| 2.3  | The Encoding Description . . . . .                              | 36     |
| 2.4  | The Profile Description . . . . .                               | 50     |
| 2.5  | Non-TEI Metadata . . . . .                                      | 59     |
| 2.6  | The Revision Description . . . . .                              | 60     |
| 2.7  | Minimal and Recommended Headers . . . . .                       | 61     |
| 2.8  | Note for Library Cataloguers . . . . .                          | 64     |
| 2.9  | The TEI Header Module . . . . .                                 | 65     |
| 3    | Elements Available in All TEI Documents . . . . .               | 66     |
| 3.1  | Paragraphs . . . . .  | 67     |
| 3.2  | Treatment of Punctuation . . . . .                              | 68     |
| 3.3  | Highlighting and Quotation . . . . .                            | 70     |
| 3.4  | Simple Editorial Changes . . . . .                              | 82     |
| 3.5  | Names, Numbers, Dates, Abbreviations, and Addresses . . . . .   | 88     |
| 3.6  | Simple Links and Cross-References . . . . .                     | 100    |
| 3.7  | Lists . . . . .   | 103    |
| 3.8  | Notes, Annotation, and Indexing . . . . .                       | 107    |
| 3.9  | Graphics and Other Non-textual Components . . . . .             | 113    |
| 3.10 | Reference Systems . . . . .                                     | 115    |
| 3.11 | Bibliographic Citations and References . . . . .                | 124    |
| 3.12 | Passages of Verse or Drama . . . . .                            | 149    |
| 3.13 | Overview of the Core Module . . . . .                           | 154    |
| 4    | Default Text Structure . . . . .                                | 156    |
| 4.1  | Divisions of the Body . . . . .                                 | 158    |
| 4.2  | Elements Common to All Divisions . . . . .                      | 164    |
| 4.3  | Grouped and Floating Texts . . . . .                            | 170    |

|      |   |     |
|------|---|-----|
| 4.4  | Virtual Divisions . . . . .   | 179 |
| 4.5  | Front Matter . . . . .  | 180 |
| 4.6  | Title Pages . . . . .   | 183 |
| 4.7  | Back Matter . . . . .   | 184 |
| 4.8  | Module for Default Text Structure . . . . .                             | 186 |
| 5    | Characters, Glyphs, and Writing Modes . . . . .                         | 187 |
| 5.1  | Is Your Journey Really Necessary? . . . . .                             | 187 |
| 5.2  | Markup Constructs for Representation of Characters and Glyphs . . . . . | 188 |
| 5.3  | Annotating Characters . . . . .   | 193 |
| 5.4  | Adding New Characters . . . . .   | 195 |
| 5.5  | How to Use Code Points from the Private Use Area . . . . .              | 197 |
| 5.6  | Writing Modes . . . . .   | 197 |
| 5.7  | Examples of Different Writing Modes . . . . .                           | 199 |
| 5.8  | Text Rotation . . . . .   | 206 |
| 5.9  | Caveat . . . . .  | 209 |
| 5.10 | Formal Definition . . . . .   | 209 |
| 6    | Verse . . . . .   | 210 |
| 6.1  | Structural Divisions of Verse Texts . . . . .                           | 210 |
| 6.2  | Components of the Verse Line . . . . .                                  | 213 |
| 6.3  | Encoding Textual Structures Across Verses . . . . .                     | 216 |
| 6.4  | Rhyme and Metrical Analysis . . . . .                                   | 216 |
| 6.5  | Rhyme . . . . .   | 220 |
| 6.6  | Metrical Notation Declaration . . . . .                                 | 222 |
| 6.7  | Encoding Procedures for Other Verse Features . . . . .                  | 225 |
| 6.8  | Module for Verse . . . . .  | 225 |
| 7    | Performance Texts . . . . .   | 226 |
| 7.1  | Front and Back Matter . . . . .   | 226 |
| 7.2  | The Body of a Performance Text . . . . .                                | 234 |
| 7.3  | Other Types of Performance Text . . . . .                               | 248 |
| 7.4  | Module for Performance Texts . . . . .                                  | 251 |
| 8    | Transcriptions of Speech . . . . .                                      | 252 |
| 8.1  | General Considerations and Overview . . . . .                           | 252 |
| 8.2  | Documenting the Source of Transcribed Speech . . . . .                  | 254 |
| 8.3  | Elements Unique to Spoken Texts . . . . .                               | 257 |
| 8.4  | Elements Defined Elsewhere . . . . .                                    | 264 |
| 8.5  | Module for Transcribed Speech . . . . .                                 | 274 |
| 9    | Dictionaries . . . . .  | 275 |
| 9.1  | Dictionary Body and Overall Structure . . . . .                         | 275 |
| 9.2  | The Structure of Dictionary Entries . . . . .                           | 278 |
| 9.3  | Top-level Constituents of Entries . . . . .                             | 283 |
| 9.4  | Headword and Pronunciation References . . . . .                         | 301 |
| 9.5  | Typographic and Lexical Information in Dictionary Data . . . . .        | 303 |
| 9.6  | Unstructured Entries . . . . .  | 311 |
| 9.7  | The Dictionary Module . . . . .   | 313 |
| 10   | Manuscript Description . . . . .  | 314 |
| 10.1 | Overview . . . . .  | 314 |
| 10.2 | The Manuscript Description Element . . . . .                            | 314 |
| 10.3 | Phrase-level Elements . . . . .   | 318 |
| 10.4 | The Manuscript Identifier . . . . .                                     | 327 |
| 10.5 | The Manuscript Heading . . . . .  | 330 |
| 10.6 | Intellectual Content . . . . .  | 331 |
| 10.7 | Physical Description . . . . .  | 338 |
| 10.8 | History . . . . .   | 350 |
| 10.9 | Additional Information . . . . .  | 352 |

|       |   |     |
|-------|---|-----|
| 10.10 | Manuscript Parts . . . . .  | 355 |
| 10.11 | Manuscript Fragments . . . . .  | 356 |
| 10.12 | Module for Manuscript Description . . . . .                             | 357 |
| 11    | Representation of Primary Sources . . . . .                             | 358 |
| 11.1  | Digital Facsimiles . . . . .  | 358 |
| 11.2  | Combining Transcription with Facsimile . . . . .                        | 365 |
| 11.3  | Scope of Transcriptions . . . . .                                       | 370 |
| 11.4  | Advanced Uses of surface and zone . . . . .                             | 404 |
| 11.5  | Aspects of Layout . . . . .   | 406 |
| 11.6  | Headers, Footers, and Similar Matter . . . . .                          | 409 |
| 11.7  | Identifying Changes and Revisions . . . . .                             | 410 |
| 11.8  | Other Primary Source Features not Covered in these Guidelines . . . . . | 414 |
| 11.9  | Module for Transcription of Primary Sources . . . . .                   | 414 |
| 12    | Critical Apparatus . . . . .  | 415 |
| 12.1  | The Apparatus Entry, Readings, and Witnesses . . . . .                  | 415 |
| 12.2  | Linking the Apparatus to the Text . . . . .                             | 426 |
| 12.3  | Using Apparatus Elements in Transcriptions . . . . .                    | 433 |
| 12.4  | Strategies for Encoding Variation . . . . .                             | 434 |
| 12.5  | Module for Critical Apparatus . . . . .                                 | 435 |
| 13    | Names, Dates, People, and Places . . . . .                              | 437 |
| 13.1  | Attribute Classes Defined by This Module . . . . .                      | 437 |
| 13.2  | Names . . . . .   | 441 |
| 13.3  | Biographical and Prosopographical Data . . . . .                        | 452 |
| 13.4  | Module for Names and Dates . . . . .                                    | 481 |
| 14    | Tables, Formulæ, Graphics and Notated Music . . . . .                   | 483 |
| 14.1  | Tables . . . . .  | 483 |
| 14.2  | Formulæ and Mathematical Expressions . . . . .                          | 488 |
| 14.3  | Notated Music in Written Text . . . . .                                 | 491 |
| 14.4  | Specific Elements for Graphic Images . . . . .                          | 493 |
| 14.5  | Overview of Basic Graphics Concepts . . . . .                           | 496 |
| 14.6  | Graphic Image Formats . . . . .   | 497 |
| 14.7  | Module for Tables, Formulæ, Notated Music, and Graphics . . . . .       | 499 |
| 15    | Language Corpora . . . . .  | 500 |
| 15.1  | Varieties of Composite Text . . . . .                                   | 500 |
| 15.2  | Contextual Information . . . . .  | 502 |
| 15.3  | Associating Contextual Information with a Text . . . . .                | 507 |
| 15.4  | Linguistic Annotation of Corpora . . . . .                              | 512 |
| 15.5  | Recommendations for the Encoding of Large Corpora . . . . .             | 513 |
| 15.6  | Module for Language Corpora . . . . .                                   | 513 |
| 16    | Linking, Segmentation, and Alignment . . . . .                          | 514 |
| 16.1  | Links . . . . .   | 514 |
| 16.2  | Pointing Mechanisms . . . . .   | 521 |
| 16.3  | Blocks, Segments, and Anchors . . . . .                                 | 532 |
| 16.4  | Correspondence and Alignment . . . . .                                  | 537 |
| 16.5  | Synchronization . . . . .   | 544 |
| 16.6  | Identical Elements and Virtual Copies . . . . .                         | 548 |
| 16.7  | Aggregation . . . . .   | 550 |
| 16.8  | Alternation . . . . .   | 555 |
| 16.9  | Stand-off Markup . . . . .  | 560 |
| 16.10 | Connecting Analytic and Textual Markup . . . . .                        | 565 |
| 16.11 | Module for Linking, Segmentation, and Alignment . . . . .               | 565 |
| 17    | Simple Analytic Mechanisms . . . . .                                    | 566 |
| 17.1  | Linguistic Segment Categories . . . . .                                 | 566 |
| 17.2  | Global Attributes for Simple Analyses . . . . .                         | 574 |

|       |  |      |
|-------|--|------|
| 17.3  | Spans and Interpretations . . . . .                                  | 574  |
| 17.4  | Linguistic Annotation . . . . .                                      | 579  |
| 17.5  | Module for Analysis and Interpretation . . . . .                     | 583  |
| 18    | Feature Structures . . . . .   | 584  |
| 18.1  | Organization of this Chapter . . . . .                               | 584  |
| 18.2  | Elementary Feature Structures and the Binary Feature Value . . . . . | 584  |
| 18.3  | Other Atomic Feature Values . . . . .                                | 586  |
| 18.4  | Feature Libraries and Feature-Value Libraries . . . . .              | 588  |
| 18.5  | Feature Structures as Complex Feature Values . . . . .               | 590  |

22 November 1928 – 26 November 1993
- Antonio Zampolli  
1937 – 22 August 2003
- Sebastian Rahtz  
13 February 1955 – 15 March 2016

## iii Preface and Acknowledgments

This publication constitutes the fifth distinct version of the *Guidelines for Electronic Text Encoding and Interchange*, and the first complete revision since the appearance of P3 in 1994. It includes substantial amounts of new material and a major revision of the underlying technical infrastructure. With this version, these Guidelines enter a new stage in their development as a community-maintained open source project. This edition is the first version to have benefitted from the close overview and oversight of an elected TEI Technical Council. The editors are therefore particularly pleased to acknowledge with gratitude the hard work and dedication put into this project by the Council over the last five years.

The Chair of the TEI Board sits on the Technical Council, and the Board appoints the Chair of the Technical Council and one other member of the Council. Other Council members are all elected by the Consortium membership, and serve periods of up to two years at a time. The names and affiliations of all Council members who served during the production of this edition of the Guidelines are listed below.

### Board Chair

- 2004–2005: Julia Flanders (Brown University)
- 2006: Matthew Zimmerman (New York University)
- 2007–2011: Daniel O'Donnell (University of Lethbridge)
- 2011: Martin Mueller (Northwestern University)
- 2011–2012: John Unsworth (University of Illinois at Urbana-Champaign / Brandeis University)
- 2012–2015: Elena Pierazzo (King's College London / Université Stendhal-Grenoble 3)
- 2016: Michelle Dalmau (Indiana University)

### Council Chair

- 2002–2003: John Unsworth (University of Virginia)
- 2003–2007: Christian Wittern (Kyoto University)
- 2008–2011: Laurent Romary (Max Planck Digital Library / Inria & Humboldt-Universität zu Berlin)
- 2012–2014: James Cummings (University of Oxford)
- 2015–2016: Hugh Cayless (Duke University)

### Members Appointed by the TEI Board

- 2001–2009: Sebastian Rahtz (University of Oxford)
- 2010–2014: Lou Burnard (University of Oxford / TGE Adonis / Independent Consultant)

### Appointed Editors

- 2001–2007: Syd Bauman (Brown University)
- 2001–2007: Lou Burnard (University of Oxford)

### Elected Members

- 2011–2012: Piotr Bański (University of Warsaw)
- 2010–2013: Brett Barney (University of Nebraska)
- 2013–2016: Syd Bauman (Brown University / Northeastern University)
- 2016–2017: Elisa Beshero-Bondar (University of Pittsburgh at Greensburg)
- 2003–2006: Alejandro Bia (University of Alicante)
- 2004–2007: David Birnbaum (University of Pittsburgh)
- 2008–2013: Gabriel Bodard (King's College London)
- 2008–2009: Peter Boot (Huygens Institute for Netherlands History)
- 2007–2008: Tone Merete Bruvik (University of Bergen)
- 2015–2016: Lou Burnard (Independent Consultant)
- 2013–2016: Hugh Cayless (New York University / Duke University)

- 2014–2015: Fabio Ciotti (University of Rome "Tor Vergata")
- 2007–2009: Arianna Ciula (King's College London / European Science Foundation)
- 2005–2017: James Cummings (University of Oxford)
- 2002–2007, 2010: Matthew Driscoll (University of Copenhagen)
- 2002–2004: David Durand (Ingenta plc)
- 2002–2004: Tomas Erjavec (Jozef Stefan Institute, Ljubljana)
- 2014–2015: Stefanie Gehrke (Biblissima)
- 2010–2013: Kevin Hawkins (University of Michigan)
- 2010–2015: Martin Holmes (University of Victoria)
- 2002: Fotis Jannidis (University of Munich)
- 2006: Amit Kumar (University of Illinois at Urbana-Champaign)
- Stefan Majewski (Austrian National Library)
- 2002: Martin Mueller (Northwestern University)
- 2013–2014, 2016–2017: Elli Mylonas (Brown University)
- 2010–2011: Julianne Nyhan (University of Trier / University College London)
- 2008–2011: Elena Pierazzo (King's College London)
- 2006–2007, 2009–2010: Dot Porter (University of Kentucky / Digital Humanities Observatory / Indiana University)
- 2002–2003: Merillee Proffitt (Research Libraries Group)
- 2002: Peter Robinson (De Montfort University)
- 2009–2014: Sebastian Rahtz (University of Oxford)
- 2002: Geoffrey Rockwell (Macmaster University)
- 2002–2007: Laurent Romary (Inria / CNRS / Max Planck Digital Library)
- 2008–2009, 2012–2015: Paul Schaffner (University of Michigan)
- 2016–2017: Marina Scholger
- 2003–2007: Susan Schreibman (University of Maryland)
- 2008–2009: David Sewell (University of Virginia)
- 2004–2005: Natasha Smith (University of North Carolina at Chapel Hill)
- 2014–2017: Peter Stadler (Carl-Maria-von-Weber-Gesamtausgabe / University of Paderborn)
- 2008–2009: Manfred Thaller (University of Cologne)
- 2006–2007: Conal Tuohy (Victoria University of Wellington)
- 2016–2017: Magdalena Turska (eXist Solutions)
- 2004–2005: Edward Vanhoutte (Royal Academy of Dutch Language and Literature)
- 2015–2016: Raffaele Vigiante (University of Maryland)
- 2005–2008: John Walsh (Indiana University)
- 2012–2013: Rebecca Welzenbach (University of Michigan)
- 2002–2005: Perry Willett (Indiana University / University of Michigan)
- 2011–2012: Stuart Yeates (New Zealand Electronic Text Centre)

The bulk of the Council's work has been carried out by email and by regular telephone conference. In addition, the Council has held many two-day face-to-face meetings. During production of P5, these meetings were generously hosted by the following institutions:

- King's College, London (2002)

- Oxford University Computing Services (2003)
- Royal Academy of Dutch Language and Literature, Ghent (2004)
- AFNOR: Association française de normalisation, Paris (2005)
- Institute for Research in Humanities, Kyoto University (2006)
- Berlin-Brandenburgische Akademie der Wissenschaften, Berlin (2007)
- National University of Ireland, Galway (2008)
- Ecole Normale Supérieure, Lyon (2009)
- Royal Irish Academy, Dublin (2010)
- Big Ten Center, Chicago (2011)
- Inria, Paris (2011)
- University of Michigan, Ann Arbor (2012)
- University of Oxford (2012)
- Brown University (2013)
- University of Oxford (2013)
- University of Oxford (2014)
- Duke University (2014)

During the production of TEI P5, the Council chartered a number of smaller workgroups and similar activities, each of which made significant contribution to the intellectual content of the work. Active members of these are listed below:

**Character Set Workgroup** Active between July 2001 and January 2005, this group revised and developed the recommendations now forming chapters *vi Languages and Character Sets* and *5. Characters, Glyphs, and Writing Modes*. It was chaired by Christian Wittern, and its membership included: Deborah Anderson (Berkeley); Michael Beddow (independent scholar); David Birnbaum (Pittsburgh University); Martin Duerst (W3C/Keio University); Patrick Durusau (Society of Biblical Literature); Tomohiko Morioka (Kyoto University); and Espen Ore (National Library of Norway).

**Meta Taskforce** Active between February 2003 and February 2005, this group developed the material now forming *22. Documentation Elements*. It was chaired by Sebastian Rahtz, and its membership included: Alejandro Bia; David G. Durand; Laurent Romary; Norman Walsh (Sun Microsystems); and Christian Wittern.

**Workgroup on Stand-Off Markup, XLink and XPointer** Active between February 2002 and January 2006, this group reviewed and expanded the material now largely forming part of *16. Linking, Segmentation, and Alignment*. It was chaired by David G. Durand, and its membership included: Jean Carletta (Edinburgh University); Chris Caton (University of Oxford); Jessica P. Hekman (Ingenta plc); Nancy M. Ide (Vassar College); and Fabio Vitali (University of Bologna).

**Manuscript Description Task Force** Active between February 2003 and December 2005, this group reviewed and finalised the material now forming *10. Manuscript Description*. It was chaired by Matthew Driscoll and comprised David Birnbaum and Merrilee Proffitt, in addition to the TEI Editors.

**Names and Places Activity** Active between January 2006 and May 2007, this group formulated the new material now forming part of *13. Names, Dates, People, and Places*. It was chaired by Matthew Driscoll, and its membership included Gabriel Bodard (King's College London); Arianna Ciula; James Cummings; Tom Elliott (University of North Carolina at Chapel Hill); Øyvind Eide (University of Oslo); Leif Isaksen (Oxford Archaeology plc); Richard Light (private consultant); Tadeusz Piotrowski (Opole University); Sebastian Rahtz; and Tatiana Timcenko (Vilnius University).

**Joint TEI/ISO Activity on Feature Structures** Active between January 2003 and August 2007, this group reviewed the material now presented in *18. Feature Structures* and revised it for inclusion in ISO Standard 24610. It was chaired by Kiyong Lee (Korea University), and its active membership included the following: Harry Bunt (Tilburg); Lionel Clément (INRIA); Eric de la Clergerie (INRIA); Thierry Declerck (Saarbrücken); Patrick Drouin (University of Montréal); Lee Gillam (Surrey University); and Kōiti Hasida (ICOT).

From 2000 to 2008 the TEI had two appointed Editors, Lou Burnard (University of Oxford) and Syd Bauman (Brown University), who served *ex officio* on the Council and, as far as possible, on all Council workgroups.

The council also oversees an Internationalization and Localization project, led by Sebastian Rahtz and with funding from the ALLC. This activity, ongoing since October 2005, is engaged in translating key parts of the P5 source into a variety of languages.

Production of the translations currently included in P5 has been coordinated by the following:

**Chinese** Marcus Bingenheimer (Chung-hwa Institute of Buddhist Studies, Taipei / Temple University) and Weining Hwang (Würzburg University)

**French** Pierre-Yves Duchemin (ENSSIB); Jean-Luc Benoit (ATILF); Anila Angjeli (BnF); Joëlle Bellec Martini (BnF); Marie-France Claerebout (Aldine); Magali Le Coënt (BIUSJ); Florence Clavaud (EnC); Cécile Pierre (BIUSJ).

**German** Werner Wegstein (Würzburg University)

**Italian** Marco Venuti (University of Venice) and Letizia Cirillo (University of Bologna)

**Japanese** Ohya Kazushi (Tsurumi University)

**Korean** Beom-mo Kang and Jungha Hong (Korea University)

**Spanish** Carmen Arronis Llopis (University of Alicante) and Alejandro Bia (Miguel Hernández University)

Any one who works closely with the TEI Guidelines, whether as translator, editor, or reader is constantly reminded of the ambitious scope and exceptionally high editorial standards set by the original project, now approaching twenty years ago. It is appropriate therefore to retain a sense of the history of this document, as it has evolved since its first appearance in 1990, and to acknowledge with gratitude the contributions made to that evolution by very many individuals and institutions around the world. The original prefatory notes to each major edition of the Guidelines recording these names are therefore preserved in an appendix to the current edition (see *Appendix G Prefatory Notes*).

## iv About These Guidelines

These Guidelines have been developed and are maintained by the Text Encoding Initiative Consortium (TEI); see *iv.2 Historical Background*. They are addressed to anyone who works with any kind of textual resource in digital form.

They make recommendations about suitable ways of representing those features of textual resources which need to be identified explicitly in order to facilitate processing by computer programs. In particular, they specify a set of markers (or *tags*) which may be inserted in the electronic representation of the text, in order to mark the text structure and other features of interest. Many, or most, computer programs depend on the presence of such explicit markers for their functionality, since without them a digitized text appears to be nothing but a sequence of undifferentiated bits. The success of the World Wide Web, for example, is partly a consequence of its use of such markup to indicate such features as headings and lists on individual pages, and to indicate links between pages. The process of inserting such explicit markers for implicit textual features is often called ‘markup’, or equivalently within this work ‘encoding’; the term ‘tagging’ is also used informally. We use the term *encoding scheme* or *markup language* to denote the complete set of rules associated with the use of markup in a given context; we use the term *markup vocabulary* for the specific set of markers or named distinctions employed by a given encoding scheme. Thus, this work both describes the TEI encoding scheme, and documents the TEI markup vocabulary.

The TEI encoding scheme is of particular usefulness in facilitating the loss-free interchange of data amongst individuals and research groups using different programs, computer systems, or application software. Since they contain an inventory of the features most often deployed for computer-based text processing, these Guidelines are also useful as a starting point for those designing new systems and creating new materials, even where interchange of information is not a primary objective.

These Guidelines apply to texts in any natural language, of any date, in any literary genre or text type, without restriction on form or content. They treat both continuous materials (‘running text’) and discontinuous materials such as dictionaries and linguistic corpora. Though principally directed to the needs of the scholarly research community, these Guidelines are not restricted to esoteric academic applications. They are also useful for librarians maintaining and documenting electronic materials, and for publishers and others creating or distributing electronic texts. Although they focus on problems of representing in electronic form texts which already exist in traditional media, these Guidelines are also applicable to textual material which is ‘born digital’. We believe them to be adequate to the widest variety of currently existing practices in using digital textual data, but by no means limited to them.

The rules and recommendations made in these Guidelines are expressed in terms of what is currently the most widely-used markup language for digital resources of all kinds: the Extensible Markup Language (XML), as defined by the World Wide Web Consortium’s XML Recommendation. However, the TEI encoding scheme itself does not depend on this language; it was originally formulated in terms of SGML (the ISO Standard Generalized Markup Language), a predecessor of XML, and may in future years be re-expressed in other ways as the field of markup develops and matures. For more information on markup languages see chapter *v A Gentle Introduction to XML*; for more information on the associated character encoding issues see chapter *vi Languages and Character Sets*.

This document provides the authoritative and complete statement of the requirements and usage of the TEI encoding scheme. As such, although it includes numerous small examples, it must be stressed that this work is intended to be a reference manual rather than a tutorial guide.

The remainder of this chapter comprises three sections. The first gives an overview of the structure and notational conventions used throughout these Guidelines. The second enumerates the design principles underlying the TEI scheme and the application environments in which it may be found useful. Finally, the third section gives a brief account of the origins and development of the Text Encoding Initiative itself.

### iv.1 Structure and Notational Conventions of this Document

The remaining two sections of the front matter to these Guidelines provide background tutorial material for those unfamiliar with basic markup technologies. Following the present introductory section, we present a detailed introduction to XML itself, intended to cover in a relatively painless manner as much as the novice user of the TEI scheme needs to know about markup languages in general and XML in particular. This is followed by a discussion of the general principles underlying current practice in the representation of different languages and writing systems in digital form. This chapter is largely intended for the user unfamiliar with the Unicode encoding systems, though the expert may also find its historical overview of interest.

The body of this edition of these Guidelines proper contains 23 chapters arranged in increasing order of specialist interest. The first five chapters discuss in depth matters likely to be of importance to anyone intending to apply the

TEI scheme to virtually any kind of text. The next seven focus on particular kinds of text: verse, drama, spoken text, dictionaries, and manuscript materials. The next nine chapters deal with a wide range of topics, one or more of which are likely to be of interest in specialist applications of various kinds. The last two chapters deal with the XML encoding used to represent the TEI scheme itself, and provide technical information about its implementation. The last chapter also defines the notion of TEI conformance and its implications for interchange of materials produced according to these Guidelines.

As noted above, this is a reference work, and is not intended to be read through from beginning to end. However, the reader wishing to understand the full potential of the TEI scheme will need a thorough grasp of the material covered by the first four chapters and the last two. Beyond that, the reader is recommended to select according to their specific interests: one of the strengths of the TEI architecture is its modular nature.

As far as possible, extensive cross referencing is provided wherever related topics are dealt with; these are particularly effective in the online version of these Guidelines. In addition, a series of technical appendixes provide detailed formal definitions for every element, every class, and every macro discussed in the body of the work; these are also cross linked as appropriate. Finally, a detailed bibliography is provided, which identifies the source of many examples cited in the text as well as documenting works referred to, and listing other relevant publications.

As an aid to the reader, most chapters of these Guidelines follow the same basic organization. The chapter begins with an overview of the subjects treated within it, linked to the following subsections. Within each section where new elements are described, a summary table is first given, which provides their names and a brief description of their intended usage. This is then followed where appropriate by further discussion of each element, including wherever possible usage examples taken somewhat eclectically from a variety of real sources. These examples are not intended to be exhaustive, but rather to suggest typical ways in which the elements concerned may usefully be applied. Where appropriate, a link to a statement of the source for most examples is provided in the online version. Within the examples, use of whitespace such as newlines or indentation is simply intended to aid legibility, and is not prescriptive or normative.

Wherever TEI elements or classes are mentioned in the text, they are linked in the online version to the relevant reference specification for the element or class concerned. Element names are always given in the form `<name>`, where ‘name’ is the *generic identifier* of the element; empty elements such as `<pb>` or `<anchor>` include a closing slash to distinguish them wherever they are discussed. References to attributes take the form *attname*, where ‘attname’ is the name of the attribute. References to classes are also presented as links, for example `model.divLike` for a model class, and `att.global` for an attribute class.

### iv.1.1 TEI Naming Conventions

These Guidelines use a more or less consistent set of conventions in the naming of XML elements and classes. This section summarizes those conventions.

#### Element and Attribute Names

An unadorned name such as ‘blort’ is the name of a TEI element or attribute.<sup>1</sup>

The following conventions apply to the choice of names:

- Elements are given generic identifiers as far as possible consisting of one or more *tokens*, by which we mean whole words or recognisable abbreviations of them, taken from the English language.
- Where an element name contains more than one token, the first letter of the second token, and of any subsequent ones, is capitalized, as in for example `<biblStruct>`, `<listPerson>`. This ‘camelCasing’ is used also for attribute names and symbolic values.
- Module names also use whole words, for the most part, but are always all lower case.
- The specification for an element or attribute whose name contains abbreviations generally also includes a `<gloss>` element providing the expanded sense of the name.
- An element specification may also contain approved translations for element or attribute names in one or more other languages using the `<altIdent>` element; this is not however generally done in TEI P5.

Whole words are generally preferred for clarity. The following abbreviations are however commonly used within generic identifiers:

---

<sup>1</sup>During generation of TEI RelaxNG schema fragments, the patterns corresponding with these TEI names are given a prefix `tei` to allow them to co-exist with names from other XML namespace. This prefix is not visible to the end user, and is not used in TEI documentation. When generating multi-namespace schemas, however, the user needs to be aware of them.

- att** attribute
- bibl** bibliographic description or reference in a bibliography
- cat** category, especially as used in text classification
- char** character, typically a Unicode character
- doc** document: this usually refers to the original source document which is being encoded,
- decl** declaration: has a specific sense in the TEI Header, as discussed in 2.1.2. *Types of Content in the TEI Header*
- desc** description: has a specific sense in the TEI header, as discussed in 2.1.2. *Types of Content in the TEI Header*
- grp** group. In TEI usage, a group is distinguished from a list in that the former associates several objects which act as a single entity, while the latter does not. For example, a <linkGrp> combines several <link> elements which have certain properties in common, whereas a <listBibl> simply lists a number of otherwise unrelated <bibl> elements.
- interp** interpretation or analysis
- lang** (natural) language
- ms** manuscript
- org** organization, that is, a named group of people or legal entity
- rdg** reading or version found in a specific witness
- ref** reference or link
- spec** technical specification or definition
- stmt** statement: used in a specific sense in the TEI header, as discussed in 2.1.2. *Types of Content in the TEI Header*
- struct** structured: that is, containing a specific set of named elements rather than ‘mixed content’
- val** value, for example of a variable or an attribute
- wit** witness: that is, a specific document which attests specific readings in a textual tradition or apparatus

Some abbreviations are used inconsistently: for example, <add> is an addition, and <addSpan> is a spanning addition, but <addName> is an additional name, not the name of an addition. Such inconsistencies are relatively few in number, and it is hoped to remove them in subsequent revisions of these Guidelines.

Some elements have very short abbreviated names: these are for the most part elements which are likely to be used very frequently in a marked up text, for example <p> (paragraph), <s> (segment) <hi> (highlighted phrase), <ptr> (pointer), <div> (division) etc. We do not specifically list such elements here: as noted above, an expansion of each such abbreviated name is provided within the documentation using the <gloss> element .

### iv.1.2 Class, Macro, and Datatype Names

All named objects other than elements and attributes have one of the following prefixes, which indicate whether the object is a module, an attribute class, a model class, a datatype, or a macro:

| Component         | Name    | Example           |
|-------------------|---------|-------------------|
| Attribute Classes | att.*   | att.global        |
| Model Classes     | model.* | model.biblPart    |
| Macros            | macro.* | macro.paraContent |
| Datatypes         | data.*  | data.pointer      |

The concepts of model class, attribute class, etc. are defined in 1. *The TEI Infrastructure*. Here we simply note some conventions about their naming.

The following rules apply to attribute class names:

- Attribute class names take the form **att.XXX**, where XXX is typically an adjective, or a series of adjectives separated by dots, describing a property common to the attributes which make up the class.

- Attributes with the same name are considered to have the same semantics, whether the attribute is inherited from a class, or locally defined.

The following rules apply to model class names:

- Model classes have names beginning `model`, followed by a *root name*, and zero or more suffixes as described below.
- A root name may be the name of an element, generally the prototypical parent or sibling for elements which are members of the class.
- The first suffix should be `Part`, if the class members are all children of the element named `rootname`; or `Like`, if the class members are all siblings of the element named `rootname`.
- The rootname `global` is used to indicate that class members are permitted anywhere in a TEI document.
- Additional suffixes may be added, prefixed by a dot, to distinguish subclasses, semantic or structural.

For example, the class of elements which can form part of a `<div>` is called `model.divPart`. This class includes as a subclass the elements which can form part of a `<div>` in a spoken text, which is named `model.divPart.spoken`

### iv.1.3 Design Principles

Because of its roots in the humanities research community, the TEI scheme is driven by its original goal of serving the needs of research, and is therefore committed to providing a maximum of comprehensibility, flexibility, and extensibility. More specific design goals of the TEI have been that these Guidelines should:

- provide a standard format for data interchange
- provide guidance for the encoding of texts in this format
- support the encoding of all kinds of features of all kinds of texts studied by researchers
- be application independent

This has led to a number of important design decisions, such as:

- the choice of XML and Unicode
- the provision of a large predefined tag set
- encodings for different views of text
- alternative encodings for the same textual features
- mechanisms for user-defined modification of the scheme

We discuss some of these goals in more detail below.

The goal of creating a common interchange format which is application independent requires the definition of a specific markup syntax as well as the definition of a large set of elements or concepts. The syntax of the recommendations made in this document conforms to the World Wide Web Consortium's XML Recommendation (Bray et al. (eds.) (2006)) but their definition is as far as possible independent of any particular schema language.

The goal of providing guidance for text encoding suggests that recommendations be made as to what textual features should be recorded in various situations. However, when selecting certain features for encoding in preference to others, these Guidelines have tended to prefer generic solutions to specific ones, and to avoid areas where no consensus exists, while attempting to accommodate as many diverse views as feasible. Consequently, the TEI Guidelines make (with relatively rare exceptions) no suggestions or restrictions as to the relative importance of textual features. The philosophy of these Guidelines is 'if you want to encode this feature, do it this way'—but very few features are mandatory. In the same spirit, while these Guidelines very rarely require you to encode any particular feature, they do require you to be honest about which features you have encoded, that is, to respect the meanings and usage rules they recommend for specific elements and attributes proposed.

The requirement to support all kinds of materials likely to be of interest in research has largely conditioned the development of the TEI into a very flexible and modular system. The development of other XML vocabularies or standards is typically motivated by the desire to create a single fully specified encoding scheme for use in a well-defined application domain. By contrast, the TEI is intended for use in a large number of rather ill-defined and often overlapping domains. It achieves its generality by means of the modular architecture described in 1. *The TEI*

*Infrastructure* which enables each user to create a schema appropriate to their needs without compromising the interoperability of their data.

The Guidelines have been written largely with a focus on text capture (i.e. the representation in electronic form of an already existing copy text in another medium) rather than text creation (where no such copy text exists). Hence the frequent use of terms like ‘transcription’, ‘original’, ‘copy text’, etc. However, these Guidelines are equally applicable to text creation, although certain elements, such as <sourceDesc>, and certain attributes, such as the rendition indicators, will not be relevant in this case.

Concerning text capture the TEI Guidelines do not specify a particular approach to the problem of fidelity to the source text and recoverability of the original; such a choice is the responsibility of the text encoder. The current version of these Guidelines, however, provides a more fully elaborated set of tags for markup of rhetorical, linguistic, and simple typographic characteristics of the text than for detailed markup of page layout or for fine distinctions among type fonts or manuscript hands. It should be noted also that, with the present version of these Guidelines, it is no longer necessarily the case that an unmediated version of the source text can be recovered from an encoded text simply by removing the markup.

In these Guidelines, no hard and fast distinction is drawn between ‘objective’ and ‘subjective’ information or between ‘representation’ and ‘interpretation’. These distinctions, though widely made and often useful in narrow, well-defined contexts, are perhaps best interpreted as distinctions between issues on which there is a scholarly consensus and issues where no such consensus exists. Such consensus has been, and no doubt will be, subject to change. The TEI Guidelines do not make suggestions or restrictions as to which of these features should be encoded. The use of the terms *descriptive* and *interpretive* about different types of encoding in these Guidelines is not intended to support any particular view on these theoretical issues. Historically, it reflects a purely practical division of responsibility amongst the original working committees (see further *iv.2 Historical Background*).

In general, the accuracy and the reliability of the encoding and the appropriateness of the interpretation is for the individual user of the text to determine. The Guidelines provide a means of documenting the encoding in such a way that a user of the text can know the reasoning behind that encoding, and the general interpretive decisions on which it is based. The TEI header may be used to document and justify many such aspects of the encoding, but the choice of TEI elements for a particular feature is in itself a statement about the interpretation reached by the encoder.

In many situations more than one view of a text is needed since no absolute recommendation to embody one specific view of text can apply to all texts and all approaches to them. Within limits, the syntax of XML ensures that some encodings can be ignored for some purposes. To enable encoding multiple views, these Guidelines not only treat a variety of textual features, but sometimes provide several alternative encodings for what appear to be identical textual phenomena. These Guidelines offer the possibility of encoding many different views of the text, simultaneously if necessary. Where different views of the formal structure of a text are required, as opposed to different annotations on a single structural view, however, the formal syntax of XML (which requires a single hierarchical view of text structure) poses some problems; recommendations concerning ways of overcoming or circumventing that restriction are discussed in chapter 20. *Non-hierarchical Structures*.

In brief, the TEI Guidelines define a general-purpose encoding scheme which makes it possible to encode different views of text, possibly intended for different applications, serving the majority of scholarly purposes of text studies in the humanities. Because no predefined encoding scheme can possibly serve all research purposes, the TEI scheme is designed to facilitate both selection from a wide range of predefined markup choices, and the addition of new (non-TEI) markup options. By providing a formally verifiable means of extending the TEI recommendations, the TEI makes it simple for such user-identified modifications to be incorporated into future releases of these Guidelines as they evolve. The underlying mechanisms which support these aspects of the scheme are introduced in chapter 1. *The TEI Infrastructure*, and detailed discussions of their use provided in chapter 23. *Using the TEI*.

### iv.1.4 Intended Use

We envisage three primary functions for these Guidelines:

- guidance for individual or local practice in text creation and data capture;
- support of data interchange;
- support of application-independent local processing.

These three functions are so thoroughly interwoven in practice that it is hardly possible to address any one without addressing the others. However, the distinction provides a useful framework for discussing the possible role of these Guidelines in work with electronic texts.

## Use in Text Capture and Text Creation

The description of textual features found in the chapters which follow should provide a useful checklist from which scholars planning to create electronic texts should select the subset of features suitable for their project.

Problems specific to text creation or text ‘capture’ have not been considered explicitly in this document. These Guidelines are not concerned with the process by which a digital text comes into being: it can be typed by hand, scanned from a printed book or typescript, read from a typesetter’s tape, or acquired from another researcher who may have used another markup scheme (or no explicit markup at all).

We include here only some general points which are often raised about markup and the process of data capture.

XML can appear distressingly verbose, particularly when (as in these Guidelines) the names of tags and attributes are chosen for clarity and not for brevity. Editor macros and keyboard shortcuts can allow a typist to enter frequently used tags with single keystrokes. It is often possible to transform word-processed or scanned text automatically. Markup-aware software can help with maintaining the hierarchical structure of the document, and display the document with visual formatting rather than raw tags.

The techniques described in chapter 23.3. *Personalization and Customization* may be used to develop simpler data capture TEI-conformant schemas, for example with limited numbers of elements, or with shorter names for the tags being used most often. Documents created with such schemas may then be automatically converted to a more elaborated TEI form.

## Use for Interchange

The TEI format may simply be used as an interchange format, permitting projects to share resources even when their local encoding schemes differ. If there are  $n$  different encoding formats, to provide mappings between each possible pair of formats requires  $n \times (n-1)$  translations; with an interchange format, only  $2 \times n$  such mappings are needed. However, for such translations to be carried out without loss of information, the interchange format chosen must be as expressive (in a formal sense) as any of the target formats; this is a further reason for the TEI’s provision of both highly abstract or generic encodings and highly specific ones.

To translate between any pair of encoding schemes implies:

1. identifying the sets of textual features distinguished by the two schemes;
2. determining where the two sets of features correspond;
3. creating a suitable set of mappings.

For example, to translate from encoding scheme X into the TEI scheme:

1. Make a list of all the textual features distinguished in X.
2. Identify the corresponding feature in the TEI scheme. There are three possibilities for each feature:
  - (a) the feature exists in both X and the TEI scheme;
  - (b) X has a feature which is absent from the TEI scheme;
  - (c) X has a feature which corresponds with more than one feature in the TEI scheme.

The first case is a trivial renaming. The second will require an extension to the TEI scheme, as described in chapter 23.3. *Personalization and Customization*. The third is more problematic, but not impossible, provided that a consistent choice can be made (and documented) amongst the alternatives.

The ease with which this translation can be defined will of course depend on the clarity with which scheme X represents the features it encodes.

Translating from the TEI into scheme X follows the same pattern, except that if a TEI feature has no equivalent in X, and X cannot be extended, information must be lost in translation.

The rules defining conformance to these Guidelines are given in some detail in chapter 23.4. *Conformance*. The basic principles informing those rules may be summarized as follows:

1. The TEI *abstract model* (that is, the set of categorical distinctions which it defines) must be respected. The correspondence between a tag X and the semantic function assigned to it by these Guidelines may not be changed; such changes are known as *tag abuse* and strongly deprecated.

2. A TEI document must be expressed as a valid XML-conformant document which uses the TEI namespace appropriately. If, for example, the document encodes features not provided by these Guidelines, such extensions may not be associated with the TEI namespace.
3. It must be possible to validate a TEI document against a schema derived from these Guidelines, possibly with extensions provided in the recommended manner.

### Use for Local Processing

Machine-readable text can be manipulated in many ways; some users:

- edit texts (e.g. word processors, syntax-directed editors)
- edit, display, and link texts in hypertext systems
- format and print texts using desktop publishing systems, or batch-oriented formatting programs
- load texts into free-text retrieval databases or conventional databases
- unload texts from databases as search results or for export to other software
- search texts for words or phrases
- perform content analysis on texts
- collate texts for critical editions
- scan texts for automatic indexing or similar purposes
- parse texts linguistically
- analyze texts stylistically
- scan verse texts metrically
- link text and images

These applications cover a wide range of likely uses but are by no means exhaustive. The aim has been to make the TEI Guidelines useful for encoding the same texts for different purposes. We have avoided anything which would restrict the use of the text for other applications. We have also tried not to omit anything essential to any single application.

Because the TEI format is expressed using XML, almost any modern text processing system is able to process it, and new TEI-aware software systems are able to build on a solid base of existing software libraries.

## iv.2 Historical Background

The Text Encoding Initiative grew out of a planning conference sponsored by the Association for Computers and the Humanities (ACH) and funded by the U.S. National Endowment for the Humanities (NEH), which was held at Vassar College in November 1987. At this conference some thirty representatives of text archives, scholarly societies, and research projects met to discuss the feasibility of a standard encoding scheme and to make recommendations for its scope, structure, content, and drafting. During the conference, the Association for Computational Linguistics and the Association for Literary and Linguistic Computing agreed to join ACH as sponsors of a project to develop these Guidelines. The outcome of the conference was a set of principles (the ‘Poughkeepsie Principles’, Burnard (1988)), which determined the further course of the project.

The Text Encoding Initiative project began in June 1988 with funding from the NEH, soon followed by further funding from the Commission of the European Communities, the Andrew W. Mellon Foundation, and the Social Science and Humanities Research Council of Canada. Four working committees, composed of distinguished scholars and researchers from both Europe and North America, were named to deal with problems of text documentation, text representation, text analysis and interpretation, and metalanguage and syntax issues. Each committee was charged with the task of identifying ‘significant particularities’ in a range of texts, and two editors appointed to harmonize the resulting recommendations.

A first draft version (P1, with the ‘P’ here and subsequently standing for ‘Proposal’) of the Guidelines was distributed in July 1990 under the title *Guidelines for the Encoding and Interchange of Machine-Readable Texts*. Extensive public comment and further work on areas not covered in this version resulted in the drafting of a revised version, TEI P2, distribution of which began in April 1992. This version included substantial amounts of new material, resulting from work carried out by several specialist working groups, set up in 1990 and 1991 to propose extensions

and revisions to the text of P1. The overall organization, both of the draft itself and of the scheme it describes, was entirely revised and reorganized in response to public comment on the first draft.

In June 1993 an Advisory Board met to review the current state of the TEI Guidelines, and recommended the formal publication of the work done to that time. That version of the TEI Guidelines, TEI P3, consolidated the work published as parts of TEI P2, along with some additional new material and was finally published in May of 1994 without the label *draft*, thus marking the conclusion of the initial development work.

In February of 1998 the World Wide Web Consortium issued a final Recommendation for the Extensible Markup Language, XML.<sup>2</sup> Following the rapid take-up of this new standard metalanguage, it became evident that the TEI Guidelines (which had been published originally as an SGML application) needed to be re-expressed in this new formalism if they were to survive. The TEI editors, with abundant assistance from others who had developed and used TEI, developed an update plan, and made tentative decisions on relevant syntactic issues.

In January of 1999, the University of Virginia and the University of Bergen formally proposed the creation of an international membership organization, to be known as the TEI Consortium, which would maintain, develop, and promote the TEI. Shortly thereafter, two further institutions with longstanding ties to the TEI (Brown University and Oxford University) joined them in formulating an Agreement to Establish a Consortium for the Maintenance of the Text Encoding Initiative (An Agreement to Establish a Consortium for the Maintenance of the Text Encoding Initiative (March 1999)), on which basis the TEI Consortium was eventually established and incorporated as a not-for-profit legal entity at the end of the year 2000. The first members of the new TEI Board took office during January of 2001.

The TEI Consortium was established in order to maintain a permanent home for the TEI as a democratically constituted, academically and economically independent, self-sustaining, non-profit organization. In addition, the TEI Consortium was intended to foster a broad-based user community with sustained involvement in the future development and widespread use of the TEI Guidelines (Burnard (2000)).

To oversee and manage the revision process in collaboration with the TEI Editors, the TEI Board formed a Technical Council, with a membership elected from the TEI user community. The Council met for the first time in January 2002 at King's College London. Its first task was to oversee production of an XML version of the TEI Guidelines, updating P3 to enable users to work with the emerging XML toolset. This, the P4 version of the Guidelines, was published in June 2002. It was essentially an XML version of P3, making no substantive changes to the constraints expressed in the schemas apart from those necessitated by the shift to XML, and changing only corrigible errors identified in the prose of the P3 Guidelines. However, given that P3 had by this time been in steady use since 1994, it was clear that a substantial revision of its content was necessary, and work began immediately on the P5 version of the Guidelines. This was planned as a thorough overhaul, involving a public call for features and new development in a number of important areas not previously addressed including character encoding, graphics, manuscript description, biographical and geographical data, and the encoding language in which the TEI Guidelines themselves are written.

The members of the TEI Council and its associated workgroups are listed in *iii Preface and Acknowledgments*. In preparing this edition, they have been attentive to the requirements and practice of the widest possible range of TEI users, who are now to be found in many different research communities across the world, and have been largely instrumental in transforming the TEI from a grant-supported international research project into a self-sustaining community-based effort. One effect of the incorporation of the TEI has been the legal requirement to hold an annual meeting of the Consortium members; these meetings have emerged as an invaluable opportunity to sustain and reinforce that sense of community.

The present work is therefore the result of a sustained period of consultation, drafting, and revision, with input from many different experts. Whatever merits it may have are to be attributed to them; the Editors accept responsibility only for the errors remaining.

## iv.3 Future Developments and Version Numbers

The encoding recommended by this document may be used without fear that future versions of the TEI scheme will be inconsistent with it in fundamental ways. The TEI will be sensitive, in revising these Guidelines, to the possible problems which revision might pose for those who are already using this version of these Guidelines.

---

<sup>2</sup>XML was originally developed as a way of publishing on the World Wide Web richly encoded documents such as those for which the TEI was designed. Several TEI participants contributed heavily to the development of XML, most notably XML's senior co-editor C. M. Sperberg-McQueen, who served as the North American editor for the TEI Guidelines from their inception until 1999.

With TEI P5, a version numbering system is introduced following the pattern specified by the Unicode Consortium: the first digit identifies a major version number, the second digit a minor version number, and the third digit a sub-minor version number. The TEI undertakes that no change will be made to the formal expression of these Guidelines (that is, a TEI schema, as defined in *23.4. Conformance*) such that documents conformant to a given major numbered release cease to be compatible with a subsequent release of the same major number. Moreover, as far as possible, new minor releases will be made only for the purpose of adding new compatible features, or of correcting errors in existing features.

