<delSpan>`, `<gap>`, were added to the `m.Edit` class;
  - a new class `m.editIncl` was defined, with members `<addSpan>`, `<delSpan>`, and `<gap>`; this class was then added to the global inclusion class `m.globIncl` along with `<anchor>` (erroneously a member of the `m.Seg` class, from which it is now removed), `m.metadata` and `m.refsys`;
- added `<name>` element to `m.addrPart` class;
- added `<dateline>` to `m.divtop` and `m.divbot` classes;
- added `<epilogue>` and `<castList>` to `m.dramafront` class;
- added `<divGen>` to `m.front` class;
- added `<dateline>` to `m.divtop` and `m.divtop` classes;
- added `<u>` element to `a.declaring` class;
- defined new class `m.fmchunk` (front matter chunk), comprising `<argument>`, `<byline>`, `<docAuthor>`, `<docDate>`, `<docEdition>`, `<docImprint>`, `<docTitle>`, `<epigraph>`, `<head>`, and `<titlePart>` for use in simplification of the content model for `<front>` element;
- defined new element `<ab>` (anonymous block), and added it to the `m.chunk` class;
- corrected an error whereby global attributes were not properly defined for elements specifying a non-default value for any of the `a.global` attributes: elements affected include: `<foreign>`, `<hi>`, `<del>`, `<pb>`, `<lb>`, `<cb>`, `<language>`, `<anchor>`, and `<when>`;
- changed content models to permit empty `<list>` and empty `<availability>` elements;
- changed content model for `<series>` element to permit `#PCDATA`;
- changed content model for `<setting>` element to permit `<date>` element as a direct child;
- added a *key* attribute to the `<distance>` element, for consistency with other elements in its class;
- changed content model for `<orgName>` element to make it more consistent with e.g. `<persName>`;
- changed content model for `<opener>` element to include `<argument>`, `<byline>`, and `<epigraph>`;
- changed content models for `<app>`, `<rdgGrp>`, and `<wit>` elements;
- revised attributes on `<hand>` element.

A number of content models were changed with a view to easing the creation of an XML compatible version of the Guidelines. Specifically:

- removed ampersand connectors from `<cit>`, `<respStmt>`, `<publicationStmt>`, and `<graph>`;
- changed the mixed content models for `<sense>`, `<re>`, `<persName>`, `<placeName>`, `<geogName>`, `<dateStruct>`, `<timeStruct>`, and `<dateline>` to make them XML-conformant.

### Outstanding Errors

A small number of other known problems remain uncorrected in this version and are briefly listed below. Please watch the TEI mailing list for announcements of their correction.

- elements of class `model.inter` don't always behave as they should (e.g. one cannot insert a `<table>` before anything else in a `<div>`);
- some mixed-content problems consequent on the definition of `macro.specialPara` need to be addressed systematically; in particular, the treatment of list items or notes which contain several paragraphs continues to surprise many users: no whitespace is allowed between the paragraphs;
- the *resp* attributes on editorial elements are not consistently defined;
- the discussions of DTD invocation, and the DTD itself, all use system identifiers instead of formal public identifiers.

Our next priority however will be the production of a fully XML-compliant version of the TEI DTD, work on which is already well advanced.

C.M. Sperberg-McQueen and Lou Burnard, May 1999

## G.5 Preface (April 1994)

These Guidelines are the result of over five years' effort by members of the research and academic community within the framework of an international cooperative project called the Text Encoding Initiative (TEI), established in 1987 under the joint sponsorship of the Association for Computers and the Humanities, the Association for Computational Linguistics, and the Association for Literary and Linguistic Computing.

The impetus for the project came from the humanities computing community, which sought a common encoding scheme for complex textual structures in order to reduce the diversity of existing encoding practices, simplify processing by machine, and encourage the sharing of electronic texts. It soon became apparent that a sufficiently flexible scheme could provide solutions for text encoding problems generally. The scope of the TEI was therefore broadened to meet the varied encoding requirements of any discipline or application. Thus, the TEI became the only systematized attempt to develop a fully general text encoding model and set of encoding conventions based upon it, suitable for processing and analysis of any type of text, in any language, and intended to serve the increasing range of existing (and potential) applications and use.

What is published here is a major milestone in this effort. It provides a single, coherent framework for all kinds of text encoding which is hardware-, software- and application-independent. Within this framework, it specifies encoding conventions for a number of key text types and features. The ongoing work of the TEI is to extend the scheme presented here to cover additional text types and features, as well as to continue to refine its encoding recommendations on the basis of extensive experience with their actual application and use.