The Guidelines are currently maintained as an open source project on the Github site <https://github.com/TEIC/TEI>, from which released and development versions may be freely downloaded. See Previous Releases of P5 for information on how to find specific versions of TEI releases (Guidelines, schemas etc.). Notice of errors detected and enhancements requested may be submitted at <https://github.com/TEIC/TEI/issues>.

## v A Gentle Introduction to XML

The encoding scheme defined by these Guidelines is formulated as an application of the Extensible Markup Language (XML) (Bray et al. (eds.) (2006)). XML is widely used for the definition of device-independent, system-independent methods of storing and processing texts in electronic form. It is now also the interchange and communication format used by many applications on the World Wide Web. In the present chapter we informally introduce some of its basic concepts and attempt to explain to the reader encountering them for the first time how and why they are used in the TEI scheme. More detailed technical accounts of TEI practice in this respect are provided in chapters 23. *Using the TEI*, 1. *The TEI Infrastructure*, and 22. *Documentation Elements* of these Guidelines.

Strictly speaking, XML is a *metalanguage*, that is, a language used to describe other languages, in this case, *markup* languages. Historically, the word *markup* has been used to describe annotation or other marks within a text intended to instruct a compositor or typist how a particular passage should be printed or laid out. Examples include wavy underlining to indicate boldface, special symbols for passages to be omitted or printed in a particular font, and so forth. As the formatting and printing of texts was automated, the term was extended to cover all sorts of special codes inserted into electronic texts to govern formatting, printing, or other processing.

Generalizing from that sense, we define *markup*, or (synonymously) *encoding*, as any means of making explicit an interpretation of a text. Of course, all printed texts are implicitly encoded (or marked up) in this sense: punctuation marks, capitalization, disposition of letters around the page, even the spaces between words all might be regarded as a kind of markup, the purpose of which is to help the human reader determine where one word ends and another begins, or how to identify gross structural features such as headings or simple syntactic units such as dependent clauses or sentences. Encoding a text for computer processing is, in principle, like transcribing a manuscript from *scriptio continua*<sup>3</sup>; it is a process of making explicit what is conjectural or implicit, a process of directing the user as to how the content of the text should be (or has been) interpreted.

By *markup language* we mean a set of markup conventions used together for encoding texts. A markup language must specify how markup is to be distinguished from text, what markup is allowed, what markup is required, and what the markup means. XML provides the means for doing the first three; documentation such as these Guidelines is required for the last.

The present chapter attempts to give an informal introduction to those parts of XML of which a proper understanding is necessary to make best use of these Guidelines. The interested reader should also consult one or more of the many excellent introductory textbooks and web sites now available on the subject.<sup>4</sup>

### v.1 What's Special about XML?

XML has three highly distinctive advantages:

1. it places emphasis on descriptive rather than procedural markup;
2. it distinguishes the concepts of syntactic correctness and of *validity* with respect to a *document type definition*;
3. it is independent of any one hardware or software system.

These three aspects are discussed briefly below, and then in more depth in the remainder of this chapter.

XML is frequently compared with HTML, the language in which web pages have generally been written, which shares some of the above characteristics. Compared with HTML, however, XML has some other important features:

- XML is *extensible*: it does not consist of a fixed set of tags;
- XML documents must be *well-formed* according to a defined syntax;
- an XML document can be formally *validated* against a schema of some kind;
- XML is more interested in the meaning of data than in its presentation.

<sup>3</sup>In the 'continuous writing' characteristic of manuscripts from the early classical period, words are written continuously with no intervening spaces or punctuation.

<sup>4</sup>New textbooks and websites about XML appear at regular intervals and to select any one of them would be invidious. some recommended online courses include <http://www.w3schools.com/xml/default.asp> and <http://www.ibm.com/developerworks/training/ondemandskills/index.html>.

### v.1.1 Descriptive Markup

In a descriptive markup system, the markup codes used do little more than categorize parts of a document. Markup codes such as `<para>` or `\end{list}` simply identify a portion of a document and assert of it that ‘the following item is a paragraph’, or ‘this is the end of the most recently begun list’, etc. By contrast, a procedural markup system defines what processing is to be carried out at particular points in a document: ‘call procedure PARA with parameters 42, b, and x here’ or ‘move the left margin 2 quads left, move the right margin 2 quads right, skip down one line, and go to the new left margin,’ etc. In XML, the instructions needed to process a document for some particular purpose (for example, to format it) are sharply distinguished from the markup used to describe it.

Usually, the markup or other information needed to process a document will be maintained separately from the document itself, typically in a distinct document called a *stylesheet*, though it may do much more than simply define the rendition or visual appearance of a document.<sup>5</sup>

When descriptive markup is used, the same document can readily be processed in many different ways, using only those parts of it which are considered relevant. For example, a content analysis program might disregard entirely the footnotes embedded in an annotated text, while a formatting program might extract and collect them all together for printing at the end of each chapter. Different kinds of processing can be carried out with the same part of a file. For example, one program might extract names of persons and places from a document to create an index or database, while another, operating on the same text, but using a different stylesheet, might print names of persons and places in a distinctive typeface.

### v.1.2 Types of Document

A second key aspect of XML is its notion of a *document type*: documents are regarded as having types, just as other objects processed by computers do. The type of a document is formally defined by its constituent parts and their structure. The definition of a ‘report’, for example, might be that it consisted of a ‘title’ and possibly an ‘author’, followed by an ‘abstract’ and a sequence of one or more ‘paragraphs’. Anything lacking a title, according to this formal definition, would not formally be a report, and neither would a sequence of paragraphs followed by an abstract, whatever other report-like characteristics these might have for the human reader.

If documents are of known types, a special-purpose program (called a *parser*), once provided with an unambiguous definition of a document type, can check that any document claiming to be of that type does in fact conform to the specification. A parser can check that all elements specified for a particular document type are present and no others, that they are combined in appropriate ways, correctly ordered, and so forth. More significantly, different documents of the same type can be processed in a uniform way. Programs can be written which take advantage of the knowledge encapsulated in the document type information, and which can thus behave in a more ‘intelligent’ fashion.

### v.1.3 Data Independence

A basic design goal of XML is to ensure that documents encoded according to its provisions can move from one hardware and software environment to another without loss of information. The two features discussed so far both address this requirement at an abstract level; the third feature addresses it at the level of the strings of data characters that make up a document. All XML documents, whatever languages or writing systems they employ, use the same underlying character encoding (that is, the same method of representing as binary data those graphic forms making up a particular writing system).<sup>6</sup> This encoding is defined by an international standard,<sup>7</sup> which is implemented by a universal character set maintained by an industry group called the Unicode Consortium, and known as Unicode.<sup>8</sup> Unicode provides a standardized way of representing any of the many thousands of discrete symbols making up the world's writing systems, past and present.

Most modern computing systems now support Unicode directly; for those which do not, XML provides a mechanism for the indirect representation of single characters by means of their character number, known as *character references*; see further *v.6.1 Character References*.

---

<sup>5</sup>We do not here discuss in any detail the ways that a stylesheet can be used or defined, nor do we discuss the popular W3C Stylesheet Languages XSLT and CSS. See further Berglund (ed.) (2006), Clark (ed.) (1999), and Lie and Bos (eds.) (1999).

<sup>6</sup>See *Extensible Markup Language (XML) 1.0*, available from <http://www.w3.org/TR/REC-xml/>, Section 2.2 Characters.

<sup>7</sup>ISO/IEC 10646-1993 *Information Technology – Universal Multiple-Octet Coded Character Set (UCS)*

<sup>8</sup>See <http://www.unicode.org/>

## v.2 Textual Structures

A text is not an undifferentiated sequence of words, much less of bytes. For different purposes, it may be divided into many different units, of different types or sizes. A prose text such as this one might be divided into sections, chapters, paragraphs, and sentences. A verse text might be divided into cantos, stanzas, and lines. Once printed, sequences of prose and verse might be divided into volumes, gatherings, and pages.

Structural units of this kind are most often used to identify specific locations or refer to points within a text ('the third sentence of the second paragraph in chapter ten'; 'canto 10, line 1234'; 'page 412', etc.) but they may also be used to subdivide a text into meaningful fragments for analytic purposes ('is the average sentence length of section 2 different from that of section 5?' 'how many paragraphs separate each occurrence of the word *nature*? how many pages?'). Other structural units are more clearly analytic, in that they characterize a section of a text. A dramatic text might regard each speech by a different character as a unit of one kind, and stage directions or pieces of action as units of another kind. Such an analysis is less useful for locating parts of the text ('the 93rd speech by Horatio in Act 2') than for facilitating comparisons between the words used by one character and those of another, or those used by the same character at different points of the play.

In a prose text one might similarly wish to regard as units of different types passages in direct or indirect speech, passages employing different stylistic registers (narrative, polemic, commentary, argument, etc.), passages of different authorship and so forth. And for certain types of analysis (most notably textual criticism) the physical appearance of one particular printed or manuscript source may be of importance: paradoxically, one may wish to use descriptive markup to describe presentational features such as typeface, line breaks, use of whitespace and so forth.

These textual structures overlap with one another in complex and unpredictable ways. Particularly when dealing with texts as instantiated by paper technology, the reader needs to be aware of both the physical organization of the book and the logical structure of the work it contains. Many great works (Sterne's *Tristram Shandy* for example) cannot be fully appreciated without an awareness of the interplay between narrative units (such as chapters or paragraphs) and presentational ones (such as page divisions). For many types of research, the interplay among different levels of analysis is crucial: the extent to which syntactic structure and narrative structure mesh, or fail to mesh, for example, or the extent to which phonological structures reflect morphology.

## v.3 XML Structures

This section describes the simple and consistent mechanism for the markup or identification of textual structure provided by XML. It also describes the methods XML provides for the expression of rules defining how units of textual structure can meaningfully be combined in a text.

### v.3.1 Elements

The technical term used in XML for a textual unit, viewed as a structural component, is *element*. Different types of elements are given different names, but XML provides no way of expressing the meaning of a particular type of element, other than its relationship to other element types. That is, all one can say about an element called (say) `<blort>` is that instances of it may (or may not) occur within elements of type `<farble>`, and that it may (or may not) be decomposed into elements of type `<blortette>`. It should be stressed that XML is entirely unconcerned with the *semantics* of textual elements, because these are considered to be application dependent. It is up to the creators of XML vocabularies (such as these Guidelines) to choose intelligible element names and to define their intended use in text markup. That is the chief purpose of documents such as the TEI Guidelines. From the need to choose element names indicative of function comes the technical term for the name of an element type, which is *generic identifier*, or GI.

Within a marked-up text (a *document instance*), each element must be explicitly marked or tagged in some way. This is done by inserting a tag at the beginning of the element (a *start-tag*) and another at its end (an *end-tag*). The start- and end-tag pair are used to bracket off element occurrences within the running text, in rather the same way as different types of parentheses or quotation marks are used in conventional punctuation. For example, a quotation element in a text might be tagged as follows:

```
... Rosalind's
remarks <quote>This is the silliest stuff that ere I heard
of!</quote> clearly indicate ...
```

As this example shows, a start-tag takes the form `<quote>`, where the opening angle bracket indicates the start of the start-tag, ‘quote’ is the generic identifier of the element that is being delimited, and the closing angle bracket indicates the end of the start-tag. An end-tag takes an identical form, except that the opening angle bracket is followed by a solidus (slash) character, so that the corresponding end-tag is `</quote>`.<sup>9</sup> The material between the start-tag and the end-tag (the string of words “This is the silliest stuff that ere I heard of” in the example above) is known as the *content* of the element. Sometimes there may be nothing between the start and the end-tag; in this case the two may optionally be merged together into a single composite tag with the solidus at the end, like this: `<quote/>`.

### v.3.2 Content Models: an Example

An element may be *empty*, that is, it may have no content at all, or it may contain just a sequence of characters with no other elements. Often, however, elements of one type will be *embedded* (contained entirely) within elements of a different type.

To illustrate this, we will consider a very simple structural model. Let us assume that we wish to identify within an anthology only poems, their headings, and the stanzas and lines of which they are composed. In XML terms, our *document type* is the *anthology*, and it consists of a series of *poems*. Each poem has embedded within it one element, a *heading*, and several occurrences of another, a *stanza*, each stanza having embedded within it a number of *line* elements. Fully marked up, a text conforming to this model might appear as follows:

```
<anthology>
  <poem>
    <heading>The SICK ROSE</heading>
    <stanza>
      <line>0 Rose thou art sick.</line>
      <line>The invisible worm,</line>
      <line>That flies in the night</line>
      <line>In the howling storm:</line>
    </stanza>
    <stanza>
      <line>Has found out thy bed</line>
      <line>Of crimson joy:</line>
      <line>And his dark secret love</line>
      <line>Does thy life destroy.</line>
    </stanza>
  </poem>
  <!-- more poems go here -->
</anthology>
```

It should be stressed that this example does *not* use the names proposed for corresponding elements elsewhere in these Guidelines: the above is thus *not* a valid TEI document.<sup>10</sup> It will, however, serve as an introduction to the basic notions of XML. Whitespace and line breaks have been added to the example for the sake of visual clarity only; they have no particular significance in the XML encoding itself. Also, the line

```
<!-- more poems go here -->
```

is an XML *comment* and is not treated as part of the text.

As it stands, the above example is what is known as a *well-formed* XML document because it obeys the following simple rules:

1. there is a single element enclosing the whole document: this is known as the *root element* (`<anthology>` in our case);

<sup>9</sup>Because the opening angle bracket has this special function in an XML document, special steps must be taken to use that character for other purposes (for example, as the mathematical less-than operator); see further section [v.6.1 Character References](#).

<sup>10</sup>The element names here have been chosen for clarity of exposition; there is, however, a TEI element corresponding to each.

2. each element is completely contained by the root element, or by an element that is so contained; elements do not partially overlap one another;
3. a tag explicitly marks the start and end of each element.

A well-formed XML document can be processed in a number of useful ways. A simple indexing program could extract only the relevant text elements in order to make a list of headings, first lines, or words used in the poem text; a simple formatting program could insert blank lines between stanzas, perhaps indenting the first line of each, or inserting a stanza number. Different parts of each poem could be typeset in different ways. A more ambitious analytic program could relate the use of punctuation marks to stanzaic and metrical divisions.<sup>11</sup> Scholars wishing to see the implications of changing the stanza or line divisions chosen by the editor of this poem can do so simply by altering the position of the tags. And of course, the text as presented above can be transported from one computer to another and processed by any program (or person) capable of making sense of the tags embedded within it with no need for the sort of transformations and translations needed for files which have been saved in one or other of the proprietary formats preferred by most word-processing programs.

As we noted above, one of the attractions of XML is that it enables us to make up our own names for the elements rather than requiring us always to use names predefined by other agencies. Clearly, however, if we wish to exchange our poems with others, or to include poems others have marked up in our anthology, we will need to know a bit more about the names used for the tags. The means that XML provides for this is called a *namespace*. In our simple example, the tags just contain a simple name. As we shall see, it is also possible to use tags that include a *qualified name*, that is, a name with an optional prefix identifying the set of names to which it belongs. For example, we have defined an element `<line>` for the purpose of marking lines of verse. Another person might, however, define an element called `<line>` for the purpose of marking typographic lines, or drawn lines. Because of these different meanings, if we wish to share data it will be necessary to distinguish the two 'line' components in our marked-up texts. This is achieved by including a *namespace prefix* within the markup, for example like this:

```
<my:line>This is one of my lines</my:line>
<!-- ... -->
<yr:line>This is one of your lines</yr:line>
```

This feature is particularly important if we have different definitions of what a 'line' is, of course, but there are many occasions when it is useful to distinguish groups of tags belonging to different 'markup vocabularies'; we discuss this further below (*v.6.3 Namespaces*). One particularly useful namespace prefix is predefined for XML: it is `xml` and we will see examples of its use below.

Namespaces allow us to represent the fact that a name belongs to a group of names, but don't allow us to do much more by way of checking the integrity or accuracy of our tagging. Simple well-formedness alone is not enough for the full range of what might be useful in marking up a document. It might well be useful if, in the process of preparing our digital anthology, a computer system could check some basic rules about how stanzas, lines, and headings can sensibly co-occur in a document. It would be even more useful if the system could check that stanzas are always tagged `<stanza>` and not occasionally `<canto>` or `<Stanza>`. An XML document in which such rules have been checked is technically known as a *valid* document, and the ability to perform such validation is one of the key advantages of using XML. To carry this out, some way of formally stating the criteria for successful validation is necessary: in XML this formal statement is provided by an additional document known as a *schema*.<sup>12</sup>

### v.3.3 Validating a Document's Structure

The design of a schema may be as lax or as restrictive as the occasion warrants. A balance must be struck between the convenience of following simple rules and the complexity of handling real texts. This is particularly the case when the rules being defined relate to texts that already exist: the designer may have only the haziest of notions as to an ancient text's original purpose or meaning and hence find it very difficult to specify consistent rules about its

<sup>11</sup>Note that this simple example has not addressed the problem of marking elements such as sentences explicitly; the implications of this are discussed in section *v.4 Complicating the Issue*.

<sup>12</sup>The older terms *Document Type Declaration* and *Document Type Definition*, both abbreviated as DTD, may also be encountered. Throughout these Guidelines we use the term *schema* for any kind of formal document grammar.

structure. On the other hand, where a new text is being prepared to an exact specification, for entry into a textual database of some kind for example, the more precisely stated the rules, the better they can be enforced. Even in the case where an existing text is being marked up, it may be beneficial to define a restrictive set of rules relating to one particular view or hypothesis about the text—if only as a means of testing the usefulness of that view or hypothesis. A schema designed for use by a small project or team is likely to take a different position on such issues than one intended for use by a large and possibly fragmented community. It is important to remember that every schema results from an interpretation of a text. There is no single schema encompassing the absolute truth about any text, although it may be convenient to privilege some schemas above others for particular types of analysis.

XML is widely used in environments where uniformity of document structure is a major desideratum. In the production of technical documentation, for example, it is of major importance that sections and subsections should be properly nested, that cross-references should be properly resolved and so forth. In such situations, documents are seen as raw material to match against predefined sets of rules. As discussed above, however, the use of simple rules can also greatly simplify the task of tagging accurately elements of less rigidly constrained texts. By making these rules explicit, the scholar reduces his or her own burdens in marking up and verifying the electronic text, while also being forced to make explicit an interpretation of the structure and significant particularities of the text being encoded.

### v.3.4 An Example Schema

A schema can be expressed in a number of different ways; frequently-encountered methods include the Document Type Definition (DTD) language which XML inherited from SGML; the XML Schema language (<http://www.w3.org/XML/Schema>) defined by the W3C; and the RELAX NG language (<http://relaxng.org/>) originally developed within the OASIS Technical Committee and now an ISO standard<sup>13</sup>. In this chapter, and throughout these Guidelines, we give examples using the ‘compact syntax’ of RELAX NG, but the specifications within these Guidelines are expressed in a way that is largely independent of the specific language in which a schema generated from them is expressed.<sup>14</sup> Although we will use the RELAX NG compact syntax for illustration in what follows, the reader should bear in mind that analogous concepts are expressed differently in other schema languages.

The following schema might be used to validate our example poem:

```
anthology_p = element anthology { poem_p+ }
poem_p = element poem { heading_p?, stanza_p+ }
stanza_p = element stanza { line_p+ }
heading_p = element heading { text }
line_p = element line { text }
start = anthology_p
```

Note that this is not the only way in which a RELAX NG schema might be written;<sup>15</sup> we have adopted this idiom, however, because it matches that used throughout the rest of these Guidelines.

A RELAX NG schema expresses rules about the possible structure of a document in terms of *patterns*; that is, it defines a number of named patterns, each of which acts as a kind of template against which an input document can be matched. The meaning of a pattern is expressed in a schema by reference to other patterns, or to a small number of built-in fundamental concepts, as we shall see. In the example above, the word to the left of the equals sign is the pattern's name, and the material following it declares a meaning for the pattern. Patterns may also be of particular types; the ones that interest us here are called *element patterns* and *attribute patterns*. In this example we see definitions for five element patterns. Note that we have used similar names for the pattern and the element which the pattern describes: so, for example, the line `anthology_p = element anthology {poem_p+}` defines an element pattern called `anthology_p`, the value of which defines an element called `anthology`. These naming conventions are arbitrary; we could use the same name for the pattern as for the element, since the two are

---

<sup>13</sup>ISO/IEC FDIS 19757-2 Document Schema Definition Language (DSDL) -- Part 2: Regular-grammar-based validation -- RELAX NG

<sup>14</sup>See further 22. *Documentation Elements* and 23.5. *Implementation of an ODD System*. In practice, the only part of a TEI element specification not expressed using TEI-defined syntax is the content model for an element, which is expressed using the RELAX NG schema language for reasons of processing convenience. RELAX NG uses its own XML vocabulary to define content models, which is adopted by the TEI for the same purpose.

<sup>15</sup>For a good tutorial introduction to RELAX NG, see van der Vlist (2004).

syntactically quite distinct. The name, or *generic identifier*, of the element follows the word ‘element’, and the *content model* for the element is given within the curly braces following that. Each of these parts is discussed further below.

The last line of the schema above tells a RELAX NG validator which element (or elements) in a document can be used as the root element: in our case only `<anthology>`. This enables the validator to detect whether a particular document is well-formed but incomplete; it also simplifies the processing task by providing an ‘entry point’.

### Generic Identifier

Following the word ‘element’ each pattern declaration gives the generic identifier (often abbreviated to GI) of the element being defined, for example *poem*, *heading*, etc. A GI may contain letters, digits, hyphens, underscore characters, or full stops, but must begin with a letter.<sup>16</sup> Uppercase and lowercase letters are quite distinct: an element with the GI `<foo>` is *not* the same as an element with the GI `<Foo>`; the root element of a TEI-conformant document is `<TEI>`, *not* `<tei>`.

### Content Model

The second part of each declaration, enclosed in curly braces, is called the *content model* of the element being defined, because it specifies what may legitimately be contained within it. In RELAX NG, the content model is defined in terms of other patterns, either by embedding them, or (as in our examples above) by naming or referring to them. The RELAX NG compact syntax also uses a small number of reserved words to identify other possible contents for an element, of which by far the most commonly encountered is `text`, as in this example: it means that the element being defined may contain any valid character data, but no elements. If an XML document is thought of as a structure like a family tree, with a single ancestor at the top (in our case, this would be `<anthology>`), then almost always, following the branches of the tree downwards (for example, from `<anthology>` to `<poem>` to `<stanza>` to `<line>` and `<heading>`) will lead eventually to `text`. In our example, `<heading>` and `<line>` are so defined, since their content models say `text` only and name no embedded elements.

### Occurrence Indicators

The declaration for `<stanza>` in the example above states that a stanza consists of one or more lines. It uses an *occurrence indicator* (the plus sign) to indicate how many times something matching the pattern `line_p` may be repeated. There are three occurrence indicators: the plus sign, the question mark, and the asterisk or star. The plus sign means that the pattern can match one or more times; the question mark means that it may match at most once but is not mandatory; the star means that the pattern concerned is not mandatory, but may match more than once. Thus, if the content model for `<stanza>` were `{line_p*}`, stanzas with no lines would be possible as well as those with more than one line. If it were `{line_p?}`, again empty stanzas would be countenanced, but no stanza could have more than a single line. The declaration for `<poem>` in the example above thus states that a `<poem>` cannot have more than one heading, but may have none, and that it must have at least one `<stanza>` and may have several.

### Connectors

The content model `{heading_p?, stanza_p+}` contains more than one component, and thus needs additionally to specify the order in which these patterns (`<heading_p>` and `<stanza_p>`) may appear. This ordering is determined by the *connector* (the comma) used between its components. The comma connector indicates that the patterns concerned must appear in the sequence given. Another commonly encountered connector is the vertical bar, representing alternation. If the comma in this example were replaced by a vertical bar, then a `<poem>` would consist of either a heading or just stanzas—but not both!

### Groups

In our example so far, the components of each content model have been either single patterns or `text`. It is quite permissible, however, to define content models in which the components are lists of patterns, combined by connectors. Such lists may also be modified by occurrence indicators and themselves combined by connectors. To demonstrate these facilities, let us expand our example to include non-stanzaic types of verse. For the sake of demonstration, we will categorize poems as one of the following: *stanzaic*, *couplets*, or *blank* (or *stichic*). A blank-

<sup>16</sup>In XML, a single colon may also appear in a GI, where it has a special significance related to the use of *namespaces*, as further discussed in section v.6.3 *Namespaces*. The characters defined by Unicode as *combining characters* and as *extenders* are also permitted, as are logograms such as Chinese characters.

verse poem consists simply of lines (we ignore the possibility of verse paragraphs for the moment),<sup>17</sup> so no additional elements need be defined for it. A couplet is defined as a `<firstLine>` followed by a `<secondLine>`.

```
couplet_ p = element couplet {firstLine_ p, secondLine_ p}
```

The patterns `firstLine_p` and `secondLine_p` define elements `<firstLine>` and `<secondLine>` (which are distinguished to enable studies of rhyme scheme, for example<sup>18</sup>); these will have exactly the same content model as the existing `<line>` element. We will therefore add the following two lines to our example schema:

```
firstLine_ p = element firstLine {text} secondLine_ p = element secondLine {text}
```

Next, we can change the declaration for the `<poem>` element to include all three possibilities:

```
poem_ p = element poem  
{ heading_ p?, ( stanza_ p+ | couplet_ p+ | line_ p+ ) }
```

That is, a poem consists of an optional heading, followed by one or several stanzas, or one or several couplets, or one or several lines. Note the difference between this declaration and the following:

```
poem_ p = element poem  
{ heading_ p?, ( stanza_ p | couplet_ p | line_ p )+ }
```

The second version, by applying the occurrence indicator to the group rather than to each element within it, would allow a single poem to contain a mixture of stanzas, couplets, and lines.

A group of this kind can contain `text` as well as named elements: this combination, known as *mixed content*, allows for elements in which the sub-components appear with intervening stretches of character data. For example, if we wished to mark place names wherever they appear inside our verse lines, then, assuming we have also added a pattern for the `<name>` element, we could change the definition for `<line>` to

```
line_ p = element  
line { ( text | name_ p )* }
```

Some XML schema languages place no constraints on the way that mixed content models may be defined, but in the XML DTD language, when `text` appears with other elements in a content model, it must always appear as the first option in an alternation; it may appear once only, and in the outermost model group; and if the group containing it is repeated, the star operator must be used. Although these constraints do not apply to (for example) schemas expressed in the RELAX NG language, all TEI content models currently obey them.

Quite complex models can easily be built up in this way, to match the structural complexity of many types of text. As a further example, consider the case of stanzaic verse in which a refrain or chorus appears. Like a stanza, a

---

<sup>17</sup>It will not have escaped the astute reader that the fact that verse paragraphs need not start on a line boundary seriously complicates the issue; see further section *v.4 Complicating the Issue*.

<sup>18</sup>This is however a rather artificial example; XPath, for example, provides ways of distinguishing elements in an XML structure by their position without the need to give them distinct names.

refrain consists of repetitions of the line element. A refrain can appear at the start of a poem only, or as an optional addition following each stanza. This could be expressed by a pattern such as the following:

```
refrain_p = element refrain {line_p+}
poem_p = element poem {heading_p?, ( line_p+ | (refrain_p?, (stanza_p,
refrain_p?)+ ) ) }
```

That is, a poem consists of an optional heading, followed by either a sequence of lines or an unnamed group, which starts with an optional refrain and is followed by one or more occurrences of another group, each member of which is composed of a stanza followed by an optional refrain. A sequence such as *refrain - stanza - stanza - refrain* follows this pattern, as does the sequence *stanza - refrain - stanza - refrain*. The sequence *refrain - refrain - stanza - stanza* does not, however, and neither does the sequence *stanza - refrain - refrain - stanza*. Among other conditions made explicit by this content model are the requirements that at least one stanza must appear in a poem, if it is not composed simply of lines, and that if there is both a heading and a stanza they must appear in that order.

Note that the apparent complexity of this model derives from the constraints expressed informally above. A simpler model, such as

```
poem_p =
element poem {heading_p?, (line_p | refrain_p | stanza_p)+ }
```

would not enforce any of them, and would therefore permit such anomalies as a poem consisting only of refrains, or an arbitrary mixture of lines and refrains.

## v.4 Complicating the Issue

In the simple cases described so far, we have assumed that one can identify the immediate constituents of every element in a textual structure. A poem consists of stanzas, and an anthology consists of poems. Stanzas do not float around unattached to poems or combined into some other unrelated element; a poem cannot contain an anthology. All the elements of a given document type may be arranged into a hierarchic structure like a family tree, with a single ancestor at one end and many children (mostly the elements containing simple text) at the other. For example, we could represent an anthology containing two poems, the first of which contains two four-line stanzas and the second a single stanza, by a tree structure like the following figure:

This graphic representation of the structure of an XML document is close to the abstract model implicit in most XML processing systems. Most such systems now use a standardized way of accessing parts of an XML document called *XPath*.<sup>19</sup> XPath gives us a non-graphical way of referring to any part of an XML document: for example, we might refer to the last line of Blake's poem as `/anthology/poem[1]/stanza[2]/line[4]`. The square brackets here indicate a numerical selection: we are talking about the fourth line in the second stanza of the first poem in the anthology. If we left out all the square-bracketed selections, the corresponding XPath expression would refer to all lines contained by stanzas contained by poems contained by anthologies. An XPath expression can refer to any collection of elements: for example, the expression `/anthology/poem` refers to all poems in an anthology and the expression `/anthology/poem/heading` refers to all their headings.

The solidus within an XPath expression behaves in much the same way as the solidus or backslash in a filename specification: it indicates that the item to the left directly contains the item to the right of it. In XPath it is also possible to indicate that any number of other items may intervene by repeating the solidus. For example, the XPath expression `/anthology/poem//line[1]` will refer to the first line of each poem in the anthology, irrespective of whether it is in a stanza.

Clearly, there are many such trees that might be drawn to describe the structure of this or other anthologies. Some of them might be representable as further subdivisions of this tree: for example, we might subdivide the lines into

<sup>19</sup>The official specification is at Clark and DeRose (eds.) (1999); many introductory tutorials are available in the XML references cited above and elsewhere on the Web: good beginners' tutorials include [http://www.w3schools.com/xml/xpath\\_intro.asp](http://www.w3schools.com/xml/xpath_intro.asp) and <http://www.zvon.org/xxl/XPathTutorial/>, the latter being available in several languages.

individual words, since in our simple example no word crosses a line boundary. Surprisingly perhaps, this grossly simplified view of what text is (memorably termed an *ordered hierarchy of content objects* (OHCO) view of text by Renear *et al.*<sup>20</sup>) turns out to be very effective for a large number of purposes. It is not, however, adequate for the full complexity of real textual structures, for which more complex mechanisms need to be employed. There are many other trees that might be drawn which do *not* fit within the anthology model which we have presented so far. We might, for example, be interested in syntactic structures or other linguistic constructs, which rarely respect the formal boundaries of verse. Or, to take a simpler example, we might want to represent the pagination of different editions of the same text.

In the OHCO model of text, representation of cases where different elements overlap so that several different trees may be identified in the same document is generally problematic. All the elements marked up in a document, no matter what namespace they belong to, must fit within a single hierarchy. To represent overlapping structures, therefore, a single hierarchy must be chosen, and the points at which other hierarchies intersect with it marked. For example, we might choose the verse structure as our primary hierarchy, and then mark the pagination by means of empty elements inserted at the boundary points between one page and the next. Or we could represent alternative hierarchies by means of the pointing and linking mechanisms described in chapter 16. *Linking, Segmentation, and Alignment* of these Guidelines. These mechanisms all depend on the use of *attributes*, which may be used both to identify particular elements within a document and to point to, link, or align them into arbitrary structures.

## v.5 Attributes

In the XML context, the word *attribute*, like some other words, has a specific technical sense. It is used to describe information that is in some sense descriptive of a specific element occurrence but not regarded as part of its content. For example, you might wish to add a *status* attribute to occurrences of some elements in a document to indicate their degree of reliability, or to add an *identifier* attribute so that you could refer to particular element occurrences from elsewhere within a document. Attributes are useful in precisely such circumstances.

Although different elements may have attributes with the same name (for example, in the TEI scheme, every element is defined as having an attribute named *n*), they are always regarded as different, and may have different values assigned to them. If an element has been defined as having attributes, the attribute values are supplied in

<sup>20</sup>See Renear *et al.* (1996).

the document instance as *attribute-value pairs* inside the start-tag for the element occurrence. An end-tag cannot contain an attribute-value specification, since it would be redundant.

The order in which attribute-value pairs are supplied inside a tag has no significance; they must, however, be separated by at least one whitespace (blank, newline, or tab) character. The value part must always be given inside matching quotation marks, either single or double<sup>21</sup>.

For example:

```
<poem xml:id="Poem1" status="draft"> ... </poem>
```

Here attribute values are being specified for two attributes previously declared for the `<poem>` element: *xml:id* and *status*. For the instance of a `<poem>` in this example, represented here by an ellipsis, the *xml:id* attribute has the value P1 and the *status* attribute has the value draft. An XML processor can use the values of the attributes in any way it chooses; for example, a `<poem>` in which the *status* attribute has the value draft might be formatted differently from one in which the same attribute has the value revised; another processor might use the same attribute to determine whether or not poem elements are to be processed at all. The *xml:id* attribute is a slightly special case in that, by convention, it is always used to supply a unique value to identify a particular element occurrence, which may be used for cross-reference purposes, as discussed further below (*v.5.2 Identifiers and Indicators*).

### v.5.1 Declaring Attributes

Attributes are declared in a schema in the same way as elements. As well as specifying an attribute's name and the element to which it is to be attached, it is possible to specify (within limits) what kind of value is acceptable for an attribute.

In the compact syntax of RELAX NG, an attribute is defined by means of an attribute pattern, like the following:

```
att.status = attribute status {"draft" | "revised" | "published"}
```

This defines a new pattern, called `att.status`, whose value is an attribute pattern defining an attribute named *status*. Attribute names are subject to the same restrictions as other names in XML; they need not be unique across the whole schema, however, but only within the list of attributes for a given element.

A pattern defining the possible values for this attribute is given within the curly braces, in just the same way as a content model is given for an element pattern. In this case, the attribute's value must be one of the strings presented explicitly above.

The attribute pattern definition must be included or referenced within the definition for every element to which the attribute is attached. We therefore modify the definition for the `poem_p` pattern given above as follows:

```
poem_p = element poem {att.status?, heading_ p?, stanza_ p+}
```

In RELAX NG, an element pattern simply includes any attribute patterns applicable to it along with its other constituents, as shown above. Attribute patterns can also be grouped and alternated in the same way as element patterns, though this particular feature is not widely used in the TEI scheme, since it is not available to the same extent in all schema languages. Because a question mark follows the reference to the `att.status` pattern in our example, a document in which the *status* attribute is not specified will still be valid; without this occurrence indicator the *status* attribute would be required.

Instead of supplying a list of explicit values, an attribute pattern can specify that the attribute must have a value of a particular type, for example a text string, a numeric value, a normalized date, etc. This is accomplished by supplying a pattern that refers to a *datatype*. In the example above, because a list of acceptable values is predefined,

<sup>21</sup>In the unlikely event that both kinds of quotation marks are needed within the quoted string, either or both can also be presented in escaped form, using the predefined character entities `&apos;` or `&quot;`;

a parser can check that no `<poem>` is defined for which the *status* attribute does not have one of draft, revised, or published as its value. By contrast, with a definition such as

```
att.status =
attribute status {text}
```

a parser would accept almost any unbroken string of characters (*status*="awful", *status*="awe-ful", or *status*="12345678") as valid for this attribute. Sometimes, of course, the set of possible values cannot be predefined. Where it can, as in this case, it is generally better to do so.

Schema languages vary widely in the extent to which they support validation of attribute values. Some languages predefine a small set of possibilities. Others allow the schema designer to use values from a predefined 'library' of possible datatypes, or to add their own definitions, possibly of great complexity. A 'datatype' might be something fairly general (any positive integer), something very specific or idiosyncratic (any four-character string ending with "T"), or somewhere between the two. In the RELAX NG schemas used by the TEI, general patterns have been defined for about half a dozen datatypes (using the W3C Schema Datatype Library, and discussed further in DTYPES). In addition to the two possibilities already mentioned—plain text or an explicit list of possible strings—other datatypes likely to be encountered include the following:

**boolean** values must be either true or false

**numeric** values must represent a numeric quantity of some kind

**date** values must represent a possible date and time in some calendar

Two further datatypes of particular usefulness in managing XML documents are commonly known as **ID**—for identifier—and **URI**—for Universal Resource Indicator, or pointer for short. These are discussed in the next section.

### v.5.2 Identifiers and Indicators

It is often necessary to refer to an occurrence of one textual element from within another, an obvious example being phrases such as 'see note 6' or 'as discussed in chapter 5'. When a text is being produced the actual numbers associated with the notes or chapters may not be certain. If we are using descriptive markup, such things as page or chapter numbers, being entirely matters of presentation, will not in any case be present in the marked-up text: they will be assigned by whatever processor is operating on the text (and may indeed differ in different applications). XML therefore predefines an attribute that may be used to provide any element occurrence with a special identifier, a kind of label, which may be used to refer to it from anywhere else: since it is defined in the XML namespace, the name of this attribute is *xml:id* and it is used throughout the TEI schema. Because it is intended to act as an identifier, its values must be unique within a given document. The cross-reference itself will be supplied by an element bearing an attribute of a specific kind, which must also be declared in the schema.

Suppose, for example, we wish to include a reference within the notes on one poem that refers to another poem. We will first need to provide some way of attaching a label to each poem: this is easily done using the *xml:id* attribute. Note that not every poem need carry an *xml:id* attribute and the parser may safely ignore the lack of one in those that do not. Only poems to which we intend to refer need use this attribute; for each such poem we should now include in its start-tag some unique identifier, for example:

```
<poem xml:id="Rose"> ... </poem>
<poem xml:id="P40"> ... </poem>
<poem> ... </poem>
```

Next we need to define a new element for the cross-reference itself. This will not have any content—it is only a pointer—but it has an attribute, the value of which will be the identifier of the element pointed at. This is achieved by the following definition:

```
poemRef_p = element poemRef {attribute target {anyURI}, empty}
```

The `<poemRef>` element has no content, but a single attribute called *target*. The value of this attribute must be a pointer or web reference of type `anyURI`,<sup>22</sup> furthermore, because there is no indication of optionality on the attribute pattern, it must be supplied on each occurrence—a `<poemRef>` with no referent is an impossibility.

With these declarations in force, we can now encode a reference to the poem whose *xml:id* attribute specifies that its identifier is Rose as follows:

```
Blake's poem on the sick rose
<poemRef target="#Rose"/> ...
```

A processor may take any number of actions when it encounters a link encoded in this way: a formatter might construct an exact page and line reference for the location of the poem in the current document and insert it, or just quote the poem's title or first lines. A hypertext style processor might use this element as a signal to activate a link to the poem being referred to, for example by displaying it in a new window. Note, however, that the purpose of the XML markup is simply to indicate that a cross-reference exists: it does not necessarily determine what the processor is to do with it.

The target of a URI can be located anywhere: it may not necessarily be part of the same document, nor even located on the same computer system. Equally, it can be a resource of any kind, not necessarily an XML document or document fragment. It is thus a very convenient way of including references to non-XML data such as image files within a document. If, for example, we wished to include an illustration containing a reproduction of Blake's original in our anthology, the most appropriate method would probably be to define a new element called (for the sake of argument) `<graphic>` with a *target* attribute of datatype URI:

```
graphic_p = element graphic {att.url, empty} att.url =
attribute url {anyURI}
```

With these additions to the schema, we can now represent the location of the illustration within our text like this:

```
<poem>
  <graphic url="http://en.wikisource.org/wiki/Image:Blake_sick_rose.jpg"/>
</poem>
```

By providing a location from which a reproduction of the required image can be downloaded, this encoding makes it possible for appropriate software able to display the image as well as record its existence.

Attributes form part of the structure of an XML document in the same way as elements, and can therefore be accessed using XPath. For example, to refer to all the poems in our anthology whose *status* attribute has the value `draft`, we might use an XPath such as `/anthology/poem[@status='draft']`. To find the headings of all such poems, we would use the XPath `/anthology/poem[@status='draft']/heading`.

## v.6 Other Components of an XML Document

In addition to the elements and attributes so far discussed, an XML document can contain a few other formally distinct things. An XML document may contain references to predefined strings of data that a validator must resolve before attempting to validate the document's structure; these are called *entity references*. They may be useful as a means of providing 'boilerplate' text or representing character data which cannot easily be keyboarded. An XML

<sup>22</sup>The word 'anyURI' is a predefined name, used in schema languages to mean that any *Uniform Resource Identifier* (URI) may be supplied here. The accepted syntax for URIs is an Internet Standard, defined in <http://tools.ietf.org/html/rfc3986>. `anyURI` is one of the *datatypes* defined by the W3C Schema datatype library.

document may also contain arbitrary signals or flags for use when the document is processed in a particular way by some class of processor (a common example in document production is the need to force a formatter to start a new page at some specific point in a document); such flags are called *processing instructions*. And, as noted earlier, an XML document may also contain instances of elements taken from some other *namespace*. We discuss each of these three cases in the rest of this section.

### v.6.1 Character References

As mentioned above, all XML documents use the same internal character encoding. Since not all computer systems currently support this encoding directly, a special syntax is defined that can be used to represent individual characters from the Unicode character set in a portable way by providing their numeric value, in decimal or hexadecimal notation.

For example, the character *é* is represented within an XML document as the Unicode character with hexadecimal value 00E9. If such a document is being prepared on (or exported to) a system using a different character set in which this character is not available, it may instead be represented by the character reference `&#x00E9`; (the X indicating that what follows is a hexadecimal value) or `&#0233`; (its decimal equivalent). References of this type do not need to be predefined, since the underlying character encoding for XML is always the same.

To aid legibility, however, it is also possible to use a mnemonic name (such as *eacute*) for such character references, provided that each such name is mapped to the required Unicode value by means of a construct known as an *entity declaration*. A reference to a named character entity always takes the form of an ampersand, followed by the name, followed by a semicolon. For example an XML document containing the string ‘T&C’ might be encoded as `T&C`.

There is a small set of such character entity references that do not have to be declared because they form part of the definition of XML. These include the names used for characters such as the ampersand (*amp*) and the open angle bracket or less-than sign (*lt*), which could not easily otherwise be included in an XML document without ambiguity. Other predeclared entity names are those for quotation marks (*quot* and *apos* for double and single respectively), and for completeness the closing angle bracket or greater-than sign (*gt*).

For all other named character entities, a set of entity declarations must be provided to an XML processor before the document referring to them can be validated. The declaration itself uses a non-XML syntax inherited from SGML; for example, to define an entity named *eacute* with the replacement value *é*, the declaration could have any of the following forms:

```
<!ENTITY eacute "é">
```

or, using hexadecimal notation:

```
<!ENTITY eacute "&#xe9;">
```

or, using decimal notation:

```
<!ENTITY eacute "&#233;">
```

Entities of this kind are useful also for *string substitution* purposes, where the same text needs to be repeated uniformly throughout a text. For example, if a declaration such as

```
<!ENTITY TEI "Text Encoding Initiative">
```

is included with a document, then references such as `&TEI;` may be used within it, each of which will be expanded in the same way and replaced by the string ‘Text Encoding Initiative’ before the text is validated.

## v.6.2 Processing Instructions

Although one of the aims of using XML is to remove any information specific to the processing of a document from the document itself, it is occasionally very convenient to be able to include such information—if only so that it can be clearly distinguished from the structure of the document. As suggested above, one common example is the need, when processing an XML document for printed output, to include a suggestion that the formatting processor might use to determine where to begin a new page of output. Page-breaking decisions are usually best made by the formatting engine alone, but there will always be occasions when it may be necessary to override these. An XML processing instruction inserted into the document is one very simple and effective way of doing this without interfering with other aspects of the markup.

Here is an example XML processing instruction:

```
<?tex \newpage ?>
```

It begins with `<?` and ends with `?>`. In between are two space-separated strings: by convention, the first is the name of some processor (`tex` in the above example) and the second is some data intended for the use of that processor (in this case, the instruction to start a new page). The only constraint placed by XML on the strings is that the first one must be a valid XML name; the other can be any arbitrary sequence of characters, not including the closing character-sequence `?>`.

A construct which looks like a processing instruction (but is not) is the *XML declaration* which can be supplied at the beginning of an XML document, for example:

```
<?xml version="1.0" encoding="iso-8859-1"?>
```

The XML declaration specifies the version number of the XML Recommendation applicable to the document it introduces (in this case, version 1.0), and optionally also the character encoding used to represent the Unicode characters within it. By default an XML document uses the character encoding UTF-8 or UTF-16; in this case, the 16-bit characters of Unicode have been mapped to the 8-bit character set known as ISO 8859-1; any characters present in the document but not available in the target character set will therefore need to be represented as character references (*v.6.1 Character References*). The XML declaration is purely documentary, but if it is wrong many XML-aware processors will be unable to process the associated text.

## v.6.3 Namespaces

A valid XML document necessarily specifies the schema in which its constituent elements are defined. However, a well-formed XML document is not required to specify its schema (indeed, it may not even have a schema). It would still be useful to indicate that the element names used in it have some defined provenance. Furthermore, it might be desirable to include in a document elements that are defined (possibly differently) in different schemas. A cabinet-maker's schema might well define an element called `<table>` with very different characteristics from those of a documentalist's.

The concept of *namespace* was introduced into the XML language as a means of addressing these and related problems. If the markup of an XML document is thought of as an expression in some language, then a namespace may be thought of as analogous to the lexicon of that language. Just as a document can contain words taken from different languages, so a well-formed XML document can include elements taken from different namespaces. A namespace resembles a schema in that we may say that a given set of elements ‘belongs to’ a given namespace, or are ‘defined by’ a given schema. However, a schema is a set of element definitions, whereas a namespace is really only a property of a collection of elements: the only tangible form it takes in an XML document is its distinctive *prefix* and the identifying *name* associated with it.

Suppose for example that we wish to extend our anthology to include a complex diagram. We might start by considering whether or not to extend our simple schema to include XML markup for such features as arcs, polygons,

and other graphical elements. XML can be used to represent any kind of structure, not simply text, and there are clear advantages to having our text and our diagrams all expressed in the same way.

Fortunately we do not need to invent a schema for the representation of graphical components such as diagrams; it already exists in the shape of the Scalable Vector Graphics (SVG) language defined by the W3C.<sup>23</sup> SVG is a widely used and rich XML vocabulary for representing all kinds of two-dimensional graphics; it is also well supported by existing software. Using an SVG-aware drawing package, we can easily draw our diagram and save it in XML format for inclusion within our anthology. When we do so, we need to indicate that this part of the document contains elements taken from the SVG namespace, if only to ensure that processing software does not confuse our `<line>` element with the SVG `<line>`, which means something quite different.

An XML document need not specify any namespace: it is then said to use the ‘null’ namespace. Alternatively, the root element of a document may supply a default namespace, understood to apply to all elements which have no namespace prefix. This is the function of the `xmlns` attribute which provides a unique name for the default namespace, in the form of a URI:

```
<anthology>  
<!-- anthology markup elements here -->  
</anthology>
```

In exactly the same way, on the root element for each part of our document which uses the SVG language, we might introduce the SVG namespace name:

```
<anthology>  
<!-- anthology markup elements here -->  
  <svg xmlns="http://www.w3.org/2000/svg">  
    <!-- SVG markup elements here -->  
  </svg>  
<!-- more anthology markup elements here -->  
</anthology>
```

Although a namespace name usually uses the URI (Uniform Resource Identifier) syntax, it is not treated as an online address and an XML processor regards it just as a string, providing a longer name for the namespace.

The `xmlns` attribute can also be used to associate a short prefix name with the namespace it defines. This is very useful if we want to mingle elements from different namespaces within the same document, since the prefix can be attached to any element, overriding the implicit namespace for itself (but not its children):

```
<anthology  
  xmlns:svg="http://www.w3.org/2000/svg">  
<!-- anthology markup elements here -->  
  <svg:svg>  
    <!-- SVG markup elements here -->  
  </svg:svg>  
<!-- more anthology markup elements here -->  
</anthology>
```

There is no limit on the number of namespaces that a document can use. Provided that each is uniquely identified, an XML processor can identify those that are relevant, and validate them appropriately. To extend our example further, we might decide to add a linguistic analysis to each of the poems, using a set of elements such as `<aux>`, `<adj>`, etc., derived from some pre-existing XML vocabulary for linguistic analysis.

---

<sup>23</sup>The W3C Recommendation is defined at <http://www.w3.org/Graphics/SVG/>.

```

<anthology
  xmlns:gram="http://www.gram.org"
  xmlns:svg="http://www.w3.org/2000/svg">

<!-- anthology markup elements here -->
  <svg:svg>
<!-- SVG markup elements here -->
  </svg:svg>
  <line>
    <gram:itj>0</gram:itj>
    <gram:nom>Rose</gram:nom>
    <gram:pron>thou</gram:pron>
    <gram:aux>art</gram:aux>
    <gram:adj>sick</gram:adj>
  </line>
</anthology>

```

### Marked Sections

We mentioned above that the syntax of XML requires the encoder to take special action if characters with a syntactic meaning in XML (such as the left angle bracket or ampersand) are to be used in a document to stand for themselves, rather than to signal the start of a tag or an entity reference respectively. The predefined entities `&amp;`, `&lt;`, and `&gt;` provide one method of dealing with this problem, if the number of occurrences of such things is small. Other methods may be considered when the number is large, as in an XML document like the present Guidelines, which contains hundreds of examples of XML markup. One is to label the XML examples as belonging to a different namespace from that of the document itself, which is the approach taken in the present Guidelines. Another and simpler approach is provided by one of the features inherited by XML from its parent SGML: the ‘marked section’.

A marked section is a block of text within an XML document introduced by the characters `<![CDATA[` and terminated by the characters `]]>`. Between these rather strange brackets, markup recognition is turned off, and any tags or entity references encountered are therefore treated as if they were plain text. For example, when we come to write the users' manual for our anthology, we may find ourselves often producing text like the following:

```

Here is an example of the use of the <gi>line</gi> element:
<![CDATA[<line>[...]</line>]]>

```

## v.7 Putting It All Together

In this chapter we have discussed most of the components of an XML document and its associated schema. We have described informally how an XML document is represented, and also introduced one way of representing the rules a RELAX NG validator might use to validate it. In a working system, the following issues will also need to be addressed:

- how does a processor determine the schema (or schemas) that should be used to validate a given XML document instance?
- if a document contains entity references that must be processed before the document can be validated, where are those entities defined?
- an XML document instance may be stored in a number of different operating system files; how should they be assembled together?
- how does a processor determine which stylesheets it should use when processing an XML document, or how to interpret any processing instructions it contains?
- how does a processor enforce more exact validation than simple datatypes permit (for example of element content)?

Different schema languages and different XML processing systems take very different positions on all of these topics, since none of them is explicitly addressed in the XML specification itself. Consequently, the best answer is likely to be specific to a particular software environment and schema language. Since this chapter is concerned with XML considered independently of its processing environment, we only address them in summary detail here.

### v.7.1 Associating Entity Definitions with a Document Instance

In *v.6.1 Character References* we introduced the syntax used for the definition of named character entities such as `eacute`, which XML inherited from SGML. Different schema languages vary in the ways they make a collection of such definitions available to an XML processor, but fortunately there is one method that all current schema languages support.

As well as, and following, the XML declaration (*v.6.2 Processing Instructions*), an XML document instance may be prefixed with a special **DOCTYPE** statement. This declarative statement has been inherited by XML from SGML; in its full form it provides a large number of facilities, but we are here concerned only with the small subset of those facilities recognized by all schema languages.

Here is an example DOCTYPE statement which we might consider prefixing to the final version of our anthology:

```
<!DOCTYPE anthology [  
<!ENTITY mdash "ߞ">  
<!ENTITY legalese "This document is available under a Creative Commons  
Share and Enjoy Licence">  
>
```

Any XML processor encountering this statement will use it to add the two named entities it defines to those already predefined for XML. Before the document instance itself is validated, any references to these entities will be expanded to the character string given. Thus, wherever in the document instance the string `&legalese;` appears, it will be replaced by the formulation above. This makes life a little easier for those keyboarding our anthology.<sup>24</sup> The word `anthology` following the string DOCTYPE in this example is, of course, the name of the root element of the document to which this declaration is prefixed; however, only an XML DTD processor will take note of this fact.

### v.7.2 Associating a Document Instance with Its Schema

In the past, different schema languages adopted entirely different attitudes to this question, leading to a variety of different methods of associating schemas with document instances. However, a W3C Working Group Note, *Associating Schemas with XML documents*, (<http://www.w3.org/TR/xml-model/>) now provides a standardized method of doing this through the use of a processing instruction:

```
<?xml-model href="http://www.tei-c.org/release/xml/tei/custom/schema/relaxng/tei_  
all.rng"?)>
```

The *href pseudo-attribute* points to the location of the schema. This is the only mandatory pseudo-attribute, but others can be added to give more information about the schema:

```
<?xml-model href="burgess.rng"  
title="Anthony Burgess Project Schema"  
schematypens="http://relaxng.org/ns/structure/1.0"  
type="application/xml"  
?>
```

See the XML Model WG Note for more information on the pseudo-attributes available and how to use them.

---

<sup>24</sup>And, indeed, for those responsible for deciding the licensing conditions if they change their minds later.

A document instance may be valid according to many different schemas, each appropriate to a different processing task. All of these may be expressed in the same way:

```
<?xml-model href="tei_tite.xsd" type="application/xml" ?>
<?xml-model href="checkNames.sch" type="application/xml" schematypens="http://purl.oclc.org/dsdl/s
?>
```

This example includes a standard schema in XML Schema format, along with a schematron schema which might be used for checking the format and linking of names.

Any modern XML processing software tool will provide convenient methods of validating documents which are appropriate to the particular schema language chosen. In the interests of maximizing portability of document instances, they should contain as little processing-specific information as possible.

### v.7.3 Assembling Multiple Resources into a Single Document

As we have already indicated, a single XML document may be made up of several different operating system files that need to be pulled together by a processor before the whole document can be validated. The XML DTD language defines a special kind of entity (a *system entity*) that can be used to embed references to whole files into a document for this purpose, in much the same way as the character or string entities discussed in *v.6.1 Character References*. Neither RELAX NG nor W3C Schema directly supports this mechanism, however, and we do not discuss it further here.

An alternative way of achieving the same effect is to use a special kind of pointer element to refer to the resources that need to be assembled, in exactly the same way as we proposed for the illustration in our anthology. The W3C Recommendation *XML Inclusions (XInclude)*<sup>25</sup> defines a generic mechanism for this purpose, which is supported by an increasing number of XML processors.

### v.7.4 Stylesheet Association and Processing

As mentioned above, the processing of an XML document will usually involve the use of one or more stylesheets, often but not exclusively to provide specific details of how the document should be displayed or rendered. In general, there is no reason to associate a document instance with any specific stylesheet and the schema languages we have discussed so far do not therefore make any special provision for such association. The association is made when the stylesheet processor is invoked, and is thus entirely application-specific.

However, since one very common application for XML documents is to serve them as browsable documents over the Web, the W3C has defined a procedure and a syntax for associating a document instance with its stylesheet (see <http://www.w3.org/TR/xml-stylesheet/>). This Recommendation allows a document to supply a link to a default stylesheet and also to categorize the stylesheet according to its *MIME type*, for example to indicate whether the stylesheet is written in CSS or XSLT, using a specialized form of processing instruction.

Assuming therefore that we have made a CSS-conformant stylesheet for our anthology and stored it in a file called `anthology.css` which is available from the same location as the anthology itself, we could make it available over the Web simply by adding a processing instruction like the following to the anthology:

```
<?xml-stylesheet href="anthology.css" type="text/css"?>
```

Multiple stylesheets can be defined for the same document, and options are available to specify how a web browser should select amongst them. For example, if the document also contained a directive:

```
<?xml-stylesheet href="anthology_m.css" type="text/css" media="mobile"?>
```

<sup>25</sup><http://www.w3.org/TR/xinclude/>.

a different stylesheet called `anthology_m.css` could be used when rendering the document on a handheld device such as a mobile phone.

Most modern web browsers support CSS (although the extent of their implementation varies), and some of them support XSLT.

### Content Validation

As we noted above, most schema languages provide some degree of datatype validation for attribute values (*v.5.1 Declaring Attributes*). They vary greatly in the validation facilities they offer for the content of elements, other than the syntactic constraints already discussed. Thus, while we may very easily check that our `<stanza>` elements contain only `<line>` elements, we cannot easily check that `<line>` elements contain between five and 500 correctly-spelled English words, should we wish to constrain our poetry in such a way. Also, because attributes and elements are treated differently, it is difficult or impossible to express co-occurrence constraints: for example, if the *status* of a poem is `draft` we might wish to permit elements such as `<editorialQuery>` within its content, but not otherwise.

The XML DTD language offers very little beyond syntactic checking of element content. By contrast, a major impetus behind the design and development of the W3C schema language was the addition of a much more general and powerful constraint language to the existing structural constraints of XML DTDs. In RELAX NG the opposite approach was taken, in that all datatype validation, whether of attributes or element content, is regarded as external to the schema language. For attributes, as we have seen, RELAX NG makes use of the W3C Schema Datatype Library (but permits use of others). Because RELAX NG treats both elements and attributes as special cases of patterns, the same datatype validation facilities are available for element content as for attribute values; it is unlike other schema languages in this respect. In addition, for content validation, a different component of DSDL known as Schematron can be used. Schematron is a pattern matching (rather than a grammar-based) language, which allows us to test the components of a document against templates that express constraints such as those mentioned above.

Like other XML processors, Schematron uses XPath to identify parts of an XML document; in addition, it provides elements that describe assertions to be tested and conditions which must be validated, as well as elements to report the results of the test.

## vi Languages and Character Sets

The documents which users of these Guidelines may wish to encode encompass all kinds of material, potentially expressed in the full range of written and spoken human languages, including the extinct, the non-existent, and the conjectural. Because of this wide scope, special attention has been paid to two particular aspects of the representation of linguistic information often taken for granted: language identification and character encoding.

Even within a single document, material in many different languages may be encountered. Human culture, and the texts which embody it, is intrinsically multilingual, and shows no sign of ceasing to be so. Traditional philologists and modern computational linguists alike work in a polyglot world, in which code-switching (in the linguistic sense) and accurate representation of differing language systems constitute the norm, not the exception. The current increased interest in studies of linguistic diversity, most notably in the recording and documentation of endangered languages, is one aspect of this long standing tradition. Because of their historical importance, the needs of endangered and even extinct languages must be taken into account when formulating Guidelines and recommendations such as these.

Beyond the sheer number and diversity of human languages, it should be remembered that in their written forms they may deploy a huge variety of scripts or writing systems. These scripts are in turn composed of smaller units, which for simplicity we term here characters. A primary goal when encoding a text should be to capture enough information for subsequent users of it correctly to identify both language, script, and constituent characters. In this chapter we address this requirement, and propose recommended mechanisms to indicate the languages, scripts and characters used in a document or a part thereof.

Identification of language is dealt with in *vi.1 Language Identification*. In summary, it recommends the use of pre-defined identifiers for a language where these are available, as they increasingly are, in part as a result of the twin pressures of an increasing demand for language-specific software and an increased interest in language documentation. Where such identifiers are not available or not standardized, these Guidelines recommend a way of documenting language identifiers and their significance, in the same way as other metadata is documented in the TEI header.

Standardization of the means available to represent characters and scripts has moved on considerably since the publication of the first version of these Guidelines. At that time, it was essential to explicitly document the characters and encoded character sets used by almost any digital resource if it was to have any chance of being usable across different computer platforms or environments, but this is no longer the case. With the availability of the Unicode standard, more than 110,000 different characters representing almost all of the world's current writing systems are available and usable in any XML processing environment without formality. Nevertheless, however large the number of standardized characters, there will always be a need to encode documents which use non-standard characters and glyphs, particularly but not exclusively in historical material. Furthermore, the full potential of Unicode is still not yet realized in all software which users of these Guidelines are likely to encounter. The second part of this chapter therefore discusses in some detail the concepts and practice underlying this standard, and also introduces the methods available for extending beyond it, which are more fully discussed in *5. Characters, Glyphs, and Writing Modes*.

### vi.1 Language Identification

Identification of the language a document or part thereof is written in is a crucial requirement for many envisioned usages of an electronic document. The TEI therefore accommodates this need in the following way:

- A global attribute *xml:lang* is defined for all TEI elements. Its value identifies the language and writing system used.
- The TEI header has a section set aside for the information about the languages used in a document: see further *2.4.2. Language Usage*.

The value of the attribute *xml:lang* identifies the language using a coded value. For maximal compatibility with existing processes, the identifier for the language must be constructed as in *Best Current Practice 47*<sup>26</sup>. This *same* identifier has to be used to identify the corresponding <language> element in the TEI header, if one is present.

The first part of BCP 47 is called *Tags for Identifying Languages*, and proposes the following mechanism for constructing an identifier (tag) for languages as administered by the Internet Assigned Numbers Authority (IANA). The tag is assembled from a sequence of subtags separated by the hyphen (-, U+002D) character. It gives the language

<sup>26</sup>Currently BCP 47 comprises two Internet Engineering Task Force documents, referred to separately as RFC 5646 and RFC 4647; over time, other IETF documents may succeed these as the best current practice.

(possibly further identified with a sublanguage), a script, and a region for the language, each possibly followed by a variant subtag.

The authoritative list of registered subtags is maintained by IANA and is available at <http://www.iana.org/assignments/language-subtag-registry>. For a good general overview of the construction of language tags, see <http://www.w3.org/International/articles/language-tags/>, and for a practical step-by-step guide, see <https://www.w3.org/International/questions/qa-choosing-language-tags.en.php>.

In addition to the list of registered subtags, BCP 47 provides extensions that can be employed by private convention. The constructs provided can thus be used to generate identifiers for any language, past and present, in any usage in any area of the world. If such private extensions are used within the context of the TEI, they should be documented within the <language> element of the TEI header, which might also provide a prose description of the language described by the language tag.

While language, region, and script can be adequately identified using this mechanism, there is only very rough provision to express a dimension of time for the language of a document; those codes provided (e.g. `gRC` for ‘Greek, Ancient (to 1453)’) might not reflect the segments appropriate for a text at hand. Text encoders might express the time window of the language used in the document by means of the extension mechanism defined in BCP 47 and relate that to a <date> element in the corresponding <language> section of the TEI header.

Equivalences to language identifiers by other authorities can be given in the <language> section as well, but no formal mechanism for doing so has been defined.

The scope of the language identification extends to the whole subtree of the document anchored at the element that carries the *xml:lang* attribute, including all elements and those attributes, if any, where a language might apply.<sup>27</sup>

## vi.2 Characters and Character Sets

All document encoding has to do with representing one thing by another in an agreed and systematic way. Applied to the smallest distinctive units in any given writing system, which for the moment we may loosely call ‘characters’, such representation raises surprisingly complex and troublesome issues. The reasons are partly historical and partly to do with conceptual unclarity about what is involved in identifying, encoding, processing and rendering the characters of a natural language.

### vi.2.1 Historical Considerations

When the first methods of representing text for storage or transmission by machines were devised, long before the development of computers, the overriding aim was to identify the smallest set of symbols needed to convey the essential semantic content, and to encode that symbol set in the most economical way that the storage or transmission media allowed. The initial outcome were systems that encoded only such content as could be expressed in uppercase letters in the Latin script, plus a few punctuation marks and some ‘control characters’ needed to regulate the storage and transmission devices. Such encodings, originally developed for telegraphy, strongly influenced the way the pioneers of computing conceived of and implemented the handling of text, with consequences that are with us still.

For many years after the invention of computers, the way they represented text continued to be constrained by the imperative to use expensive resources with maximal efficiency. Even when storage and processing costs began their dramatic fall, the Anglo-centric outlook of most hardware designers and software engineers hampered initiatives to devise a more generous and flexible model for text representation. The wish to retain compatibility with ‘legacy’ data was an additional disincentive. Eventually, tension in East Asia between commitment to technological progress and the inability of existing computers to cope with local writing systems led to decisive developments. Japanese, Korean and Chinese standards bodies, who long before the advent of computers had been engaged in the specification of character sets, joined with computer manufacturers and software houses to devise ways of mapping those character sets to numeric encodings and processing the resulting text data.

Unfortunately, in the early years there was little or no co-ordination among either the national standards bodies or the manufacturers concerned, so that although commercial necessity dictated that these various local standards were all compatible with the representation of US-American English, they were not straightforwardly compatible with one another. Even within Japan itself there emerged a number of mutually incompatible systems, thanks to a mixture of commercial rivalry, disagreements about how best to manage certain intractable problems, and the fact

---

<sup>27</sup>This excludes all attributes where a non-textual datatype has been specified, for example tokens, boolean values, dates, and predefined value lists.

that such pioneering work inevitably involved some false starts, leading to incompatibilities even between successive products of the same bodies. Roughly at the same time, and for similar reasons, multiple and incompatible ways of representing languages that use Cyrillic scripts were devised, along with methods of encoding ancient writing systems which inevitably could not aim for compatibility with other writing systems apart from basic Latin script. Many of the earliest projects that fed into the TEI were shaped in this developmental phase of the computerized representation of texts, and it was also the context in which SGML was devised and finalized.

SGML had of necessity to offer ways of coping with multiple writing systems in multiple representations; or rather, it provided a framework within which SGML-compliant applications capable of handling such multiple representations might be developed by those with sufficient financial and personnel resources (such as are seldom found in academia). Earlier editions of these Guidelines offered advice on character set and writing system issues addressed to the condition of those for whom SGML was the only feasible option. That advice must now be substantially altered because of two closely-related developments: the availability of the ISO/Unicode character set as an international standard, and the emergence of XML and related technologies which are committed to the theory and practice of character representation which Unicode embodies.

### vi.2.2 Terminology and Key Concepts

Before the significance of Unicode and the implications of the association between XML and Unicode can be adequately explained, it is necessary to clarify some key concepts and attempt to establish an adequately precise terminology for them.

Figure 1: Examples of the small latin *a* rendered with different fonts.

The word ‘character’ will not of itself take us very far towards greater terminological precision. It tends to be used to refer indiscriminately both to the visible symbol on a page and to the letter or ideograph which that symbol represents, two things that it is essential to keep conceptually distinct. The visible symbol obviously has some aspects by which we interpret it as representing one character rather than another; but its appearance may also be significantly determined by features that have no effect on our notion of which character in a writing system it represents. A familiar instance is the lowercase *a*, which in printed texts may be represented either by a ‘single storey’ symbol (cf. figure 1 in the examples from Baskerville SemiBold or Century) or by a ‘two storey’ version (as in figure 1 in the examples from ArialRegular or Andale Mono Regular). We say that the single and double-storey symbols both represent one and the same *abstract character a* using two different *glyphs*. Similarly, an uppercase *A* in a serif typeface has additional strokes that are absent from the same letter when printed using a sans-serif typeface, so that once again we have differing glyphs standing for the same abstract character. In 1 there is even a font, Capitals Regular, in which the glyph for the lowercase letter *a* looks like a typical glyph for the character uppercase *A*. The distinction between abstract characters and glyphs is fundamental to all machine processing of documents.

In most scholarly encoding projects, the accurate recording of the abstract characters which make up the text is of prime importance, because it is the essential prerequisite of digitizing and processing the document without semantic loss. In many cases (though there are important exceptions, to be touched on shortly) it may not be necessary to encode the specific glyphs used to render those abstract characters in the original document. An encoding that faithfully registers the abstract characters of a document allows us to search and analyse our document’s content,

language and structure and access its full semantics. That same encoding, however, may not contain sufficient information to allow an exact visual representation of the glyphs in the source text or manuscript to be recreated.

The importance of this distinction between information content and its visual representation is not always immediately apparent to people unused to the specific complexities of text handling by machine. Such users tend to ask first what (in order of conceptual priority) should actually be their very last question: how do I get a physical image that looks like character x in my source document to appear on to the screen or the output page? Their first question should in fact be: how can I get an abstract representation of character x into my encoded document in a way that will be universally and unambiguously identifiable, no matter what it happens to look like in printout or on any particular display? And occasionally the response they receive as a result of their misguided initial question is a custom ‘solution’ that satisfies their immediate rendering wishes at the price of making their underlying document unintelligible to other users (or even to the original user in other times and places) because it encodes the abstract character in an idiosyncratic way.

That said, there will certainly be documents or projects where it is a matter of scholarly significance that the compositor or scribe chose to represent a given abstract character using one particular glyph or set of strokes rather than a semantically-equivalent but visually distinct alternative, and in that case the specific appearance of the form will have to be encoded on one way or another. But that encoding need not (and in most cases will not) involve a notation that visually resembles the original, any more than italicized text in an original document will be represented by the use of italic characters in the encoded version.

A collection of the abstract characters needed to represent documents in a given writing system is known as a *character set*, and the character set or *character repertoire* of a processing or rendering device is the set of abstract characters that it is equipped to recognize and handle appropriately. There is, however, a subtle distinction between these two parallel uses of the same term, involving one more key concept which it is essential to grasp. The character set of a document (or the writing system in which it is recorded) is purely a collection of abstract characters. But the character set of a computing device is a set of abstract characters which have been mapped in a well-defined way to a set of numbers or *code points* by which the device represents those abstract characters internally. It can therefore be referred to as a *coded character set*, meaning a set of abstract characters each of which has been assigned a numerical code point (or in some instances a sequence of code points) which unambiguously identifies the character concerned.

It is now possible to use this terminology to say what Unicode is: it is a coded character set, devised and actively maintained by an international public body, where each abstract character is identified by a unique name and assigned a distinctive code point.<sup>28</sup> Unicode is distinguished from other, earlier and co-existing coded character sets by its (current and potential) size and scope; its built-in provision for (in practical terms) limitless expansion; the range and quality of linguistic and computational expertise on which it draws; the commitment in principle (and to an increasing degree in practice) to implement it by all important providers of hardware and software worldwide; and the stability, authority and accessibility it derives from its status as an international public standard.

### vi.2.3 Abstract Characters, Glyphs and Encoding Scheme Design

The distinction between abstract characters and glyphs can be crucial when devising an encoding scheme. Users performing text retrieval, searching or concordancing will expect the system to recognize and treat different glyphs as instances of the same character; but when perusing the text itself they may well expect to see glyph variants preserved and rendered. When encoding a pre-existing text, the encoder must determine whether a particular letter or symbol is a character or a glyphic variant. A detailed model of the relationship between characters and glyphs has been developed within the Unicode Consortium and an ISO work group (ISO/IEC JTC1 SC2/WG2). Its report (Unicode Technical Report 17: Character Encoding Model) will form the base for much future standards work.

The model makes explicit the distinction between two different properties of the components of written language:

- their content, i.e. its meaning and phonetic value (represented by a character)
- their graphical appearance (represented by a glyph)

When searching for information, a system generally operates on the content aspects of characters, with little or no attention to their appearance. A layout or formatting process, on the other hand, must of necessity be concerned with the exact appearance of characters. Of course, some operations (hyphenation for example) require attention

---

<sup>28</sup>Although only Unicode is mentioned here explicitly, it should be noted that the character repertoire and assigned code points of Unicode and the ISO standard 10646 are identical and maintained in a way that ensures this continues to be the case.

to both kinds of feature, but in general the kind of text encoding described in these Guidelines tends to focus on content rather than appearance (see further 3.3. *Highlighting and Quotation*).

An encoder wishing to record information about which glyphs are present in a given document may do so at either or both of two levels:

- the level of character encoding, using an appropriate Unicode code point to represent the glyph concerned
- the markup level, with the glyph indicated via appropriate elements and/or attributes

The encoding practice adopted may be guided by, among other things, an assessment of the most frequent uses to which the encoded text will be put. For example, if recognition of identical characters represented by a variety of glyphs is the main priority, it may be advisable to represent the glyph variations at markup level, so that the character value can be immediately exposed to the indexing and retrieval software. Plainly, an encoding project will need to consider such issues carefully and embody the outcome of their deliberations in local manuals of procedure to ensure encoding consistency. Using Unicode code points to represent glyph information requires that such choices be documented in the TEI header. Such documentation cannot of itself guarantee proper display of the desired glyph but at least makes the intention of the encoder discoverable.

At present the Unicode Standard does not offer detailed specifications for the encoding of glyph variations. These Guidelines do give some recommendations; some discussion of related matters is given in 11. *Representation of Primary Sources* and 5. *Characters, Glyphs, and Writing Modes* offers some features for the definition of variant glyphs.

#### vi.2.4 Entry of Characters.

Text characters may be entered into a document using any of three methods, in any convenient combination. First, where suitable input facilities make this possible, the characters concerned may be entered directly into the document, either by normal keystrokes or by the use of one of the *Input Method Editors* (IMEs) commonly used for the entry of logographic characters. This is most likely to be convenient where the display used for text entry and/or the printer used to produce output for proofreading purposes is capable of rendering the characters concerned using correct and readily identifiable glyphs. Where such easily checkable rendering is not available, or where there is no suitable method of inputting certain characters directly, they may be input by one of two possible forms of indirect notation or ‘reference’.

The first form of reference is a *Numeric Character Reference* (NCR), which takes the general form `&#D`; where `D` is an integer representing the code point of the character in base 10, or `&#xH`; , where `H` is the code point in hexadecimal notation. This has the advantage that no declaration of what this notation means is required anywhere in the document instance or its associated schema. Every XML processor is capable of recognising NCRs and replacing them with the required code point value without needing access to any additional data. The disadvantage of NCRs as a means of entering, representing and proofing character data is that most human beings find them anything but ‘readable’ and it is all too easy for the wrong character to be entered in error and retained undetected.

The second form of reference is a *Character Entity Reference* (though, as explained below, this should not be taken to imply that such entities constitute a ‘type’ that could be distinctively recognized by a processing system). Character entity references can (and indeed should) have names whose significance is apparent to humans, but each and every entity name has to be associated with its replacement (which as explained below should be a character value, possibly in the form of a NCR) via a formal declaration in the document’s internal or external subset. This, however, is not needed for Character Entities defined by the XML standard, namely `&` (&#amp;#x26;), `>` (&#x27;), `<` (&#x27;), `'` (&#x27;), and `"` (&#x27;). For a large number of characters defined by Unicode and commonly used in documents, there are ISO entity sets declaring mnemonic names which should be used wherever feasible: XML compatible character entity declarations using ISO names and suitable for inclusion into the subset are available on the TEI web sites.

Where characters are not defined in Unicode and so have to be assigned both a local code point and a local entity name of the project’s choosing (see *Non-Unicode Characters in XML Documents* below) it is highly desirable to follow the same nomenclature principles as ISO and to emulate the practice in the ISO character entity declarations of appending a string giving the character a unique descriptive name as a comment to the actual entity declaration. In addition, where different groups or projects are working on texts with geographical, historical, linguistic or other similarities that give rise to common issues of character encoding, it is highly advisable in the interests of consistency that they should consult one another when devising entity names. The TEI mailing list may provide a suitable first point of contact for such consultations. Further advice on the matter of locally-defined characters is contained in Chapter 25 *Representation of non-standard Characters and Glyphs*.

### vi.2.5 Output of Characters

Rendering of the encoded text is a complicated process that depends largely on the purpose, external requirements, local equipment and so forth, it is thus outside the scope of coverage for these Guidelines.

It might however nevertheless be helpful to put some of the terminology used for the rendering process in the context of the discussion of this chapter. As was mentioned above, Unicode encodes abstract characters, not specific glyphs. For any process that makes characters visible, however, concrete, specifically designed glyph shapes have to be used. For a printing process, for example, these shapes describe exactly at which point ink has to be put on the paper and which areas have to be left blank. If we want to print a character from the Latin script, besides the selection of the overall glyph shape, this process also requires that a specific weight of the font has been selected, a specific size and to what degree the shape should be slanted. Beyond individual characters, the overall typesetting process also follows specific rules of how to calculate the distance between characters, how much whitespace occurs between words, at which points line breaks might occur and so forth.

If we concern ourselves only with the rendering process of the characters themselves, leaving out all these other parameters, we will realize that of all the information required for this process, only a small amount will be drawn from the encoded text itself. This information is the code point used to encode the character in the document. With this information, the font selected for printing will be queried to provide a glyph shape for this character. Some modern font formats (e.g. OpenType) do implement a sophisticated mapping from a code point to the glyph selected, which might take into account surrounding characters (to create ligatures where necessary) and the language or even area this character is printed for to accommodate different typesetting traditions and differences in the usage of glyphs.

A TEI document might provide some of the information that is required for this process for example by identifying the linguistic context with the *xml:lang* attribute. The selection of fonts and sizes is usually done in a stylesheet, while the actual layout of a page is determined by the typesetting system used. Similarly, if a document is rendered for publication on the Web, information of this kind can be shipped with the document in a stylesheet.<sup>29</sup>

### vi.2.6 Unicode and XML

The devisers of the XML standard took the view that Unicode should be the only means of representing abstract characters which conformant XML processors were obliged to support. That certainly does not preclude the use of other character encoding schemes or character sets in documents which are to be handled by XML processors, but it does mean that all the abstract characters which are encoded as characters (as distinct from being represented indirectly via markup) in an XML document must either possess an assigned code point within the public Unicode standard, or be assigned a code point devised by and specific to the local project, taken from a reserved range set aside by the standard expressly for this purpose, the so-called *Private Use Areas* or PUAs. For the vast majority of projects to which these Guidelines are applicable, the Unicode standard will already offer code points for all the abstract characters their documents employ, and so the requirement that all such characters should be resolvable by XML processors to Unicode code points will not involve any representation via markup or use of PUA code points. Indeed, such projects are not obliged by their choice of XML to use Unicode in their documents. Provided they correctly declare at the requisite points any non-Unicode coded character set they may use, ensure that all their XML processors support their declared encoding, and then consistently employ that encoding in strict conformity with their declarations, they need not consciously concern themselves with Unicode unless and until they feel it is appropriate to do so.

#### Non-Unicode Character Sets and XML Processors

There are, however, strict limits to the way conformant XML processors handle documents whose character set is not Unicode, and unless these limits are understood it is likely that projects not yet ready to commit to Unicode across the board will run into unexpected and baffling problems as they attempt to operate with their legacy character encodings. First, it must be repeated that nothing in the XML standard *requires* conformant processors to handle non-Unicode documents. But even if there were any actual processors which on that basis refused to process non-Unicode documents, that would not limit their usefulness as severely as might at first appear. The reason is that there is a way of internally representing Unicode code points (explained further in *Encoding Errors Related to UTF-8* below) where there is no detectable difference between a document which is actually encoded in ASCII employing only 7-bit values and one which is encoded in Unicode but which happens to contain only the abstract characters

---

<sup>29</sup>The World Wide Web Consortium provides recommendations for two standard stylesheet languages: either CSS or XSL could be used for this purpose.

encompassed by the 7-bit ASCII standard. And the XML standard specifies that this way of representing Unicode is the one which processors must assume as the default for any document that does not explicitly declare an encoding. At a stroke, this provision ensures that all pure 7-bit ASCII encoded documents can be processed without further ado by all conformant XML processors. Add to this the provision, also within the XML standard, that allows any Unicode code point to be indirectly specified using only 7-bit ASCII characters via a Numeric Character Reference (NCR), and the upshot is that all documents in non-Unicode encodings which can be pre-processed to rewrite any characters outside the 7-bit ASCII range as Unicode code points in NCR notation (a simple batch procedure for which software is readily available) can be handled even by processors which have no inbuilt support for any encoding other than Unicode.

In fact, every XML processor so far released has implemented methods, specified in the standard though not mandatory, which allow the processing of documents in at least some non-Unicode character sets. Such processors include in their documentation a statement of the non-Unicode encodings they support, and the use of such an encoding must be declared to the processor in the correct way.

To avoid confusion when taking advantage of such encoding support, it is first of all essential to grasp that an encoding declaration in an XML document is indeed simply a declaration: it is not an incantation that magically converts the document that follows into the encoding concerned. It is a common error to think that simply declaring a document's encoding to be, say ISO-8859-1 (or for that matter UTF-8 or UTF-16, the representations of Unicode for which support is mandatory) is sufficient to 'make it so'. Such a declaration is useless unless the document that follows actually is encoded strictly in conformance with the declaration. Some of the circumstances in which that may not in fact be the case are outlined in *vi.2.9 Issues Arising from the Internal Representations of Unicode* below. Secondly, an encoding declaration does not somehow switch an XML processor into a mode where it works entirely in the declared encoding for as long as the declaration is in scope. On the contrary, all it does is instruct the processor to pass its input through a filter that immediately converts all the code points in the declared encoding into their Unicode counterparts; from that point onwards the document as seen by all subsequent stages of processing is actually in Unicode, even though that may not be apparent to the user. Thirdly, this invariable internal conversion has a crucial consequence: the fact that a processor can successfully accept a document in a non-Unicode encoding does not mean that it will necessarily convert any output it may produce back into the declared input encoding. Internally, the document has been converted to and processed in Unicode, and there is nothing in the XML standard that requires the reverse conversion to be performed at the output stage. Most processors go beyond the standard by offering a facility to output in various encodings: but whether it is available and how to use it must be ascertained from the processor's documentation. Should it be unavailable or unreliable, the output may need to be post-processed through a character convertor to restore the original encoding, and again such software is freely available and easy to use.

### Non-Unicode Characters in XML Documents

In the cases considered in the preceding section, there was a suitable Unicode code point corresponding to each abstract character contained in the non-Unicode character set of the input document. In such instances, the mandatory internal conversion to Unicode carried out by the processor can be more or less transparent to a user who wishes to continue to work with a non-Unicode character set. Things become rather different when the non-Unicode character set contains abstract characters for which there is no code point in the Unicode standard, or when a project that is attempting to work in Unicode throughout finds that it needs to represent abstract characters not currently provided for in the Unicode standard. Here, a significant difference between SGML and XML emerges in a rather troublesome way.

Following their agenda to devise a subset of SGML that would be significantly easier to implement, the authors of the XML specification decided that one particular type of entity available in SGML, known as an internal SDATA entity, should not be carried over into XML. It would be idle to question that decision here, but its consequences for the handling of abstract characters for which there is no Unicode definition were significant.

The procedures recommended in earlier versions of these Guidelines for encoding, processing and exchanging what we might call locally defined abstract characters were reliant on the availability of entities declared as of type SDATA, but that type is not supported in XML, and there is therefore no ready equivalent for XML-based projects to the recommendations previously offered.<sup>30</sup> Entities in XML are really only of two basic types, parsed and unparsed.

---

<sup>30</sup>In essence, when an SGML parser encounters a reference to an entity of type SDATA, it supplies to the application which it is servicing the name of that entity, as found in the document, plus a pointer to a location somewhere on the local system, and what is present at that location may in turn allow or instruct the application to do one of a number of things, including looking up the entity name in a table and deriving information

Unparsed entities are of no relevance here. References to parsed entities in an XML document result in only one kind of behaviour: when they appear in the parser's input stream, the parser expects to be able to resolve them by locating a declaration in the document's internal or external subset which maps the entity name to its replacement text. The parser then inserts that replacement text into the document in place of the entity reference, which is discarded without trace. The act of replacement is not notified to the application, except where it fails because the entity is undeclared or the declaration is in some way defective (in which case the parser signals a fatal error and stops.)

Though for explanatory convenience much XML-related documentation, including these Guidelines, refers specifically to Character Entities and Character Entity References, a character entity in XML is not a distinct 'type' in the sense that 'type' is understood in Computer Science terminology, for example when referring to the type of an attribute. Hence there is no way in which editing or other software can check that the replacement to be inserted is indeed a single character or its equivalent rather than an arbitrary chunk of text, possibly including markup. A character entity is simply a general entity whose replacement text happens to be declared as a character value or a NCR representing that value. This has two important consequences if it is proposed to use such an entity reference to stand for a character that has no Unicode equivalent. First, the entity name reference will disappear at an early stage in the parse and be replaced by the declared value of the entity, so that no processing which requires access in the parsed document to the entity reference as originally entered is possible. Secondly, if a character entity is to be used as a true equivalent to a normal character, and consequently be employed at all points in a document where a single character could legitimately occur (apart from in element and attribute names, where no references of any kind are allowed) then it is essential that its replacement value indeed be pure character data. If the replacement value of the entity were to contain any markup, or a processing instruction, there would be many places in a document where simple character data would be legitimate, but where the substitution of markup or some other replacement could cause the document to become invalid or malformed. Taken together, these considerations mean that the transparent use of a CER to stand for a non-Unicode character in an XML document is simply not possible.

### vi.2.7 Special Aspects of Unicode Character Definitions Compatibility Characters

The principles of Unicode are judiciously tempered with pragmatism. This means, among other things, that the actual repertoire of characters which the standard encodes, especially those parts dating from its earlier days, include a number of items which on a strict interpretation of the Unicode Consortium's theoretical approach should not have been regarded as abstract characters in their own right. Some of these characters are grouped together into a code-point regions assigned to *compatibility characters*. Ligatures are a case in point. Ligatures (e.g. the joining of adjacent lowercase letters 's' and 't' or 'f' and 'i' in Latin scripts, whether produced by a scribal practice of not lifting the pen between strokes or dictated by the aesthetics of a type design) are representational features with no added semantic value beyond that of the two letters they unite (though for historians of typography their presence and form in a given edition may be of scholarly significance). However, by the time the Unicode standard was first being debated, it had become common practice to include single glyphs representing the more common ligatures in the repertoires of some typesetting devices and high-end printers, and for the coded character sets built into those devices to use a single code point for such glyphs, even though they represent two distinct abstract characters. So as to increase the acceptance of Unicode among the makers and users of such devices, it was agreed that some such pseudo-characters should be incorporated into the standard as compatibility characters. Nevertheless, if a project requires the presence of such ligatured forms to be encoded, this should normally be done via markup, not by the use of a compatibility character. That way, the presence of the ligature can still be identified (and, if desired, rendered visually) where appropriate, but indexing and retrieval software will treat the code points in the document as a simple sequential occurrence of the two constituent characters concerned and so correctly align their semantics with non-ligatured equivalents. Such ligatures should not be confused with digraphs (usually) indicating diphthongs, as in the French word "cœur". A digraph is an atomic orthographic unit representing an abstract character in its own right, not purely an amalgamation of glyphs, and indexing and retrieval software must treat it as such. Where a digraph occurs in a source text, it should normally be encoded using the appropriate code point for the single abstract character which it represents, either by direct entry of the character concerned or through the appropriate CER or NCR.

---

about the referenced entity which can trigger specific behaviours in the application appropriate to the processing of that abstract character. There is however no way to make an XML parser do anything of the kind in response to an entity reference.

## Precomposed and Combining Characters and Normalization

The treatment of characters with diacritical marks within Unicode shows a similar combination of rigour and pragmatism. It is obvious enough that it would be feasible to represent many characters with diacritical marks in Latin and some other scripts by a sequence of code points, where one code point designated the base character and the remainder represented one or more diacritical marks that were to be combined with the base character to produce an appropriate glyphic rendering of the abstract character concerned. From its earliest phase, the Unicode Consortium espoused this view in theory but was prepared in practice to compromise by assigning single code points to *precomposed* characters which were already commonly assigned a single distinctive code point in existing encoding schemes. This means, however, that for quite a large number of commonly-occurring abstract characters, Unicode has two different, but logically and semantically equivalent encodings: a *precomposed* single code point, and a code point sequence of a base character plus one or more *combining* diacritics. Scripts more recently added to Unicode no longer exhibit this code-point duplication (in current practice no new precomposed characters are defined where the use of combining characters is possible) but this does nothing to remove the problem caused by the duplications from older character sets that have been permanently embodied in Unicode. Together with essentially analogous issues arising from the encoding of certain East Asian ideographs. This duplication gives rise to the need to practice *normalization* of Unicode documents. Normalization is the process of ensuring that a given abstract character is represented in one way only in a given Unicode document or document collection. The Unicode Consortium provides four standard normalization forms, of which the Normalization Form C (NFC) seems to be most appropriate for text encoding projects. The NFC, as far as possible, defines conversions for all base characters followed by one or more combining characters into the corresponding precomposed characters. The World Wide Web Consortium has produced a document entitled *Character Model for the World Wide Web 1.0*<sup>31</sup>, which among other things discusses normalization issues and outlines some relevant principles. An authoritative reference is Unicode Standard Annex #15 *Unicode Normalization Forms*<sup>32</sup>. Individual projects will have to decide how far their decisions on normalization need be influenced by the fact that at present, by no means all hardware or software can correctly render (or even consistently identify) abstract characters encoded using combining symbols.

It is important that every Unicode-based project should agree on, consistently implement and fully document a comprehensive and coherent normalization practice. As well as ensuring data integrity within a given project, a consistently implemented and properly documented normalization policy is essential for successful document interchange.

### Character Semantics

In addition to the Universal Character Set itself, the Unicode Consortium maintains a database of additional character semantics<sup>33</sup>. This includes names for each character code point and normative properties for it. Character properties, as given in this database, determine the semantics and thus the intended use of a code point or character. It also contains information that might be needed for correctly processing this character for different purposes. This database is an important reference in determining which Unicode code point to use to encode a certain character.

In addition to the printed documentation and lists made available by the Unicode consortium, the information it contains may also be accessed by a number of search systems over the Web (e.g. <http://www.eki.ee/letter/>). Examples of character properties included in the database include case, numeric value, directionality, and, where applicable status as a 'compatibility character'<sup>34</sup>. Where a project undertakes local definition of characters with code point in the PUA, it is desirable that any relevant additional information about the characters concerned should be recorded in an analogous way, as further discussed under 5. *Characters, Glyphs, and Writing Modes*.

## vi.2.8 Character Entities in Non-validated Documents

An important difference between SGML and XML is that the latter allows for the processing of non-validated documents. Since validity and validation are central TEI concerns, it is unlikely that documents prepared according to these Guidelines will ever be designed or implemented as merely well-formed in the XML sense. However in the domain of XML technologies, even where a document invokes a DTD or schema, it is not always necessarily the case that an XML processor will perform a full validation of it. XSLT transformation is a common case in point. By

<sup>31</sup> Available at <http://www.w3.org/TR/charmod/>.

<sup>32</sup> available at <http://www.unicode.org/reports/tr15/>

<sup>33</sup> <http://www.unicode.org/ucd/>

<sup>34</sup> For further details, see *The Unicode Character Property Model* (Unicode Technical Report #23), at <http://www.unicode.org/reports/tr23/>.

the workflow stage at which a document is handed off to an XSLT process for transformation, it is likely that its associated DTD or schema will already have fulfilled its role of integrity assurance and quality control, and so it may be undesirable to add validation to the processing overhead. For this reason, most XSLT processors do not attempt validation by default, even if a DTD or schema is declared and accessible. This can, however, create a problem where parsed entities, (and character entities in particular in the present context) are referenced. A validating parser reads all entity declarations from the DTD (including those for character entities) in the initial phase of processing, so that they can be resolved as and when required. However, where no validation takes place, it cannot automatically be assumed that the parser will be able to resolve such entities in all circumstances. The XML standard requires a non-validating parser to read and act on entity declarations only if they are located within the document's internal subset (which does not, of course, mean that the entity declarations have to be manually merged into the document instance in advance of processing: character entity sets, for instance, count as being in the internal subset if they are placed there via a parameter entity, as is normal TEI practice). Some parsers when in non-validating mode will also access entity declarations in the external subset, but this behaviour is not mandated by the standard and should not be relied upon. Provided these facts are borne in mind, the presence of character entities in a document when parser validation is switched off should not cause any difficulties.

### vi.2.9 Issues Arising from the Internal Representations of Unicode

In theory it should not be necessary for encoders to have any knowledge of the various ways in which Unicode code points can be represented internally within a document or in the memory of a processing system, but experience shows that problems frequently arise in this area because of mistaken practice or defective software, and in order to recognize the resulting symptoms and correct their causes an outline knowledge of certain aspects of Unicode internal representation is desirable.

#### Encoding Errors Related to UTF-8

The code points assigned by Unicode 3.0 and later are notionally 32-bit integers, and the most straightforward way to represent each such integer in computer storage would be to use 4 eight-bit bytes. However, many of the code points for characters most commonly used in Latin scripts can be represented in one byte only and the vast majority of the remainder which are in common use (including those assigned from the most frequently used PUA range) can be expressed in two bytes alone. This accounts for the use of UTF-8 and UTF-16 and their special place in the XML standard. UTF-8 and UTF-16 are ways of representing 32-bit code points in an economical way.

UTF-8 is a variable length-encoding: the more significant bits there are in the underlying code point (or in everyday terminology the bigger the number used to represent the character), the more bytes UTF-8 uses to encode it. What makes UTF-8 particularly attractive for representing Latin scripts, explaining its status as the default encoding in XML documents, is that all code points that can be expressed in seven or fewer bits (the 127 values in the original ASCII character set) are also encoded as the same seven or fewer bits (and therefore in a single byte) in UTF-8. That is why a document which is actually encoded in pure 7-bit ASCII can be fed to an XML processor without alteration and without its encoding being explicitly declared: the processor will regard it as being in the UTF-8 representation of Unicode and be able to handle it correctly on that basis.

However, even within the domain of Latin-based scripts, some projects have documents which use characters from 8 bit extensions to ASCII, e.g. those in the ISO-8859-n series of encodings, and the way characters which under ISO-8859-n use all eight bits are encoded in UTF-8 is significantly different, giving rise to puzzling errors. Abstract characters that have a *single* byte code point where the highest bit is set (that is, they have a decimal numeric representation between 129 and 255) are encoded in ISO-8859-n as a *single* byte with the same value as the code point. But in UTF-8 code-point values inside that range are expressed as a *two* byte sequence. That is to say, the abstract character in question is no longer represented in the file or in memory by the same number as its code-point value: it is *transformed* (hence the T in UTF) into a sequence of two different numbers. Now as a side-effect of the way such UTF-8 sequences are derived from the underlying code-point value, many of the single-byte eight-bit values employed in ISO-8859-n encodings are illegal in UTF-8.

This complicated situation has a simple consequence which can cause great bewilderment. XML processors will effortlessly handle character data in pure 7-bit ASCII without that encoding needing to be declared to the parser, and will similarly accept documents encoded in an undeclared ISO-8859-n encoding if they happen to use no characters outside the strict ASCII subset of the ISO character sets; but the parse will immediately fail if an eight-bit character from an ISO-8859-n set is encountered in the input stream, unless the document's encoding has been explicitly and correctly declared. Explicitly declaring the encoding ought to solve the problem, and if the file is correctly encoded

throughout, it will do so. But since text editors and word processors are currently acquiring different degrees of Unicode support at different rates, projects are likely to find that they have to deal with some files encoded in UTF-8 along with others in, say, ISO-8859-1. Such encoding differences may go unnoticed, especially if the proportion of characters where the internal encodings are distinguishable is relatively small (for example in a long English text with a smattering of French words). If in the process of document preparation two such files have been merged, or intermixed via ‘cut and paste’ techniques, it is all too possible that the internal encodings of the resulting files will have become mixed as well. Thanks to misplaced notions of ‘user friendliness’ some current editing software silently corrects such miscodings as it displays the text, so that they remain hidden until the XML parser terminates with a fatal ‘invalid character’ error.

Where erroneously mixed encodings are the source of such an error, altering the encoding declaration will not solve the problem, though it may obfuscate it. Eight-bit character codes in a file declared as UTF-8 will always stop the parser. More insidiously, UTF-8 sequences in a file declared as ISO-8859-1 will not halt the parse, but will cause data corruption, because the parser will silently but erroneously convert each byte in every UTF-8 sequence into a spurious separate character, introducing semantic errors which may not become apparent until much later in the processing chain.

In projects that routinely handle documents in non-Latin scripts, everyone is well aware of the need to ensure correct and consistent encoding, so in such places mixed encoding problems seldom arise, and when they do are readily identified and remedied. Real confusion tends to arise, however, in projects which have a low awareness of the issues because they employ predominantly unaccented Latin characters, with only thinly-distributed instances of accented letters, or other ‘special characters’ where the internal representation under ISO-8859-n and UTF-8 are different (such as the copyright symbol, or, a frequent troublemaker where eventual HTML output is envisaged, the ‘non-breaking space’). Even, or especially, if such projects view themselves as concerned only with English documents, the close relationship between XML and Unicode means they will need to acquire an understanding of these encoding issues and develop procedures which assure consistency and integrity of encoding and its correct declaration, including the use of appropriate software for transcoding and verification.