We therefore offer these Guidelines to the user community for use in the same spirit of active collaboration and cooperation with which they have so far been developed. The TEI is committed to actively supporting the widespread and large-scale use of the Guidelines which, with the publication of this volume, is now for the first time possible. In addition, we anticipate that users of the TEI Guidelines will in some instances adapt and extend them as necessary to suit particular needs; we invite such users to engage in the further development of these Guidelines by working with us as they do so.

Like any standard which is actually used, these Guidelines do not represent a static finished work, but rather one which will evolve over time with the active involvement of its community of users. We invite and encourage the participation of the user community in this process, in order to ensure that the TEI Guidelines become and remain useful in all sorts of work with machine-readable texts.

This document was made possible in part by financial support from the U.S. National Endowment for the Humanities, an independent federal agency; Directorate General XIII of the Commission of the European Communities; the Andrew W. Mellon Foundation; and the Social Science and Humanities Research Council of Canada. Direct and indirect support has also been received from the University of Illinois at Chicago, the Oxford University Computing Services, the University of Arizona, the University of Oslo and Queen's University (Kingston, Ont.), Bellcore (Bell Communications Research), the Istituto di Linguistica Computazionale (C.N.R.) Pisa, the British Academy, and Ohio State University, as well as the employers and host institutions of the members of the TEI working committees and work groups listed in the acknowledgments.

The production of this document has been greatly facilitated by the willingness of many software vendors to provide us with evaluation versions of their products. Most parts of this text have been processed at some time

by almost every currently available SGML-aware software system. In particular, we gratefully acknowledge the assistance of the following vendors:

- Berger-Levrault AIS s.a. (for Balise);
- E2S n.v. (for E2S Advanced SGML Editor);
- Electronic Book Technology (for DynaText);
- SEMA Group and Yard Software (for Mark-It and Write-It);
- Software Exoterica (for CheckMark and Xtran);
- SoftQuad, Inc., (for Author/Editor and RulesBuilder);
- Xerox Corporation (for Ventura Publisher).

Details of the software actually used to produce the current document are given in the colophon at the end of the work.

## G.6 Acknowledgments

Many people have given of their time, energy, expertise, and support in the creation of this document; it is unfortunately not possible to thank them all adequately. Below are listed those who have served as formal members of the TEI's Work Groups and Working Committees during its six-year history; others not so officially enfranchised also contributed much to the quality of the result.

The editors take this opportunity to acknowledge our debt to those who have patiently endured and corrected our misunderstandings of their work; we hope that they will feel the wait has not been in vain. For any errors and inconsistencies remaining, we must accept responsibility; any virtue in what is here presented, we gladly ascribe to the energies of the keen intellects listed below.

C. M. Sperberg-McQueen and Lou Burnard

### TEI Working Committees (1990-1993)

Not all members listed were able to serve throughout the development of the Guidelines.

**Committee on Text Documentation:** Chair: Dominik Wujastyk (Wellcome Institute for the History of Medicine)

Members 1990–1992: J. D. Byrum (Library of Congress); Marianne Gaunt (Rutgers University); Richard Giordano (Manchester University); Barbara Ann Kipfer (Independent Consultant); Hans Jørgen Marker (Danish Data Archive, Odense); Marcia Taylor (University of Essex);

**Committee on Text Representation** Chair: Stig Johansson (University of Oslo)

Members 1990–1992: Roberto Cencioni (Commission of the European Communities); David R. Chesnutt (University of South Carolina); Robin C. Cover (Dallas Theological Seminary); Steven J. DeRose (Electronic Book Technology Inc); David G. Durand (Boston University); Susan M. Hockey (Oxford University Computing Service); Claus Huitfeldt (University of Bergen); Francisco Marcos-Marin (University Madrid); Elli Mylonas (Harvard University); Wilhelm Ott (University of Tübingen); Allen H. Renear (Brown University); Manfred Thaller (Max-Planck-Institut für Geschichte, Göttingen)

**Committee on Text Analysis and Interpretation** Chair: D. Terence Langendoen (University of Arizona)

Members 1990–1992: Robert Amsler (Bell Communications Research); Stephen Anderson (Johns Hopkins University); Branimir Boguraev (IBM T. J. Watson Research Center); Nicoletta Calzolari (University of Pisa); Robert Ingria (Bolt Beranek Newman Inc); Winfried Lenders (University of Bonn); Mitch Marcus (University of Pennsylvania); Nelleke Oostdijk (University of Nijmegen); William Poser (Stanford University); Beatrice Santorini (University of Pennsylvania); Gary Simons (Summer Institute of Linguistics); Antonio Zampolli, University of Pisa.