### Encoding Errors Related to UTF-16

The advantages of UTF-8 as an internal representation of Unicode code points outlined above do not obtain where documents are in scripts other than Latin, Cyrillic or Hebrew. Where characters with code points in the sixteen-bit range (two-byte) predominate, UTF-8 is inappropriate, because it requires three or more bytes to represent each abstract character. Here the preferred representation of Unicode (which all XML-conformant parsers must support) is UTF-16, where each code point corresponding to an abstract character is represented in two eight-bit bytes<sup>35</sup>. This encoding presents a different hazard, especially while support for Unicode in editing software is relatively uneven and immature. Because the code points are represented as sixteen-bit integers stored (in most popular computers) in two separate bytes, the order in which those bytes are stored becomes important. This is dependent on the underlying hardware. In the realm of desktop computing, Macintosh machines, for example, store (on disk as well as in memory) byte pairs representing 16-bit integers with the higher-value byte first, whereas PCs using Intel processors store the bytes in the reverse order (this is often referred to with Swiftian nomenclature as *big-endian* versus *little-endian* byte order). This means that if a semantically identical plain text file encoded in UTF-16 is prepared on a Macintosh and on a PC, and the two files are then saved to disk, each byte pair in one file will be in the reverse order from the corresponding byte pair in the other file. To avoid the obvious incompatibility problems, the XML standard requires that all documents whose declared encoding is UTF-16 must begin with a special pseudo-character which is not itself part of the document, but merely a Byte Order Marker (BOM) from which the processor can determine the byte order of the document that follows. Now the insertion of a correct BOM and the consistent maintenance of the byte order throughout the file ought to be taken care of transparently by software, but experience, especially from environments where work is distributed across big-endian and little-endian hardware, shows that this cannot always be taken for granted in the current state of software development. As with mixed encoding problems involving UTF-8, inconsistent byte-order in UTF-16 files seems to be the result of merging or cutting and pasting between files using software which does not correctly enforce byte order integrity, and out of misconceived ‘user friendliness’ which conceals byte-order inconsistencies from the user. Once more, the result can be files which look correct in an editor, but which the XML parser either rejects outright or silently passes on in a seriously garbled form. Again, to avoid the

<sup>35</sup>The use of ‘surrogate’ values to represent code points beyond the 16-bit range is passed over here, since it adds a complication that does not affect the key points at issue

consequent errors, projects need to cultivate an informed awareness of relevant encoding issues and devise policies to avoid them in the first place or detect them at an early stage.

# 1 The TEI Infrastructure

This chapter describes the infrastructure for the encoding scheme defined by these Guidelines. It introduces the conceptual framework within which the following chapters are to be understood, and the means by which that conceptual framework is implemented. It assumes some familiarity with XML and XML schemas (see chapter *v A Gentle Introduction to XML*) but is intended to be accessible to any user of these Guidelines. Other chapters supply further technical details, in particular chapter 22. *Documentation Elements* which describes the XML schema used to express these Guidelines themselves, and chapter 23. *Using the TEI* which combines a discussion of modification and conformance issues with a description of the intended behaviour of an ODD processor; these chapters should be read by anyone intending to implement a new TEI-based system.

The TEI encoding scheme consists of a number of *modules*, each of which declares particular XML elements and their attributes. Part of an element's declaration includes its assignment to one or more element *classes*. Another part defines its possible content and attributes with reference to these classes. This indirection gives the TEI system much of its strength and its flexibility. Elements may be combined more or less freely to form a *schema* appropriate to a particular set of requirements. It is also easy to add new elements which reference existing classes or elements to a schema, as it is to exclude some of the elements provided by any module included in a schema.

In principle, a TEI schema may be constructed using any combination of modules. However, certain TEI modules are of particular importance, and should always be included in all but exceptional circumstances: the module `tei` described in the present chapter is of this kind because it defines classes, macros, and datatypes which are used by all other modules. The `core` module, defined in chapter 3. *Elements Available in All TEI Documents* contains declarations for elements and attributes which are likely to be needed in almost any kind of document, and is therefore recommended for global use. The `header` module defined in chapter 2. *The TEI Header* provides declarations for the metadata elements and attributes constituting the TEI header, a component which is required for TEI conformance, while the `textstructure` module defined in chapter 4. *Default Text Structure* declares basic structural elements needed for the encoding of most book-like objects. Most schemas will therefore need to include these four modules.

The specification for a TEI schema is itself a TEI document, using elements from the module described in chapter 22. *Documentation Elements*: we refer to such a document informally as an *ODD* document, from the design goal originally formulated for the system: 'One Document Does it all'. Stylesheets for maintaining and processing ODD documents are maintained by the TEI, and these Guidelines are also maintained as such a document. As further discussed in 23.5. *Implementation of an ODD System*, an ODD document can be processed to generate a schema expressed using any of the three schema languages currently in wide use: the XML DTD language, the ISO RELAX NG language, or the W3C Schema language, as well as to generate documentation such as the *Guidelines* and their associated web site.

The bulk of this chapter describes the TEI infrastructure module itself. Although it may be skipped at a first reading, an understanding of the topics addressed here is essential for anyone planning to take full advantage of the TEI customization techniques described in chapter 23.3. *Personalization and Customization*.

The chapter begins by briefly characterizing each of the modules available in the TEI scheme. Section 1.2. *Defining a TEI Schema* describes in general terms the method of constructing a TEI schema in a specific schema language such as XML DTD language, RELAX NG, or W3C Schema.

The next and largest part of the chapter introduces the attribute and element classes used to define groups of elements and their characteristics (section 1.3. *The TEI Class System*).

Finally, section 1.4. *Macros* introduces the concept of *macros*, which are used to express some commonly used content models, and lists the *datatypes* used to constrain the range of legal values for TEI attributes (section DTYPES).

## 1.1 TEI Modules

These Guidelines define several hundred elements and attributes for marking up documents of any kind. Each definition has the following components:

- a prose description
- a formal declaration, expressed using a special-purpose XML vocabulary defined by these Guidelines in combination with elements taken from the ISO schema language RELAX NG
- usage examples

Each chapter of these Guidelines presents a group of related elements, and also defines a corresponding set of declarations, which we call a *module*. All the definitions are collected together in the reference sections provided as an appendix. Formal declarations for a given chapter are collected together within the corresponding module. For convenience, each element is assigned to a single module, typically for use in some specific application area, or to support a particular kind of usage. A module is thus simply a convenient way of grouping together a number of associated element declarations. In the simple case, a TEI schema is made by combining together a small number of modules, as further described in section 1.2. *Defining a TEI Schema* below.

The following table lists the modules defined by the current release of these Guidelines:

| Module name   | Formal public identifier             | Where defined  |
|---------------|--------------------------------------|--|
| analysis      | Analysis and Interpretation          | <i>17. Simple Analytic Mechanisms</i>                  |
| certainty     | Certainty and Uncertainty            | <i>21. Certainty, Precision, and Responsibility</i>    |
| core          | Common Core                          | <i>3. Elements Available in All TEI Documents</i>      |
| corpus        | Metadata for Language Corpora        | <i>15. Language Corpora</i>                            |
| dictionaries  | Print Dictionaries                   | <i>9. Dictionaries</i>                                 |
| drama         | Performance Texts                    | <i>7. Performance Texts</i>                            |
| figures       | Tables, Formulae, Figures            | <i>14. Tables, Formulæ, Graphics and Notated Music</i> |
| gaiji         | Character and Glyph Documentation    | <i>5. Characters, Glyphs, and Writing Modes</i>        |
| header        | Common Metadata                      | <i>2. The TEI Header</i>                               |
| iso-fs        | Feature Structures                   | <i>18. Feature Structures</i>                          |
| linking       | Linking, Segmentation, and Alignment | <i>16. Linking, Segmentation, and Alignment</i>        |
| msdescription | Manuscript Description               | <i>10. Manuscript Description</i>                      |
| namesdates    | Names, Dates, People, and Places     | <i>13. Names, Dates, People, and Places</i>            |
| nets          | Graphs, Networks, and Trees          | <i>19. Graphs, Networks, and Trees</i>                 |
| spoken        | Transcribed Speech                   | <i>8. Transcriptions of Speech</i>                     |
| tagdocs       | Documentation Elements               | <i>22. Documentation Elements</i>                      |
| tei           | TEI Infrastructure                   | <i>1. The TEI Infrastructure</i>                       |
| textcrit      | Text Criticism                       | <i>12. Critical Apparatus</i>                          |
| textstructure | Default Text Structure               | <i>4. Default Text Structure</i>                       |
| transcr       | Transcription of Primary Sources     | <i>11. Representation of Primary Sources</i>           |
| verse         | Verse                                | <i>6. Verse</i>  |

For each module listed above, the corresponding chapter gives a full description of the classes, elements, and macros which it makes available when it is included in a schema. Other chapters of these Guidelines explore other aspects of using the TEI scheme.

## 1.2 Defining a TEI Schema

To determine that an XML document is valid (as opposed to merely well-formed), its structure must be checked against a schema, as discussed in chapter *v A Gentle Introduction to XML*. For a valid TEI document, this schema must be a conformant TEI schema, as further defined in chapter 23.4. *Conformance*. Local systems may allow their schema to be implicit, but for interchange purposes the schema associated with a document *must* be made explicit. The method of doing this recommended by these Guidelines is to provide explicitly or by reference a TEI schema specification against which the document may be validated.

A TEI-conformant schema is a specific combination of TEI modules, possibly also including additional declarations that modify the element and attribute declarations contained by each module, for example to suppress or rename some elements. The TEI provides an application-independent way of specifying a TEI schema by means of the <schemaSpec> element defined in chapter 22. *Documentation Elements*. The same system may also be used to specify a schema which extends the TEI by adding new elements explicitly, or by reference to other XML vocabularies. In either case, the specification may be processed to generate a formal schema, expressed in a variety of specific schema languages, such as XML DTD language, RELAX NG, or W3C Schema. These output schemas can then be used by an

XML processor such as a validator or editor to validate or otherwise process documents. Further information about the processing of a TEI formal specification is given in chapter 23. *Using the TEI*.

### 1.2.1 A Simple Customization

The simplest customization of the TEI scheme combines just the four recommended modules mentioned above. In ODD format, this schema specification takes this form:

```
<schemaSpec ident="TEI-minimal" start="TEI">
  <moduleRef key="tei"/>
  <moduleRef key="header"/>
  <moduleRef key="core"/>
  <moduleRef key="textstructure"/>
</schemaSpec>
```

This schema specification contains references to each of four modules, identified by the *key* attribute on the <moduleRef> element. The schema specification itself is also given an identifier (*TEI-minimal*). An ODD processor will generate an appropriate schema from this set of declarations, expressed using the XML DTD language, the ISO RELAX NG language, the W3C Schema language, or in principle any other adequately powerful schema language. The resulting schema may then be associated with the document instance by one of a number of different mechanisms, as further described in chapter *v A Gentle Introduction to XML*. The start point (or root element) of document instances to be validated against the schema is specified by means of the *start* attribute. Further information about the processing of an ODD specification is given in 23.5. *Implementation of an ODD System*.

### 1.2.2 A Larger Customization

These Guidelines introduce each of the modules making up the TEI scheme one by one, and therefore, for clarity of exposition, each chapter focusses on elements drawn from a single module. In reality, of course, the markup of a text will draw on elements taken from many different modules, partly because texts are heterogeneous objects, and partly because encoders have different goals. Some examples of this heterogeneity include:

- a text may be a collection of other texts of different types: for example, an anthology of prose, verse, and drama;
- a text may contain other smaller, embedded texts: for example, a poem or song included in a prose narrative;
- some sections of a text may be written in one form, and others in a different form: for example, a novel where some chapters are in prose, others take the form of dictionary entries, and still others the form of scenes in a play;
- an encoded text may include detailed analytic annotation, for example of rhetorical or linguistic features;
- an encoded text may combine a literal transcription with a diplomatic edition of the same or different sources;
- the description of a text may require additional specialized metadata elements, for example when describing manuscript material in detail.

The TEI provides mechanisms to support all of these and many other use cases. The architecture permits elements and attributes from any combination of modules to co-exist within a single schema. Within particular modules, elements and attributes are provided to support differing views of the ‘granularity’ of a text, for example:

- a definition of a corpus or collection as a series of <TEI> documents, sharing a common TEI header (see chapter 15. *Language Corpora*)
- a definition of composite texts which combine optional front- and back-matter with a group of collected texts, themselves possibly composite (see section 4.3.1. *Grouped Texts*)
- an element for the representation of *embedded texts*, where one narrative appears to ‘float’ within another (see section 4.3.2. *Floating Texts*)

Subsequent chapters of these Guidelines describe in detail markup constructs appropriate for these and many other possible features of interest. The markup constructs can be combined as needed for any given set of applications or project.

For example, a project aiming to produce an ambitious digital edition of a collection of manuscript materials, to include detailed metadata about each source, digital images of the content, along with a detailed transcription of each

source, and a supporting biographical and geographical database might need a schema combining several modules, as follows:

```
<schemaSpec ident="TEI-PROJECT" start="TEI">
  <moduleRef key="tei"/>
  <moduleRef key="header"/>
  <moduleRef key="core"/>
  <moduleRef key="textstructure"/>
  <moduleRef key="msdescription"/>
  <!-- manuscript description -->
  <moduleRef key="transcr"/>
  <!-- transcription of primary sources -->
  <moduleRef key="figures"/>
  <!-- figures and tables -->
  <moduleRef key="namesdates"/>
  <!-- names, dates, people, and places -->
</schemaSpec>
```

Alternatively, a simpler schema might be used for a part of such a project: those preparing the transcriptions, for example, might need only elements from the `core`, `textstructure`, and `transcr` modules, and might therefore prefer to use a simpler schema such as that generated by the following:

```
<schemaSpec ident="TEI-TRANSCR" start="TEI">
  <moduleRef key="tei"/>
  <moduleRef key="core"/>
  <moduleRef key="textstructure"/>
  <moduleRef key="transcr"/>
</schemaSpec>
```

The TEI architecture also supports more detailed customization beyond the simple selection of modules. A schema may suppress elements from a module, suppress some of their attributes, change their names, or even add new elements and attributes. Detailed discussion of the kind of modification possible in this way is provided in 23.3. *Personalization and Customization* and conformance rules relating to their application are discussed in 23.4. *Conformance*. These facilities are available for any schema language (though some features may not be available in all languages). The ODD language also makes it possible to combine TEI and non-TEI modules into a single schema, provided that the non-TEI module is expressed using the RELAX NG schema language (see further 22.8.2. *Combining TEI and Non-TEI Modules*).

## 1.3 The TEI Class System

The TEI scheme distinguishes about five hundred different elements. To aid comprehension, modularity, and modification, the majority of these elements are formally classified in some way. Classes are used to express two distinct kinds of commonality among elements. The elements of a class may share some set of attributes, or they may appear in the same locations in a content model. A class is known as an *attribute class* if its members share attributes, and as a *model class* if its members appear in the same locations. In either case, an element is said to *inherit* properties from any classes of which it is a member.

Classes (and therefore elements which are members of those classes) may also inherit properties from other classes. For example, supposing that class A is a member (or a *subclass*) of class B, any element which is a member of class A will inherit not only the properties defined by class A, but also those defined by class B. In such a situation, we also say that class B is a *superclass* of class A. The properties of a superclass are inherited by all members of its subclasses.

A basic understanding of the classes into which the TEI scheme is organized is strongly recommended and is essential for any successful customization of the system.

### 1.3.1 Attribute Classes

An attribute class groups together elements which share some set of common attributes. Attribute classes are given names composed of the prefix `att.`, often followed by an adjective. For example, the members of the class

`att.canonical` have in common a *key* and a *ref* attribute, both of which are inherited from their membership in the class rather than individually defined for each element. These attributes are said to be defined by (or inherited from) the `att.canonical` class. If another element were to be added to the TEI scheme for which these attributes were considered useful, the simplest way to provide them would be to make the new element a member of the `att.canonical` class. Note also that this method ensures that the attributes in question are always defined in the same way, taking the same default values etc., no matter which element they are attached to.

Some attribute classes are defined within the `tei` infrastructural module and are thus globally available. Other attribute classes are specific to particular modules and thus defined in other chapters. Attributes defined by such classes will not be available unless the module concerned is included in a schema.

The attributes provided by an attribute class are those specified by the class itself, either directly, or by inheritance from another class. For example, the attribute class `att.pointing.group` provides attributes *domains* and *targFunc* to all of its members. This class is however a subclass of the `att.pointing` class, from which its members also inherit the attributes *target*, *targetLang* and *evaluate*. Members of the class `att.pointing` will thus have these three attributes, while members of the class `att.pointing.group` will have all five.

Note that some modules define superclasses of an existing infrastructural class. For example, the global attribute class `att.divLike` makes attributes *org* and *sample* available, while the `att.metrical` class, which is specific to the `verse` module, provides attributes *met*, *real*, and *rhyme*. Because `att.metrical` is defined as a superclass of `att.divLike`, all five of these attributes are available to elements; the declaration for `att.metrical` adds its three attributes to the three already defined by `att.divLike` when the `verse` module is included in a schema. If, however, this module is not included in a schema, then the `att.divLike` class supplies only the two attributes first mentioned.

Attributes specific to particular modules are documented along with the relevant module rather than in the present chapter. One particular attribute class, known as `att.global`, is common to all modules, and is therefore described in some detail in the next section. A full list of all attribute classes is given in *Appendix B Attribute Classes* below.

### 1.3.1.1 Global Attributes

The following attributes are defined for every TEI element.

**`att.global`** provides attributes common to all elements in the TEI encoding scheme.

`@xml:id` (identifier) provides a unique identifier for the element bearing the attribute.

`@n` (number) gives a number (or other label) for an element, which is not necessarily unique within the document.

`@xml:lang` (language) indicates the language of the element content using a ‘tag’ generated according to BCP 47.

`@rend [att.global.rendition]` (rendition) indicates how the element in question was rendered or presented in the source text.

`@style [att.global.rendition]` contains an expression in some formal style definition language which defines the rendering or presentation used for this element in the source text

`@rendition [att.global.rendition]` points to a description of the rendering or presentation used for this element in the source text.

`@xml:base` provides a base URI reference with which applications can resolve relative URI references into absolute URI references.

`@xml:space` signals an intention about how white space should be managed by applications.

These attributes are optionally available for any TEI element; none of them is required. Their usage is discussed in the following subsections.

**1.3.1.1.1 Element Identifiers and Labels** The value supplied for the *xml:id* attribute must be a legal *name*, as defined in the World Wide Web Consortium's XML Recommendation. This means that it must begin with a letter, or the underscore character ('\_'), and contain no characters other than letters, digits, hyphens, underscores, full stops, and certain combining and extension characters.<sup>36</sup>

<sup>36</sup>The colon is also by default a valid name character; however, it has a specific purpose in XML (to indicate namespace prefixes), and may not therefore be used in any other way within a name.

In XML names (and thus the values of *xml:id* in an XML TEI document) uppercase and lowercase letters are distinguished, and thus *partTime* and *parttime* are two distinctly different names, and could (though perhaps unwisely) be used to denote two different element occurrences.

If two elements are given the same identifier, a validating XML parser will signal a syntax error. The following example, therefore, is *not* valid:

```
<p
    xml:id="PAGE1"><q>What's it going to be then, eh?</q></p> <p
    xml:id="PAGE1">There was me, that is Alex, and my three droogs, that is Pete,
    Georgie, and Dim, ... </p>
```

For a discussion of methods of providing unique identifiers for elements, see section 3.10.2. *Creating New Reference Systems*.

The *n* attribute also provides an identifying name or number for an element, but in this case the information need not be a legal *xml:id* value. Its value may be any string of characters; typically it is a number or other similar enumerator or label. For example, the numbers given to the items of a numbered list may be recorded with the *n* attribute; this would make it possible to record errors in the numeration of the original, as in this list of chapters, transcribed from a faulty original in which the number 10 is used twice, and 11 is omitted:

```
<list rend="numbered">
  <item n="1">About These Guidelines</item>
  <item n="2">A Gentle Introduction to XML</item>
  <item n="9">Verse</item>
  <item n="10">Drama</item>
  <item n="10">Spoken Materials </item>
  <item n="12">Dictionaries</item>
</list>
```

The *n* attribute may also be used to record non-unique names associated with elements in a text, possibly together with a unique identifier as in the following example:

```
<div type="book" n="one" xml:id="TXT0101">
  <!-- ... -->
  <div type="stanza" n="xlii">
    <!-- ... -->
  </div>
</div>
```

As noted above there is no requirement to record a value for either the *xml:id* or the *n* attribute. Any XML processor can identify the sequential position of one element within another in an XML document without any additional tagging. An encoding in which each line of a long poem is explicitly labelled with its numerical sequence such as the following

```
<l n="1">
  <!-- ... -->
</l>
<l n="2">
  <!-- ... -->
</l>
<l n="3">
  <!-- ... -->
</l>
```

```

<!-- ... -->
<l n="100">
<!-- ... -->
</l>

```

is therefore probably redundant.

**1.3.1.1.2 Language Indicators** The *xml:lang* attribute indicates the natural language and writing system applicable to the content of a given element. If it is not specified, the value is inherited from that of the immediately enclosing element. As a rule, therefore, it is simplest to specify the base language of the text on the <TEI> element, and allow most elements to take the default value for *xml:lang*; the language of an element then need be explicitly specified only for elements in languages other than the base language. For this reason, it is recommended practice to supply a default value for the *xml:lang* attribute, either on the <TEI> root element, or on both the <teiHeader> and the <text> element. The latter is appropriate in the not uncommon case where the text element in a TEI document uses a different default language from that of the TEI header attached to it. Other language shifts in the source should be explicitly identified by use of the *xml:lang* attribute on an element at an appropriate level wherever possible.

In the following example schematic, an English language TEI header is attached to an English language text:

```

<TEI xml:lang="en" xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
<!-- ... -->
  </teiHeader>
  <text>
<!-- ... -->
  </text>
</TEI>

```

The same effect would be obtained by specifying the default language for both header and text:

```

<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader xml:lang="en">
<!-- ... -->
  </teiHeader>
  <text xml:lang="en">
<!-- ... -->
  </text>
</TEI>

```

The latter approach is necessary in the case where the two differ: for example, where an English language header is applied to a French text:

```

<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader xml:lang="en">
<!-- ... -->
  </teiHeader>
  <text xml:lang="fr">
<!-- ... -->
  </text>
</TEI>

```

The same principle applies at any hierarchic level. In the following example, the default language of the text is French, but one section of it is in German:

```
<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader xml:lang="en">
<!-- ... -->
  </teiHeader>
  <text xml:lang="fr">
    <body>
      <div>
<!-- chapter one is in French -->
      </div>
      <div xml:lang="de">
<!-- chapter two is in German -->
      </div>
      <div>
<!-- chapter three is French -->
      </div>
<!-- ... -->
    </body>
  </text>
</TEI>
```

Similarly, in the following example the *xml:lang* attribute on the `<term>` element allows us to record the fact that the technical terms used are Latin rather than English; no *xml:lang* attribute is needed on the `<q>` element, by contrast, because it is in the same language as its parent.

```
<p xml:lang="en">The
constitution declares <q>that no bill of attainder or <term xml:lang="la">ex post
facto</term> law shall be passed.</q> ...</p>
```

Note that in cases where it is advisable or necessary to identify the language of the text that is pointed at, the (non-global) attribute *targetLang* should be used, for example in

```
<ptr target="x12" targetLang="fr"/>
```

the pointer references text written in French.

The values used for the *xml:lang* and *targetLang* attributes must be constructed in a particular way, using values from standard lists. See further *vi.1 Language Identification*.

Additional information about a particular language may be supplied in the `<language>` element within the header (see section 2.4.2. *Language Usage*).

**1.3.1.1.3 Rendition Indicators** The *rend*, *rendition*, and *style* attributes are all used to give information about the physical presentation of the text in the source. In the following example, *rend* is used to indicate that both the emphasized word and the proper name are printed in italics:

```
<p> ... Their motives <emph rend="italics">might</emph> be pure
and pious; but he was equally alarmed by his knowledge of the ambitious
<name rend="italics">Bohemond</name>, and his ignorance of the Transalpine chiefs:
...</p>
```

The same effect might be achieved using the *style* attribute, as follows:

```
<p> ... Their motives <emph style="font-style: italic">might</emph> be pure and pious;
but he was equally alarmed by his knowledge of
the ambitious <name style="font-style: italic">Bohemond</name>, and his ignorance of
the Transalpine chiefs: ...</p>
```

If all or most `<emph>` and `<name>` elements are rendered in the text by italics, it will be more convenient to register that fact in the TEI header once and for all (using the `<rendition>` element discussed below) and specify a *rend* or *style* value only for any elements which deviate from the stated rendition.

The main difference between *rend* attribute and *style* is that the value used for the former may contain one or more tokens from any vocabulary devised by the encoder, separated by space characters, whereas the value used for the latter must be a single string taken from a formally-defined style definition language such as CSS. The *rend* attribute values are sequence-indeterminate set of whitespace-separated tokens, whereas *style* values allow whitespace and sequence relationships as part of the formally-defined style definition language.

The `<rendition>` element defined in 2.3.4. *The Tagging Declaration* may be used to hold repeatedly-used format descriptions. A `<rendition>` element can then be associated with any element, either by default, or by means of the global *rendition* attribute. For example:

```
<tagsDecl>
<!-- define italic style using CSS -->
<rendition xml:id="IT" scheme="css">font-style: italic</rendition>
<!-- define a serif font family -->
<rendition xml:id="FontRoman" scheme="css">font-family: serif</rendition>
<!-- set italic style as default for the emph and hi elements -->
<namespace name="http://www.tei-c.org/ns/1.0">
  <tagUsage gi="emph" render="#IT"/>
  <tagUsage gi="hi" render="#IT"/>
<!-- set the default font-family for the text element -->
  <tagUsage gi="text" render="#FontRoman"/>
</namespace>
</tagsDecl>
<!-- ... -->
<text>
  <body>
    <div>
      <p rendition="#IT">
<!-- this paragraph uses the seriffed font, but is in italic-->
      </p>
      <p>
<!-- this paragraph uses the seriffed font, but is not in
italic -->
      </p>
    </div>
  </body>
</text>
```

The *rendition* attribute always points to one or more `<rendition>` elements, each of which defines some aspect of the rendering or appearance of the text in its original form. These details may most conveniently be described using a formal style definition language, such as CSS (Lie and Bos (eds.) (1999)) or XSL-FO (Berglund (ed.) (2006)); in some other formal language developed for a specific project; or even informally in running prose. Although languages such as CSS and XSL-FO are generally used to describe document output to screen or print, they nonetheless provide formal and precise mechanisms for describing the appearance of source documents, especially print documents, but also many aspects of manuscript documents. For example, both CSS and XSL-FO provide mechanisms for describing typefaces, weight, and styles; character and line spacing; and so on.

As noted above, the *style* attribute is provided for encoders wishing to describe the appearance of individual source elements using a language such as CSS directly rather than by reference to a <rendition> element. Its value may be any expression in the chosen formal style definition language.

Formal definition languages such as CSS typically identify a series of *properties* (such as font-style or margin-left) for which *values* are specified. A sequence of such property-value pairs makes up a stylesheet. The TEI uses such languages simply to describe the appearance of a source document, rather than to control how it should be formatted.

In the TEI scheme, it is possible to supply information about the appearance of elements within a source document in the following distinct ways:

1. One or more properties may be specified as the default for all elements of a given type, using the *render* attribute to point to <rendition> elements ;
2. One or more properties may be specified for individual element occurrences, using the *rend* attribute with any convenient set of one or more sequence-indeterminate tokens;
3. One or more properties may be specified for individual element occurrences, using the *rendition* attribute to point to <rendition> elements;
4. One or more properties may be supplied explicitly for individual element occurrences, using the *style* attribute.

If the same property is specified in more than one of the above ways, the one with the highest number in the list above is understood to be applicable. The resulting properties from each way are then combined to provide the full set of property-value pairs applicable to the given element, and (by default) to all of its children.

For simplicity of processing, the same formal style definition should be used throughout; however, the architecture does permit this to be varied, by using the *scheme* attribute to indicate a different language for one or more <rendition> elements. Care should be taken to ensure that such values can be meaningfully combined. Similar considerations apply to the use of the *rend* attribute, if this is used in combination with either *rendition* or *style*.

Note that these TEI attributes always describe the rendition or appearance of the source document, *not* intended output renditions, although often the two may be closely related.

**1.3.1.1.4 Evaluation of Links** Several TEI elements carry attributes whose values are defined as **anyURI**, meaning that such attributes supply a link or pointer, typically expressed as a URL. Like other XML applications, the TEI allows use of a special attribute to set the context within which relative URLs are to be evaluated. The global attribute *xml:base* is defined as part of the XML specification and belongs to the XML namespace rather than the TEI namespace. We do not describe it in detail here: reference information about *xml:base* is provided by Marsh (ed.) (2001)

In essence *xml:base* is used to set a context for all relative URLs within the scope of the element on which it is specified. For example:

```
<body>
  <div xml:base="http://www.example.org/somewhere.xml">
    <p>
<!--... -->
      <ptr target="#p1"/>
<!--... -->
    </p>
  </div>
  <div>
    <p>
<!--... -->
      <ptr target="#p1"/>
<!--... -->
    </p>
  </div>
</body>
```

The first <ptr> element here is within the scope of a <div> which supplies a value for *xml:base*; its target is therefore to be found at <http://www.example.org/somewhere.xml#p1>. The second <ptr>, however, is within the

scope of a <div> which does not change the default context, and its target is therefore some element within the current document with the value `p1` for its *xml:id* attribute. Further discussion of this element and its effect on TEI linking methods is provided in chapter 16. *Linking, Segmentation, and Alignment*.

**1.3.1.1.5 XML Whitespace** The global attribute *xml:space* provides a mechanism for indicating to systems processing an XML file how they should treat whitespace, that is, any sequences of consecutive tab (`#x09`), space (`#x20`), carriage return (`#x0D`) or linefeed (`#x0A`) characters. Like *xml:id* this attribute is defined as part of the XML specification and belongs to the XML namespace rather than the TEI namespace. Complete information about this attribute is provided by section 2.10 of the XML Specification; here we provide a summary of how its use affects users of the TEI scheme.

The *xml:space* attribute has only two permitted values: `preserve` and `default`. The first indicates that whitespace in a text node—every carriage return, every tab, etc.—should be maintained as is when the document is processed. The second (which is implied when the attribute is not supplied), indicates that whitespace should be handled ‘as appropriate’. Exactly what is deemed appropriate is left unspecified by the XML Recommendation.

These Guidelines assume one of two different ways of processing whitespace will apply in a given case, depending on an element's content model. For an element that can contain only other elements with no intervening non-whitespace characters, whitespace is considered to have no semantic significance, and should therefore be discarded by a processor. For example, in a <choice> element, such as

```
<choice>
  <sic>1724</sic>
  <corr>1728</corr>
</choice>
```

since non-whitespace text is not permitted between the <choice> start-tag and the <sic> tags or between the <sic> and <corr> tags, any whitespace found there has no significance and can be ignored completely by a processor.

Similarly, the <address> element has a content model containing only elements: any punctuation or whitespace required between the lines of an address must therefore be supplied by the processor, as any whitespace present in the input document will be ignored.

Elements with content models of this type are comparatively unusual in the TEI: a list of them is provided in the TEI release file `stripspace.xsl.model`, formatted there for use as an `<xsl:strip-space>` command for XSL stylesheets.

Most TEI elements permit what is known as mixed-content: that is, they can contain both text and other elements. Here the assumption of these Guidelines is that whitespace will be normalized. This means that all space, carriage return, linefeed, and tab characters are converted into spaces, all consecutive spaces are then deleted and replaced by one space, and then space immediately after a start-tag or immediately before an end-tag is deleted. The result is that this encoding,

```
<persName>
  <forename>Edward</forename>
  <forename>George</forename>
  <surname type="linked">Bulwer-Lytton</surname>, <roleName>Baron Lytton of
  <placeName>Knebworth</placeName>
</roleName>
</persName>
```

would be rendered as ‘Edward George Bulwer-Lytton, Baron Lytton of Knebworth’. The space before his name has been removed, a space is included between his forenames, the comma is preserved, and the newlines within his name have all been removed.

If the default treatment described above is not appropriate for a mixed content element, the processing required may be described in the <encodingDesc> element of the TEI header, but generic XML processing tools may not take note of this.

Alternatively, the *xml:space* attribute may be supplied with a value of `preserve` in order to indicate that every space, tab, carriage return and linefeed character found within that element in the document being processed is significant.

Typically, the result of that processing will be to retain the whitespace characters in the output. Thus if the above example began `<persName xml:space="preserve">`, the resulting text would most likely be rendered over five lines, indented, and with a blank line following.

The `xml:space="preserve"` attribute is rarely used in TEI documents because such layout features are generally captured with less risk and more precision by using native TEI elements such as `<lb>` or `<space>`, or by using the rendition attributes described in section 1.3.1.1.3. *Rendition Indicators*.

### 1.3.2 Model Classes

As noted above, the members of a given TEI model class share the property that they can all appear in the same location within a document. Wherever possible, the content model of a TEI element is expressed not directly in terms of specific elements, but indirectly in terms of particular model classes. This makes content models simpler and more consistent; it also makes them much easier to understand and to modify.

Like attribute classes, model classes may have subclasses or superclasses. Just as elements inherit from a class the ability to appear in certain locations of a document (wherever the class can appear), so all members of a subclass inherit the ability to appear wherever any superclass can appear. To some extent, the class system thus provides a way of reducing the whole TEI galaxy of elements into a tidy hierarchy. This is however not entirely the case.

In fact, the nature of a given class of elements can be considered along two dimensions: as noted, it defines a set of places where the class members are permitted within the document hierarchy; it also implies a semantic grouping of some kind. For example, the very large class of elements which can appear within a paragraph comprises a number of other classes, all of which have the same structural property, but which differ in their field of application. Some are related to highlighting, while others relate to names or places, and so on. In some cases, the 'set of places where class members are permitted' is very constrained: it may just be within one specific element, or one class of element, for example. In other cases, elements may be permitted to appear in very many places, or in more than one such set of places.

These factors are reflected in the way that model classes are named. If a model class has a name containing part, such as `model.divPart` or `model.biblPart` then it is primarily defined in terms of its structural location. For example, those elements (or classes of element) which appear as content of a `<div>` constitute the `model.divPart` class; those which appear as content of a `<bibl>` constitute the `model.biblPart` class. If, however, a model class has a name containing like, such as `model.biblLike` or `model.nameLike`, the implication is that its members all have some additional semantic property in common, for example containing a bibliographic description, or containing some form of name, respectively. These semantically-motivated classes often provide a useful way of dividing up large structurally-motivated classes: for example, the very general structural class `model.pPart.data` ('data elements that form part of a paragraph') has four semantically-motivated member classes (`model.addressLike`, `model.dateLike`, `model.measureLike`, and `model.nameLike`), the last of these being itself a superclass with several members.

Although most classes are defined by the `tei` infrastructure module, a class cannot be populated unless some other specific module is included in a schema, since element declarations are contained by modules. Classes are not declared 'top down', but instead gain their members as a consequence of individual elements' declaration of their membership. The same class may therefore contain different members, depending on which modules are active. Consequently, the content model of a given element (being expressed in terms of model classes) may differ depending on which modules are active.

Some classes contain only a single member, even when all modules are loaded. One reason for declaring such a class is to make it easier for a customization to add new member elements in a specific place, particularly in areas where the TEI does not make fully elaborated proposals. For example, the TEI class `model.rdgLike`, initially empty, is expanded by the `textcrit` module to include just the TEI `<rdg>` element. A project wishing to add an alternative way of structuring text-critical information could do so by defining their own elements and adding it to this class.

Another reason for declaring single-member classes is where the class members are not needed in all documents, but appear in the same place as elements which are very frequently required. For example, the specialized element `<g>` used to represent a non-Unicode character or glyph is provided as the only member of the `model.gLike` class when the `gaiji` module is added to a schema. References to this class are included in almost every content model, since if it is used at all the `<g>` must be available wherever text is available; however these references have no effect unless the `gaiji` module is loaded.

At the other end of the scale, a few of the classes predefined by the `tei` module are subsequently populated with very

many members. For example, the class `model.pPart.edit` groups all the classes of element for simple editorial correction and transcription which can appear within a `<p>` or paragraph element. The `CORE` module alone adds more than fifty elements to this class; the `namesdates` module adds another twenty, as does the `tagdocs` module. Since the `<p>` element is one of the basic building blocks of a TEI document it is not surprising that each module will need to add elements to it. The class system here provides a very convenient way of controlling the resulting complexity. Typically, elements are not added directly to these very general classes, but via some intermediate semantically-motivated class.

Just as there are a few classes which have a single member, so there are some classes which are used only once in the TEI architecture. These classes, which have no superclass and therefore do not fit into the class hierarchy defined here, are a convenient way of maintaining elements which are highly structured internally, but which appear from the outside to be uniform objects like others at the same level.<sup>37</sup> Members of such classes can only ever appear within one element, or one class of elements. For example, the class `model.addrPart` is used only to express the content model for the element `<address>`; it references some other classes of elements, which can appear elsewhere, and also some elements which can only appear inside an address.

### 1.3.2.1 Informal Element Classifications

Most TEI elements may also be informally classified as belonging to one of the following groupings:

**divisions** high level, possibly self-nesting, major divisions of texts. These elements populate such classes as `model.divLike` or `model.divLike`, and typically form the largest component units of a text.

**chunks** elements such as paragraphs and other paragraph-level elements, which can appear directly within texts or within divisions of them, but not (usually) within other chunks. These elements populate the class `model.divPart`, either directly or by means of other classes such as `model.pLike` (paragraph-like elements), `model.entryLike`, etc.

**phrase-level elements** elements such as highlighted phrases, book titles, or editorial corrections which can occur only within chunks, but not between them (and thus cannot appear directly within a division). These elements populate the class `model.phrase`.<sup>38</sup>

The TEI also identifies two further groupings derived from these three:

**inter-level elements** elements such as lists, notes, quotations, etc. which can appear either between chunks (as children of a `<div>`) or within them; these elements populate the class `model.inter`. Note that this class is not a superset of the `model.phrase` and `model.divPart` classes but rather a distinct grouping of elements which are both chunk-like and phrase-like. However, the classes `model.phrase`, `model.pLike`, and `model.inter` are all disjoint.

**components** elements which can appear directly within texts or text divisions; this is a combination of the inter- and chunk- level elements defined above. These elements populate the class `model.common`, which is defined as a superset of the classes `model.divPart`, `model.inter`, and (when the dictionary module is included in a schema) `model.entryLike`.

Broadly speaking, the front, body, and back of a text each comprises a series of components, optionally grouped into divisions.

As noted above, some elements do not belong to any model class, and some model classes are not readily associated with any of the above informal groupings. However, over two-thirds of the 564 elements defined in the present edition of these Guidelines are classified in this way, and future editions of these recommendations will extend and develop this classification scheme.

A complete alphabetical list of all model classes is provided in *Appendix A Model Classes*.

## 1.4 Macros

The infrastructure module defined by this chapter also declares a number of *macros*, or shortcut names for frequently occurring parts of other declarations. Macros are used in two ways in the TEI scheme: to stand for frequently-

<sup>37</sup>In former editions of these Guidelines, such elements were known metaphorically as ‘crystals’.

<sup>38</sup>Note that in this context, *phrase* means any string of characters, and can apply to individual words, parts of words, and groups of words indifferently; it does not refer only to linguistically-motivated phrasal units. This may cause confusion for readers accustomed to applying the word in a more restrictive sense.

| Content model           | Number of elements using this | Description  |
|-------------------------|-------------------------------|--|
| macro.paraContent       | 0                             | defines the content of paragraphs and similar elements.  |
| macro.limitedContent    | 0                             | defines the content of prose elements that are not used for transcription of extant materials.   |
| macro.phraseSeq         | 0                             | defines a sequence of character data and phrase-level elements.  |
| macro.phraseSeq.limited | 0                             | defines a sequence of character data and those phrase-level elements that are not typically used for transcribing extant documents.  |
| macro.specialPara       | 0                             | defines the content model of elements such as notes or list items, which either contain a series of component-level elements or else have the same structure as a paragraph, containing a series of phrase-level and inter-level elements. |
| macro.xtext             | 0                             | defines a sequence of character data and gaiji elements.   |
| macro.anyXML            | 0                             | defines a content model within which any XML elements are permitted  |

Table 3:

encountered content models, or parts of content models (1.4.1. *Standard Content Models*); and to stand for attribute datatypes (DTYPES).

### 1.4.1 Standard Content Models

As far as possible, the TEI schemas use the following set of frequently-encountered content models to help achieve consistency among different elements.

**macro.paraContent** (paragraph content) defines the content of paragraphs and similar elements.

**macro.limitedContent** (paragraph content) defines the content of prose elements that are not used for transcription of extant materials.

**macro.phraseSeq** (phrase sequence) defines a sequence of character data and phrase-level elements.

**macro.phraseSeq.limited** (limited phrase sequence) defines a sequence of character data and those phrase-level elements that are not typically used for transcribing extant documents.

**macro.schemaPattern** provides a pattern to match elements from the chosen schema language

**macro.specialPara** ('special' paragraph content) defines the content model of elements such as notes or list items, which either contain a series of component-level elements or else have the same structure as a paragraph, containing a series of phrase-level and inter-level elements.

**macro.xtext** (extended text) defines a sequence of character data and gaiji elements.

The present version of the TEI Guidelines includes some 564 different elements. Table 1 shows, in descending order of frequency, the seven most commonly used content models.

### 1.4.2 Datatype Specifications

The values which attributes may take in a TEI schema are defined, for the most part, by reference to a TEI *datatype specification*. Each such specification is defined in terms of other primitive datatypes, derived mostly from W3C Schema Datatypes, literal values, or other datatypes. This indirection makes it possible for a TEI application to set constraints either globally or in individual cases, by redefining the datatype definition or the reference to it respectively. In some cases, the TEI datatype includes additional usage constraints which cannot be enforced by existing schema languages, although a TEI-compliant processor should attempt to validate them (see further discussion in chapter 23.4. *Conformance*).

The following element is used to define a TEI datatype:

**<dataSpec>** (datatype specification) documents a datatype.

TEI-defined datatypes may be grouped into those which define normalized values for numeric quantities, probabilities, or temporal expressions, those which define various kinds of shorthand codes or keys, and those which define pointers or links.

The following datatypes are used for attributes which are intended to hold normalized values of various kinds. First, expressions of quantity or probability:

**teidata.certainty** defines the range of attribute values expressing a degree of certainty.

**teidata.probability** defines the range of attribute values expressing a probability.

**teidata.numeric** defines the range of attribute values used for numeric values.

**teidata.interval** defines attribute values used to express an interval value.

**teidata.percentage** defines attribute values used to express a percentage value.

**teidata.count** defines the range of attribute values used for a non-negative integer value used as a count.

Examples of attributes using the **teidata.probability** datatype include *degree* on <damage> or <certainty>; examples of **teidata.numeric** include *quantity* on members of the **att.measurement** class or *value* on <numeric>; examples of **teidata.count** include *cols* on <cell> and <table>.

Next, the datatypes used for attributes which are intended to hold normalized dates or times, durations, truth values, and language identifiers:

**teidata.duration.w3c** defines the range of attribute values available for representation of a duration in time using W3C datatypes.

**teidata.duration.iso** defines the range of attribute values available for representation of a duration in time using ISO 8601 standard formats

**teidata.temporal.w3c** defines the range of attribute values expressing a temporal expression such as a date, a time, or a combination of them, that conform to the *W3C XML Schema Part 2: Datatypes Second Edition* specification.

**teidata.temporal.iso** defines the range of attribute values expressing a temporal expression such as a date, a time, or a combination of them, that conform to the international standard *Data elements and interchange formats – Information interchange – Representation of dates and times*.

**teidata.truthValue** defines the range of attribute values used to express a truth value.

**teidata.xTruthValue** (extended truth value) defines the range of attribute values used to express a truth value which may be unknown.

**teidata.language** defines the range of attribute values used to identify a particular combination of human language and writing system.

Note that in each of these cases the values used are those recommended by existing international standards: ISO 8601 as profiled by *XML Schema Part 2: Datatypes Second Edition* in the case of durations, times, and date; W3C Schema datatypes in the case of truth values; and BCP 47 in the case of language.

The following datatypes have more specialized uses:

**teidata.namespace** defines the range of attribute values used to indicate XML namespaces as defined by the W3C Namespaces in XML Technical Recommendation.

**teidata.outputMeasurement** defines a range of values for use in specifying the size of an object that is intended for display.

**teidata.pattern** defines attribute values which are expressed as a regular expression.

**teidata.point** defines the data type used to express a point in cartesian space.

**teidata.pointer** defines the range of attribute values used to provide a single URI, absolute or relative, pointing to some other resource, either within the current document or elsewhere.

**teidata.version** defines the range of attribute values which may be used to specify a TEI or Unicode version number.

**teidata.versionNumber** defines the range of attribute values used for version numbers.

**teidata.replacement** defines attribute values which contain a replacement template.

**teidata.xpath** defines attribute values which contain an XPath expression.

By far the largest number of TEI attributes take values which are coded values or names of some kind. These values may be constrained or defined in a number of different ways, each of which is given a different name, as follows:

**teidata.word** defines the range of attribute values expressed as a single word or token.

**teidata.text** defines the range of attribute values used to express some kind of identifying string as a single sequence of unicode characters possibly including whitespace.

**teidata.name** defines the range of attribute values expressed as an XML Name.

**teidata.enumerated** defines the range of attribute values expressed as a single XML name taken from a list of documented possibilities.

**teidata.sex** defines the range of attribute values used to identify human or animal sex.

**teidata.xmlName** defines attribute values which contain an XML name.

Attributes of type **teidata.word**, such as *age* on <person>, are used to supply an identifier expressed as any kind of single token or word. The TEI places a few constraints on the characters which may be used for this purpose: only Unicode characters classified as letters, digits, punctuation characters, or symbols can appear in an attribute value of this kind. Note in particular that such values cannot include whitespace characters. Legal values include *cholmondeley*, *été*, *1234*, *e\_content*, or *xml:id*, but not *grand wazoo*. Attributes of this kind are sometimes used to associate (by co-reference) elements of different types.

Where identifiers are defined externally, for example as part of a database or file system, the inability to include whitespace or other special characters in a value may be problematic. In other cases, it may also be simply more convenient to supply a short sequence of natural language words including spaces as a single value. For these reasons, we also provide a datatype **teidata.text** which does permit whitespace and indeed any other Unicode character. Legal values include *cholmondeley*, *été*, *1234*, *e-content*, *xml:id*, and *grand wazoo*. This datatype should be used with care since XML will not normalize whitespace characters within it: for example the values *n="a b"* (two spaces) and *n="a b"* (three spaces) would be considered distinct. This case should be distinguished from that of an attribute permitting multiple values, each of which may be separated by whitespace which *will* be normalized (see further *22.5.4.1. Datatypes*).

Attributes of type **teidata.name** are similar to those of type **teidata.word**, but with the additional constraint that they must be legal XML identifiers, as defined by the XML 1.0 specification, or successors. Hence, they may not begin with digits or punctuation characters. Legal identifiers include *cholmondeley*, *été*, *e\_content*, or *xml:id*, but not *grand wazoo* or *1234*. Attributes of this kind are typically used to represent XML element or attribute names.

Attributes of type **teidata.enumerated**, such as *new* on <shift> or *evidence* supplied by **att.editLike**, have the same definition as **teidata.word** above, with the added constraint that the word supplied is taken from a specific list of possibilities. In each case, the element or class specification which includes the definition for the attribute will also contain a list of possible values, together with a prose description of their intended significance. This list may be open (in which case the list is advisory), or closed (in which case it determines the range of legal values). In this latter case, the datatype will not be **teidata.enumerated**, but an explicit list of the possible values.

An attribute may, of course, take more than one value of a given type, for example a list of pointer values, or a list of words. In the TEI scheme, this information is regarded as a property of the <datatype> element used to document the attribute in question rather than as a distinct 'datatype', and is provided by the *minOccurs* or *maxOccurs* attribute. See further *22.5.4.1. Datatypes*.

In a small number of cases, an attribute may take a value of either one datatype or another. These cases are considered as distinct datatypes:

**teidata.probCert** defines a range of attribute values which can be expressed either as a numeric probability or as a coded certainty value.

**teidata.unboundedInt** defines an attribute value which can be either any non-negative integer or the string "unbounded".

**teidata.nullOrName** defines attribute values which contain either the null string or an XML name.

## 1.5 The TEI Infrastructure Module

The **tei** module defined by this chapter is a required component of any TEI schema. It provides declarations for all datatypes, and initial declarations for the attribute classes, model classes, and macros used by other modules in the TEI scheme. Its components are listed below in alphabetical order:

**Module tei:** Declarations for classes, datatypes, and macros available to all TEI modules

- *Classes defined:* att.ascribed att.breaking att.cReferencing att.canonical att.citing att.damaged att.dataable att.dataable.w3c att.datcat att.declarable att.declaring att.dimensions att.divLike att.docStatus att.duration.iso att.duration.w3c att.editLike att.edition att.fragmentable att.global att.global.rendition att.global.responsibility att.handFeatures att.internetMedia att.interpLike att.measurement att.media att.naming att.notated att.personal att.placement att.pointing att.pointing.group att.ranging att.readFrom att.resourced att.scoping att.segLike att.sortable att.source att.spanning att.styleDef att.tableDecoration att.timed att.transcriptional att.translatable att.typed att.written model.addrPart model.addressLike model.applicationLike model.availabilityPart model.biblLike model.biblPart model.castItemPart model.catDescPart model.certLike model.choicePart model.common model.correspActionPart model.correspContextPart model.correspDescPart model.dateLike model.descLike model.dimLike model.div1Like model.div2Like model.div3Like model.div4Like model.div5Like model.div6Like model.div7Like model.divBottom model.divBottomPart model.divGenLike model.divLike model.divPart model.divTop model.divTopPart model.divWrapper model.editorialDeclPart model.egLike model.emphLike model.encodingDescPart model.entryPart model.entryPart.top model.eventLike model.featureVal model.featureVal.complex model.featureVal.single model.frontPart model.frontPart.drama model.gLike model.global model.global.edit model.global.meta model.glossLike model.graphicLike model.headLike model.hiLike model.highlighted model.imprintPart model.inter model.lLike model.lPart model.labelLike model.limitedPhrase model.linePart model.listLike model.measureLike model.milestoneLike model.msItemPart model.msQuoteLike model.nameLike model.nameLike.agent model.noteLike model.oddDecl model.oddRef model.offsetLike model.orgPart model.orgStateLike model.pLike model.pLike.front model.pPart.data model.pPart.edit model.pPart.editorial model.pPart.msdesc model.pPart.transcriptional model.persStateLike model.personLike model.personPart model.phrase model.phrase.xml model.physDescPart model.placeLike model.placeNamePart model.placeStateLike model.profileDescPart model.ptrLike model.publicationStmtPart.agency model.publicationStmtPart.detail model.qLike model.quoteLike model.resourceLike model.respLike model.segLike model.settingPart model.sourceDescPart model.specDescLike model.stageLike model.teiHeaderPart model.textDescPart model.titlepagePart
- *Macros defined:* data.certainty data.count data.duration.iso data.duration.w3c data.enumerated data.interval data.language data.name data.namespace data.numeric data.outputMeasurement data.pattern data.percentage data.point data.pointer data.probability data.replacement data.sex data.temporal.iso data.temporal.w3c data.text data.truthValue data.version data.versionNumber data.word data.xTruthValue data.xmlName data.xpath macro.anyXML macro.limitedContent macro.paraContent macro.phraseSeq macro.phraseSeq.limited macro.specialPara macro.xtext teidata.certainty teidata.count teidata.duration.iso teidata.duration.w3c teidata.enumerated teidata.interval teidata.language teidata.name teidata.namespace teidata.nullOrName teidata.numeric teidata.outputMeasurement teidata.pattern teidata.percentage teidata.point teidata.pointer teidata.probCert teidata.probability teidata.replacement teidata.sex teidata.temporal.iso teidata.temporal.w3c teidata.text teidata.truthValue teidata.unboundedInt teidata.version teidata.versionNumber teidata.word teidata.xTruthValue teidata.xmlName teidata.xpath

The order in which declarations are made within the infrastructure module is critical, since several class declarations refer to others, which must therefore precede them. Other constraints on the order of declarations derive from the way in which the modularity of the TEI scheme is implemented in different schema languages. The XML DTD fragment implementing this TEI module makes extensive use of *parameter entities* and *marked sections* to effect a kind of conditional construction; the RELAX NG schema fragment similarly predeclares a number of patterns with null ('notAllowed') values. These issues are further discussed in chapter 23.5. *Implementation of an ODD System.*

## 1.6 Deprecated datatype macros

The following datatype macros are retained for backwards compatibility but will be removed at a future release.

## 2 The TEI Header

This chapter addresses the problems of describing an encoded work so that the text itself, its source, its encoding, and its revisions are all thoroughly documented. Such documentation is equally necessary for scholars using the texts, for software processing them, and for cataloguers in libraries and archives. Together these descriptions and declarations provide an electronic analogue to the title page attached to a printed work. They also constitute an equivalent for the content of the code books or introductory manuals customarily accompanying electronic data sets.

Every TEI-conformant text must carry such a set of descriptions, prefixed to it and encoded as described in this chapter. The set is known as the *TEI header*, tagged <teiHeader>, and has five major parts:

1. a *file description*, tagged <fileDesc>, containing a full bibliographical description of the computer file itself, from which a user of the text could derive a proper bibliographic citation, or which a librarian or archivist could use in creating a catalogue entry recording its presence within a library or archive. The term *computer file* here is to be understood as referring to the whole entity or document described by the header, even when this is stored in several distinct operating system files. The file description also includes information about the source or sources from which the electronic document was derived. The TEI elements used to encode the file description are described in section 2.2. *The File Description* below.
2. an *encoding description*, tagged <encodingDesc>, which describes the relationship between an electronic text and its source or sources. It allows for detailed description of whether (or how) the text was normalized during transcription, how the encoder resolved ambiguities in the source, what levels of encoding or analysis were applied, and similar matters. The TEI elements used to encode the encoding description are described in section 2.3. *The Encoding Description* below.
3. a *text profile*, tagged <profileDesc>, containing classificatory and contextual information about the text, such as its subject matter, the situation in which it was produced, the individuals described by or participating in producing it, and so forth. Such a text profile is of particular use in highly structured composite texts such as corpora or language collections, where it is often highly desirable to enforce a controlled descriptive vocabulary or to perform retrievals from a body of text in terms of text type or origin. The text profile may however be of use in any form of automatic text processing. The TEI elements used to encode the profile description are described in section 2.4. *The Profile Description* below.
4. a container element, tagged <xenoData>, which allows easy inclusion of metadata from non-TEI schemes (i.e., other than elements in the TEI namespace). For example, the MARC record for the encoded document might be included using MARCXML or MODS. A simple set of metadata for harvesting might be included encoded in Dublin Core.
5. a *revision history*, tagged <revisionDesc>, which allows the encoder to provide a history of changes made during the development of the electronic text. The revision history is important for *version control* and for resolving questions about the history of a file. The TEI elements used to encode the revision description are described in section 2.6. *The Revision Description* below.

A TEI header can be a very large and complex object, or it may be a very simple one. Some application areas (for example, the construction of language corpora and the transcription of spoken texts) may require more specialized and detailed information than others. The present proposals therefore define both a *core* set of elements (all of which may be used without formality in any TEI header) and some additional elements which become available within the header as the result of including additional specialized modules within the schema. When the module for language corpora (described in chapter 15. *Language Corpora*) is in use, for example, several additional elements are available, as further detailed in that chapter.

The next section of the present chapter briefly introduces the overall structure of the header and the kinds of data it may contain. This is followed by a detailed description of all the constituent elements which may be used in the core header. Section 2.7. *Minimal and Recommended Headers*, at the end of the present chapter, discusses the recommended content of a minimal TEI header and its relation to standard library cataloguing practices.

## 2.1 Organization of the TEI Header

### 2.1.1 The TEI Header and Its Components

The `<teiHeader>` element should be clearly distinguished from the *front matter* of the text itself (for which see section 4.5. *Front Matter*). A composite text, such as a corpus or collection, may contain several headers, as further discussed below. In the general case, however, a TEI-conformant text will contain a single `<teiHeader>` element, followed by a single `<text>` or `<facsimile>` element, or both.

The header element has the following description:

**<teiHeader>** (TEI header) supplies descriptive and declarative metadata associated with a digital resource or set of resources.

**@type** specifies the kind of document to which the header is attached, for example whether it is a corpus or individual text.

As discussed above, the `<teiHeader>` element has five principal components:

**<fileDesc>** (file description) contains a full bibliographic description of an electronic file.

**<encodingDesc>** (encoding description) documents the relationship between an electronic text and the source or sources from which it was derived.

**<profileDesc>** (text-profile description) provides a detailed description of non-bibliographic aspects of a text, specifically the languages and sublanguages used, the situation in which it was produced, the participants and their setting.

**<xenodata>** (outside metadata) provides a container element into which metadata in non-TEI formats may be placed.

**<revisionDesc>** (revision description) summarizes the revision history for a file.

Of these, only the `<fileDesc>` element is required in all TEI headers; the others are optional. That is, only one of the five components of the TEI header (the `<fileDesc>`) is mandatory, and it also has some mandatory components, as further discussed in 2.2. *The File Description* below. The smallest possible valid TEI Header thus looks like this:

```
<teiHeader>
  <fileDesc>
    <titleStmt>
      <title>
<!-- title of the resource -->
      </title>
    </titleStmt>
    <publicationStmt>
      <p>
<!-- Information about distribution of the resource -->
      </p>
    </publicationStmt>
    <sourceDesc>
      <p>
<!-- Information about source from which the resource derives -->
      </p>
    </sourceDesc>
  </fileDesc>
</teiHeader>
```

The content of the elements making up a TEI header may be given in any language, not necessarily that of the text to which the header applies, and not necessarily English. As elsewhere, the *xml:lang* attribute should be used at an appropriate level to specify the language. For example, in the following schematic example, an English text has been given a French header:

```
<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader xml:lang="fr">
```

```

<!-- ... -->
</teiHeader>
<text xml:lang="en">
<!-- ... -->
</text>
</TEI>

```

In the case of language corpora or collections, it may be desirable to record header information either at the level of the individual components in the corpus or collection, or at the level of the corpus or collection itself (more details concerning the tagging of composite texts are given in section 15. *Language Corpora*, which should be read in conjunction with the current chapter). A corpus may thus take the form:

```

<teiCorpus xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
<!-- corpus-level metadata here -->
  </teiHeader>
  <TEI>
    <teiHeader>
<!-- metadata specific to this text here -->
    </teiHeader>
    <text>
<!-- ... -->
    </text>
  </TEI>
  <TEI>
    <teiHeader>
<!-- metadata specific to this text here -->
    </teiHeader>
    <text>
<!-- ... -->
    </text>
  </TEI>
</teiCorpus>

```

### 2.1.2 Types of Content in the TEI Header

The elements occurring within the TEI header may contain several types of content; the following list indicates how these types of content are described in the following sections:

**free prose** Most elements contain simple running prose at some level. Many elements may contain either prose (possibly organized into paragraphs) or more specific elements, which themselves contain prose. In this chapter's descriptions of element content, the phrase *prose description* should be understood to imply a series of paragraphs, each marked as a <p> element. The word *phrase*, by contrast, should be understood to imply character data, interspersed as need be with phrase-level elements, but not organized into paragraphs. For more information on paragraphs, highlighted phrases, lists, etc., see section 3.1. *Paragraphs*.

**grouping elements** Elements whose names end with the suffix *Stmt* (e.g. <editionStmt>, <titleStmt>) and the <xenodata> element enclose a group of specialized elements recording some structured information. In the case of the bibliographic elements, the suffix *Stmt* is used in names of elements corresponding to the 'areas' of the International Standard Bibliographic Description.<sup>39</sup> In the case of the <xenodata> element, the specialized elements are not TEI elements, but rather come from some other metadata scheme. In most cases grouping elements may contain prose descriptions as an alternative to the set of specialized elements, thus allowing the

<sup>39</sup>For more information on this highly influential family of standards, first proposed in 1969 by the International Federation of Library Associations, see <http://www.ifla.org/VII/s13/pubs/isbd.htm>. On the relation between the TEI proposals and other standards for bibliographic description, see further section 2.8. *Note for Library Cataloguers*.

encoder to choose whether or not the information concerned should be presented in a structured form or in prose.

**declarations** Elements whose names end with the suffix *Decl* (e.g. <tagsDecl>, <refsDecl>) enclose information about specific encoding practices applied in the electronic text; often these practices are described in coded form. Typically, such information takes the form of a series of declarations, identifying a code with some more complex structure or description. A declaration which applies to more than one text or division of a text need not be repeated in the header of each such text or subdivision. Instead, the *decls* attribute of each text (or subdivision of the text) to which the declaration applies may be used to supply a cross-reference to it, as further described in section 15.3. *Associating Contextual Information with a Text*.

**descriptions** Elements whose names end with the suffix *Desc* (e.g. <settingDesc>, <projectDesc>) contain a prose description, possibly, but not necessarily, organized under some specific headings by suggested sub-elements.

### 2.1.3 Model Classes in the TEI Header

The TEI header provides a very rich collection of metadata categories, but makes no claim to be exhaustive. It is certainly the case that individual projects may wish to record specialized metadata which either does not fit within one of the predefined categories identified by the TEI header or requires a more specialized element structure than is proposed here. To overcome this problem, the encoder may elect to define additional elements using the customization methods discussed in 23.3. *Personalization and Customization*. The TEI class system makes such customizations simpler to effect and easier to use in interchange.

These classes are specific to parts of the header:

**model.applicationLike** groups elements used to record application-specific information about a document in its header.

|             |  |
|-------------|--|
| application | provides information about an application which has acted upon the document. |
|-------------|--|

**model.availabilityPart** groups elements such as licences and paragraphs of text which may appear as part of an availability statement

|         |   |
|---------|---|
| licence | contains information about a licence or other legal agreement applicable to the text. |
|---------|---|

**model.catDescPart** groups component elements of the TEI header Category Description.

|          |   |
|----------|---|
| textDesc | (text description) provides a description of a text in terms of its situational parameters. |
|----------|---|

**model.editorialDeclPart** groups elements which may be used inside <editorialDecl> and appear multiple times.

|                |   |
|----------------|---|
| correction     | (correction principles) states how and under what circumstances corrections have been made in the text.                                 |
| hyphenation    | summarizes the way in which hyphenation in a source text has been treated in an encoded version of it.                                  |
| interpretation | describes the scope of any analytic or interpretive information added to the text in addition to the transcription.                     |
| normalization  | indicates the extent of normalization or regularization of the original source carried out in converting it to electronic form.         |
| punctuation    | specifies editorial practice adopted with respect to punctuation marks in the original.   |
| quotation      | specifies editorial practice adopted with respect to quotation marks in the original.   |
| segmentation   | describes the principles according to which the text has been segmented, for example into sentences, tone-units, graphemic strata, etc. |

`stdVals` (standard values) specifies the format used when standardized date or number values are supplied.

**model.encodingDescPart** groups elements which may be used inside `<encodingDesc>` and appear multiple times.

|                                |  |
|--------------------------------|--|
| <code>appInfo</code>           | (application information) records information about an application which has edited the TEI file.  |
| <code>charDecl</code>          | (character declarations) provides information about nonstandard characters and glyphs.   |
| <code>classDecl</code>         | (classification declarations) contains one or more taxonomies defining any classificatory codes used elsewhere in the text.  |
| <code>editorialDecl</code>     | (editorial practice declaration) provides details of editorial principles and practices applied during the encoding of a text.   |
| <code>fsdDecl</code>           | (feature system declaration) provides a feature system declaration comprising one or more feature structure declarations or feature structure declaration links.   |
| <code>geoDecl</code>           | (geographic coordinates declaration) documents the notation and the datum used for geographic coordinates expressed as content of the <code>&lt;geo&gt;</code> element elsewhere within the document.  |
| <code>listPrefixDef</code>     | (list of prefix definitions) contains a list of definitions of prefixing schemes used in <code>data.pointer</code> values, showing how abbreviated URIs using each scheme may be expanded into full URIs.  |
| <code>metDecl</code>           | (metrical notation declaration) documents the notation employed to represent a metrical pattern when this is specified as the value of a <i>met</i> , <i>real</i> , or <i>rhyme</i> attribute on any structural element of a metrical text (e.g. <code>&lt;lg&gt;</code> , <code>&lt;l&gt;</code> , or <code>&lt;seg&gt;</code> ). |
| <code>projectDesc</code>       | (project description) describes in detail the aim or purpose for which an electronic file was encoded, together with any other relevant information concerning the process by which it was assembled or collected.   |
| <code>refsDecl</code>          | (references declaration) specifies how canonical references are constructed for this text.   |
| <code>samplingDecl</code>      | (sampling declaration) contains a prose description of the rationale and methods used in sampling texts in the creation of a corpus or collection.   |
| <code>schemaSpec</code>        | (schema specification) generates a TEI-conformant schema and documentation for it.   |
| <code>styleDefDecl</code>      | (style definition language declaration) specifies the name of the formal language in which style or renditional information is supplied elsewhere in the document. The specific version of the scheme may also be supplied.  |
| <code>tagsDecl</code>          | (tagging declaration) provides detailed information about the tagging applied to a document.   |
| <code>transcriptionDesc</code> | describes the set of transcription conventions used, particularly for spoken material.   |
| <code>variantEncoding</code>   | declares the method used to encode text-critical variants.   |

**model.profileDescPart** groups elements which may be used inside `<profileDesc>` and appear multiple times.

|                           |   |
|---------------------------|---|
| <code>abstract</code>     | contains a summary or formal abstract prefixed to an existing source document by the encoder.                         |
| <code>calendarDesc</code> | (calendar description) contains a description of the calendar system used in any dating expression found in the text. |
| <code>correspDesc</code>  | (correspondence description) contains a description of the actions related to one act of correspondence.              |
| <code>creation</code>     | contains information about the creation of a text.  |

|               |   |
|---------------|---|
| handNotes     | contains one or more <handNote> elements documenting the different hands identified within the source texts.  |
| langUsage     | (language usage) describes the languages, sublanguages, registers, dialects, etc. represented within a text.  |
| listTranspose | supplies a list of transpositions, each of which is indicated at some point in a document typically by means of metamarks.  |
| particDesc    | (participation description) describes the identifiable speakers, voices, or other participants in any kind of text or other persons named or otherwise referred to in a text, edition, or metadata. |
| settingDesc   | (setting description) describes the setting or settings within which a language interaction takes place, or other places otherwise referred to in a text, edition, or metadata.                     |
| textClass     | (text classification) groups information which describes the nature or topic of a text in terms of a standard classification scheme, thesaurus, etc.  |
| textDesc      | (text description) provides a description of a text in terms of its situational parameters.   |

**model.teiHeaderPart** groups high level elements which may appear more than once in a TEI header.

|              |  |
|--------------|--|
| encodingDesc | (encoding description) documents the relationship between an electronic text and the source or sources from which it was derived.  |
| profileDesc  | (text-profile description) provides a detailed description of non-bibliographic aspects of a text, specifically the languages and sublanguages used, the situation in which it was produced, the participants and their setting. |
| xenoData     | (outside metadata) provides a container element into which metadata in non-TEI formats may be placed.  |

**model.sourceDescPart** groups elements which may be used inside <sourceDesc> and appear multiple times.

|               |   |
|---------------|---|
| recordingStmt | (recording statement) describes a set of recordings used as the basis for transcription of a spoken text. |
| scriptStmt    | (script statement) contains a citation giving details of the script used for a spoken text.               |

**model.textDescPart** groups elements used to categorize a text for example in terms of its situational parameters.

|              |   |
|--------------|---|
| channel      | (primary channel) describes the medium or channel by which a text is delivered or experienced. For a written text, this might be print, manuscript, email, etc.; for a spoken one, radio, telephone, face-to-face, etc. |
| constitution | describes the internal composition of a text or text sample, for example as fragmentary, complete, etc.   |
| derivation   | describes the nature and extent of originality of this text.  |
| domain       | (domain of use) describes the most important social context in which the text was realized or for which it is intended, for example private vs. public, education, religion, etc.                                       |
| factuality   | describes the extent to which the text may be regarded as imaginative or non-imaginative, that is, as describing a fictional or a non-fictional world.  |
| interaction  | describes the extent, cardinality and nature of any interaction among those producing and experiencing the text, for example in the form of response or interjection, commentary, etc.                                  |
| preparedness | describes the extent to which a text may be regarded as prepared or spontaneous.  |

## 2.2 The File Description

This section describes the <fileDesc> element, which is the first component of the <teiHeader> element.

The bibliographic description of a machine-readable or digital text resembles in structure that of a book, an article, or any other kind of textual object. The file description element of the TEI header has therefore been closely modelled on existing standards in library cataloguing; it should thus provide enough information to allow users to give standard bibliographic references to the electronic text, and to allow cataloguers to catalogue it. Bibliographic citations occurring elsewhere in the header, and also in the text itself, are derived from the same model (on bibliographic citations in general, see further section 3.11. *Bibliographic Citations and References*). See further section 2.8. *Note for Library Cataloguers*.

The bibliographic description of an electronic text should be supplied by the mandatory <fileDesc> element:

**<fileDesc>** (file description) contains a full bibliographic description of an electronic file.

The <fileDesc> element contains three mandatory elements and four optional elements, each of which is described in more detail in sections 2.2.1. *The Title Statement* to 2.2.6. *The Notes Statement* below. These elements are listed below in the order in which they must be given within the <fileDesc> element.

**<titleStmt>** (title statement) groups information about the title of a work and those responsible for its content.

**<editionStmt>** (edition statement) groups information relating to one edition of a text.

**<extent>** describes the approximate size of a text stored on some carrier medium or of some other object, digital or non-digital, specified in any convenient units.

**<publicationStmt>** (publication statement) groups information concerning the publication or distribution of an electronic or other text.

**<seriesStmt>** (series statement) groups information about the series, if any, to which a publication belongs.

**<notesStmt>** (notes statement) collects together any notes providing information about a text additional to that recorded in other parts of the bibliographic description.

**<sourceDesc>** (source description) describes the source from which an electronic text was derived or generated, typically a bibliographic description in the case of a digitized text, or a phrase such as "born digital" for a text which has no previous existence.

A complete file description containing all possible sub-elements might look like this:

```
<teiHeader>
  <fileDesc>
    <titleStmt>
      <title>
<!-- title of the resource -->
      </title>
    </titleStmt>
    <editionStmt>
      <p>
<!-- information about the edition of the
resource -->
      </p>
    </editionStmt>
    <extent>
<!-- description of the size of the resource -->
    </extent>
    <publicationStmt>
      <p>
<!-- information about the distribution
of the resource -->
      </p>
    </publicationStmt>
    <seriesStmt>
      <p>
<!-- information about any series to which
```

```

the resource belongs -->
  </p>
</seriesStmt>
<notesStmt>
  <note>
<!-- notes on other aspects of the resource -->
  </note>
</notesStmt>
<sourceDesc>
  <p>
<!-- information about the source from which
the resource was derived -->
  </p>
</sourceDesc>
</fileDesc>
</teiHeader>

```

Of these elements, only the <titleStmt>, <publicationStmt>, and <sourceDesc> are required; the others may be omitted unless considered useful.

### 2.2.1 The Title Statement

The <titleStmt> element is the first component of the <fileDesc> element, and is mandatory:

**<titleStmt>** (title statement) groups information about the title of a work and those responsible for its content.

It contains the title given to the electronic work, together with one or more optional *statements of responsibility* which identify the encoder, editor, author, compiler, or other parties responsible for it:

**<title>** contains a title for any kind of work.

**<author>** in a bibliographic reference, contains the name(s) of an author, personal or corporate, of a work; for example in the same form as that provided by a recognized bibliographic name authority.

**<editor>** contains a secondary statement of responsibility for a bibliographic item, for example the name of an individual, institution or organization, (or of several such) acting as editor, compiler, translator, etc.

**<sponsor>** specifies the name of a sponsoring organization or institution.

**<funder>** (funding body) specifies the name of an individual, institution, or organization responsible for the funding of a project or text.

**<principal>** (principal researcher) supplies the name of the principal researcher responsible for the creation of an electronic text.

**<respStmt>** (statement of responsibility) supplies a statement of responsibility for the intellectual content of a text, edition, recording, or series, where the specialized elements for authors, editors, etc. do not suffice or do not apply. May also be used to encode information about individuals or organizations which have played a role in the production or distribution of a bibliographic work.

**<resp>** (responsibility) contains a phrase describing the nature of a person's intellectual responsibility, or an organization's role in the production or distribution of a work.

**<name>** (name, proper noun) contains a proper noun or noun phrase.

The <title> element contains the chief name of the electronic work, including any alternative title or subtitles it may have. It may be repeated, if the work has more than one title (perhaps in different languages) and takes whatever form is considered appropriate by its creator. Where the electronic work is derived from an existing source text, it is strongly recommended that the title for the former should be derived from the latter, but clearly distinguishable from it, for example by the addition of a phrase such as ': an electronic transcription' or 'a digital edition'. This will distinguish the electronic work from the source text in citations and in catalogues which contain descriptions of both types of material.

The electronic work will also have an external name (its 'filename' or 'data set name') or reference number on the computer system where it resides at any time. This name is likely to change frequently, as new copies of the file are made on the computer system. Its form is entirely dependent on the particular computer system in use and thus

cannot always easily be transferred from one system to another. Moreover, a given work may be composed of many files. For these reasons, these Guidelines strongly recommend that such names should *not* be used as the <title> for any electronic work.

Helpful guidance on the formulation of useful descriptive titles in difficult cases may be found in chapter 25 of Anglo-American Cataloguing Rules (2002–2005) or another national cataloguing code.

The elements <author>, <editor>, <sponsor>, <funder>, and <principal>, are specializations of the more general <respStmt> element. These elements are used to provide the *statements of responsibility* which identify the person(s) responsible for the intellectual or artistic content of an item and any corporate bodies from which it emanates.

Any number of such statements may occur within the title statement. At a minimum, identify the author of the text and (where appropriate) the creator of the file. If the bibliographic description is for a corpus, identify the creator of the corpus. Optionally include also names of others involved in the transcription or elaboration of the text, sponsors, and funding agencies. The name of the person responsible for physical data input need not normally be recorded, unless that person is also intellectually responsible for some aspect of the creation of the file.

Where the person whose responsibility is to be documented is not an author, sponsor, funding body, or principal researcher, the <respStmt> element should be used. This has two subcomponents: a <name> element identifying a responsible individual or organization, and a <resp> element indicating the nature of the responsibility. No specific recommendations are made at this time as to appropriate content for the <resp>: it should make clear the nature of the responsibility concerned, as in the examples below.

Names given may be personal names or corporate names. Give all names in the form in which the persons or bodies wish to be publicly cited. This would usually be the fullest form of the name, including first names.<sup>40</sup>

Examples:

```
<titleStmt>
  <title>Capgrave's Life of St. John Norbert: a
    machine-readable transcription</title>
  <respStmt>
    <resp>compiled by</resp>
    <name>P.J. Lucas</name>
  </respStmt>
</titleStmt>
```

```
<titleStmt>
  <title>Two stories by Edgar Allen Poe: electronic version</title>
  <author>Poe, Edgar Allen (1809-1849)</author>
  <respStmt>
    <resp>compiled by</resp>
    <name>James D. Benson</name>
  </respStmt>
</titleStmt>
```

```
<titleStmt>
  <title>Yogadarśanam (arthāt
    yogasūtrapūṭḥaḥ):
    a digital edition.</title>
  <title>The Yogasūtras of Patañjali:
    a digital edition.</title>
  <funder>Wellcome Institute for the History of Medicine</funder>
  <principal>Dominik Wujastyk</principal>
```

---

<sup>40</sup> Agencies compiling catalogues of machine-readable files are recommended to use available authority lists, such as the Library of Congress Name Authority List, for all common personal names.

```

<respStmt>
  <name>Wieslaw Mical</name>
  <resp>data entry and proof correction</resp>
</respStmt>
<respStmt>
  <name>Jan Hajic</name>
  <resp>conversion to TEI-conformant markup</resp>
</respStmt>
</titleStmt>

```

### 2.2.2 The Edition Statement

The `<editionStmt>` element is the second component of the `<fileDesc>` element. It is optional but recommended.

**<editionStmt>** (edition statement) groups information relating to one edition of a text.

It contains either phrases or more specialized elements identifying the edition and those responsible for it:

**<edition>** describes the particularities of one edition of a text.

**<respStmt>** (statement of responsibility) supplies a statement of responsibility for the intellectual content of a text, edition, recording, or series, where the specialized elements for authors, editors, etc. do not suffice or do not apply. May also be used to encode information about individuals or organizations which have played a role in the production or distribution of a bibliographic work.

**<name>** (name, proper noun) contains a proper noun or noun phrase.

**<resp>** (responsibility) contains a phrase describing the nature of a person's intellectual responsibility, or an organization's role in the production or distribution of a work.

For printed texts, the word *edition* applies to the set of all the identical copies of an item produced from one master copy and issued by a particular publishing agency or a group of such agencies. A change in the identity of the distributing body or bodies does not normally constitute a change of edition, while a change in the master copy does.

For electronic texts, the notion of a 'master copy' is not entirely appropriate, since they are far more easily copied and modified than printed ones; nonetheless the term *edition* may be used for a particular state of a machine-readable text at which substantive changes are made and fixed. Synonymous terms used in these Guidelines are *version*, *level*, and *release*. The words *revision* and *update*, by contrast, are used for minor changes to a file which do not amount to a new edition.

No simple rule can specify how 'substantive' changes have to be before they are regarded as producing a new edition, rather than a simple update. The general principle proposed here is that the production of a new edition entails a significant change in the intellectual content of the file, rather than its encoding or appearance. The addition of analytic coding to a text would thus constitute a new edition, while automatic conversion from one coded representation to another would not. Changes relating to the character code or physical storage details, corrections of misspellings, simple changes in the arrangement of the contents and changes in the output format do not normally constitute a new edition, whereas the addition of new information (e.g. a linguistic analysis expressed in part-of-speech tagging, sound or graphics, referential links to external data sets) almost always does.

Clearly, there will always be borderline cases and the matter is somewhat arbitrary. The simplest rule is: if you think that your file is a new edition, then call it such. An edition statement is optional for the first release of a computer file; it is mandatory for each later release, though this requirement cannot be enforced by the parser.

Note that *all* changes in a file considered significant, whether or not they are regarded as constituting a new edition or simply a new revision, should be independently noted in the revision description section of the file header (see section 2.6. *The Revision Description*).

The `<edition>` element should contain phrases describing the edition or version, including the word *edition*, *version*, or equivalent, together with a number or date, or terms indicating difference from other editions such as *new edition*, *revised edition* etc. Any dates that occur within the edition statement should be marked with the `<date>` element. The *n* attribute of the `<edition>` element may be used as elsewhere to supply any formal identification (such as a version number) for the edition.

One or more `<respStmt>` elements may also be used to supply statements of responsibility for the edition in question. These may refer to individuals or corporate bodies and can indicate functions such as that of a reviser, or

can name the person or body responsible for the provision of supplementary matter, of appendices, etc., in a new edition. For further detail on the <respStmt> element, see section 3.11. *Bibliographic Citations and References*.

Some examples follow:

```
<editionStmt>
  <edition n="P2">Second draft, substantially
    extended, revised, and corrected.</edition>
</editionStmt>
```

```
<editionStmt>
  <edition>Student's edition, <date>June 1987</date>
</edition>
  <respStmt>
    <resp>New annotations by</resp>
    <name>George Brown</name>
  </respStmt>
</editionStmt>
```

### 2.2.3 Type and Extent of File

The <extent> element is the third component of the <fileDesc> element. It is optional.

**<extent>** describes the approximate size of a text stored on some carrier medium or of some other object, digital or non-digital, specified in any convenient units.

For printed books, information about the carrier, such as the kind of medium used and its size, are of great importance in cataloguing procedures. The print-oriented rules for bibliographic description of an item's medium and extent need some re-interpretation when applied to electronic media. An electronic file exists as a distinct entity quite independently of its carrier and remains the same intellectual object whether it is stored on a magnetic tape, a CD-ROM, a set of floppy disks, or as a file on a mainframe computer. Since, moreover, these Guidelines are specifically aimed at facilitating transparent document storage and interchange, any purely machine-dependent information should be irrelevant as far as the file header is concerned.

This is particularly true of information about *file-type* although library-oriented rules for cataloguing often distinguish two types of computer file: 'data' and 'programs'. This distinction is quite difficult to draw in some cases, for example, hypermedia or texts with built in search and retrieval software.

Although it is equally system-dependent, some measure of the size of the computer file may be of use for cataloguing and other practical purposes. Because the measurement and expression of file size is fraught with difficulties, only very general recommendations are possible; the element <extent> is provided for this purpose. It contains a phrase indicating the size or approximate size of the computer file in one of the following ways:

- in bytes of a specified length (e.g. '4000 16-bit bytes')
- as falling within a range of categories, for example:
  - less than 1 Mb
  - between 1 Mb and 5 Mb
  - between 6 Mb and 10 Mb
  - over 10 Mb
- in terms of any convenient logical units (for example, words or sentences, citations, paragraphs)
- in terms of any convenient physical units (for example, blocks, disks, tapes)

The use of standard abbreviations for units of quantity is recommended where applicable, here as elsewhere (see <http://physics.nist.gov/cuu/Units/binary.html>).

Examples:

```

<extent>between 1 and
2 Mb</extent>
<extent>4.2 MiB</extent>
<extent>4532 bytes</extent>
<extent>3200 sentences</extent>
<extent>Five 90 mm High Density Diskettes</extent>

```

The <measure> element and its attributes may be used to supply machine-tractable or normalised versions of the size or sizes given, as in the following example:

```

<extent>
  <measure unit="MiB" quantity="4.2">About four megabytes</measure>
  <measure unit="pages" quantity="245">245 pages of source
    material</measure>
</extent>

```

Note that when more than one <measure> is supplied in a single <extent>, the implication is that all the measurements apply to the whole resource.

#### 2.2.4 Publication, Distribution, Licensing, etc.

The <publicationStmt> element is the fourth component of the <fileDesc> element and is mandatory. Its function is to name the agency by which a resource is made available (for example, a publisher or distributor) and to supply any additional information about the way in which it is made available such as licensing conditions, identifying numbers, etc.

**<publicationStmt>** (publication statement) groups information concerning the publication or distribution of an electronic or other text.

It may contain either a simple prose description organized as one or more paragraphs, or the more specialised elements described below.

A structured publication statement must begin with one of the following elements:

**<publisher>** provides the name of the organization responsible for the publication or distribution of a bibliographic item.

**<distributor>** supplies the name of a person or other agency responsible for the distribution of a text.

**<authority>** (release authority) supplies the name of a person or other agency responsible for making a work available, other than a publisher or distributor.

These elements form the `model.publicationStmtPart.agency` class; if the agency making the resource available is unknown, but other structured information about it is available, an explicit statement such as 'publisher unknown' should be used.

The *publisher* is the person or institution by whose authority a given edition of the file is made public. The *distributor* is the person or institution from whom copies of the text may be obtained. Where a text is not considered formally published, but is nevertheless made available for circulation by some individual or organization, this person or institution is termed the *release authority*.

Whichever of these elements is chosen, it may be followed by one or more of the following elements, which together form the `model.publicationStmtPart.detail` class

**<pubPlace>** (publication place) contains the name of the place where a bibliographic item was published.

**<address>** contains a postal address, for example of a publisher, an organization, or an individual.

**<idno>** (identifier) supplies any form of identifier used to identify some object, such as a bibliographic item, a person, a title, an organization, etc. in a standardized way.

**@type** categorizes the identifier, for example as an ISBN, Social Security number, etc.

**<availability>** supplies information about the availability of a text, for example any restrictions on its use or distribution, its copyright status, any licence applying to it, etc.

**@status** supplies a code identifying the current availability of the text.

**<date>** contains a date in any format.

**<licence>** contains information about a licence or other legal agreement applicable to the text.

Here is a simple example:

```
<publicationStmt>
  <publisher>Oxford University Press</publisher>
  <pubPlace>Oxford</pubPlace>
  <date>1989</date>
  <idno type="ISBN">0-19-254705-4</idno>
  <availability>
    <p>Copyright 1989, Oxford University Press</p>
  </availability>
</publicationStmt>
```

The `model.publicationStmtPart.detail` elements all supply additional information relating to the publisher, distributor, or release authority immediately preceding them. In the following example, Benson is identified as responsible for distribution of some resource at the date and place cited:

```
<publicationStmt>
  <authority>James D. Benson</authority>
  <pubPlace>London</pubPlace>
  <date>1994</date>
</publicationStmt>
```

A resource may have (for example) both a publisher and a distributor, or more than one publisher each using different identifiers for the same resource, and so on. For this reason, the sequence of at least one `model.publicationStmtPart.agency` element followed by zero or more `model.publicationStmtPart.detail` elements may be repeated as often as necessary.

The following example shows a resource published by one agency (Sigma Press) at one address and date, which is also distributed by another (Oxford Text Archive), with a specified identifier and a different date:

```
<publicationStmt>
  <publisher>Sigma Press</publisher>
  <address>
    <addrLine>21 High Street,</addrLine>
    <addrLine>Wilmslow,</addrLine>
    <addrLine>Cheshire M24 3DF</addrLine>
  </address>
  <date>1991</date>
  <distributor>Oxford Text Archive</distributor>
  <idno type="OTA">1256</idno>
  <availability>
    <p>Available with prior consent of depositor for
      purposes of academic research and teaching only.</p>
  </availability>
  <date>1994</date>
</publicationStmt>
```

The `<date>` element used within `<publicationStmt>` always refers to the date of publication, first distribution, or initial release. If the text was created at some other date, this may be recorded using the `<creation>` element within the `<profileDesc>` element. Other useful dates (such as dates of collection of data) may be given using a note in the `<notesStmt>` element.

The `<availability>` element may be used, as above, to provide a simple prose statement of any restrictions concerning the distribution of the resource. Alternatively, a more formal statement of the licensing conditions applicable may be provided using the `<licence>` element:

```
<publicationStmt>
  <publisher>University of Victoria Humanities Computing and Media Centre</publisher>
  <pubPlace>Victoria, BC</pubPlace>
  <date>2011</date>
  <availability status="restricted">
    <licence target="http://creativecommons.org/licenses/by-sa/3.0/"> Distributed under
a Creative Commons Attribution-ShareAlike 3.0 Unported License
    </licence>
  </availability>
</publicationStmt>
```

Note here the use of the *target* attribute to point to a location from which the licence document itself may be obtained. Alternatively, the licence document may simply be contained within the `<licence>` element.

### 2.2.5 The Series Statement

The `<seriesStmt>` element is the fifth component of the `<fileDesc>` element and is optional.

**<seriesStmt>** (series statement) groups information about the series, if any, to which a publication belongs.

In bibliographic parlance, a *series* may be defined in one of the following ways:

- A group of separate items related to one another by the fact that each item bears, in addition to its own title proper, a collective title applying to the group as a whole. The individual items may or may not be numbered.
- Each of two or more volumes of essays, lectures, articles, or other items, similar in character and issued in sequence.
- A separately numbered sequence of volumes within a series or serial.

The `<seriesStmt>` element may contain a prose description or one or more of the following more specific elements:

**<title>** contains a title for any kind of work.

**<idno>** (identifier) supplies any form of identifier used to identify some object, such as a bibliographic item, a person, a title, an organization, etc. in a standardized way.

**<respStmt>** (statement of responsibility) supplies a statement of responsibility for the intellectual content of a text, edition, recording, or series, where the specialized elements for authors, editors, etc. do not suffice or do not apply. May also be used to encode information about individuals or organizations which have played a role in the production or distribution of a bibliographic work.

**<resp>** (responsibility) contains a phrase describing the nature of a person's intellectual responsibility, or an organization's role in the production or distribution of a work.

**<name>** (name, proper noun) contains a proper noun or noun phrase.

The `<idno>` may be used to supply any identifying number associated with the item, including both standard numbers such as an ISSN and particular issue numbers. (Arabic numerals separated by punctuation are recommended for this purpose: 6.19.33, for example, rather than VI/xix:33). Its *type* attribute is used to categorize the number further, taking the value ISSN for an ISSN for example.

Examples:

```
<seriesStmt>
  <title level="s">Machine-Readable Texts for the Study of
  Indian Literature</title>
  <respStmt>
    <resp>ed. by</resp>
    <name>Jan Gonda</name>
  </respStmt>
  <biblScope unit="vol">1.2</biblScope>
```

```
<idno type="ISSN">0 345 6789</idno>
</seriesStmt>
```

## 2.2.6 The Notes Statement

The <notesStmt> element is the sixth component of the <fileDesc> element and is optional. If used, it contains one or more <note> elements, each containing a single piece of descriptive information of the kind treated as ‘general notes’ in traditional bibliographic descriptions.

**<notesStmt>** (notes statement) collects together any notes providing information about a text additional to that recorded in other parts of the bibliographic description.

**<note>** contains a note or annotation.

Some information found in the notes area in conventional bibliography has been assigned specific elements in these Guidelines; in particular the following items should be tagged as indicated, rather than as general notes:

- the nature, scope, artistic form, or purpose of the file; also the genre or other intellectual category to which it may belong: e.g. ‘Text types: newspaper editorials and reportage, science fiction, westerns, and detective stories’. These should be formally described within the <profileDesc> element (section 2.4. *The Profile Description*).
- an abstract or summary of the content of a document which has been supplied by the encoder because no such abstract forms part of the content of the source. This should be supplied in the <abstract> element within the <profileDesc> element (section 2.4. *The Profile Description*).
- summary description providing a factual, non-evaluative account of the subject content of the file: e.g. ‘Transcribes interviews on general topics with native speakers of English in 17 cities during the spring and summer of 1963’. These should also be formally described within the <profileDesc> element (section 2.4. *The Profile Description*).
- bibliographic details relating to the source or sources of an electronic text: e.g. ‘Transcribed from the Norton facsimile of the 1623 Folio’. These should be formally described in the <sourceDesc> element (section 2.2.7. *The Source Description*).
- further information relating to publication, distribution, or release of the text, including sources from which the text may be obtained, any restrictions on its use or formal terms on its availability. These should be placed in the appropriate division of the <publicationStmt> element (section 2.2.4. *Publication, Distribution, Licensing, etc.*).
- publicly documented numbers associated with the file: e.g. ‘ICPSR study number 1803’ or ‘Oxford Text Archive text number 1243’. These should be placed in an <idno> element within the appropriate division of the <publicationStmt> element. International Standard Serial Numbers (ISSN), International Standard Book Numbers (ISBN), and other internationally agreed upon standard numbers that uniquely identify an item, should be treated in the same way, rather than as specialized bibliographic notes.

Nevertheless, the <notesStmt> element may be used to record potentially significant details about the file and its features, e.g.:

- dates, when they are relevant to the content or condition of the computer file: e.g. ‘manual dated 1983’, ‘Interview wave I: Apr. 1989; wave II: Jan. 1990’
- names of persons or bodies connected with the technical production, administration, or consulting functions of the effort which produced the file, if these are not named in statements of responsibility in the title or edition statements of the file description: e.g. ‘Historical commentary provided by Mark Cohen’
- availability of the file in an additional medium or information not already recorded about the availability of documentation: e.g. ‘User manual is loose-leaf in eleven paginated sections’
- language of work and abstract, if not encoded in the <langUsage> element, e.g. ‘Text in English with summaries in French and German’
- The unique name assigned to a serial by the International Serials Data System (ISDS), if not encoded in an <idno>
- lists of related publications, either describing the source itself, or concerned with the creation or use of the electronic work, e.g. ‘Texts used in Burrows (1987)’

Each such item of information may be tagged using the general-purpose <note> element, which is described in section 3.8. *Notes, Annotation, and Indexing*. Groups of notes are contained within the <notesStmt> element, as in the following example:

```
<notesStmt>
  <note>Historical commentary provided by Mark Cohen.</note>
  <note>OCR scanning done at University of Toronto.</note>
</notesStmt>
```

There are advantages, however, to encoding such information with more precise elements elsewhere in the TEI header, when such elements are available. For example, the notes above might be encoded as follows:

```
<titleStmt>
  <title>...</title>
  <respStmt>
    <persName>Mark Cohen</persName>
    <resp>historical commentary</resp>
  </respStmt>
  <respStmt>
    <orgName>University of Toronto</orgName>
    <resp>OCR scanning</resp>
  </respStmt>
</titleStmt>
```

### 2.2.7 The Source Description

The <sourceDesc> element is the seventh and final component of the <fileDesc> element. It is a mandatory element and is used to record details of the source or sources from which a computer file is derived. This might be a printed text or manuscript, another computer file, an audio or video recording of some kind, or a combination of these. An electronic file may also have no source, if what is being catalogued is an original text created in electronic form.

**<sourceDesc>** (source description) describes the source from which an electronic text was derived or generated, typically a bibliographic description in the case of a digitized text, or a phrase such as "born digital" for a text which has no previous existence.

The <sourceDesc> element may contain little more than a simple prose description, or a brief note stating that the document has no source:

```
<sourceDesc>
  <p>Born digital.</p>
</sourceDesc>
```

Alternatively, it may contain elements drawn from the following three classes:

**model.biblLike** groups elements containing a bibliographic description.

|            |  |
|------------|--|
| bibl       | (bibliographic citation) contains a loosely-structured bibliographic citation of which the sub-components may or may not be explicitly tagged.                 |
| biblFull   | (fully-structured bibliographic citation) contains a fully-structured bibliographic citation, in which all components of the TEI file description are present. |
| biblStruct | (structured bibliographic citation) contains a structured bibliographic citation, in which only bibliographic sub-elements appear and in a specified order.    |
| listBibl   | (citation list) contains a list of bibliographic citations of any kind.  |
| msDesc     | (manuscript description) contains a description of a single identifiable manuscript or other text-bearing object.  |

**model.sourceDescPart** groups elements which may be used inside <sourceDesc> and appear multiple times.

|               |   |
|---------------|---|
| recordingStmt | (recording statement) describes a set of recordings used as the basis for transcription of a spoken text. |
| scriptStmt    | (script statement) contains a citation giving details of the script used for a spoken text.               |

**model.listLike** groups list-like elements.

|            |  |
|------------|--|
| list       | contains any sequence of items organized as a list.  |
| listApp    | (list of apparatus entries) contains a list of apparatus entries.  |
| listEvent  | (list of events) contains a list of descriptions, each of which provides information about an identifiable event.  |
| listNym    | (list of canonical names) contains a list of nyms, that is, standardized names for any thing.  |
| listOrg    | (list of organizations) contains a list of elements, each of which provides information about an identifiable organization.  |
| listPerson | (list of persons) contains a list of descriptions, each of which provides information about an identifiable person or a group of people, for example the participants in a language interaction, or the people referred to in a historical source. |
| listPlace  | (list of places) contains a list of places, optionally followed by a list of relationships (other than containment) defined amongst them.  |
| listWit    | (witness list) lists definitions for all the witnesses referred to by a critical apparatus, optionally grouped hierarchically.   |
| table      | contains text displayed in tabular form, in rows and columns.  |

These classes make available by default a range of ways of providing bibliographic citations which specify the provenance of the text. For written or printed sources, the source may be described in the same way as any other bibliographic citation, using one of the following elements:

**<bibl>** (bibliographic citation) contains a loosely-structured bibliographic citation of which the sub-components may or may not be explicitly tagged.

**<biblStruct>** (structured bibliographic citation) contains a structured bibliographic citation, in which only bibliographic sub-elements appear and in a specified order.

**<listBibl>** (citation list) contains a list of bibliographic citations of any kind.

These elements are described in more detail in section 3.11. *Bibliographic Citations and References*. Using them, a source might be described in very simple terms:

```
<sourceDesc>
  <bibl>The first folio of Shakespeare, prepared by
    Charlton Hinman (The Norton Facsimile, 1968)</bibl>
</sourceDesc>
```

or with more elaboration:

```
<sourceDesc>
  <biblStruct xml:lang="fr">
    <monogr>
      <author>Eugène Sue</author>
      <title>Martin, l'enfant trouvé</title>
      <title type="sub">Mémoires d'un valet de chambre</title>
```

```

    <imprint>
      <pubPlace>Bruxelles et Leipzig</pubPlace>
      <publisher>C. Muquardt</publisher>
      <date when="1846">1846</date>
    </imprint>
  </monogr>
</biblStruct>
</sourceDesc>

```

When the header describes a text derived from some pre-existing TEI-conformant or other digital document, it may be simpler to use the following element, which is designed specifically for documents derived from texts which were ‘born digital’:

**<biblFull>** (fully-structured bibliographic citation) contains a fully-structured bibliographic citation, in which all components of the TEI file description are present.