**Committee on Metalanguage and Syntax** Chair: David T. Barnard (Queen's University)

Members 1990–1994: David G. Durand (Boston University); Jean-Pierre Gaspart (Associated Consultants and Software Engineers sa/nv); Nancy M. Ide (Vassar College); Lynne A. Price (Software Exoterica / Xerox PARC); Frank Tompa (University of Waterloo); Giovanni Battista Varile (Commission of the European Communities).

In addition, the two TEI editors served *ex officio* on each committee.

Following publication of the first draft of the TEI Guidelines (P1) in November 1990, a number of specialist work groups were charged with responsibility for drafting revisions and extensions, which, together with material already presented in P1, constitute the basis of the present work.

In addition, many members of the work groups listed below met on three occasions to review the emerging proposals in detail at technical review meetings convened by the TEI Steering Committee. These meetings, held in Myrdal, Norway (November 1991), Chicago (May 1992) and Oxford (May 1993), were largely responsible for the technical content and organization of the present work. Attendants at these meetings are starred in the list below.

- TR1 Character sets** Chair: Harry Gaylord\* (University of Groningen); Syun Tutiya\* (Chiba University).
- TR2 Text criticism** Chair: Peter Robinson\* (Oxford University); David Chesnutt\* (University of South Carolina); Robin Cover\* (Dallas Theological Seminary); Robert Kraft (University of Pennsylvania); Peter Shillingsburg (Mississippi State University).
- TR3 Hypertext and hypermedia** Chair: Steven J. DeRose\* (Electronic Book Technologies Inc); David Durand (Boston University); Edward A. Fox (Virginia State University); Eve Wilson (University of Kent).
- TR4 Formulæ, Tables, figures, and graphics** Chair: Paul Ellison\* (University of Exeter); Anders Berglund (Independent Consultant); Dale Waldt (Thompson Professional Publishing).
- TR6 Language corpora** Chair: Douglas Biber\* (University of Northern Arizona); Jeremy Clear (Birmingham University); Gunnel Engwall (University of Stockholm).
- TR9 Manuscripts and codicology** Chair: Claus Huitfeldt\* (University of Bergen); Dino Buzzetti (University of Bologna); Jacqueline Hamesse (University of Louvain); Mary Keeler (Georgetown University); Christian Kloesel (Indiana University); Allen Renear\* (Brown University); Donald Spaeth (Glasgow University).
- TR10 Verse** Chair: David Robey\* (University of Manchester); Elaine Brennan\* (Brown University); David Chisholm (University of Arizona); Willard McCarty (University of Toronto).
- TR11 Drama and performance texts** Chair: Elli Mylonas\* (Harvard University); John Lavagnino\* (Brandeis University); Rosanne Potter (University of Iowa).
- TR12 Literary prose** Chair Thomas N. Corns\* (University of Wales); Christian Delcourt (University of Liège).
- AI1 Linguistic description** Chair: D. Terence Langendoen\* (University of Arizona); Stephen R. Anderson (Johns Hopkins University); Nicoletta Calzolari (University of Pisa); Geoffrey Sampson\* (University of Sussex); Gary Simons\* (Summer Institute of Linguistics).
- AI2 Spoken text** Chair: Stig Johansson\* (University of Oslo); Jane Edwards (University of California at Berkeley); Andrew Rosta (University College London).
- AI3 Literary studies** Chair: Paul Fortier\* (University of Manitoba); Christian Delcourt (University of Liège); Ian Lancashire (University of Toronto); Rosanne Potter (University of Iowa); David Robey\* (University of Manchester).
- AI4 Historical studies** Chair: Daniel Greenstein\* (University of Glasgow); Peter Denley (Queen Mary Westfield College, London); Ingo Kropac (University of Graz); Hans Jørgen Marker (Danish Data Archive, Odense); Jan Oldervoll (University of Tromsø); Kevin Schurer (University of Cambridge); Donald Spaeth (Glasgow University); Manfred Thaller (Max-Planck-Institut für Geschichte, Göttingen).<sup>133</sup>
- AI5 Print dictionaries** Chairs: Robert Amsler\* (Bell Communications Research) and Nicoletta Calzolari (University of Pisa); Susan Armstrong-Warwick (University of Geneva); John Fought (University of Pennsylvania); Louise Guthrie (University of New Mexico); Nancy M. Ide\* (Vassar College); Frank Tompa (University of Waterloo); Carol Van Ess-Dykema (US Department of Defense); Jean Veronis (University of Aix-en-Provence).
- AI6 Machine lexica** Chair: Robert Ingria\* (Bolt Beranek Newman Inc); Susan Armstrong-Warwick (University of Geneva); Nicoletta Calzolari (University of Pisa).
- AI7 Terminological data** Chair: Alan Melby\* (Brigham Young University) Gerhard Budin (University of Vienna); Gregory Shreve (Kent State University); Richard Strehlow (Oak Ridge National Laboratory); Sue Ellen Wright (Kent State University).