For further discussion see section 2.2.8. *Computer Files Derived from Other Computer Files*.

When the module for manuscript description is included in a schema, this class also makes available the following element:

**<msDesc>** (manuscript description) contains a description of a single identifiable manuscript or other text-bearing object.

This element enables the encoder to record very detailed information about one or more manuscript or analogous sources, as further discussed in 10. *Manuscript Description*.

The `model.sourceDescPart` class also makes available additional elements when additional modules are included. For example, when the `spoken` module is included, the `<sourceDesc>` element may also include the following special-purpose elements, intended for cases where an electronic text is derived from a spoken text rather than a written one:

**<scriptStmt>** (script statement) contains a citation giving details of the script used for a spoken text.

**<recordingStmt>** (recording statement) describes a set of recordings used as the basis for transcription of a spoken text.

Full descriptions of these elements and their contents are given in section 8.2. *Documenting the Source of Transcribed Speech*.

A single electronic text may be derived from multiple source documents, in whole or in part. The `<sourceDesc>` may therefore contain a `<listBibl>` element grouping together `<bibl>`, `<biblStruct>`, or `<msDesc>` elements for each of the sources concerned. It is also possible to repeat the `<sourceDesc>` element in such a case. The *decls* attribute described in section 15.3. *Associating Contextual Information with a Text* may be used to associate parts of the encoded text with the bibliographic element from which it derives in either case.

The source description may also include lists of names, persons, places, etc. when these are considered to form part of the source for an encoded document. When such information is recorded using the specialized elements discussed in the `namesdates` module (13. *Names, Dates, People, and Places*), the class `model.listLike` makes available the following elements to hold such information:

**<listNym>** (list of canonical names) contains a list of nyms, that is, standardized names for any thing.

**<listOrg>** (list of organizations) contains a list of elements, each of which provides information about an identifiable organization.

**<listPerson>** (list of persons) contains a list of descriptions, each of which provides information about an identifiable person or a group of people, for example the participants in a language interaction, or the people referred to in a historical source.

**<listPlace>** (list of places) contains a list of places, optionally followed by a list of relationships (other than containment) defined amongst them.

### 2.2.8 Computer Files Derived from Other Computer Files

If a computer file (call it B) is derived not from a printed source but from another computer file (call it A) which includes a TEI header, then the source text of computer file B is another computer file, A. The five sections of A's file header will need to be incorporated into the new header for B in slightly differing ways, as listed below:

**fileDesc** A's file description should be copied into the <sourceDesc> section of B's file description, enclosed within a <biblFull> element

**profileDesc** A's <profileDesc> should be copied into B's, in principle unchanged; it may however be expanded by project-specific information relating to B.

**encodingDesc** A's encoding practice may or (more likely) may not be the same as B's. Since the object of the encoding description is to define the relationship between the current file and its source, in principle only changes in encoding practice between A and B need be documented in B. The relationship between A and its source(s) is then only recoverable from the original header of A. In practice it may be more convenient to create a new complete <encodingDesc> for B based on A's.

**xenoData** B is a new computer file, with a different source than A's source (namely, A). Thus it is unlikely that metadata from other schemes about A or its source can be copied wholesale to B, although there may be similarities.

**revisionDesc** B is a new computer file, and should therefore have a new revision description. If, however, it is felt useful to include some information from A's <revisionDesc>, for example dates of major updates or versions, such information must be clearly marked as relating to A rather than to B.

This concludes the discussion of the <fileDesc> element and its contents.

## 2.3 The Encoding Description

The <encodingDesc> element is the second major subdivision of the TEI header. It specifies the methods and editorial principles which governed the transcription or encoding of the text in hand and may also include sets of coded definitions used by other components of the header. Though not formally required, its use is highly recommended.

**<encodingDesc>** (encoding description) documents the relationship between an electronic text and the source or sources from which it was derived.

The encoding description may contain any combination of paragraphs of text, marked up using the <p> element, along with more specialized elements taken from the `model.encodingDescPart` class. By default, this class makes available the following elements:

**<projectDesc>** (project description) describes in detail the aim or purpose for which an electronic file was encoded, together with any other relevant information concerning the process by which it was assembled or collected.

**<samplingDecl>** (sampling declaration) contains a prose description of the rationale and methods used in sampling texts in the creation of a corpus or collection.

**<editorialDecl>** (editorial practice declaration) provides details of editorial principles and practices applied during the encoding of a text.

**<tagsDecl>** (tagging declaration) provides detailed information about the tagging applied to a document.

**<styleDefDecl>** (style definition language declaration) specifies the name of the formal language in which style or renditional information is supplied elsewhere in the document. The specific version of the scheme may also be supplied.

**<refsDecl>** (references declaration) specifies how canonical references are constructed for this text.

**<classDecl>** (classification declarations) contains one or more taxonomies defining any classificatory codes used elsewhere in the text.

**<geoDecl>** (geographic coordinates declaration) documents the notation and the datum used for geographic coordinates expressed as content of the <geo> element elsewhere within the document.

**<schemaSpec>** (schema specification) generates a TEI-conformant schema and documentation for it.

Each of these elements is further described in the appropriate section below. Other modules have the ability to extend this class; examples are noted in section 2.3.11. *Module-Specific Declarations*

### 2.3.1 The Project Description

The <projectDesc> element may be used to describe, in prose, the purpose for which a digital resource was created, together with any other relevant information concerning the process by which it was assembled or collected. This

is of particular importance for corpora or miscellaneous collections, but may be of use for any text, for example to explain why one kind of encoding practice has been followed rather than another.

**<projectDesc>** (project description) describes in detail the aim or purpose for which an electronic file was encoded, together with any other relevant information concerning the process by which it was assembled or collected.

For example:

```
<encodingDesc>
  <projectDesc>
    <p>Texts collected for use in the
      Claremont Shakespeare Clinic, June 1990.</p>
  </projectDesc>
</encodingDesc>
```

### 2.3.2 The Sampling Declaration

The `<samplingDecl>` element may be used to describe, in prose, the rationale and methods used in selecting texts, or parts of text, for inclusion in the resource.

**<samplingDecl>** (sampling declaration) contains a prose description of the rationale and methods used in sampling texts in the creation of a corpus or collection.

It should include information about such matters as

- the size of individual samples
- the method or methods by which they were selected
- the underlying population being sampled
- the object of the sampling procedure used

but is not restricted to these.

```
<samplingDecl>
  <p>Samples of 2000 words taken from the beginning of the text.</p>
</samplingDecl>
```

It may also include a simple description of any parts of the source text included or excluded.

```
<samplingDecl>
  <p>Text of stories only has been transcribed. Pull quotes, captions,
    and advertisements have been silently omitted. Any mathematical
    expressions requiring symbols not present in the ISOnum or ISOpub
    entity sets have been omitted, and their place marked with a GAP
    element.</p>
</samplingDecl>
```

A sampling declaration which applies to more than one text or division of a text need not be repeated in the header of each such text. Instead, the *decls* attribute of each text (or subdivision of the text) to which the sampling declaration applies may be used to supply a cross-reference to it, as further described in section 15.3. *Associating Contextual Information with a Text*.

### 2.3.3 The Editorial Practices Declaration

The `<editorialDecl>` element is used to provide details of the editorial practices applied during the encoding of a text.

**<editorialDecl>** (editorial practice declaration) provides details of editorial principles and practices applied during the encoding of a text.

It may contain a prose description only, or one or more of a set of specialized elements, members of the TEI `model.editorialDeclPart` class. Where an encoder wishes to record an editorial policy not specified above, this may be done by adding a new element to this class, using the mechanisms discussed in chapter 23.3. *Personalization and Customization*.

Some of these policy elements carry attributes to support automated processing of certain well-defined editorial decisions; all of them contain a prose description of the editorial principles adopted with respect to the particular feature concerned. Examples of the kinds of questions which these descriptions are intended to answer are given in the list below.

**<correction>** (correction principles) states how and under what circumstances corrections have been made in the text.

**@status** indicates the degree of correction applied to the text.

**@method** indicates the method adopted to indicate corrections within the text.

Was the text corrected during or after data capture? If so, were corrections made silently or are they marked using the tags described in section 3.4. *Simple Editorial Changes*? What principles have been adopted with respect to omissions, truncations, dubious corrections, alternate readings, false starts, repetitions, etc.?

**<normalization>** indicates the extent of normalization or regularization of the original source carried out in converting it to electronic form.

**@source** indicates a bibliographic description or other resource documenting the principles underlying the normalization carried out.

**@method** indicates the method adopted to indicate normalizations within the text.

Was the text normalized, for example by regularizing any non-standard spellings, dialect forms, etc.? If so, were normalizations performed silently or are they marked using the tags described in section 3.4. *Simple Editorial Changes*? What authority was used for the regularization? Also, what principles were used when normalizing numbers to provide the standard values for the *value* attribute described in section 3.5.3. *Numbers and Measures* and what format used for them?

**<quotation>** specifies editorial practice adopted with respect to quotation marks in the original.

**@marks** (quotation marks) indicates whether or not quotation marks have been retained as content within the text.

How were quotation marks processed? Are apostrophes and quotation marks distinguished? How? Are quotation marks retained as content in the text or replaced by markup? Are there any special conventions regarding for example the use of single or double quotation marks when nested? Is the file consistent in its practice or has this not been checked? See section 3.3.3. *Quotation* for discussion of ways in which quotation marks may be encoded.

**<hyphenation>** summarizes the way in which hyphenation in a source text has been treated in an encoded version of it.

**@eol** (end-of-line) indicates whether or not end-of-line hyphenation has been retained in a text.

Does the encoding distinguish ‘soft’ and ‘hard’ hyphens? What principle has been adopted with respect to end-of-line hyphenation where source lineation has not been retained? Have soft hyphens been silently removed, and if so what is the effect on lineation and pagination? See section 3.2.2. *Hyphenation* for discussion of ways in which hyphenation may be encoded.

**<segmentation>** describes the principles according to which the text has been segmented, for example into sentences, tone-units, graphemic strata, etc.

How is the text segmented? If `<s>` or `<seg>` segmentation units have been used to divide up the text for analysis, how are they marked and how was the segmentation arrived at?

**<stdVals>** (standard values) specifies the format used when standardized date or number values are supplied.

In most cases, attributes bearing standardized values (such as the *when* or *when-iso* attribute on dates) should conform to a defined W3C or ISO datatype. In cases where this is not appropriate, this element may be used to describe the standardization methods underlying the values supplied.

**<interpretation>** describes the scope of any analytic or interpretive information added to the text in addition to the transcription.

Has any analytic or ‘interpretive’ information been provided—that is, information which is felt to be non-obvious, or potentially contentious? If so, how was it generated? How was it encoded? If feature-structure analysis has been used, are `<fsdDecl>` elements (section 18.11. *Feature System Declaration*) present?

**<punctuation>** specifies editorial practice adopted with respect to punctuation marks in the original.

How has the encoding of punctuation marks present in the original source been treated? For example, has it been normalised, or suppressed in favour of descriptive markup? If it has been retained, is it located within or around elements such as `<quote>` which are normally associated with quotations?

Any information about the editorial principles applied not falling under one of the above headings should be recorded in a distinct list of items. Experience shows that a full record should be kept of decisions relating to editorial principles and encoding practice, both for future users of the text and for the project which produced the text in the first instance. Some simple examples follow:

```
<editorialDecl>
<segmentation>
  <p>
    <gi>s</gi> elements mark orthographic sentences and
      are numbered sequentially
      within their parent <gi>div</gi> element
  </p>
</segmentation>
<interpretation>
  <p>The part of speech analysis applied throughout section 4 was
    added by hand and has not been checked.</p>
</interpretation>
<correction>
  <p>Errors in transcription controlled by using the
    WordPerfect spelling checker.</p>
</correction>
<normalization source="http://szotar.sztaki.hu/webster/">
  <p>All words converted to Modern American spelling following
    Websters 9th Collegiate dictionary.</p>
</normalization>
```

```

<quotation marks="all">
  <p>All opening quotation marks represented by entity reference
  <ident type="ge">odq</ident>; all closing quotation marks
  represented by entity reference <ident type="ge">cdq</ident>.</p>
</quotation>
</editorialDecl>

```

An editorial practices declaration which applies to more than one text or division of a text need not be repeated in the header of each such text. Instead, the *decls* attribute of each text (or subdivision of the text) to which it applies may be used to supply a cross-reference to it, as further described in section 15.3. *Associating Contextual Information with a Text*.

### 2.3.4 The Tagging Declaration

The `<tagsDecl>` element is used to record the following information about the tagging used within a particular document:

- the namespace to which elements appearing within the transcribed text belong.
- how often particular elements appear within the text, so that a recipient can validate the integrity of a text during interchange.
- any comment relating to the usage of particular elements not specified elsewhere in the header.
- a default rendition applicable to all instances of an element.

This information is conveyed by the following elements:

**<rendition>** supplies information about the rendition or appearance of one or more elements in the source text.

*@selector* contains a selector or series of selectors specifying the elements to which the contained style description applies, expressed in the language specified in the *scheme* attribute.

**att.styleDef** provides attributes to specify the name of a formal definition language used to provide formatting or rendition information.

*@scheme* identifies the language used to describe the rendition.

*@schemeVersion* supplies a version number for the style language provided in *scheme*.

**<namespace>** supplies the formal name of the namespace to which the elements documented by its children belong.

**<tagUsage>** documents the usage of a specific element within a specified document.

The `<tagsDecl>` element is descriptive, rather than prescriptive: if used, it simply documents practice in the TEI document containing it. The elements constituting a TEI customization file (discussed in chapter 22. *Documentation Elements*) by contrast document expected practice in a number of documents, and may thus be used prescriptively. If there is an inconsistency between the actual state of a document and what is documented by its `<tagsDecl>`, then the latter should be corrected. If there is an inconsistency between a document and what is required by the customization file, or a schema derived from it, then it will usually be the document that requires correction.

The `<tagsDecl>` element consists of an optional sequence of `<rendition>` elements, each of which must bear a unique identifier, followed by an optional sequence of one or more `<namespace>` elements, each of which contains a series of `<tagUsage>` elements, up to one for each element type from that namespace occurring within the associated `<text>` element. Note that these `<tagUsage>` elements must be nested within a `<namespace>` element, and cannot appear directly within the `<tagsDecl>` element.

#### 2.3.4.1 Rendition

The `<rendition>` element allows the encoder to specify how one or more elements are rendered in the original source in any of the following ways:

- using an informal prose description
- using a standard stylesheet language such as CSS or XSL-FO
- using a project-defined formal language

One or more such specifications may be associated with elements of a document in three ways:

- the *render* attribute of the appropriate <tagUsage> element may be used to indicate a default rendition for all occurrences of the named element
- the *selector* attribute on any <rendition> element may be used to select a collection of elements to which it applies
- the global *rendition* attribute may be used on any element to indicate its rendition, overriding or complementing any supplied default value

The global *rend* and *style* attributes may also be used to describe the rendering of an element. See further 1.3.1.1.3. *Rendition Indicators*

For example, the following schematic shows how an encoder might specify that all <p> elements are by default to be rendered using one set of specifications identified as style1, while <hi> elements are to use a different set, identified as style2:

```
<tagsDecl>
  <rendition xml:id="style1"> ... description of one default rendition here ...
</rendition>
  <rendition xml:id="style2"> ... description of another default rendition here ...
</rendition>
  <namespace name="http://www.tei-c.org/ns/1.0">
    <tagUsage gi="p" render="#style1"> ... </tagUsage>
    <tagUsage gi="hi" render="#style2"> ... </tagUsage>
  </namespace>
</tagsDecl>
<!-- elsewhere in the document -->
<p>This paragraph, mostly rendered in style1, contains a few words
<hi>rendered in style2</hi>
</p>
<p rendition="#style2">This paragraph is all rendered in style2</p>
<p>This is back to style1</p>
```

As noted above, the content of a <rendition> element may describe the appearance of the source material using prose, a project-defined formal language, or any standard languages such as the Cascading Stylesheet Language (Bos et al. (eds.) (2011)) or the XML vocabulary for specifying formatting semantics which forms a part of the W3C's Extensible Stylesheet Language (Berglund (ed.) (2006)). A <styleDefDecl> element (2.3.5. *The Default Style Definition Language Declaration*) may be supplied within the <encodingDesc> to specify which of these applies by default; it may be overridden for one or more specific <rendition> elements using the *scheme* attribute.

In the above example, all <p> elements are styled in the same way, as are all <hi> elements, except where *rendition* is used to override the default at the element level. However, suppose that all paragraphs in the <front> of a text appear in a large font, with significant top and bottom margins, while paragraphs in the main <body> are in regular font size and have no top and bottom margins. This would be difficult to express using <tagUsage>; and it would be inefficient to have to provide repeated *rendition* attributes on every paragraph in one or the other context. Instead, we can use the *selector* attribute on <rendition> for a more elegant solution:

```
<rendition scheme="css" selector="front p">
font-size: 110%;
margin-top: 0.5em;
margin-bottom: 0.5em;
</rendition>
```

```
<rendition scheme="css" selector="body p">
font-size: 100%;
margin-top: 0;
```

```
margin-bottom: 0;
</rendition>
```

It is recommended that in a single text, either `<rendition>/selector` or `<tagUsage>/render` be used; the combination of both is potentially confusing and harder to process.

In the following extended example we consider how to capture the appearance of a typical early 20th century titlepage, such as that in the following figure: Elements for the encoding of the information on a titlepage are

presented in 4.6. *Title Pages*; here we consider how we might go about encoding some of the visual information as well, using the `<rendition>` element and its corresponding attributes.

First we define a rendition element for each aspect of the source page rendition that we wish to retain. Details of CSS are given in Bos et al. (eds.) (2011); we use it here simply to provide a vocabulary with which to describe such aspects as font size and style, letter and line spacing, colour, etc. Note that the purpose of this encoding is to describe the original, rather than specify how it should be reproduced, although the two are obviously closely linked.

```
<styleDefDecl scheme="css"
  schemeVersion="2.1"/>
<!-- ... -->
```

```

<tagsDecl>
  <rendition xml:id="center">text-align: center;</rendition>
  <rendition xml:id="small">font-size: small;</rendition>
  <rendition xml:id="large">font-size: large;</rendition>
  <rendition xml:id="x-large">font-size: x-large;</rendition>
  <rendition xml:id="xx-large">font-size: xx-large;</rendition>
  <rendition xml:id="expanded">letter-spacing: +3pt;</rendition>
  <rendition xml:id="x-space">line-height: 150%;</rendition>
  <rendition xml:id="xx-space">line-height: 200%;</rendition>
  <rendition xml:id="red">color: red;</rendition>
</tagsDecl>

```

The global *rendition* attribute can now be used to specify on any element which of the above rendition features apply to it. For example, a title page might be encoded as follows:

```

<titlePage>
  <docTitle rendition="#center #x-space">
    <titlePart>
      <lb/>
      <hi rendition="#x-large">THE POEMS</hi>
      <lb/>
      <hi rendition="#small">OF</hi>
      <lb/>
      <hi rendition="#red #xx-large">ALGERNON CHARLES SWINBURNE</hi>
      <lb/>
      <hi rendition="#large #xx-space">IN SIX VOLUMES</hi>
    </titlePart>
    <titlePart rendition="#xx-space">
      <lb/> VOLUME I.
    </titlePart>
    <hi rendition="#red #x-large">POEMS AND BALLADS</hi>
    <lb/>
    <hi rendition="#x-space">FIRST SERIES</hi>
  </titlePart>
</docTitle>
<docImprint rendition="#center">
  <lb/>
  <pubPlace rendition="#xx-space">LONDON</pubPlace>
  <lb/>
  <publisher rendition="#red #expanded">CHATTO & WINDUS</publisher>
  <lb/>
  <docDate when="1904" rendition="#small">1904</docDate>
</docImprint>
</titlePage>

```

When CSS is used as the style definition language, the *scope* attribute may be used to specify CSS pseudo-elements. These pseudo-elements are used to specify styling applicable to only a portion of the given text. For example, the *first-letter* pseudo-element defines styling to be applied to the first letter in the targeted element, while the *before* and *after* pseudo-elements can be used often in conjunction with the "content" property to add additional characters which need to be added before or after the element content to make it more closely resemble the appearance of the source.

For example, assuming that a text has been encoded using the `<q>` element to enclose passages in quotation marks, but the quotation marks themselves have been routinely omitted from the encoding, a set of renditions such as the following:

```
<rendition xml:id="quoteBefore"
  scheme="css" scope="before">content:
  '';</rendition>
<rendition xml:id="quoteAfter" scheme="css"
  scope="after">content:
  '';</rendition>
```

might be used to predefine pseudo-elements `quoteBefore` and `quoteAfter`. Where a `<q>` element is actually rendered in the source with initial and final quotation marks, it may then be encoded as follows:

```
<q rendition="#quoteBefore #quoteAfter">Four score and seven years
ago...</q>
```

### 2.3.4.2 Tag Usage

As noted above, each `<namespace>` element, if present, should contain up to one occurrence of a `<tagUsage>` element for each element type from the given namespace that occurs within the outermost `<text>` element associated with the `<teiHeader>` in which it appears.<sup>41</sup> The `<tagUsage>` element may be used to supply a count of the number of occurrences of this element within the text, which is given as the value of its *occurs* attribute. It may also be used to hold any additional usage information, which is supplied as running prose within the element itself.

For example:

```
<tagUsage gi="hi" occurs="28"> Used only to mark English words italicised in the copy
text.
</tagUsage>
```

This indicates that the `<hi>` element appears a total of 28 times in the `<text>` element in question, and that the encoder has used it to mark italicised English words only.

The *withId* attribute may optionally be used to specify how many of the occurrences of the element in question bear a value for the global *xml:id* attribute, as in the following example:

```
<tagUsage gi="pb" occurs="321" withId="321"> Marks page breaks in the York
(1734) edition only </tagUsage>
```

This indicates that the `<pb>` element occurs 321 times, on each of which an identifier is provided.

The content of the `<tagUsage>` element is not susceptible of automatic processing. It should not therefore be used to hold information for which provision is already made by other components of the encoding description. A TEI-conformant document is not required to provide any `<tagUsage>` elements or *occurs* attributes, but if it does, then the counts provided must correspond with the number of such elements present in the associated `<text>`.

### 2.3.5 The Default Style Definition Language Declaration

The content of the `<rendition>` element, the value of its *selector* attribute, and the value of the *style* attribute are expressed using one of a small number of formally defined style definition languages. For ease of processing, it is strongly recommended to use a single such language throughout an encoding project, although the TEI system permits a mixture.

The element `<styleDefDecl>`, a sibling of the `<tagsDecl>` element, is used to supply the name of the default style definition language. The name is supplied as the value of the *scheme* attribute and may take any of the following values:

<sup>41</sup>In the case of a TEI corpus (*15. Language Corpora*), a `<tagsDecl>` in a corpus header will describe tag usage across the whole corpus, while one in an individual text header will describe tag usage for the individual text concerned.

**free** Informal free text description

**css** Cascading Stylesheet Language

**xslfo** Extensible Stylesheet Language Formatting Objects

**other** A user-defined formal description language

. The *schemeVersion* attribute may be used to supply the precise version of the style definition language used, and the content of this element, if any, may supply additional information.

When the *style* attribute is used, its value must always be expressed using whichever default style definition language is in force. If more than one occurrence of the `<styleDefDecl>` is provided, there will be more than one default available, and the *decls* attribute must be used to select which is applicable in a given context, as discussed in section 15.3. *Associating Contextual Information with a Text*.

### 2.3.6 The Reference System Declaration

The `<refsDecl>` element is used to document the way in which any standard referencing scheme built into the encoding works.

**<refsDecl>** (references declaration) specifies how canonical references are constructed for this text.

It may contain either a series of prose paragraphs or the following specialized elements:

**<cRefPattern>** (canonical reference pattern) specifies an expression and replacement pattern for transforming a canonical reference into a URI.

**<refState>** (reference state) specifies one component of a canonical reference defined by the milestone method.

**att.patternReplacement** provides attributes for regular-expression matching and replacement.

*@matchPattern* specifies a regular expression against which the values of other attributes can be matched.

*@replacementPattern* specifies a ‘replacement pattern’, that is, the skeleton of a relative or absolute URI containing references to groups in the *matchPattern* which, once subpattern substitution has been performed, complete the URI.

Note that not all possible referencing schemes are equally easily supported by current software systems. A choice must be made between the convenience of the encoder and the likely efficiency of the particular software applications envisaged, in this context as in many others. For a more detailed discussion of referencing systems supported by these Guidelines, see section 3.10. *Reference Systems* below.

A referencing scheme may be described in one of three ways using this element:

- as a prose description
- as a series of pairs of regular expressions and XPaths
- as a concatenation of sequentially organized *milestones*

Each method is described in more detail below. Only one method can be used within a single `<refsDecl>` element.

More than one `<refsDecl>` element can be included in the header if more than one canonical reference scheme is to be used in the same document, but the current proposals do not check for mutual inconsistency.

#### 2.3.6.1 Prose Method

The referencing scheme may be specified within the `<refsDecl>` by a simple prose description. Such a description should indicate which elements carry identifying information, and whether this information is represented as attribute values or as content. Any special rules about how the information is to be interpreted when reading or generating a reference string should also be specified here. Such a prose description cannot be processed automatically, and this method of specifying the structure of a canonical reference system is therefore not recommended for automatic processing.

For example:

```
<refsDecl>
  <p>The <att>n</att> attribute of each text in this corpus carries a
    unique identifying code for the whole text. The title of the text is
```

```

held as the content of the first <gi>head</gi> element within each
text. The <att>n</att> attribute on each <gi>div1</gi> and
<gi>div2</gi> contains the canonical reference for each such
division, in the form 'XX.yyy', where XX is the book number in Roman
numerals, and yyy the section number in arabic. Line breaks are
marked by empty <gi>lb</gi> elements, each of which includes the
through line number in Casaubon's edition as the value of its
<gi>n</gi> attribute.</p>
<p>The through line number and the text identifier uniquely identify
any line. A canonical reference may be made up by concatenating the
<gi>n</gi> values from the <gi>text</gi>, <gi>div1</gi>, or
<gi>div2</gi> and calculating the line number within each part.</p>
</refsDecl>

```

### 2.3.6.2 Search-and-Replace Method

This method often requires a significant investment of effort initially, but permits extremely flexible addressing. For details, see section 16.2.5. *Canonical References*.

**<cRefPattern>** (canonical reference pattern) specifies an expression and replacement pattern for transforming a canonical reference into a URI.

### 2.3.6.3 Milestone Method

This method is appropriate when only 'milestone' tags (see section 3.10.3. *Milestone Elements*) are available to provide the required referencing information. It does not provide any abilities which cannot be mimicked by the search-and-replace referencing method discussed in the previous section, but in the cases where it applies, it provides a somewhat simpler notation.

A reference based on milestone tags concatenates the values specified by one or more such tags. Since each tag marks the point at which a value changes, it may be regarded as specifying the *refState* of a variable. A reference declaration using this method therefore specifies the individual components of the canonical reference as a sequence of <refState> elements:

**<refState>** (reference state) specifies one component of a canonical reference defined by the milestone method.

**@*delim*** (delimiter) supplies a delimiting string following the reference component.

**@*length*** specifies the fixed length of the reference component.

**att.milestoneUnit** provides an attribute to indicate the type of section which is changing at a specific milestone.

**@*unit*** provides a conventional name for the kind of section changing at this milestone.

For example, the reference 'Matthew 12:34' might be thought of as representing the state of three variables: the **book** variable is in state 'Matthew'; the **chapter** variable is in state '12', and the **verse** variable is in state '34'. If milestone tagging has been used, there should be a tag marking the point in the text at which each of the above 'variables' changes its state.<sup>42</sup> To find 'Matthew 12:34' therefore an application must scan left to right through the text, monitoring changes in the state of each of these three variables as it does so. When all three are simultaneously in the required state, the desired point will have been reached. There may of course be several such points.

The *delim* and *length* attributes are used to specify components of a canonical reference using this method in exactly the same way as for the stepwise method described in the preceding section. The other attributes are used to determine which instances of <milestone> tags in the text are to be checked for state-changes. A state-change is signalled whenever a new <milestone> tag is found with *unit* and, optionally, *ed* attributes identical to those of the <refState> element in question. The value for the new state may be given explicitly by the *n* attribute on the <milestone> element, or it may be implied, if the *n* attribute is not specified.

For example, for canonical references in the form *xx.yyy* where the *xx* represents the page number in the first edition, and *yyy* the line number within this page, a reference system declaration such as the following would be appropriate:

<sup>42</sup>On the <milestone> tag itself, what are here referred to as 'variables' are identified by the combination of the *ed* and *unit* attributes.

```
<refsDecl>
  <refState ed="first" unit="page" length="2"
    delim="."/>
  <refState ed="first" unit="line" length="3"/>
</refsDecl>
```

This implies that milestone tags of the form

```
<milestone n="II" ed="first" unit="page"/>
<milestone ed="first" unit="line"/>
```

will be found throughout the text, marking the positions at which page and line numbers change. Note that no value has been specified for the *n* attribute on the second milestone tag above; this implies that its value at each state change is monotonically increased. For more detail on the use of milestone tags, see section 3.10.3. *Milestone Elements*.

The milestone referencing scheme, though conceptually simple, is not supported by a generic XML parser. Its use places a correspondingly greater burden of verification and accuracy on the encoder.

A reference system declaration which applies to more than one text or division of a text need not be repeated in the header of each such text. Instead, the *decls* attribute of each text (or subdivision of the text) to which the declaration applies may be used to supply a cross-reference to it, as further described in section 15.3. *Associating Contextual Information with a Text*.

### 2.3.7 The Classification Declaration

The `<classDecl>` element is used to group together definitions or sources for any descriptive classification schemes used by other parts of the header. Each such scheme is represented by a `<taxonomy>` element, which may contain either a simple bibliographic citation, or a definition of the descriptive typology concerned; the following elements are used in defining a descriptive classification scheme:

**<classDecl>** (classification declarations) contains one or more taxonomies defining any classificatory codes used elsewhere in the text.

**<taxonomy>** defines a typology either implicitly, by means of a bibliographic citation, or explicitly by a structured taxonomy.

**<category>** contains an individual descriptive category, possibly nested within a superordinate category, within a user-defined taxonomy.

**<catDesc>** (category description) describes some category within a taxonomy or text typology, either in the form of a brief prose description or in terms of the situational parameters used by the TEI formal `textDesc`.

The `<taxonomy>` element has two slightly different, but related, functions. For well-recognized and documented public classification schemes, such as Dewey or other published descriptive thesauri, it contains simply a bibliographic citation indicating where a full description of a particular taxonomy may be found.

```
<taxonomy xml:id="DDC12">
  <bibl>
    <title>Dewey Decimal Classification</title>
    <edition>Abridged Edition 12</edition>
  </bibl>
</taxonomy>
```

For less easily accessible schemes, the `<taxonomy>` element contains a description of the taxonomy itself as well as an optional bibliographic citation. The description consists of a number of `<category>` elements, each defining a single category within the given typology. The category is defined by the contents of a nested `<catDesc>` element, which may contain either a phrase describing the category, or any number of elements from the `model.catDescPart` class. When the corpus module is included in a schema, this class provides the `<textDesc>` element whose

components allow the definition of a text type in terms of a set of ‘situational parameters’ (see further section 15.2.1. *The Text Description*; if the corpus module is not included in a schema, this class is empty and the <catDesc> element may contain only plain text.

If the category is subdivided, each subdivision is represented by a nested <category> element, having the same structure. Categories may be nested to an arbitrary depth in order to reflect the hierarchical structure of the taxonomy. Each <category> element bears a unique *xml:id* attribute, which is used as the target for <catRef> elements referring to it.

```
<taxonomy xml:id="b">
  <bibl>Brown Corpus</bibl>
  <category xml:id="b.a">
    <catDesc>Press Reportage</catDesc>
    <category xml:id="b.a1">
      <catDesc>Daily</catDesc>
    </category>
    <category xml:id="b.a2">
      <catDesc>Sunday</catDesc>
    </category>
    <category xml:id="b.a3">
      <catDesc>National</catDesc>
    </category>
    <category xml:id="b.a4">
      <catDesc>Provincial</catDesc>
    </category>
    <category xml:id="b.a5">
      <catDesc>Political</catDesc>
    </category>
    <category xml:id="b.a6">
      <catDesc>Sports</catDesc>
    </category>
  </category>
  <category xml:id="b.d">
    <catDesc>Religion</catDesc>
    <category xml:id="b.d1">
      <catDesc>Books</catDesc>
    </category>
    <category xml:id="b.d2">
      <catDesc>Periodicals and tracts</catDesc>
    </category>
  </category>
</taxonomy>
```

Linkage between a particular text and a category within such a taxonomy is made by means of the <catRef> element within the <textClass> element, as described in section 2.4.3. *The Text Classification*. Where the taxonomy permits of classification along more than one dimension, more than one category will be referenced by a particular <catRef>, as in the following example, which identifies a text with the sub-categories ‘Daily’, ‘National’, and ‘Political’ within the category ‘Press Reportage’ as defined above.

```
<catRef target="#b.a1 #b.a3 #b.a5"/>
```

A single <category> may contain more than one <catDesc> child, when for example the category is described in more than one language, as in the following example:

```

<category xml:id="lit">
  <catDesc xml:lang="pl">literatura piękna</catDesc>
  <catDesc xml:lang="en">fiction</catDesc>
  <category xml:id="litProza">
    <catDesc xml:lang="pl">proza</catDesc>
    <catDesc xml:lang="en">prose</catDesc>
  </category>
  <category xml:id="litPoezja">
    <catDesc xml:lang="pl">poezja</catDesc>
    <catDesc xml:lang="en">poetry</catDesc>
  </category>
  <category xml:id="litDramat">
    <catDesc xml:lang="pl">dramat</catDesc>
    <catDesc xml:lang="en">drama</catDesc>
  </category>
</category>

```

### 2.3.8 The Geographic Coordinates Declaration

The following element is provided to indicate (within the header of a document, or in an external location) that a particular coordinate notation, or a particular datum, has been employed in a text. The default notation is a string containing two real numbers separated by whitespace, of which the first indicates latitude and the second longitude according to the 1984 World Geodetic System (WGS84).

**<geoDecl>** (geographic coordinates declaration) documents the notation and the datum used for geographic coordinates expressed as content of the <geo> element elsewhere within the document.

*@datum* supplies a commonly used code name for the datum employed.

### 2.3.9 The Schema Specification

The <schemaSpec> element contains a schema specification. When this element appears inside <encodingDesc>, it allows embedding of a schema inside a TEI header; alternatively, this element may be used in the <body> of an ODD document. The use of ODD files, and their relationship to schemas, is described in detail in *22. Documentation Elements*.

A <schemaSpec> element contains all the information needed to generate schemas for a particular TEI customization, and the ODD documentation elements, by reference to the TEI, are more succinct than the schemas derived from them. Therefore you may find it convenient to make a copy of the <schemaSpec> from your project's ODD document inside the <teiHeader> itself, in addition to supplying an external schema and/or ODD file; if the XML file becomes separated from its schema, the schema can be regenerated at any time using the information in the <schemaSpec> element. For example:

```

<encodingDesc>
  <!-- Other encoding description elements... -->
  <schemaSpec ident="myTEICustomization"
    docLang="en" prefix="tei_" xml:lang="en">
    <moduleRef key="core"/>
    <moduleRef key="tei"/>
    <moduleRef key="header"/>
    <moduleRef key="textstructure"/>
  </schemaSpec>
</encodingDesc>

```

### 2.3.10 The Application Information Element

It is sometimes convenient to store information relating to the processing of an encoded resource within its header. Typical uses for such information might be:

- to allow an application to discover that it has previously opened or edited a file, and what version of itself was used to do that;
- to show (through a date) which application last edited the file to allow for diagnosis of any problems that might have been caused by that application;
- to allow users to discover information about an application used to edit the file
- to allow the application to declare an interest in elements of the file which it has edited, so that other applications or human editors may be more wary of making changes to those sections of the file.

The class `model.applicationLike` provides an element, `<application>`, which may be used to record such information within the `<appInfo>` element.

**<appInfo>** (application information) records information about an application which has edited the TEI file.

**<application>** provides information about an application which has acted upon the document.

`@ident` supplies an identifier for the application, independent of its version number or display name.

`@version` supplies a version number for the application, independent of its identifier or display name.

Each `<application>` element identifies the current state of one software application with regard to the current file. This element is a member of the `att.dateable` class, which provides a variety of attributes for associating this state with a date and time, or a temporal range. The `ident` and `version` attributes should be used to uniquely identify the application and its major version number (for example, ImageMarkupTool 1.5). It is not intended that an application should add a new `<application>` each time it touches the file.

The following example shows how these elements might be used to document the fact that version 1.5 of an application called 'Image Markup Tool' has an interest in two parts of a document which was last saved on June 6 2006. The parts concerned are accessible at the URLs given as target for the two `<ptr>` elements.

```
<appInfo>
  <application version="1.5"
    ident="ImageMarkupTool" notAfter="2006-06-01">
    <label>Image Markup Tool</label>
    <ptr target="#P1"/>
    <ptr target="#P2"/>
  </application>
</appInfo>
```

### 2.3.11 Module-Specific Declarations

The elements discussed so far are available to any schema. When the schema in use includes some of the more specialized TEI modules, these make available other more module-specific components of the encoding description. These are discussed fully in the documentation for the module in question, but are also noted briefly here for convenience.

The `<fsdDecl>` element is available only when the `iso-fs` module is included in a schema. Its purpose is to document the *feature system declaration* (as defined in chapter 18.11. *Feature System Declaration*) underlying any analytic *feature structures* (as defined in chapter 18. *Feature Structures*) present in the text documented by this header.

The `<metDecl>` element is available only when the `verse` module is included in a schema. Its purpose is to document any metrical notation scheme used in the text, as further discussed in section 6.4. *Rhyme and Metrical Analysis*. It consists either of a prose description or a series of `<metSym>` elements.

The `<variantEncoding>` element is available only when the `textcrit` module is included in a schema. Its purpose is to document the method used to encode textual variants in the text, as discussed in section 12.2. *Linking the Apparatus to the Text*.

## 2.4 The Profile Description

The `<profileDesc>` element is the third major subdivision of the TEI header. It is an optional element, the purpose of which is to enable information characterizing various descriptive aspects of a text or a corpus to be recorded within a single unified framework.

**<profileDesc>** (text-profile description) provides a detailed description of non-bibliographic aspects of a text, specifically the languages and sublanguages used, the situation in which it was produced, the participants and their setting.

In principle, almost any component of the header might be of importance as a means of characterizing a text. The author of a written text, its title or its date of publication, may all be regarded as characterizing it at least as strongly as any of the parameters discussed in this section. The rule of thumb applied has been to exclude from discussion here most of the information which generally forms part of a standard bibliographic style description, if only because such information has already been included elsewhere in the TEI header.

The **<profileDesc>** element contains an optional **<creation>** element, followed by any number of additional elements taken from the `model.profileDescPart` class. The default members of this class are the following :

**<abstract>** contains a summary or formal abstract prefixed to an existing source document by the encoder.

**<creation>** contains information about the creation of a text.

**<langUsage>** (language usage) describes the languages, sublanguages, registers, dialects, etc. represented within a text.

**<textClass>** (text classification) groups information which describes the nature or topic of a text in terms of a standard classification scheme, thesaurus, etc.

**<calendarDesc>** (calendar description) contains a description of the calendar system used in any dating expression found in the text.

These elements are further described in the remainder of this section.

When the `CORPUS` module described in chapter 15. *Language Corpora* is included in a schema, three further elements become available within the **<profileDesc>** element:

**<textDesc>** (text description) provides a description of a text in terms of its situational parameters.

**<particDesc>** (participation description) describes the identifiable speakers, voices, or other participants in any kind of text or other persons named or otherwise referred to in a text, edition, or metadata.

**<settingDesc>** (setting description) describes the setting or settings within which a language interaction takes place, or other places otherwise referred to in a text, edition, or metadata.

For descriptions of these elements, see section 15.2. *Contextual Information*.

When the `transcr` module for the transcription of primary sources described in chapter 11. *Representation of Primary Sources* is included in a schema, the following element becomes available within the **<profileDesc>** element:

**<handNotes>** contains one or more **<handNote>** elements documenting the different hands identified within the source texts.

For a description of this element, see section 11.3.2.1. *Document Hands*. Its purpose is to group together a number of **<handNote>** elements, each of which describes a different hand or equivalent identified within a manuscript. The **<handNote>** element can also appear within a structured manuscript description, when the `msdescription` module described in chapter 10. *Manuscript Description* is included in a schema. For this reason, the **<handNote>** element is actually declared within the header module, but is only accessible to a schema when one or other of the `transcr` or `msdescription` modules is included in a schema. See further the discussion at 11.3.2.1. *Document Hands*.

### 2.4.1 Creation

The **<creation>** element contains phrases describing the origin of the text, e.g. the date and place of its composition.

**<creation>** contains information about the creation of a text.

The date and place of composition are often of particular importance for studies of linguistic variation; since such information cannot be inferred with confidence from the bibliographic description of the copy text, the **<creation>** element may be used to provide a consistent location for this information:

```
<creation>
  <date when="1992-08">August 1992</date>
  <rs type="city">Taos, New Mexico</rs>
</creation>
```

## 2.4.2 Language Usage

The `<langUsage>` element is used within the `<profileDesc>` element to describe the languages, sublanguages, registers, dialects, etc. represented within a text. It contains one or more `<language>` elements, each of which provides information about a single language, notably the quantity of that language present in the text. Note that this element should *not* be used to supply information about any non-standard characters or glyphs used by this language; such information should be recorded in the `<charDecl>` element in the encoding description (see further 5. *Characters, Glyphs, and Writing Modes*).

**<langUsage>** (language usage) describes the languages, sublanguages, registers, dialects, etc. represented within a text.

**<language>** characterizes a single language or sublanguage used within a text.

**@usage** specifies the approximate percentage (by volume) of the text which uses this language.

**@ident** (identifier) Supplies a language code constructed as defined in BCP 47 which is used to identify the language documented by this element, and which is referenced by the global `xml:lang` attribute.

A `<language>` element may be supplied for each different language used in a document. If used, its *ident* attribute should specify an appropriate language identifier, as further discussed in section *vi.1 Language Identification*. This is particularly important if extended language identifiers have been used as the value of `xml:lang` attributes elsewhere in the document.

Here is an example of the use of this element:

```
<langUsage>
  <language ident="fr-CA" usage="60">Québécois</language>
  <language ident="en-CA" usage="20">Canadian business English</language>
  <language ident="en-GB" usage="20">British English</language>
</langUsage>
```

## 2.4.3 The Text Classification

The `<textClass>` element is used to classify a text in some way.

**<textClass>** (text classification) groups information which describes the nature or topic of a text in terms of a standard classification scheme, thesaurus, etc.

Text classification may be carried out according to one or more of the following methods:

- by reference to a recognized international classification such as the Dewey Decimal Classification, the Universal Decimal Classification, the Colon Classification, the Library of Congress Classification, or any other system widely used in library and documentation work
- by providing a set of keywords, as provided for example by British Library or Library of Congress Cataloguing in Publication data
- by referencing any other taxonomy of text categories recognized in the field concerned, or peculiar to the material in hand; this may include one based on recurring sets of values for the situational parameters defined in section 15.2.1. *The Text Description*, or the demographic elements described in section 15.2.2. *The Participant Description*

The last of these may be particularly important for dealing with existing corpora or collections, both as a means of avoiding the expense or inconvenience of reclassification and as a means of documenting the organizing principles of such materials.

The following elements are provided for this purpose:

**<keywords>** contains a list of keywords or phrases identifying the topic or nature of a text.

**@scheme** identifies the controlled vocabulary within which the set of keywords concerned is defined identifies the classification scheme within which the set of categories concerned is defined, for example by a `<taxonomy>` element, or by some other resource.

**<classCode>** (classification code) contains the classification code used for this text in some standard classification system.

**@scheme** identifies the classification system in use, as defined by for example by a `<taxonomy>` element, or some other resource.

**<catRef>** (category reference) specifies one or more defined categories within some taxonomy or text typology.

The **<keywords>** element simply categorizes an individual text by supplying a list of keywords which may describe its topic or subject matter, its form, date, etc. In some schemes, the order of items in the list is significant, for example, from major topic to minor; in others, the list has an organized substructure of its own. No recommendations are made here as to which method is to be preferred. Wherever possible, such keywords should be taken from a recognized source, such as the British Library/Library of Congress Cataloguing in Publication data in the case of printed books, or a published thesaurus appropriate to the field.

The *scheme* attribute is used to indicate the source of the keywords used, in the case where such a source exists. If the keywords are taken from an externally defined authority which is available online, this attribute should point directly to it, as in the following examples:

```
<keywords scheme="http://classificationweb.net">
  <term>Babbage, Charles</term>
  <term>Mathematicians - Great Britain - Biography</term>
</keywords>
```

```
<keywords scheme="http://id.loc.gov/authorities/about.html#lcsch">
  <term>English literature -- History and criticism -- Data processing.</term>
  <term>English literature -- History and criticism -- Theory, etc.</term>
  <term>English language -- Style -- Data processing.</term>
  <term>Style, Literary -- Data processing.</term>
</keywords>
```

If the authority file is not available online, but is generally recognized and commonly cited, a bibliographic description for it should be supplied within the **<taxonomy>** element described in section 2.3.7. *The Classification Declaration*; the *scheme* attribute may then reference that **<taxonomy>** element by means of its identifier in the usual way:

```
<keywords scheme="#welch">
  <term>ceremonials</term>
  <term>fairs</term>
  <term>street life</term>
</keywords>
<!-- elsewhere in the document -->
<taxonomy xml:id="welch">
  <bibl>
    <title>Notes on London Municipal Literature, and a Suggested
      Scheme for Its Classification</title>
    <author>Charles Welch</author>
    <edition>1895</edition>
  </bibl>
</taxonomy>
```

If no authority file exists, perhaps because the keywords used were assigned directly by an author, the *scheme* attribute should be omitted.

Alternatively, if the keyword vocabulary itself is locally defined, the *scheme* attribute will point to the local definition, which will typically be held in a **<taxonomy>** element within the **<classDecl>** part of the encoding description (see section 2.3.7. *The Classification Declaration*).

The **<classCode>** element also categorizes an individual text, by supplying a numerical or other code rather than descriptive terms. Such codes constitute a recognized classification scheme, such as the Dewey Decimal Classification. On this element, the *scheme* attribute is required; it indicates the source of the classification scheme

in the same way as for keywords: this may be a pointer of any kind, either to a TEI element, possibly in the current document, as in the <keywords> examples above, or to some canonical source for the scheme, as in the following example:

```
<classCode scheme="http://www.udcc.org/udcsummary/php/index.php">005.756</classCode>
```

The <catRef> element categorizes an individual text by pointing to one or more <category> elements using the *target* attribute, which it inherits from the `att.pointing` class. The <category> element (which is fully described in section 2.3.7. *The Classification Declaration*) holds information about a particular classification or category within a given taxonomy. Each such category must have a unique identifier, which may be supplied as the value of the *target* attribute for <catRef> elements which are regarded as falling within the category indicated.

A text may, of course, fall into more than one category, in which case more than one identifier may be supplied as the value for the *target* attribute on the <catRef> element, as in the following example:

```
<catRef target="#b.a4 #b.d2"/>
```

The *scheme* attribute may be supplied to specify the taxonomy to which the categories identified by the *target* attribute belong, if this is not adequately conveyed by the resource pointed to. For example,

```
<catRef target="#b.a4 #b.d2"
  scheme="http://www.example.com/browncorpus"/>
<catRef target="http://www.example.com/SUC/#A45"/>
```

Here the same text has been classified as of categories b.a4 and b.d2 within the Brown classification scheme (presumed to be available from <http://www.example.com/browncorpus>), and as of category 'A45' within the SUC classification scheme documented at the URL given.

In general, it is a matter of style whether to use a single <catRef> with multiple identifiers in the value of *target* or multiple <catRef> elements, each with a single identifier in the value of *target*. However, note that maintenance of a TEI document with a large number of values within a single *target* can be cumbersome.

The distinction between the <catRef> and <classCode> elements is that the values used as identifying codes are exhaustively enumerated for the former, typically within the TEI header. In the latter case, however, the values use any externally-defined scheme, and therefore may be taken from a more open-ended descriptive classification system.

### 2.4.4 Abstracts

The main purpose of the <abstract> element is to supply a brief resume or abstract for an article which was originally published without such a component. An abstract or summary forming part of the document at its creation should usually appear in the front matter (<front>) of the document.

```
<profileDesc>
  <abstract>
    <p>This paper is a draft studying
      various aspects of using the TEI
      as a reference serialization framework
      for LMF. Comments are welcome to bring
      this to a useful document for the
      community.
    </p>
  </abstract>
</profileDesc>
```

Abstracts may be provided in multiple languages, distinguished by the *xml:lang* attribute:

```
<profileDesc>
  <abstract xml:lang="en">
    <p>The recent archaeological emphasis
      on the study of settlement patterns,
      landscape and palaeoenvironments has
      shaped and re-shaped our understanding
      of the Viking settlement of Iceland.
      This paper reviews the developments
      in Icelandic archaeology, examining
      both theoretical and practical advances.
      Particular attention is paid to new
      ideas in terms of settlement patterns
      and resource exploitation. Finally,
      some of the key studies of the ecological
      consequences of the Norse
    <foreign xml:lang="is">landnám</foreign>
      are presented. </p>
  </abstract>
  <abstract xml:lang="fr">
    <p>L'accent récent des
      recherches archéologiques sur l'étude des
      configurations spatiales des colonies, de la
      géographie des sites ainsi que des éléments
      paléo-environnementaux nous mène à réexaminer
      et réévaluer nos connaissances acquises sur
      la colonisation de l'Islande par les Vikings.
      Cet article passe en revue le développement
      de l'archéologie islandaise en examinant les
      progrès théoriques et pratiques en la matière.
      Une attention particulière est portée sur
      l'étude des configurations spatiales des
      colonies ainsi qu'une considération des
      questions d'exploitation des ressources.
      Finalement, l'article présente un aperçu des
      études principales qui traitent des
      conséquences écologiques du
    <foreign xml:lang="is">landnám</foreign>
      islandais.</p>
  </abstract>
</profileDesc>
```

The same element may be used to provide other summary information supplied by the encoder, perhaps grouped together into a list of discrete items:

```
<profileDesc>
  <abstract>
    <list>
      <item>An annual HBC supply ship is
        set to the North West Coast for mid-September.</item>
      <item>
        <name key="pelly_jh">Pelly</name> writes
        to ascertain the British Government's plans
        for the lands associated with the Oregon Treaty;
        he wants to know what will happen to the HBC's
```

```

    establishment on the southern <name type="place"
    key="vancouver_island">Vancouver Island</name>.
    He adds that a former Crown grant, an 1838 exclusive
    trade-grant for the lands in question, has yet to
    expire.</item>
<item>The minutes discuss the nature of the HBC's
    original entitlements and question whether or not,
    and in what capacity, the Oregon Treaty affects the
    HBC's position. The majority council further
    investigation, and to reply cautiously and
    judiciously to the HBC inquiry.</item>
<item>A
    summary of a meeting with <name key="pelly_jh">Pelly</name> is offered in
    order to elucidate the HBC's intentions.</item>
<item>
    <name key="grey_hg">Lord Grey</name> calls
    for greater consideration on the issue of
    colonization; he asks that <name key="stephen_j">Stephen</name> write the
    Company,
    asking them to detail their intentions, and to
    state their legal opinion for entitlement.
    </item>
</list>
</abstract>
</profileDesc>

```

### 2.4.5 Calendar Description

The `<calendarDesc>` element is used within the `<profileDesc>` element to document objects referenced by means of either the *calendar* attribute on `<date>` or the *datingMethod* attribute on any member of the `att.dataable` class.

**<calendarDesc>** (calendar description) contains a description of the calendar system used in any dating expression found in the text.

This element may contain one or more `<calendar>` elements:

**<calendar>** describes a calendar or dating system used in a dating formula in the text.

Each such element contains one or more paragraphs of description for the calendar system concerned, and also supplies an identifying code for it as the value of its *xml:id* attribute.

```

<calendarDesc>
  <calendar xml:id="Gregorian">
    <p>Gregorian calendar</p>
  </calendar>
  <calendar xml:id="Stardate">
    <p>Fictional Stardate (from Star Trek series)</p>
  </calendar>
  <calendar xml:id="BP">
    <p>Calendar years before present (measured from 1950)</p>
  </calendar>
</calendarDesc>

```

This identifying code may then be referenced from any element supplying a date expressed using that calendar system:

```

<p>Captain's log <date calendar="#Stardate">stardate 23.9 rounded off
  to the nearest decimal point</date>...</p>

```

See 13.3.6.4. *Using Non-Gregorian Calendars* for details of the usage of dating attributes in conjunction with <calendar> elements in the <teiHeader>.

### 2.4.6 Correspondence Description

The <correspDesc> element is used within the <profileDesc> element to provide detailed correspondence-specific metadata, concerning in particular the communicative aspects (sending, receiving, forwarding etc.) associated with acts of correspondence.

This information is complementary to the detailed descriptions of physical objects (such as letters) associated with correspondence activities, which are typically provided by the sourceDesc element.

**<correspDesc>** (correspondence description) contains a description of the actions related to one act of correspondence.

The <correspDesc> element contains the elements <correspAction> and <correspContext>, describing the actions identified and the context in which the correspondence occurs respectively.

**<correspAction>** contains a structured description of the place, the name of a person/organization and the date related to the sending/receiving of a message or any other action related to the correspondence  
@type describes the nature of the action.

**<correspContext>** (correspondence context) provides references to preceding or following correspondence related to this piece of correspondence.

Acts of correspondence typically do not occur in isolation from each other. The <correspContext> element is used to group references relevant to the item of correspondence being described, typically to other items such as the item to which it is a reply, or the item which replies to it:

```
<correspContext>
  <ref type="replyTo" target="#CLF0102">Previous letter of <persName>Chamisso</persName>
  to <persName>de La
    Foye</persName>: <date when="1807-01-16">16 January 1807</date>
  </ref>
  <ref type="replyFrom" target="#CLF0104">Next letter of <persName>Chamisso</persName>
  to <persName>de La Foye</persName>:
  <date when="1810-05-07">07 May 1810</date>
  </ref>
</correspContext>
```

Many types of correspondence action may be distinguished. The type attribute should be used to indicate the type of action being documented, using values such as those suggested above.

The following simple example uses <correspAction> to describe the sending of a letter by Adelbert von Chamisso from Vertus on 29 January 1807 to Louis de La Foye at Caen. The date of reception is unknown:

```
<correspAction type="sentBy">
  <persName>Adelbert von Chamisso</persName>
  <placeName>Vertus</placeName>
  <date when="1807-01-29"/>
</correspAction>
<correspAction type="deliveredTo">
  <persName>Louis de La Foye</persName>
  <placeName>Caen</placeName>
  <date>unknown</date>
</correspAction>
```

Note the use of the when attribute described in 3.5.4. *Dates and Times* to provide a normalized form of the date. The content of the <date> element may be omitted, since no underlying source is being transcribed.

Several senders, recipients, etc. can be specified for a single <correspAction> if the action is considered to apply to them all acting as a single group. In the following example two people are considered to have received the communication.

```
<correspAction type="receiving">
  <persName>Hermann Hesse</persName>
  <persName>Ninon Hesse</persName>
  <placeName>Montagnola</placeName>
</correspAction>
```

The *subtype* attribute may be used to further distinguish types of action. In the following example, an e-mail is sent to two people directly and to a third by ‘carbon copy’ (cc).

```
<correspAction type="sentBy">
  <persName>PN0001</persName>
  <date when="1999-06-02"/>
</correspAction>
<correspAction type="deliveredTo"
  subtype="to">
  <persName>PN0002</persName>
</correspAction>
<correspAction type="deliveredTo"
  subtype="to">
  <persName>PN0003</persName>
</correspAction>
<correspAction type="deliveredTo"
  subtype="cc">
  <persName>PN0004</persName>
</correspAction>
```

The same person may be associated with many actions. For example, it will often be the case that the author and sender of a message are identical, and that many individual letters will need to be associated with the same person. The *sameAs* attribute defined in section 16.6. *Identical Elements and Virtual Copies* may be used to indicate that the same name applies to many actions. Its value will usually be the identifier of an element defining the person or name concerned, which is supplied elsewhere in the document.

```
<correspAction type="sentBy">
  <name sameAs="#author"/>
</correspAction>
```

It is assumed that each correspondence action applies to a single act of communication. It may however be the case that the same physical object is involved in several such acts, if for example person A sends a letter to person B, who then annotates it and sends it on to person C, or if persons A and B both use the same document to convey quite different messages. In such situations, multiple `<correspDesc>` elements should be supplied, one for each communication. In the following example, the same document contains distinct messages, sent by two different people to the same destination: `<correspDesc>` is used for each separately:

```
<correspDesc xml:id="message1">
  <correspAction type="sentBy">
    <persName>John Gneisenau Neihardt</persName>
    <placeName>Branson (Montgomery)</placeName>
    <date when="1932-12-17"/>
  </correspAction>
  <correspAction type="deliveredTo">
    <persName xml:id="JTH">Julius Temple House</persName>
    <placeName>New York</placeName>
```

```

    </correspAction>
  </correspDesc>
  <correspDesc xml:id="message2">
    <correspAction type="sentBy">
      <persName>Enid Neihardt</persName>
      <placeName>Branson (Montgomery)</placeName>
      <date when="1932-12-17"/>
    </correspAction>
    <correspAction type="deliveredTo">
      <persName sameAs="#JTH"/>
      <placeName>New York</placeName>
    </correspAction>
  </correspDesc>

```

## 2.5 Non-TEI Metadata

Projects often maintain metadata about their TEI documents in more than one form or system. For example, a project may have a database of bibliographic information on the set of documents they intend to encode. From this database, both a MARC record and a <teiHeader> are generated. The document is then encoded, during which process additional information is added to the <teiHeader> manually. Then, when the document is published on the web, a Dublin Core record is generated for discoverability of the resource. It is sometimes advantageous to store some or all of the non-TEI metadata in the TEI file.

Such non-TEI data may be placed anywhere within a TEI file (other than as the root element), as it does not affect TEI conformance. However, it is easier for humans to manage these kinds of data if they are grouped together in a single location. In addition, such grouping makes it easy to avoid accidentally flagging non-TEI data as errors during validation of the file against a TEI schema. The <xenoData> element, which may appear in the TEI Header after the <fileDesc> but before the optional <revisionDesc>, is provided for this purpose.

**<xenoData>** (outside metadata) provides a container element into which metadata in non-TEI formats may be placed.

The <xenoData> element may contain anything except TEI elements. It may contain one or more elements from outside the TEI<sup>43</sup> or data in some non-XML text format.<sup>44</sup>

In the following example, the prefix `rdf` is bound to the namespace `http://www.w3.org/1999/02/22-rdf-syntax-ns#`, the prefix `dc` is bound to the namespace `http://purl.org/dc/elements/1.1/`, and the prefix `cc` is bound to the namespace `http://web.resource.org/cc/`.

```

<xenoData
  xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#"
  xmlns:cc="http://web.resource.org/cc/"
  xmlns:dc="http://purl.org/dc/elements/1.1/">
  <rdf:RDF>
    <cc:Work rdf:about="">
      <dc:title>Applied Software Project Management - review</dc:title>
      <dc:type rdf:resource="http://purl.org/dc/dcmitype/Text"/>
      <dc:license rdf:resource="http://creativecommons.org/licenses/by-sa/2.0/uk/">
    </cc:Work>
    <cc:License rdf:about="http://creativecommons.org/licenses/by-sa/2.0/uk/">
      <cc:permits rdf:resource="http://web.resource.org/cc/Reproduction"/>
      <cc:permits rdf:resource="http://web.resource.org/cc/Distribution"/>
      <cc:requires rdf:resource="http://web.resource.org/cc/Notice"/>

```

<sup>43</sup>As is always the case when mixing elements from different namespaces in an XML document, the namespace of these non-TEI elements must be declared either on the elements themselves or on an ancestor element.

<sup>44</sup>As is always the case when using text inside an XML document, certain characters cannot occur in their normal form, and must be 'escaped'. The most common of these are LESS-THAN SIGN ('<', U+003C) and AMPERSAND ('&', U+0026), which may be escaped with `&lt;` and `&amp;` respectively. See *v.6.1 Character References*.

```

    <cc:requires rdf:resource="http://web.resource.org/cc/Attribution"/>
    <cc:permits rdf:resource="http://web.resource.org/cc/DerivativeWorks"/>
    <cc:requires rdf:resource="http://web.resource.org/cc/ShareAlike"/>
  </cc:License>
</rdf:RDF>
</xenoData>

```

## 2.6 The Revision Description

The final sub-element of the TEI header, the `<revisionDesc>` element, provides a detailed change log in which each change made to a text may be recorded. Its use is optional but highly recommended. It provides essential information for the administration of large numbers of files which are being updated, corrected, or otherwise modified as well as extremely useful documentation for files being passed from researcher to researcher or system to system. Without change logs, it is easy to confuse different versions of a file, or to remain unaware of small but important changes made in the file by some earlier link in the chain of distribution. No significant change should be made in any TEI-conformant file without corresponding entries being made in the change log.

**<revisionDesc>** (revision description) summarizes the revision history for a file.

**<listChange>** groups a number of change descriptions associated with either the creation of a source text or the revision of an encoded text.

**<change>** documents a change or set of changes made during the production of a source document, or during the revision of an electronic file.

The main purpose of the revision description is to record changes in the text to which a header is prefixed. However, it is recommended TEI practice to include entries also for significant changes in the header itself (other than the revision description itself, of course). At the very least, an entry should be supplied indicating the date of creation of the header.

The log consists of a list of entries, one for each change. Changes may be grouped and organised using either the `<listChange>` element described in section 11.7. *Identifying Changes and Revisions* or the simple `<list>` element described in section 3.7. *Lists*. Alternatively, a simple sequence of `<change>` elements may be given. The attributes *when* and *who* may be supplied for each `<change>` element to indicate its date and the person responsible for it respectively. The description of the change itself can range from a simple phrase to a series of paragraphs. If a number is to be associated with one or more changes (for example, a revision number), the global *n* attribute may be used to indicate it.

It is recommended to give changes in reverse chronological order, most recent first.

For example:

```

<!-- ... --><revisionDesc>
  <change n="RCS:1.39" when="2007-08-08"
    who="#jwernimo.lrv">Changed <val>drama.verse</val>
    <gi>lg</gi>s to <gi>p</gi>s. <note>we have opened a discussion about the need for a
new
    value for <att>type</att> of <gi>lg</gi>, <val>drama.free.verse</val>, in order
to address
    the verse of Behn which is not in regular iambic pentameter. For the time being
these
    instances are marked with a comment note until we are able to fully consider the
best way
    to encode these instances.</note>
  </change>
  <change n="RCS:1.33" when="2007-06-28"
    who="#pcaton.xzc">Added <att>key</att> and <att>reg</att>
    to <gi>name</gi>s.</change>
  <change n="RCS:1.31" when="2006-12-04"

```

```

  who="#wgui.ner">Completed renovation. Validated.</change>
</revisionDesc>

```

In the above example, the *who* attributes point to `<respStmt>` elements which have been included earlier in the `<titleStmt>` of the same header:

```

<titleStmt>
  <title>The Amorous Prince, or, the Curious Husband, 1671</title>
  <author>
    <persName ref="#abehn.aeh">Behn, Aphra</persName>
  </author>
  <respStmt xml:id="pcaton.xzc">
    <persName>Caton, Paul</persName>
    <resp>electronic publication editor</resp>
  </respStmt>
  <respStmt xml:id="wgui.ner">
    <persName>Gui, Weihsin</persName>
    <resp>encoder</resp>
  </respStmt>
  <respStmt xml:id="jwernimo.lrv">
    <persName>Wernimont, Jacqueline</persName>
    <resp>encoder</resp>
  </respStmt>
</titleStmt>

```

There is however no requirement that the `<respStmt>` be used for this person, or that the elements indicated be contained within the same document. A project might for example maintain a separate document listing all of its personnel in which they were represented using the `<person>` element described in 15.2.2. *The Participant Description*.

## 2.7 Minimal and Recommended Headers

The TEI header allows for the provision of a very large amount of information concerning the text itself, its source, its encodings, and revisions of it, as well as a wealth of descriptive information such as the languages it uses and the situation(s) in which it was produced, together with the setting and identity of participants within it. This diversity and richness reflects the diversity of uses to which it is envisaged that electronic texts conforming to these Guidelines will be put. It is emphatically *not* intended that all of the elements described above should be present in every TEI Header.

The amount of encoding in a header will depend both on the nature and the intended use of the text. At one extreme, an encoder may expect that the header will be needed only to provide a bibliographic identification of the text adequate to local needs. At the other, wishing to ensure that their texts can be used for the widest range of applications, encoders will want to document as explicitly as possible both bibliographic and descriptive information, in such a way that no prior or ancillary knowledge about the text is needed in order to process it. The header in such a case will be very full, approximating to the kind of documentation often supplied in the form of a manual. Most texts will lie somewhere between these extremes; textual corpora in particular will tend more to the latter extreme. In the remainder of this section we demonstrate first the minimal, and next a commonly recommended, level of encoding for the bibliographic information held by the TEI header.

Supplying only the minimal level of encoding required, the TEI header of a single text might look like the following example:

```

<teiHeader>
  <fileDesc>
    <titleStmt>
      <title>Thomas Paine: Common sense, a

```

```

        machine-readable transcript</title>
    <respStmt>
        <resp>compiled by</resp>
        <name>Jon K Adams</name>
    </respStmt>
</titleStmt>
<publicationStmt>
    <istributor>Oxford Text Archive</istributor>
</publicationStmt>
<sourceDesc>
    <bibl>The complete writings of Thomas Paine, collected and edited
        by Phillip S. Foner (New York, Citadel Press, 1945)</bibl>
</sourceDesc>
</fileDesc>
</teiHeader>

```

The only mandatory component of the TEI header is the <fileDesc> element. Within this, <titleStmt>, <publicationStmt>, and <sourceDesc> are all required constituents. Within the title statement, a title is required, and an author should be specified, even if it is *unknown*, as should some additional statement of responsibility, here given by the <respStmt> element. Within the <publicationStmt>, a publisher, distributor, or other agency responsible for the file must be specified. Finally, the source description should contain at the least a loosely structured bibliographic citation identifying the source of the electronic text if (as is usually the case) there is one.

We now present the same example header, expanded to include additionally recommended information, adequate to most bibliographic purposes, in particular to allow for the creation of an AACR2-conformant bibliographic record. We have also added information about the encoding principles used in this (imaginary) encoding, about the text itself (in the form of Library of Congress subject headings), and about the revision of the file.

```

<teiHeader>
  <fileDesc>
    <titleStmt>
      <title>Common sense, a machine-readable transcript</title>
      <author>Paine, Thomas (1737-1809)</author>
      <respStmt>
        <resp>compiled by</resp>
        <name>Jon K Adams</name>

Many other examples of recommended usage for the elements discussed in this chapter are provided here, in the reference index and in the associated tutorials.

## 2.8 Note for Library Cataloguers

A strong motivation in preparing the material in this chapter was to provide in the TEI header a viable chief source of information for cataloguing computer files. The TEI header is not a library catalogue record, and so will not make all of the distinctions essential in standard library work. It also includes much information generally excluded from standard bibliographic descriptions. It is the intention of the developers, however, to ensure that the information required for a catalogue record be retrievable from the TEI file header, and moreover that the mapping from the one to the other be as simple and straightforward as possible. Where the correspondence is not obvious, it may prove useful to consult one of the works which were influential in developing the content of the TEI header. These include:

*ISBD: International Standard Bibliographic Description* is an international standard setting out what information should be recorded in a description of a bibliographical item. Until a consolidated edition published in 2011, there was a general standard called ISBD(G) and separate ISBDs covering different types of material,

e.g. ISBD(M) for monographs, ISBD(ER) for electronic resources. These separate ISBDs follow the same general scheme as the main ISBD(G), but provide appropriate interpretations for the specific materials under consideration.

The *Anglo-American Cataloguing Rules (second edition)* were published in 1978, with revisions appearing periodically through 2005. AACR2 provides guidelines for the construction of catalogues in general libraries in the English-speaking world. AACR2 is explicitly based on the general framework of the ISBD(G) and the subsidiary ISBDs: it gives a description of how to describe bibliographic items and how to create access points such as subject or name headings and uniform titles. Other national cataloguing codes exist as well, including the Z44 series of standards from issued by the Association française de normalisation (AFNOR), *Regeln für die alphabetische Katalogisierung in wissenschaftlichen Bibliotheken* (RAK-WB), *Regole italiane di catalogazione per autore* (RICA), and *Система стандартов по информации, библиотечному и издательскому делу. Библиографическая запись. Библиографическое описание. Общие требования и правила составления* (ГОСТ 7.1).

The *American National Standard for Bibliographic References* was an American national standard governing bibliographic references for use in bibliographies, end-of-work lists, references in abstracting and indexing publications, and outputs from computerized bibliographic data bases. A revised version is maintained by the National Information Standards Organization (NISO). The related ISO standard is ISO 690. Other relevant national standards include BS 5605:1990, BS 6371:1983. DIN 1505-2, and ГОСТ 7.0.5.

Since the TEI file description elements are based on the ISBD areas, it should be possible to use the content of file description as the basis for a catalog record for a TEI document. However, cataloguers should be aware that the permissive nature of the TEI Guidelines may lead to divergences between practice in using the TEI file description and the comparatively strict recommendations of AACR2 and other national cataloguing codes. Such divergences as the following may preclude automatic generation of catalogue records from TEI headers:

- The TEI Guidelines do not require that text be transcribed from the ‘chief source of information’ using normalized capitalization and punctuation .
- The TEI title statement may not categorize constituent titles in the same way as prescribed by a national cataloguing code.
- The TEI title statement contains authors, editors, and other responsible parties in separate elements, with names which may not have been normalized; it does not necessarily contain a single statement of responsibility .
- There is no specific place in a TEI header to specify the *main entry* or *added entries* (*name or title headings under which a catalogue record is filed*) for the catalogue record.
- The TEI header does not require use of a particular vocabulary for subject headings nor require the use of subject headings.

## 2.9 The TEI Header Module

The module described in this chapter makes available the following components:

### Module header: The TEI Header

- *Elements defined:* abstract appInfo application authority availability biblFull cRefPattern calendar calendarDesc catDesc catRef category change classCode classDecl correction correspAction correspContext correspDesc creation distributor edition editionStmt editorialDecl encodingDesc extent fileDesc funder geoDecl handNote hyphenation idno interpretation keywords langUsage language licence listChange listPrefixDef namespace normalization notesStmt prefixDef principal profileDesc projectDesc publicationStmt punctuation quotation refState refsDecl rendition revisionDesc samplingDecl scriptNote segmentation seriesStmt sourceDesc sponsor stdVals styleDefDecl tagUsage tagsDecl taxonomy teiHeader textClass titleStmt typeNote xenoData
- *Classes defined:* att.patternReplacement

The selection and combination of modules to form a TEI schema is described in 1.2. *Defining a TEI Schema*.

### 3 Elements Available in All TEI Documents

This chapter describes elements which may appear in any kind of text and the tags used to mark them in all TEI documents. Most of these elements are freely floating phrases, which can appear at any point within the textual structure, although they must generally be contained by a higher-level element of some kind (such as a paragraph). A few of the elements described in this chapter (for example, bibliographic citations and lists) have a comparatively well-defined internal structure, but most of them have no consistent inner structure of their own. In the general case, they contain only a few words, and are often identifiable in a conventionally printed text by the use of typographic conventions such as shifts of font, use of quotation or other punctuation marks, or other changes in layout.

This chapter begins by describing the <p> tag used to mark paragraphs, the prototypical formal unit for running text in many TEI modules. This is followed, in section 3.2. *Treatment of Punctuation*, by a discussion of some specific problems associated with the interpretation of conventional punctuation, and the methods proposed by these Guidelines for resolving ambiguities therein.

The next section (section 3.3. *Highlighting and Quotation*) describes a number of phrase-level elements commonly marked by typographic features (and thus well-represented in conventional markup languages). These include features commonly marked by font shifts (section 3.3.2. *Emphasis, Foreign Words, and Unusual Language*) and features commonly marked by quotation marks (section 3.3.3. *Quotation*) as well as such features as terms, cited words, and glosses (section 3.3.4. *Terms, Glosses, Equivalents, and Descriptions*).

Section 3.4. *Simple Editorial Changes* introduces some phrase-level elements which may be used to record simple editorial interventions, such as emendation or correction of the encoded text. The elements described here constitute a simple subset of the full mechanisms for encoding such information (described in full in chapter 11. *Representation of Primary Sources*), which should be adequate to most commonly encountered situations.

The next section (section 3.5. *Names, Numbers, Dates, Abbreviations, and Addresses*) describes several phrase-level and inter-level elements which, although often of interest for analysis or processing, are rarely explicitly identified in conventional printing. These include names (section 3.5.1. *Referring Strings*), numbers and measures (section 3.5.3. *Numbers and Measures*), dates and times (section 3.5.4. *Dates and Times*), abbreviations (section 3.5.5. *Abbreviations and Their Expansions*), and addresses (section 3.5.2. *Addresses*).

In the same way, the following section (section 3.6. *Simple Links and Cross-References*) presents only a subset of the facilities available for the encoding of cross-references or text-linkage. The full story may be found in chapter 16. *Linking, Segmentation, and Alignment*; the tags presented here are intended to be usable for a wide variety of simple applications.

Sections 3.7. *Lists*, and 3.8. *Notes, Annotation, and Indexing*, describe two kinds of quasi-structural elements: lists and notes. These may appear either within chunk-level elements such as paragraphs, or between them. Several kinds of lists are catered for, of an arbitrary complexity. The section on notes discusses both notes found in the source and simple mechanisms for adding annotations of an interpretive nature during the encoding; again, only a subset of the facilities described in full elsewhere (specifically, in chapter 17. *Simple Analytic Mechanisms*) is discussed.

Section 3.9. *Graphics and Other Non-textual Components* introduces some simple ways of representing graphic or other non-textual content found in a text. A fuller discussion of the multimedia facilities supported by these Guidelines may be found in chapters 14. *Tables, Formulæ, Graphics and Notated Music* and 16. *Linking, Segmentation, and Alignment*.

Next, section 3.10. *Reference Systems*, describes methods of encoding within a text the conventional system or systems used when making references to the text. Some reference systems have attained canonical authority and must be recorded to make the text useable in normal work; in other cases, a convenient reference system must be created by the creator or analyst of an electronic text.

Like lists and notes, the bibliographic citations discussed in section 3.11. *Bibliographic Citations and References*, may be regarded as structural elements in their own right. A range of possibilities is presented for the encoding of bibliographic citations or references, which may be treated as simple phrases within a running text, or as highly-structured components suitable for inclusion in a bibliographic database.

Additional elements for the encoding of passages of verse or drama (whether prose or verse) are discussed in section 3.12. *Passages of Verse or Drama*.

The chapter concludes with a technical overview of the structure and organization of the module described here. This should be read in conjunction with chapter 1. *The TEI Infrastructure*, describing the structure of the TEI document type definition.

## 3.1 Paragraphs

The paragraph is the fundamental organizational unit for all prose texts, being the smallest regular unit into which prose can be divided. Prose can appear in all TEI texts, even those that are primarily of another genre (e.g., verse); thus the paragraph is described here, as an element which can appear in any kind of text.

Paragraphs can contain any of the other elements described within this chapter, as well as some other elements which are specific to individual text types. We distinguish *phrase-level* elements, which must be entirely contained within a paragraph and cannot appear except within one, from *chunks*, which can appear between, but not within, paragraphs, and from *inter-level* elements, which can appear either within a single paragraph or between paragraphs. The class of phrases includes emphasized or quoted phrases, names, dates, etc. The class of inter-level elements includes bibliographic citations, notes, lists, etc. The class of chunks includes the paragraph itself, and other elements which have similar structural properties, notably the `<ab>` (anonymous block) element described in 16.3. *Blocks, Segments, and Anchors*) which may be used as an alternative to the paragraph in some kinds of texts.

Because paragraphs may appear in different base or additional tag sets, their possible contents may differ in different kinds of documents. In particular, additional elements not listed in this chapter may appear in paragraphs in certain kinds of text. However, the elements described in this chapter are always by default available in all kinds of text.

The paragraph is marked using the `<p>` element:

**<p>** (paragraph) marks paragraphs in prose.

If a consistent internal subdivision of paragraphs is desired, the `<s>` or `<seg>` ('segment') elements may be used, as discussed in chapters 16. *Linking, Segmentation, and Alignment* and 17. *Simple Analytic Mechanisms* respectively. More usually, however, paragraphs have no firm internal structure, but contain prose encoded as a mix of characters, entity references, phrases marked as described in the rest of this chapter, and embedded elements like lists, figures, or tables.

Since paragraphs are usually explicitly marked in Western texts, typically by indentation, the application of the `<p>` tag usually presents few problems.

In some cases, the body of a text may comprise but a single paragraph:

```
<body>
  <p>I fully appreciate Gen. Pope's splendid achievements with their
    invaluable results; but you must know that Major Generalships in the
    Regular Army, are not as plenty as blackberries.</p>
</body>
```

This news story shows typically short journalistic paragraphs:

```
<head>SARAJEVO, Bosnia and Herzegovina, April 19</head>
<p>Serbs seized more territory in this struggling new country today as
the United States Air Force ended a two-day airlift of humanitarian
aid into the capital, Sarajevo.</p>
<p>International relief workers called on European Community nations
to step up their humanitarian aid to the former Yugoslav republic,
in conjunction with new American aid flights if necessary.</p>
<p>A special envoy from the European Community, Colin Doyle, harshly
condemned the decision by Serbs to shell Sarajevo on Saturday night
during a visit to the Bosnian capital by a senior American official,
Deputy Assistant Secretary of State Ralph R. Johnson.</p>
<p>...</p>
```

The following extract from a Russian fairy tale demonstrates how other phrase level elements (in this case `<q>` elements representing direct speech; see section 3.3.3. *Quotation*) may be nested within, but not across, paragraphs:

```

<p>A fly built a castle, a tall and mighty castle.
There came to the castle the Crawling Louse. <q>Who,
  who's in the castle? Who, who's in your house?</q>
said the Crawling Louse. <q>I, I, the Languishing Fly.
  And who art thou?</q>
  <q>I'm the Crawling Louse.</q>
</p>
<p>Then came to the castle the Leaping Flea. <q>Who,
  who's in the castle?</q> said the Leaping Flea. <q>I,
  I, the Languishing Fly, and I, the Crawling Louse. And
  who art thou?</q>
  <q>I'm the Leaping Flea.</q>
</p>
<p>Then came to the castle the Mischievous Mosquito.
<q>Who, who's in the castle?</q> said the Mischievous
Mosquito. <q>I, I, the Languishing Fly, and I, the
  Crawling Louse, and I, the Leaping Flea. And who art
  thou?</q>
  <q>I'm the Mischievous Mosquito.</q>
</p>

```

## 3.2 Treatment of Punctuation

Punctuation marks cause two distinct classes of problem for text markup: the marks may not be available in the character set used, and they may be significantly ambiguous. To some extent, the availability of the Unicode character set addresses the first of these problems, since it provides specific code points for most punctuation marks, and also the second to the extent that it distinguishes glyphs (such as stop, comma, and hyphen) which are used with different functions. Where punctuation itself is the subject of study, the element `<pc>` (punctuation character) may be used to mark it explicitly, as further discussed in *17.1.2. Below the Word Level*. Where the character used for a punctuation mark is not available in Unicode, the `<g>` element and other facilities described in chapter 5. *Characters, Glyphs, and Writing Modes* may also be used to mark its presence.

### 3.2.1 Functions of Punctuation

Punctuation is itself a form of markup, historically introduced to provide the reader with an indication about how the text should be read. As such, it is unsurprising that encoders will often wish to encode directly the purpose for which punctuation was provided, as well as, or even instead of, the punctuation itself. We discuss some typical cases below.

The *Full stop (period)* may mark (orthographic) sentence boundaries, abbreviations, decimal points, or serve as a visual aid in printing numbers. These usages can be distinguished by tagging S-units, abbreviations, and numbers, as described in sections *16.3. Blocks, Segments, and Anchors*, *3.5.5. Abbreviations and Their Expansions*, and *3.5.3. Numbers and Measures* respectively. However, there are independent reasons for tagging these, whether or not they are marked by full stops, and the polysemy of the full stop itself is perhaps no different from that of any other character in the writing system.

The *Question mark* and *exclamation mark* usually mark the end of orthographic sentences, but may also be used as a mid-sentence comment by the author (! to express surprise or some other strong feeling, ? to query a word or expression or mark a sentence as dubious in linguistic discussion). Such usages may be distinguished by marking S-units, in which case the mid-sentence uses of these punctuation marks may be left unmarked, or tagged using the `<pc>` element discussed in *17.1. Linguistic Segment Categories*.

*Dashes* are used for a variety of purposes: as a mark of omission, insertion, or interruption; to show where a new speaker takes over (in dialogue); or to introduce a list item. In the latter two cases particularly, it is clearly desirable to mark the function as well as its rendition using the elements `<q>` or `<item>`, on which see section *3.3.3. Quotation*, and section *3.7. Lists*, respectively.

*Quotation marks* may be removed from text contained by `<q>` or `<quote>` elements on editorial grounds, or they may be marked in a variety of ways; see the discussion of quotation and related features in section *3.3.3. Quotation*.

*Apostrophes* must be distinguished from single quote marks. As with hyphens, this disambiguation is best performed by selecting the appropriate Unicode character, though it may also be represented by using appropriate XML markup for quotations as suggested above. However, apostrophes have a variety of uses. In English they mark contractions, genitive forms, and (occasionally) plural forms. Full disambiguation of these uses belongs to the level of linguistic analysis and interpretation.

*Parentheses* and other marks of suspension such as dashes or ellipses are often used to signal information about the syntactic structure of a text fragment. Full disambiguation of their uses also belongs to the level of linguistic analysis and interpretation, and will therefore need to use the mechanisms discussed in chapter 17. *Simple Analytic Mechanisms*.

Where punctuation marks are disambiguated by tagging their assumed function in the text (for example, quotation), it may be debated whether they should be excluded or left as part of the text. In the case of quotation marks, it may be more convenient to distinguish opening from closing marks simply by using the appropriate Unicode character than to use the <q> element, with or without an indication of rendition.

Where segmentation of a text is performed automatically, the accuracy of the result may be considerably enhanced by a first pass in which the function of different punctuation characters is explicitly marked. This need not be done for all cases, but only where the structural function of the punctuation markup (for example as a word or phrase delimiter) is ambiguous. Thus, dots indicating abbreviation might be distinguished from dots indicating sentence end, and exclamation or question marks internal to a sentence distinguished from those which terminate one. Furthermore, when encoding historical materials, it may be considered essential to retain the original punctuation, whether by using an appropriate character code, if this is available (or using the <g> element where it is not) or by an explicit encoding using <pc>. The particular method adopted will vary depending upon the feature concerned and upon the purpose of the project.

### 3.2.2 Hyphenation

Hyphenation as a phenomenon is generally of most concern when producing formatted text for display in print or on screen: different languages and systems have developed quite sophisticated sets of rules about where hyphens may be introduced and for what reason. These generally do not concern the text encoder, since they belong to the domain of formatting and will generally be handled by the rendition software in use. In this section, we discuss issues arising from the appearance of hyphens in pre-existing formatted texts which are being re-encoded for analysis or other processing. Unicode distinguishes four characters visually similar to the hyphen, including the undifferentiated hyphen-minus (U+002D) which is retained for compatibility reasons. The hard hyphen (U+2010) is distinguished from the minus sign (U+2212) which is for use in mathematical expressions, and also from the soft hyphen (U+00AD) which may appear in 'born digital' documents to indicate places where it is acceptable to insert a hyphen when the document is formatted.

Historically, the hard hyphen has been used in printed or manuscript documents for two distinct purposes. In many languages, it is used between words to show that they function as a single syntactic or lexical unit. For example, in French, *est-ce que*; in English *body-snatcher*, *tea-party* etc. It may also have an important role in disambiguation (for example, by distinguishing say a *man-eating fish* from a *man eating fish*). Such usages, although possibly problematic when a linguistic analysis is undertaken, are not generally of concern to text encoders: the hyphen character is usually retained in the text, because it may be regarded as part of the way a compound or other lexical item is spelled. Deciding whether a compound is to be decomposed into its constituent parts, and if so how, is a different question, involving consideration of many other phenomena in addition to the simple presence of a hyphen.

When it appears at the end of a printed or written line however, the hard hyphen generally indicates that—contrary to what might be expected—a word is not yet complete, but continues on the next line (or over the next page or column or other boundary). The hyphen character is not, in this case, part of the word, but just a signal that the word continues over the break. Unfortunately, few languages distinguish these two cases visually, which necessarily poses a problem for text encoders. Suppose, for example, that we wish to investigate a diachronic English corpus for occurrences of "tea-pot" and "teapot", to find evidence for the point at which this compound becomes lexicalized. Any case where the word is hyphenated across a linebreak, like this:

```
tea-
pot
```

is entirely ambiguous: there is simply no way of deciding which of the two spellings was intended.

As elsewhere, therefore, the encoder has a range of choices:

- They may decide simply to remove any end-of-line hyphenation from the encoded text, on the grounds that its presence is purely a secondary matter of formatting. This will obviously apply also if line endings are themselves regarded as unimportant.
- Alternatively, they may decide to record the presence of the hyphen, perhaps on the grounds that it provides useful morphological information; perhaps in order to retain information about the visual appearance of the original source. In either case, they need to decide whether to record it explicitly, by including an appropriate punctuation character in the text data, or implicitly by supplying an appropriate symbolic value for one or more of the attributes on the <lb> or other milestone element used to record the fact of the line division. If the hyphen is included in the character data of the TEI document, it might be marked up using the <pc> (punctuation character) tag, which allows the encoder to express information about its function as a separator, through the *force* attribute (see 17.1.2. *Below the Word Level*).

A similar range of possibilities applies equally to the representation of other common punctuation marks, notably quotation marks, as discussed in 3.3.3. *Quotation*.

The ‘text data’ of which XML documents are composed is decomposable into smaller units, here called *orthographic tokens*, even if those units are not explicitly indicated by the XML markup. The ambiguity of the end-of-line hyphen also causes problems in the way a processor identifies such tokens in the absence of explicit markup. If token boundaries are not explicitly marked (for example using the <seg> or <w> elements), for most languages a processor will rely on character class information to determine where they are to be found: some punctuation characters are considered to be word-breaking, while others are not. In XML, the newline character in text data is a kind of whitespace, and is therefore word breaking. However, it is generally unsafe to assume that whitespace adjacent to markup tags will always be preserved, and it is decidedly unsafe to assume that markup tags themselves are equivalent to whitespace.

The <lb>, <pb>, and <cb> elements are notable exceptions to this general rule, since their function is precisely to represent (or replace) line, page, or column breaks, which, as noted above, are generally considered to be equivalent to whitespace. These elements provide a more reliable way of preserving the lineation, pagination, etc of a source document, since the encoder should not assume that (untagged) line breaks etc. in an XML source file will necessarily be preserved.

To control the intended tokenization, the encoder may use the *break* attribute on such elements to indicate whether or not the element is to be regarded as equivalent to whitespace. This attribute can take the values *yes* or *no* to indicate whether or not the element corresponds with a token boundary. The value *maybe* is also available, for cases where the encoder does not wish (or is unable) to determine whether the orthographic token concerned is broken by the line ending.

As a final complication, it should be noted that in some languages, particularly German and Dutch, the spelling of a word may be altered in the presence of end of line hyphenation. For example, in Dutch, the word *opaatje* ( *granddad*), occurring at the end of a line may be hyphenated as *opa-tje*, with a single letter *a*. An encoder wishing to preserve the original form of this orthographic token in a printed text while at the same time facilitating its recognition as the word *opaatje* will therefore need to rely on a more sophisticated process than simply removing the hyphen. This is however essentially the same as any other form of normalization accompanying the recognition of variations in spelling or morphology: as such it may be encoded using the <choice> element discussed in 3.4. *Simple Editorial Changes*, or the more sophisticated mechanisms for linguistic analysis discussed in chapter 17. *Simple Analytic Mechanisms*.

### 3.3 Highlighting and Quotation

This section deals with a variety of textual features, all of which have in common that they are frequently realized in conventional printing practice by the use of such features as underlining, italic fonts, or quotation marks, collectively referred to here as *highlighting*. After an initial discussion of this phenomenon and alternate approaches to encoding it, this section describes ways of encoding the following textual features, all of which are conventionally rendered using some kind of highlighting:

- emphasis, foreign words and other linguistically distinct uses of highlighting
- representation of speech and thought, quotation, etc.
- technical terms, glosses, etc.

### 3.3.1 What Is Highlighting?

By *highlighting* we mean the use of any combination of typographic features (font, size, hue, etc.) in a printed or written text in order to distinguish some passage of a text from its surroundings.<sup>45</sup> The purpose of highlighting is generally to draw the reader's attention to some feature or characteristic of the passage highlighted; this section describes the elements recommended by these Guidelines for the encoding of such textual features.

In conventionally printed modern texts, highlighting is often employed to identify words or phrases which are regarded as being one or more of the following:

- distinct in some way—as foreign, dialectal, archaic, technical, etc.
- emphatic, and which would for example be stressed when spoken
- not part of the body of the text, for example cross-references, titles, headings, labels, etc.
- identified with a distinct narrative stream, for example an internal monologue or commentary.
- attributed by the narrator to some other agency, either within the text or outside it: for example, direct speech or quotation.
- set apart from the text in some other way: for example, proverbial phrases, words mentioned but not used, names of persons and places in older texts, editorial corrections or additions, etc.

The textual functions indicated by highlighting may not be rendered consistently in different parts of a text or in different texts. (For example, a foreign word may appear in italics if the surrounding text is in roman, but in roman if the surrounding text is in italics.) For this reason, these Guidelines distinguish between the encoding of rendering itself and the encoding of the underlying feature expressed by it.

Highlighting as such may be encoded by using one of the global attributes *rend*, *rendition*, or *style* (see further 1.3.1.1. *Global Attributes*). This allows the encoder both to specify the function of a highlighted phrase or word, by selecting the appropriate element described here or elsewhere in these Guidelines, and to further describe the way in which it is highlighted, by means of an attribute. If the encoder wishes to offer no interpretation of the feature underlying the use of highlighting in the source text, then the `<hi>` element may be used, which indicates only that the text so tagged was highlighted in some way.

`<hi>` (highlighted) marks a word or phrase as graphically distinct from the surrounding text, for reasons concerning which no claim is made.

The `<hi>` element is provided by the `model.hiLike` class.

The possible values carried by the *rend* attribute are not formally defined in this version of the Guidelines. It may be used to document any peculiarity of the way a given segment of text was rendered in the original source text, and may thus express a very large range of typographic or other features, by no means restricted to typeface, type size, etc. The *style* attribute, by contrast, defines the way the source text was rendered using a formally defined style language, such as the W3C standard Cascading Stylesheet Language (Lie and Bos (eds.) (1999)). The complementary *rendition* attribute is used to point to one or more fragments expressed using such a language which have been predefined in the TEI header using the `<rendition>` element discussed in section 2.3.4. *The Tagging Declaration*.

Where it is both appropriate and feasible, these Guidelines recommend that the textual feature marked by the highlighting should be encoded, rather than just the simple fact of the highlighting. This is for the following reasons:

- the same kind of highlighting may be used for different purposes in different contexts
- the same textual function may be highlighted in different ways in different contexts
- for analytic purposes, it is in general more useful to know the intended function of a highlighted phrase than simply that it is distinct.

In many, if not most, cases the underlying function of a highlighted phrase will be obvious and non-controversial, since the distinctions indicated by a change of highlighting correspond with distinctions discussed elsewhere in these Guidelines. The elements available to record such distinctions are, for the most part, members of the `model.emphLike` class. This and the `model.hiLike` class mentioned above constitute the

<sup>45</sup>Although the way in which a spoken text is performed, (for example, the voice quality, loudness, etc.) might be regarded as analogous to 'highlighting' in this sense, these Guidelines recommend distinct elements for the encoding of such 'highlighting' in spoken texts. See further section 8.3.6. *Shifts*.

`model.highlighted` class, which is a phrase level class. Members of this class may appear anywhere within paragraph level elements.

The distinction between the two classes is simple, and typified by the two elements `<hi>` and `<emph>`: the former marks simply that a passage is typographically distinct in some way, while the latter asserts that a passage is linguistically emphasized for some purpose. These two properties, though often combined, are not identical. It should however be recognized, however, that cases do exist in which it is not economically feasible to mark the underlying function (e.g. in the preparation of large text corpora), as well as cases in which it is not intellectually appropriate (as in the transcription of some older materials, or in the preparation of material for the study of typographic practice). In such cases, the `<hi>` element or some other element from the `model.hiLike` class should be used.

Elements which are sometimes realized by typographic distinction but which are not discussed in this section include `<title>` (discussed in section 3.11. *Bibliographic Citations and References*) and `<name>` (discussed in section 3.5.1. *Referring Strings*).

### 3.3.2 Emphasis, Foreign Words, and Unusual Language

This subsection discusses the following elements:

**`<foreign>`** identifies a word or phrase as belonging to some language other than that of the surrounding text.

**`<emph>`** (emphasized) marks words or phrases which are stressed or emphasized for linguistic or rhetorical effect.

**`<distinct>`** identifies any word or phrase which is regarded as linguistically distinct, for example as archaic, technical, dialectal, non-preferred, etc., or as forming part of a sublanguage.

These elements are all members of the `model.emphLike` class.

#### 3.3.2.1 Foreign Words or Expressions

Words or phrases which are not in the main language of the text should be tagged as such, at least where the fact is indicated in the text. Where the word or phrase concerned is already distinguished from the rest of the text by virtue of its function (for example, because it is a name, a technical term, a quotation, a mentioned word, etc.) then the global `xml:lang` attribute should be used to specify additionally that its language distinguishes it from the surrounding text. Any element in the TEI scheme may take a `xml:lang` attribute, which specifies both the writing system and the language used by its content (see sections 1.3.1.1.2. *Language Indicators* and vi.1 *Language Identification* for discussion of this attribute and its values respectively). Where there is no other applicable element, the element `<foreign>` may be used to provide a peg onto which the `xml:lang` may be attached.

```
<q>Aren't you confusing <foreign xml:lang="la">post hoc</foreign> with
<foreign xml:lang="la">propter hoc</foreign>?</q> said the Bee Master.
<q>Wax-moth only succeed when
weak bees let them in.</q>
```

The `<foreign>` element should not be used to represent foreign words which are mentioned or glossed within the text: for these use the appropriate element from section 3.3.4. *Terms, Glosses, Equivalents, and Descriptions* below. Compare the following example sentences:

```
John eats a <foreign xml:lang="fr">croissant</foreign> every morning.
```

```
<mentioned xml:lang="fr">Croissant</mentioned> is difficult to
pronounce with your mouth full.
```

```
A <term xml:lang="fr">croissant</term> is a crescent-shaped
piece of light, buttery, pastry that is usually eaten for
breakfast, especially in France.
```

Elements which do not explicitly state the language of their content by means of an *xml:lang* attribute are understood to inherit a value for it from their parent element. In the general case, therefore, it is recommended practice to supply a default value for *xml:lang* on the root <TEI> or <text> element, as further discussed in section 1.3.1.1.2. *Language Indicators*

### 3.3.2.2 Emphatic Words and Phrases

The <emph> element is provided to mark words or phrases which are *linguistically* emphatic or stressed. Text which is only typographically ‘emphasized’ falls into the class of highlighted text, and may be tagged with the <hi> element. In printed works, emphasis is generally indicated by devices such as the use of an italic font, a large typeface, or extra wide letter spacing; in manuscripts and typescripts, it is usually indicated by the use of underlining. As the following examples demonstrate, an encoder may choose whether or not to make explicit the particular type of rendition associated with the emphasis. If a source text consistently renders a particular feature (e.g. emphasis or words in foreign languages) in a particular way, the rendering associated with that feature may be described in the TEI header using the <rendition> element. The *rend*, *rendition*, or *style* attributes may then be used to describe examples which deviate from the norm. For example, assuming that the TEI header has defined a default rendering for the <emph> element, the following encoding would use it:

```
<q>Sex, sir, is <emph>purely</emph> a question
of appetite!</q> Tarr exclaimed.
```

If on the other hand no such default has been defined for the element, the encoder may specify it informally using the *rend* attribute:

```
<q>What it all comes to is this,</q> he said.