---

<sup>133</sup>This Workgroup was jointly sponsored by the Association for History and Computing.

## Advisory Board

Members of the TEI Advisory Board during the lifetime of the project are listed below, grouped under the name of the organization represented.

**American Anthropological Association:** Chad McDaniel (University of Maryland).

**American Historical Association:** Elizabeth A. R. Brown (Brooklyn College, CUNY).

**American Philological Association:** Jocelyn Penny Small (Rutgers University).

**American Philosophical Association:** Allen Renear (Brown University).

**American Society for Information Science:** Clifford A. Lynch (University of California).

**Association for Computing Machinery, Special Interest Group for Information Retrieval:** 1989–93: Scott Deerwester (University of Chicago); 1993– : Martha Evens (Illinois Institute of Technology).

**Association for Documentary Editing:** David Chesnutt (University of South Carolina).

**Association for History and Computing:** 1989–91: Manfred Thaller, Max-Planck-Institut für Geschichte, Göttingen; 1991– : Daniel Greenstein (Glasgow University).

**Association Internationale Bible et Informatique** 1989–93: Wilhelm Ott (University of Tübingen); 1993– : Winfried Bader (University of Tübingen).

**Canadian Linguistic Association:** Anne-Maria di Sciullo (Université du Québec à Montréal)

**Dictionary Society of North America:** Barbara Ann Kipfer (Independent Consultant).

**AAP Electronic Publishing Special Interest Group:** 1989–92: Betsy Kiser (OCLC); 1992– : Deborah Bendig and Andrea Keyhani (OCLC).

**International Federation of Library Associations and Institutions:** J. D. Byrum Jr. (The Library of Congress).

**Linguistic Society of America:** Stephen Anderson (The Johns Hopkins University)

**Modern Language Association:** Randall Jones (Brigham Young University) and Ian Lancashire (University of Toronto).

## Steering Committee Membership

Members of the Steering Committee of the TEI during the preparation of this work were:

### Association for Computational Linguistics:

- 1987–1993: Robert A. Amsler (Bell Communications Research);
- 1987–1993: Donald E. Walker (Bell Communications Research);
- 1993–1994: Susan Armstrong-Warwick (University of Geneva);
- 1994–1999: Judith Klavans (Columbia University).

### Association for Computers and the Humanities:

- 1987–1999: Nancy M. Ide (Vassar College);
- 1987–1994: C. M. Sperberg-McQueen (University of Illinois at Chicago);
- 1994–1999: David Barnard (Queen's University).

### Association for Literary and Linguistic Computing:

- 1987–1999: Susan M. Hockey (Center for Electronic Texts in the Humanities);
- 1987–1999: Antonio Zampolli (University of Pisa).

## H Colophon

The text of this manual was prepared electronically on a variety of systems. Most sections were originally drafted by members of the work groups and working committees of the TEI; all have been revised by the editors to achieve greater uniformity of style and greater consistency in the tag set.

The web release of the Guidelines was created using a library of XSLT stylesheets to convert to XHTML; the PDF version for printing was produced by conversion to LaTeX markup, processed using XeLaTeX. The XSLT libraries were written by Sebastian Rahtz.

Almost every available SGML and XML editor or processing program has been used at one time or another by the TEI; but without the open source implementations of XML parsers, editors and XSLT engines by James Clark, Richard Stallman, Michael Kay, and Daniel Veillard, the TEI could not survive, and we thank these individuals. We would also like to thank the staff at SyncRO Soft SRL, creators of the oXygen editor, for their support for the TEI during the creation on P5.

Many volunteers contributed to the preparation of this release of the Guidelines; we particularly note the work of Sabine Krott, Eva Radermacher and Arianna Ciula for their work in structuring the bibliographies.

The production and release process for TEI P5 was originally developed by Sebastian Rahtz for the TEI Technical Council.

## Index

Entries in *italic font* refer to examples, with those in **bold italics** referring to examples where the indexed element is the root.