<q>
  <emph rend="italic">What does Christopher Robin do in the morning
    nowadays?</emph>
</q>
```

If the encoder wishes to express information about the rendition used in the source using a formal language such as CSS, then the *style* attribute can be used in a similar way:

```
<q>What it all comes to is this,</q> he said.

<q>
  <emph style="font-style: italic">What does Christopher Robin do in
    the morning nowadays?</emph>
</q>
```

In cases where the rendition of a source needs to be indicated several times in a document, it may be more convenient to provide a default value using the <rendition> element in the header. If a small number of distinct values are required, it may also be convenient to define them all by means of a series of <rendition> elements which can then be referenced from the elements in question by means of the global *rendition* attribute:

```
<l>Here Thou, great <name rendition="#italic">Anna</name>!
whom three Realms obey,</l>
<l>Doth sometimes Counsel take –
and sometimes <emph rendition="#italic">Tea</emph>.</l>
<!-- in the header ... -->
<rendition xml:id="italic" scheme="css">font-style: italic</rendition>
```

Further information on the use of the <rendition> element is provided at 2.3.4. *The Tagging Declaration*.

The <hi> element is used to mark words or phrases which are highlighted in some way, but for which identification of the intended distinction is difficult, controversial, or impossible. It enables an encoder simply to record the fact of highlighting, possibly describing it by the use of a *rend*, *style*, or *rendition* attribute, as discussed above, without however taking a position as to the function of the highlighting. This may also be useful if the text is to be processed in two stages: representing simply typographic distinctions during a first pass, and then replacing the <hi> elements with more specific elements in a second pass.

Some simple examples:

```
<hi rend="gothic">And this Indenture further witnesseth</hi>
that the said <hi rend="italic">Walter Shandy</hi>, merchant,
in consideration of the said intended marriage ...
```

In this example, the first highlighted phrase uses black letter or gothic print to mimic the appearance of a legal document, and italic to mark *Walter Shandy* as a name. In a second pass, the elements <head> or <label> might be appropriate for the first use, and the element <name> for the second.

```
The heaviest rain, and snow, and hail, and
sleet, could boast of the advantage over him in only one respect. They
often <hi rend="quoted">came down</hi> handsomely, and Scrooge never
did.
```

In this example, the phrase *came down* uses inverted commas to indicate a play on words.<sup>46</sup> In a second pass, the element <soCalled> might be preferred as a means of indicating that the narrator is distancing himself from this usage.

### 3.3.2.3 Other Linguistically Distinct Material

For some kinds of analysis, it may be desirable to encode the linguistic distinctiveness of words and phrases with more delicacy than is allowed by the <foreign> element. The <distinct> element is provided for this purpose. Its attributes allow for additional information characterizing the nature of the linguistic distinction to be made in two distinct ways: the *type* attribute simply assigns a user-defined code of some kind to the word or phrase which assigns it to some register, sub-language, etc. No recommendations as to the set of values for this attribute are provided at this time, as little consensus exists in the field.

Alternatively, the remaining three attributes may be used in combination to place a word or phrase on a three-dimensional scale sometimes used in descriptive linguistics, as for example in Mattheier et al, 1988. The *time* attribute places a word or phrase *diachronically*, for example as archaic, old-fashioned, contemporary, futuristic, etc.; the *space* attribute places a word or phrase *diatopically*, that is, with respect to a geographical classification, for example as national, regional, international, etc.; the *social* attribute places a word or phrase *diastratically*, that is, with respect to a social classification, for example as technical, polite, impolite, restricted, etc. Again, no recommendations are made for the values of these attributes at this time; the encoder should provide a description of the scheme used in the appropriate section of the header (see section 2.3. *The Encoding Description*).

Examples:

```
Next morning a boy in that dormitory confided to his
bosom friend, a <distinct type="psSlang">fag</distinct> of
Macrea's, that there was trouble in their midst which
King <distinct type="archaic">would fain</distinct> keep
secret.
```

---

<sup>46</sup>The Oxford English Dictionary documents the phrase *to come down* in the sense 'to bring or put down; esp. to lay down money; to make a disbursement' as being in use, mostly in colloquial or humorous contexts, from at least 1700 to the latter half of the 19th century.

```

Next morning a boy in that dormitory confided to his
bosom friend, a
<distinct time="1900" space="GB"
  social="publicschool">fag</distinct>
of Macrea's, that there was trouble in their midst which
King <distinct time="archaic">would fain</distinct> keep
secret.

```

Where more complex (or more rigorous) interpretive analyses of the associations of a word are required, the more detailed and general mechanisms described in chapter 18. *Feature Structures* should be preferred to these simple characterizations. It may also be preferable to record the kinds of analysis suggested here by means of the simple annotation element `<note>` described in section 3.8. *Notes, Annotation, and Indexing*, or the `<span>` element described in section 17.3. *Spans and Interpretations*.

### 3.3.3 Quotation

One form of presentational variation found particularly frequently in written and printed texts is the use of quotation marks. As with the typographic variations discussed in the preceding section, it is generally helpful to separate the encoding of the underlying textual feature (for example, a quotation or a piece of direct speech) from the encoding of its rendering (for example, the use of a particular style of quotation marks).

This section discusses the following elements, all of which are often rendered by the use of quotation marks:

**<q>** (quoted) contains material which is distinguished from the surrounding text using quotation marks or a similar method, for any one of a variety of reasons including, but not limited to: direct speech or thought, technical terms or jargon, authorial distance, quotations from elsewhere, and passages that are mentioned but not used.

**<said>** (speech or thought) indicates passages thought or spoken aloud, whether explicitly indicated in the source or not, whether directly or indirectly reported, whether by real people or fictional characters.

**@direct** may be used to indicate whether the quoted matter is regarded as direct or indirect speech.

**@aloud** may be used to indicate whether the quoted matter is regarded as having been vocalized or signed.

**<quote>** (quotation) contains a phrase or passage attributed by the narrator or author to some agency external to the text.

**att.source** provides attributes for pointing to the source of a bibliographic reference.

**@source** provides a pointer to the bibliographical source from which a quotation or citation is drawn.

**<cit>** (cited quotation) contains a quotation from some other document, together with a bibliographic reference to its source. In a dictionary it may contain an example text with at least one occurrence of the word form, used in the sense being described, or a translation of the headword, or an example.

**<mentioned>** marks words or phrases mentioned, not used.

**<soCalled>** contains a word or phrase for which the author or narrator indicates a disclaiming of responsibility, for example by the use of scare quotes or italics.

The elements `<mentioned>` and `<soCalled>` are members of the class `model.emphLike`; the `<q>` and `<said>` are members of the class `model.qLike` in their own right, while `<cit>` and `<quote>` are members of `model.quoteLike`, a subclass of `model.qLike`. This class is a subclass of `model.inter`; hence all of these elements are permitted both within and between paragraph-level elements.

The most common and important use of quotation marks is, of course, to mark *quotation*, by which we mean simply any part of the text which the author or narrator wishes to attribute to some agency other than the narrative voice. The `<q>` element may be used if no further distinction beyond this is judged necessary. If it is felt necessary to distinguish such passages further, for example to indicate whether they are regarded as speech, writing, or thought, either the *type* attribute or one of the more specialized elements discussed in this section may be used. For example, the element `<quote>` may be used for written passages cited from other works, or the element `<said>` for words or phrases represented as being spoken or thought by people or characters within the current work. The `<soCalled>`

element is used for cases where the author or narrator distances him or herself from the words in question without however attributing them to any other voice in particular. The `<mentioned>` element is appropriate for a case where a word or phrase is being discussed in the body of a text rather than forming part of the text directly.

As noted above, if the distinction among these various reasons why a passage is offset from surrounding text cannot be made reliably, or is not of interest, then any representation of speech, thought, or writing may simply be marked using the `<q>` element.

Quotation may be indicated in a printed source by changes in type face, by special punctuation marks (single or double or angled quotes, dashes, etc.) and by layout (indented paragraphs, etc.), or it may not be explicitly represented at all. If these characteristics are of interest, one or other of the global *rend* or *rendition* attributes discussed in section 1.3.1.1. *Global Attributes* may be used to record them.

Quotation marks themselves may, like other punctuation marks, be felt for some purposes to be worth retaining within a text, quite independently of their description by the *rend* attribute. This should generally be done using the appropriate Unicode character, or, if this is not possible, a numeric character reference (see *v.6.1 Character References*). If the encoder decides both to retain the quotation marks and to represent their function by means of an explicit tag such as `<quote>`, the quotation marks should be included within the element, rather than outside it, as in the first example below:

```
Adolphe se tourna vers lui :
<said>- Alors, Albert, quoi de neuf?</said>
<said>- Pas grand-chose.</said>
<said>- Il fait beau,</said> dit Robert.
```

Alternatively, since this use of the leading mdash is very common typographic practice, it may be considered unnecessary to retain it in the encoding. Its presence in the source might instead be signalled using one of the attributes *rend*, *style*, or *rendition*. This kind of rendering might be predefined using a `<rendition>` element, which can then be referenced using the *rendition* attribute as follows:

```
Adolphe se tourna vers lui :
<said rendition="#dashBefore">Alors,
Albert, quoi de neuf ?</said>
<said rendition="#dashBefore">Pas grand-chose.</said>
<said rendition="#dashBefore">Il fait beau,</said>
dit Robert.

<!-- ... within the header -->
<rendition xml:id="dashBefore"
  scope="before">content: '– '</rendition>
<!-- ... -->
<quotation marks="none"/>
```

Whatever policy is adopted, the encoder should document the decision in some way, for example by using the `<quotation>` element provided in the TEI header (see 2.3.3. *The Editorial Practices Declaration*) to indicate that quotation marks have not been retained in the encoding; their presence in the source is implied by the *rendition* attribute values supplied.

Whether or not the quotation marks are suppressed, their presence and nature may be described using some appropriate set of conventions in the *rend* attribute. These conventions may be entirely idiosyncratic, and hence not necessarily useful for interchange, as in the following example:

```
<said rend="pre(') post(')">Who-e debel
you?</said> – he at last said –
<said rend="pre(') post(')">you no speak-e,
damme, I kill-e.</said> And so saying,
the lighted tomahawk began flourishing
about me in the dark.
```

Such passages might more effectively be encoded without loss of rendering information by using the *rendition* attribute and its associated `<rendition>` element as described in section 2.3.4.1. *Rendition*. If the rendition of passages tagged as `<said>` is uniform throughout a text, then the *render* attribute of the `<tagUsage>` element in the header may be used to specify a default rendering, in which case the same section might simply be tagged:

```
<said>Who-e debel
you?</said> – he at last said –
<said>you no speak-e,
damme, I kill-e.</said> And so saying,
the lighted tomahawk began flourishing
about me in the dark.

<!-- in the header -->
<tagsDecl>
  <rendition xml:id="prequote" scheme="css"
    scope="before">content:"'";</rendition>
  <rendition xml:id="postquote" scheme="css"
    scope="after">content:"'";</rendition>
  <namespace name="http://www.tei-c.org/ns/1.0">
    <tagUsage gi="said"
      render="#prequote #postquote"/>
  </namespace>
</tagsDecl>
```

As members of the `att.ascribed` class, elements `<said>` and `<q>` share the following attribute: **att.ascribed** provides attributes for elements representing speech or action that can be ascribed to a specific individual.

`@who` indicates the person, or group of people, to whom the element content is ascribed.

This may be used to make explicit who is speaking:

```
Adolphe se tourna vers lui :
<said who="#Adolphe">– Alors, Albert,
quoi de neuf?</said>
<said who="#Albert">– Pas grand-chose.</said>
<said who="#Robert">– Il fait beau,</said>
dit Robert.

<!-- ... elsewhere in the document -->
<list type="speakers">
  <item xml:id="Adolphe"/>
  <item xml:id="Albert"/>
  <item xml:id="Robert"/>
</list>
```

The *who* attribute may be supplied whether or not an indication of the speaker is given explicitly in the text. It may take the form (as above) of a normalized form of the speaker's name, but its role is to act as a pointer to a location elsewhere in the text, or another document, where data about each speaker may be supplied. While this attribute could point to any source of information about the speaker available by a URI, the most appropriate place to place such information is within the *participant description* component of the TEI header, as further discussed in 15.2.2. *The Participant Description* but for simple cases like the above, a simple list of speakers located in the front or back matter of the text may suffice.

It may also be useful to distinguish representations of speech from representations of thought, in modern printed texts often indicated by a change of typeface. The *aloud* attribute is provided for this purpose, as in this example:

```
<said aloud="true">Oh yes,</said> said Henry,
<said aloud="false">I mean
Gordon Macrae, for example...</said>
<said aloud="false">Jungian
Analyst with Winebox! That's what you called him, you callous bastard,
didn't you? Eh? Eh?</said>
```

Quoted matter may be embedded within quoted matter, as when one speaker reports the speech of another:

```
<said who="#Wilson">Spaulding, he came down into the office just this day
eight weeks with this very paper in his hand, and he says:-
<said who="#WilsonSpaulding">I wish to the Lord, Mr. Wilson, that I was a
red-headed man.</said>
</said>
<!-- ... -->
<list type="speakers">
  <item xml:id="Wilson">Wilson</item>
  <item xml:id="WilsonSpaulding">Spaulding reported by Wilson</item>
<!-- ...-->
</list>
```

Direct speech nested in this way is treated in the same way as elsewhere: a change of rendition may occur, but the same element should be used. An encoder may however choose to distinguish between direct speech which contains quotations from extra-textual matter and direct speech itself, as in the following example:

```
<p>
  <said>The Lord! The Lord! It is Sakya Muni himself,</said> the lama half
sobbed; and under his breath began the wonderful Buddhist
invocation:-<said>
  <quote>
    <l>To Him the Way – the Law – Apart –</l>
    <l>Whom Maya held beneath her heart</l>
    <l>Ananda's Lord – the Bodhisat</l>
  </quote>
  And He is here! The Most Excellent Law is here also. My
  pilgrimage is well begun. And what work! What work!</said>
</p>
```

Quotations from other works are often accompanied by a reference to their source. The <cit> element may be used to group together the quotation and its associated bibliographic reference, which should be encoded using the elements for bibliographic references discussed in section 3.11. *Bibliographic Citations and References*, as in the following example.

```
<div xml:id="mm01" type="chapter">
  <head>Chapter 1</head>
  <epigraph>
    <cit>
      <quote>
        <l>Since I can do no good because a woman</l>
        <l>Reach constantly at something that is near it.</l>
      </quote>
      <bibl>
```

```

    <title>The Maid's Tragedy</title>
    <author>Beaumont and Fletcher</author>
  </bibl>
</cit>
</epigraph>
<p>Miss Brooke had that kind of beauty which seems to be thrown into
  relief by poor dress...</p>
</div>

```

Like other bibliographic references, the citation associated with a quotation may be represented simply by a cross-reference, as in this example:

```

Lexicography has shown little sign of being affected by the
work of followers of J.R. Firth, probably best summarized
in his slogan, <cit>
  <quote>You shall know a word by the company it keeps.</quote>
  <ref>(Firth, 1957)</ref>
</cit>

```

It is also common for quotations to be separated from their bibliographic reference by intervening text, which makes the use of <cit> impractical. In such circumstances, the quotation can be linked to a bibliographical reference using *source*:

```

<bibl xml:id="tlk_36">Tolkien (1936)</bibl> tells us that
<quote source="#tlk_36">
  <title>Beowulf</title> is in fact so interesting as
poetry, in places poetry so powerful, that this quite
overshadows the historical content
</quote>.

```

*source* could also be used to point to a complete external bibliographic reference in a <listBibl> elsewhere in the document, or external to it.

Unlike most of the other elements discussed in this chapter, direct speech and quotations may frequently contain other high-level elements such as paragraphs or verse lines, as well as being themselves contained by such elements. Three possible solutions exist for this well-known structural problem:

- the quotation is broken into segments, each of which is entirely contained within a paragraph
- the quotation is marked up using stand-off markup
- the quotation boundaries are represented by empty segment boundary delimiter elements

For further discussion and several examples, see chapter 20. *Non-hierarchical Structures*.

Finally, in this section, the element <soCalled> is provided for all cases in which quotation marks are used to distance the quoted text from the narrator or speaker. Common examples include the 'scare' quotes often found in newspaper headlines and advertising copy, where the effect is to cast doubts on the veracity of an assertion:

```

<head>PM dodges <soCalled>election threat</soCalled> in interview</head>

```

The same element should be used to mark a variety of special ironic usages. Some further examples follow:

```

He hated <soCalled>good</soCalled> books.

```

```
<soCalled>Croissants</soCalled> indeed! toast not good enough for you?
```

Although Chomsky's decision that all NL sentences are finite objects was never justified by arguments from the attested properties of NLS, it did have a certain **<soCalled>social</soCalled>** justification. It was commonly assumed in works on logic until fairly recently that the notion **<mentioned>language</mentioned>** is necessarily restricted to finite strings.

### 3.3.4 Terms, Glosses, Equivalent, and Descriptions

This section describes a set of textual elements which are used to provide a gloss, alternate identification, or description of something.

Technical terms are often italicized or emboldened upon first mention in printed texts; an explanation or gloss is sometimes given in quotation marks. Linguistic analyses conventionally cite words in languages under discussion in italics, providing a gloss immediately following marked with single quotation marks. Other texts in which individual words or phrases are *mentioned* (for example, as examples) rather than *used* may mark them either with italics or with quotation marks, and will gloss them less regularly.

**<term>** contains a single-word, multi-word, or symbolic designation which is regarded as a technical term.

**<gloss>** identifies a phrase or word used to provide a gloss or definition for some other word or phrase.

These elements are also members of the class `model.emphLike`.

A **<term>** may appear with or without a gloss, as may a **<mentioned>** element. Where the **<gloss>** is present, it may be linked to the term it is glossing by means of its *target* attribute. To establish such a link, the encoder should give an *xml:id* value to the **<term>** or **<mentioned>** element and provide that value, prefixed by a sharp sign, as the value of the *target* attribute on the **<gloss>** element. For example:

```
We may define <term xml:id="TDPv" rend="sc">discoursal point of view</term>
as
<gloss target="#TDPv">the relationship, expressed through discourse
structure, between the implied author or some other addresser,
and the fiction.</gloss>
```

```
<gloss rend="unmarked" target="#PRSR">A computational device that infers
structure from grammatical strings of words</gloss> is known as a
<term xml:id="PRSR">parser</term>, and much of the history of NLP over the
last 20 years has been occupied with the design of parsers.
```

In the absence of a **<gloss>** in the source text, a **<term>** can also be associated with a gloss or definition by means of its *ref* attribute, as in this imaginary example:

```
We discuss Leech's concept of <term ref="#TDPV2" rend="sc">discoursal point of
view</term> below.
```

Here, the value `#TDPV2` references some other XML element in the same document. This might be, for example, an entry in a list of technical vocabulary given in the document header, or in an appendix. This attribute could also reference an entry in some centrally maintained terminological database, perhaps using one of the pointing mechanisms discussed in section 16.2. *Pointing Mechanisms*.

Note that the element `<term>` is intended for use with words or phrases identified as terminological in nature; where words or phrases are simply being cited, discussed, or glossed in a text, it will often be more appropriate to use the `<mentioned>` element, as in the following example:

```
There is thus a striking accentual difference between a verbal
form like <mentioned xml:id="cw234" xml:lang="grc">eluthemen</mentioned>
<gloss target="#cw234">we were released,</gloss> accented on the
second syllable of the word, and its participial derivative

<mentioned xml:id="cw235" xml:lang="grc">lutheis</mentioned>
<gloss target="#cw235">released,</gloss> accented on the last.
```

For technical terminology in particular, and generally in terminological studies, it may be useful to associate an instance of a term within a text with a canonical definition for it, which is stored either elsewhere in the same text (for example in a glossary of terms) or externally, for example in a database, authority file, or published standard. The attributes *key* and *ref* discussed in section 3.5.1. *Referring Strings* below are available on the `<term>` element for this purpose.

Another group of elements is used to supply different kinds of names for objects described by the TEI. Examples of this are documentation of elements, attributes, classes (and also attribute values where appropriate), and description of glyphs.

**<altIdent>** (alternate identifier) supplies the recommended XML name for an element, class, attribute, etc. in some language.

**<desc>** (description) contains a brief description of the object documented by its parent element, including its intended usage, purpose, or application where this is appropriate.

**<equiv>** (equivalent) specifies a component which is considered equivalent to the parent element, either by co-reference, or by external link.

**@uri** (uniform resource identifier) references the underlying concept of which the parent is a representation by means of some external identifier

**@filter** references an external script which contains a method to transform instances of this element to canonical TEI

**@name** a single word which follows the rules defining a legal XML name (see <http://www.w3.org/TR/REC-xml/#dt-name>), naming the underlying concept of which the parent is a representation.

Along with the `<gloss>` element mentioned above, these elements constitute the `model.glossLike` class. They are described in more detail in 22.4.1. *Description of Components*.

### 3.3.5 Some Further Examples

As a simple example of the elements discussed here, consider the following sentence:

On the one hand the *Nibelungenlied* is associated with the new rise of romance of twelfth-century France, the *romans d'antiquité*, the romances of Chrétien de Troyes, and the German adaptations of these works by Heinrich van Veldeke, Hartmann von Aue, and Wolfram von Eschenbach.

A first approximation to the encoding of this sentence might be simply to record the fact that the phrases printed above in italics are highlighted, as follows:

```
On the one hand the <hi rend="italic">Nibelungenlied</hi> is
associated with the new rise of romance of twelfth-century France,
the <hi xml:lang="fr" rend="italic">romans d'antiquité</hi>,
the romances of Chrétien de Troyes, ...
```

This encoding would, however, lose the important distinction between an italicized title and an italicized foreign phrase. Many other phrases might also be italicized in the text, and a retrieval program seeking to identify foreign

terms (for example) would not be able to produce reliable results by simply looking for italicized words. Where economic and intellectual constraints permit, therefore, it would be preferable to encode both the function of the highlighted phrases and their appearance, as follows:

```
On the one hand the <title rend="italic">Nibelungenlied</title>
is associated with the new rise of romance of twelfth-century France,
the <foreign rend="italic">romans d'antiquité</foreign>, the
romances of Chrétien de Troyes, ...
```

In this example, the decision as to which textual features are distinguished by the highlighting is relatively uncontroversial. As a less straightforward example, consider the use of italic font in the following passage:

A pretty common case, I believe; in all *vehement* debatings. She says I am *too witty*; Anglicé, *too pert*; I, that she is *too wise*; that is to say, being likewise put into English, *not so young as she has been*: in short, she is grown so much into a *mother*, that she had forgotten she ever was a *daughter*. ...

Clearly, the word *vehement* is not italicized for the same reason as the phrase *not so young as she has been*; the former is emphasized, while the latter is proverbial. It also provides an ironic gloss for the words *too wise*, in the same way as *too pert* glosses *too witty*. The glossed phrases are not, however, technical terms or cited words, but quoted phrases, as if the writer were putting words into her own and her mother's mouths. Finally, the words *mother* and *daughter* are apparently italicized simply to oppose them in the sentence; certainly they do not fit into any of the categories so far proposed as reasons for italicizing. Note also that the word *Anglicé* is not italicized although it is not generally considered an English word.

The following sample encoding for the above passage attempts to take into account all the above points:

```
A pretty common case, I believe; in all <emph>vehement</emph>
debatings. She says I am <q rend="italic">too witty</q>;
<foreign xml:lang="la" rend="roman">Anglicé</foreign>,
<gloss rend="italic">too pert</gloss>; I, that she is
<q rend="italic"> too wise</q>; that is to say, being likewise
put into English, <gloss rend="italic">not so young as she has
been</gloss>: in short, she is grown so much into a
<hi rend="italic">mother</hi>, that she had forgotten she ever
was a <hi rend="italic">daughter</hi>.
```

### 3.4 Simple Editorial Changes

As in editing a printed text, so in encoding a text in electronic form, it may be necessary to accommodate editorial comment on the text and to render account of any changes made to the text in preparing it. The tags described in this section may be used to record such editorial interventions, whether made by the encoder, by the editor of a printed edition used as a copy text, by earlier editors, or by the copyists of manuscripts.

The tags described here handle most common types of editorial intervention and stereotyped comment; where less structured commentary of other types is to be included, it should be marked using the <note> element described in section 3.8. *Notes, Annotation, and Indexing*. Systematic interpretive annotation is also possible using the various methods described in chapter 16. *Linking, Segmentation, and Alignment*. The examples given here illustrate only simple cases of editorial intervention; in particular, they permit economical encoding of a simple set of alternative readings of a short span of text. To encode multiple views of large or heterogeneous spans of text, the mechanisms described in chapter 16. *Linking, Segmentation, and Alignment* should be used. To encode multiple witnesses of a particular text, a similar mechanism designed specifically for critical editions is described in chapter 12. *Critical Apparatus*.

For most of the elements discussed here, some encoders may wish to indicate both a *responsibility*, that is, a code indicating the person or agency responsible for making the editorial intervention in question, and also an indication of the degree of *certainty* which the encoder wishes to associate with the intervention. These requirements are served by the `att.global.responsibility` class, along with `att.source` and

**att.dimensions.** Any of the elements discussed here thus may potentially carry any of the following optional attributes:

**att.global.responsibility** provides attributes indicating the agent responsible for some aspect of the text, the markup or something asserted by the markup, and the degree of certainty associated with it.

**@cert** (certainty) signifies the degree of certainty associated with the intervention or interpretation.

**@resp** (responsible party) indicates the agency responsible for the intervention or interpretation, for example an editor or transcriber.

**att.source** provides attributes for pointing to the source of a bibliographic reference.

**@source** provides a pointer to the bibliographical source from which a quotation or citation is drawn.

**att.editLike** provides attributes describing the nature of an encoded scholarly intervention or interpretation of any kind.

**@evidence** indicates the nature of the evidence supporting the reliability or accuracy of the intervention or interpretation.

**att.dimensions** provides attributes for describing the size of physical objects.

**@unit** names the unit used for the measurement

**@quantity** specifies the length in the units specified

**@extent** indicates the size of the object concerned using a project-specific vocabulary combining quantity and units in a single string of words.

**@precision** characterizes the precision of the values specified by the other attributes.

**@scope** where the measurement summarizes more than one observation, specifies the applicability of this measurement.

Many of the elements discussed here can be used in two ways. Their primary purpose is to indicate that the text encoded as the element's content represents an editorial intervention (or non-intervention) of a specific kind, indicated by the element itself. However, pairs or other meaningful groupings of such elements can also be supplied, wrapped within a special purpose `<choice>` element:

**<choice>** groups a number of alternative encodings for the same point in a text.

This element enables the encoder to represent for example a text in its 'original' uncorrected and unaltered form, alongside the same text in one or more 'edited' forms. This usage permits software to switch automatically between one 'view' of a text and another, so that (for example) a stylesheet may be set to display either the text in its original form or after the application of editorial interventions of particular kinds.

Elements which can be combined in this way constitute the `model.choicePart` class. The default members of this class are `<sic>`, `<corr>`, `<reg>`, `<orig>`, `<unclear>`, `<abbr>`, `<expan>`, `<ex>`, `<am>` and `<seg>`; some of their functions and usage are described further below.

Three categories of editorial intervention are discussed in this section:

- indication or correction of apparent errors
- indication or regularization of variant, irregular, non-standard, or eccentric forms
- editorial additions, suppressions, and omissions

A more extended treatment of the use of these tags in transcriptional and editorial work is given in chapter 11. *Representation of Primary Sources.*

### 3.4.1 Apparent Errors

When the copy text is manifestly faulty, an encoder or transcriber may elect simply to correct it without comment, although for scholarly purposes it will often be more generally useful to record both the correction and the original state of the text. The elements described here enable all three approaches, and allows the last to be done in such a way as make it easy for software to present either the original or the correction.

**<sic>** (Latin for thus or so) contains text reproduced although apparently incorrect or inaccurate.

**<corr>** (correction) contains the correct form of a passage apparently erroneous in the copy text.

The following examples show alternative treatment of the same material. The copy text reads:

Another property of computer-assisted historical research is that data modelling must permit any one textual feature or part of a textual feature to be a part of more than one information model and to allow the researcher to draw on several such models simultaneously, for example, to select from a machine-readable text those marginal comments which indicate that the date's mentioned in the main body of the text are incorrect.

An encoder may choose to correct the typographic error, either silently or with an indication that a correction has been made, as follows:

```
... marginal comments which indicate that the <corr>dates</corr>
mentioned in the main body of the text are incorrect.
```

Alternatively, the encoder may simply record the typographic error without correcting it, either without comment or with a <sic> element to indicate the error is not a transcription error in the encoding:

```
... marginal comments which indicate that the <sic>date's</sic>
mentioned in the main body of the text are incorrect.
```

If the encoder elects both to record the original source text and to provide a correction for the sake of word-search and other programs, both <sic> and <corr> are used, wrapped in a <choice>:

```
... marginal comments which indicate that the
<choice>
  <corr>dates</corr>
  <sic>date's</sic>
</choice> mentioned in the main body of the text are
incorrect.
```

The <sic> and <corr> elements can appear in either order.

If it is desired to indicate the person or edition responsible for the emendation, this might be done as follows:

```
... marginal comments which indicate that the
<choice>
  <corr resp="#msm">dates</corr>
  <sic>date's</sic>
</choice> mentioned in the main body of the text are
incorrect.

<!-- within the header for this document ... -->
<respStmt xml:id="msm">
  <resp>editor</resp>
  <name>C.M. Sperberg-McQueen</name>
</respStmt>
```

Here the *resp* attribute has been used to indicate responsibility for the correction. Its value (#msm) is an example of the *pointer* values discussed in section 3.6. *Simple Links and Cross-References*; in this case, it points to a <respStmt> element within the TEI header, but any element might be indicated in this way, including for example a <name> element, or (if the module described in 13. *Names, Dates, People, and Places* has been included) a <person> element. The *resp* attribute is available for all elements which are members of the `att.global.responsibility` class. The same class makes available a *cert* attribute, which may be used to indicate the degree of editorial confidence in a particular correction, as in the following example:

```
An <choice>
  <corr cert="high">Autumn</corr>
  <sic>Antony</sic>
</choice> it was,
That grew the more by reaping
```

See further the discussion in section 11.3.1.3. *Correction and Conjecture*.

Where, as here, the correction takes the form of adding text not otherwise present in the text being encoded, the encoder should use the `<corr>` element. Where the correction is present in the text being encoded, and consists of some combination of visible additions and deletions, the elements `<add>` or `<del>` should be used: see further section 3.4.3. *Additions, Deletions, and Omissions* below. Where the correction takes the form of addition of material not present in the original because of physical damage or illegibility, the `<supplied>` element may be used. Where the ‘correction’ is simply a matter of expanding an abbreviation the `<ex>` element may be used. These and other elements to support the detailed encoding of authorial or scribal interventions of this kind are all provided by the module described in chapter 11. *Representation of Primary Sources*.

### 3.4.2 Regularization and Normalization

When the source text makes extensive use of variant forms or non-standard spellings, it may be desirable for a number of reasons to *regularize* it: that is, to provide ‘standard’ or ‘regularized’ forms equivalent to the non-standard forms.<sup>47</sup>

As with other such changes to the copy text, the changes may be made silently (in which case the TEI header should specify the types of silent changes made) or may be explicitly marked using the following elements:

- <reg>** (regularization) contains a reading which has been regularized or normalized in some sense.
- <orig>** (original form) contains a reading which is marked as following the original, rather than being normalized or corrected.
- <choice>** groups a number of alternative encodings for the same point in a text.

Typical applications for these elements include the production of editions intended for student or lay readers, linguistic research in which spelling or usage variation is not the main question at issue, production of spelling dictionaries, etc.

Consider this 16th-century text:

how godly a dede it is to overthrowe so wicked a race the world may judge: for my part I thinke there cannot be a greater sacryfice to God.

An encoder may choose to preserve the original spelling of this text, but simply flag it as nonstandard by using the `<orig>` element with no attributes specified, as follows:

```
<p>...how godly a <orig>dede</orig> it is to
<orig>overthrowe</orig> so wicked a race the
world may judge: for my part I <orig>thinke</orig>
there <orig>canot</orig> be a greater
<orig>sacryfice</orig> to God</p>
```

Alternatively, the encoder may simply indicate that certain words have been modernized by using the `<reg>` element with no attributes specified, as follows:

```
<p>...how godly a
<reg>deed</reg> it is to <reg>overthrow</reg> so wicked a race the
world may judge: for my part I <reg>think</reg>
there <reg>cannot</reg> be a greater
<reg>sacrifice</reg> to God.</p>
```

<sup>47</sup>In some contexts, the term *regularization* has a narrower and more specific significance than that proposed here: the `<reg>` element may be used for any kind of regularization, including normalization, standardization, and modernization.

Alternatively, the encoder may elect to record both old and new spellings, so that (for example) the same electronic text may serve as the basis of an old- or new-spelling edition:

```
<p>...how godly a <choice>
  <orig>dede</orig>
  <reg>deed</reg>
</choice> it is to
<choice>
  <orig>overthrowe</orig>
  <reg>overthrow</reg>
</choice> so wicked a race the
world may judge: for my part I <choice>
  <orig>thinke</orig>
  <reg>think</reg>
</choice>
there <choice>
  <orig>cannot</orig>
  <reg>cannot</reg>
</choice> be a greater
<choice>
  <orig>sacryfice</orig>
  <reg>sacrifice</reg>
</choice> to God.</p>
```

As elsewhere, the *resp* attribute may be used to specify the agency responsible for the regularization.

### 3.4.3 Additions, Deletions, and Omissions

The following elements are used to indicate when words or phrases have been omitted from, added to, or marked for deletion from, a text. Like the other editorial elements, they allow for a wide range of editorial practices:

**<gap>** indicates a point where material has been omitted in a transcription, whether for editorial reasons described in the TEI header, as part of sampling practice, or because the material is illegible, invisible, or inaudible.

*@reason* gives the reason for omission. Sample values include sampling, inaudible, irrelevant, cancelled.

**<unclear>** contains a word, phrase, or passage which cannot be transcribed with certainty because it is illegible or inaudible in the source.

*@reason* indicates why the material is hard to transcribe.

**<add>** (addition) contains letters, words, or phrases inserted in the source text by an author, scribe, or a previous annotator or corrector.

**<del>** (deletion) contains a letter, word, or passage deleted, marked as deleted, or otherwise indicated as superfluous or spurious in the copy text by an author, scribe, or a previous annotator or corrector.

Encoders may choose to omit parts of the copy text for reasons ranging from illegibility of the source or impossibility of transcribing it, to editorial policy, e.g. a systematic exclusion of poetry or prose from an encoding. The full details of the policy decisions concerned should be documented in the TEI header (see section 2.3. *The Encoding Description*). Each place in the text at which omission has taken place should be marked with a **<gap>** element, with optionally further information about the reason for the omission, its extent, and the person or agency responsible for it, as in the following examples:

```
<gap reason="illegible" unit="word"
  quantity="2"/>
```

```
<gap reason="overwriting illegible"
  extent="several characters"/>
```

Note that the extent of the gap may be marked precisely using attributes *unit* and *quantity*, or more descriptively using the *extent* attribute. Other, more detailed, options are also available for representing dimensions of any kind; see further 10.3.4. *Dimensions*.

The `<desc>` element may be used to supply a description of the material omitted, where that is considered useful:

```
<gap reason="sampling" extent="120"
  unit="lines">
  <desc>irrelevant commentary</desc>
</gap>
```

... Their arrangement with respect to Jupiter and to each other was as follows:

```
<gap reason="sampling" extent="2" unit="cm">
  <desc>astrological figure</desc>
</gap>
```

That is, there were two stars on the easterly side and one to the west; ...

The `<add>` and `<del>` elements may be used to record where words or phrases have been added or deleted in the copy text. They are not appropriate where longer passages have been added or deleted, which span several elements; for these, the elements `<addSpan>` and `<delSpan>` described in chapter 11.3.1.4. *Additions and Deletions* must be used.

Additions to a text may be recorded for a number of reasons. Sometimes they are marked in a distinctive way in the source text, for example by brackets or insertion above the line (*supralinear* insertion), as in the following example, taken from a 19th century manuscript:

```
The story I am going to relate is true as to its main facts,
and as to the consequences <add place="above">of
these facts</add> from which this tale takes its title.
```

The `<add>` element should not be used to mark editorial changes, such as supplying a word omitted by mistake from the source text or a passage present in another version. In these cases, either the `<corr>` or `<supplied>` tags should be used, as discussed above in section 3.4.1. *Apparent Errors*, and in section 11.3.1.3. *Correction and Conjecture*, respectively.

The `<unclear>` element is used to mark passages in the original which cannot be read with confidence, or about which the transcriber is uncertain for other reasons, as for example when transcribing a partially inaudible or illegible source. Its *reason* and *resp* attributes are used, as with the `<gap>` element, to indicate the cause of uncertainty and the person responsible for the conjectured reading.

For example:

```
<l>And where the sandy mountain Fenwick scald</l>
<l>
  <unclear reason="ink blot">The</unclear> sea between
  yet hence his pray'r prevail'd
</l>
```

or from a spoken text:

```
<p>... and then <unclear reason="passingTruck">marbled queen</unclear>...</p>
```

Where the material affected is entirely illegible or inaudible, the `<gap>` element discussed above should be used in preference.

The `<del>` element is used to mark material which is deleted in the source but which can still be read with some degree of confidence, as opposed to material which has been omitted by the encoder or transcriber either because it is entirely illegible or for some other reason. This is of particular importance in transcribing manuscript material, though deletion is also found in printed texts, sometimes for humorous purposes:

```
<l>One day I will sojourn to your shores</l>
<l>I live in the middle of England</l>
<l>But!</l>
<l>Norway! My soul resides in your watery
<del rend="overstrike">fiords fyords fiiords</del>
</l>
<l>Inlets.</l>
```

The *rend* attribute may be used to distinguish different methods of deletion in manuscript or typescript material, as in this line from the typescript of Eliot's *Waste Land*:

```
<l>
  <del rend="overtyped">Mein</del> Frisch
<del type="overstrike">schwebt</del> weht der Wind
</l>
```

Deletion in manuscript or typescript is often associated with addition:

```
<l>
  <del rend="overstrike">Inviolable</del>
  <add place="below">Inexplicable</add>
splendour of Corinthian white and gold
</l>
```

The `<subst>` element discussed in 11.3.1.5. *Substitutions* provides a way of grouping additions and deletions of this kind.

The `<del>` element should not be used where the deletion is such that material cannot be read with confidence, or read at all, or where the material has been omitted by the transcriber or editor for some other reason. Where the material deleted cannot be read with confidence, the `<unclear>` tag should be used with the *reason* attribute indicating that the difficulty of transcription is due to deletion. Where material has been omitted by the transcriber or editor, this may be indicated by use of the `<gap>` element. A deletion in which some parts may be read but not others may thus be represented by one or more `<gap>` elements intermingled with text, all contained by a `<del>` element. Text supplied or marked as unnecessary by an editor should be marked with the `<supplied>` and `<surplus>` elements (discussed in 11.3.1.7. *Text Omitted from or Supplied in the Transcription*) rather than `<add>` and `<del>`. These two sets of elements allow the encoder to distinguish editorial changes from those visible in the source text.

### 3.5 Names, Numbers, Dates, Abbreviations, and Addresses

This section describes a number of textual features which it is often convenient to distinguish from their surrounding text. Names, dates, and numbers are likely to be of particular importance to the scholar treating a text as source for a database; distinguishing such items from the surrounding text is however equally important to the scholar primarily interested in lexis.

The treatment of these textual features proposed here is not intended to be exhaustive: fuller treatments for names, numbers, measures, and dates are provided in the names and dates module (see chapter 13. *Names, Dates, People, and Places*); more detailed treatment of abbreviations is provided by the transcription module (see section 11.3.1.2. *Abbreviation and Expansion*).

### 3.5.1 Referring Strings

A *referring string* is a phrase which refers to some person, place, object, etc. Two elements are provided to mark such strings:

**<rs>** (referencing string) contains a general purpose name or referring string.

**<name>** (name, proper noun) contains a proper noun or noun phrase.

The **<name>** element is a member of the `att.typed` class, from which it inherits the following attributes:

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

**@type** characterizes the element in some sense, using any convenient classification scheme or typology.

**@subtype** provides a sub-categorization of the element, if needed

which may be used to further categorize the kind of object referred to. The **<rs>** element defines the *type* attribute locally.

Examples include:

```
<p>
  <q>My dear
  <rs type="person">Mr. Bennet</rs>
  </q>, said his lady to
him one day, <q>have you heard that <rs type="place">Netherfield Park</rs> is let at
last?</q>
</p>
```

```
<p>Collectors of water-rents were appointed by the
<rs type="org">Watering Committee</rs>.
They were paid a commission not exceeding four per
cent, and gave bond.</p>
```

```
<p>It being one of the principles of the
<rs type="org">Circumlocution Office</rs> never, on any
account whatsoever, to give a straightforward answer,
<rs type="person">Mr Barnacle</rs> said, <q>Possibly.</q>
</p>
```

As the following example shows, the **<rs>** element may be used for any reference to a person, place, etc., not only to references in the form of a proper noun or noun phrase.

```
<p>
  <q>My dear <rs type="person">Mr. Bennet</rs>
  </q>, said
<rs type="person">his lady</rs> to him one day ...
</p>
```

The **<name>** element by contrast is provided for the special case of referencing strings which consist only of proper nouns; it may be used synonymously with the **<rs>** element, or nested within it if a referring string contains a mixture of common and proper nouns. The following example shows an alternative way of encoding the short sentence from *Pride and Prejudice* quoted above:

```
<p>
  <q>My dear <name type="person">Mr. Bennet</name>,</q> said <rs type="person">his
  lady</rs> to him one day,
  <q>have you heard that <name type="place">Netherfield Park</name> is let at last?</q>
</p>
```

As the following example shows, a proper name may be nested within a referring string:

```
<rs>His Excellency the Life President, <name>Ngwazi Dr H. Kamuzu Banda</name>
</rs>
```

Simply tagging something as a name is generally not enough to enable automatic processing of personal names into the canonical forms usually required for reference purposes. The name as it appears in the text may be inconsistently spelled, partial, or vague. Moreover, name prefixes such as *van* or *de la* may or may not be included as part of the reference form of a name, depending on the language and country of origin of the bearer.

Two issues arise in this context: firstly, there may be a need to encode a regularized form of a name, distinct from the actual form in the source to hand; secondly, there may be a need to identify the particular person, place, etc. referred to by the name, irrespective of whether the name itself is normalized or not. The element `<reg>`, introduced in 3.4.2. *Regularization and Normalization* is provided for the former purpose; the attributes `key` or `ref` for the latter.

The `key` and `ref` attributes are common to all members of the `att.canonical` class and are defined as follows:

**att.canonical** provides attributes which can be used to associate a representation such as a name or title with canonical information about the object being named or referenced.

`@key` provides an externally-defined means of identifying the entity (or entities) being named, using a coded value of some kind.

`@ref` (reference) provides an explicit means of locating a full definition or identity for the entity being named by means of one or more URIs.

A very useful application for them is as a means of gathering together all references to the same individual or location scattered throughout a document:

```
<p>
  <q>My dear <rs key="BENM1" type="person"> Mr. Bennet</rs>,</q> said
  <rs key="BENM2" type="person">his lady</rs> to him one day, <q>have you heard
  that <rs key="NETP1" type="place">Netherfield Park</rs> is let at
  last?</q>
</p>
```

```
<p>
  <name key="VOM1" type="person">Mme. de Volanges</name> marie <rs key="VOM2">sa
  fille</rs>: c'est encore un secret;
  mais elle m'en a fait part hier.
</p>
```

The value of the `key` attribute may be an unexpanded code, as in the examples above, with no particular significance. More usually however, it will be an externally defined code of some kind, as provided by a standard reference source.

```
<p>
  <name key="LHR" type="airport">Heathrow</name>
</p>
```

The standard reference source should be documented using a <taxonomy> element in the TEI header.

The *ref* attribute can be used to point directly to some other resource providing more information about the entity named by the element, such as an authority record in a database, an encyclopaedia entry, another element in the same or a different document etc.

```
<p>
  <name ref="http://en.wikipedia.org/wiki/Heathrow_airport"
        type="airport">Heathrow</name>
</p>
```

This use should be distinguished from the use of a nested <reg> (regularization) element to provide the standard form of a referring string, as in this example:

```
<p>My personal life during
the administration of <rs key="POJA1" type="person">Col. Polk
  (<reg>Polk, James K.</reg>)</rs> has but poorly compensated me for the
suspended enjoyments and pursuits of private and professional
spheres</p>
```

No particular syntax is proposed for the values of the *key* attribute, since its form will depend entirely on practice within a given project. For the same reason, this attribute is not recommended in data interchange, since there is no way of ensuring that the values used by one project are distinct from those used by another. In such a situation, a preferable approach for magic tokens which follows standard practice on the Web is to use a *ref* attribute whose value is a tag URI as defined in RFC 4151. For example:

```
<p>
  <name ref="tag:projectname.org,2012:VOM1"
        type="person">Mme. de Volanges</name> marie <rs ref="tag:theworksoflaclos.org,2012:VOM2">sa
  fille</rs>: c'est encore un secret;
  mais elle m'en a fait part hier.
</p>
```

The inclusion of the domain name of the party responsible for tagging (*theworksoflaclos.org*), as specified in RFC 4151, helps ensure uniqueness of magic token values across TEI encoding projects, allowing for improved interchange of TEI documents.

The <choice> element discussed in 3.4. *Simple Editorial Changes* may be used if it is desired to record both a normalized form of a name and the name used in the source being encoded:

```
<p>
  <name ref="tag:projectname.org,2012:WADLM1"
        type="person">
    <choice>
      <orig>Walter de la Mare</orig>
      <reg>de la Mare, Walter</reg>
    </choice>
  </name>
  was born at <name ref="tag:projectname.org,2012:Ch1"
    type="place">Charlton</name>, in
  <name ref="tag:projectname.org,2012:KT1"
    type="county">Kent</name>, in 1873.
</p>
```

The `<index>` element discussed in 3.8.2. *Index Entries* may be more appropriate if the function of the regularization is to provide a consistent index:

```
<p>
  <name type="place">Montaillou</name> is not a large parish.
  At the time of the events which led to
  <name type="person">Fournier<index>
    <term>Benedict XII, Pope of Avignon (Jacques Fournier)</term>
    </index>
  </name>'s
  investigations, the local population consisted of between 200 and 250 inhabitants.
</p>
```

Although adequate for many simple applications, these methods have two inconveniences: if the name occurs many times, then its regularized form must be repeated many times; and the burden of additional XML markup in the body of the text may be inconvenient to maintain and complex to process. For applications such as onomastics, relating to persons or places named rather than the name itself, or wherever a detailed analysis of the component parts of a name is needed, the specialized elements described in chapter 13. *Names, Dates, People, and Places* or the analytical tools described in chapter 18. *Feature Structures* should be used.

### 3.5.2 Addresses

These Guidelines propose the following elements to distinguish postal and electronic addresses:

**<address>** contains a postal address, for example of a publisher, an organization, or an individual.

**<email>** (electronic mail address) contains an email address identifying a location to which email messages can be delivered.

These two elements constitute the class of `model.addressLike` elements; for other kinds of address this class may be extended by adding new elements if necessary.

These Guidelines provide no particular means for encoding the substructure of an email address (for example, distinguishing the local part from the domain part), nor of distinguishing personal email addresses from generic or fictitious ones.

```
<email>info@tei-c.org</email>
```

The simplest way of encoding a postal address is to regard it as a series of distinct lines, just as they might be written on an envelope. The following element supports this view:

**<addrLine>** (address line) contains one line of a postal address.

Here is an example of a postal address encoded using this approach:

```
<address>
  <addrLine>110 Southmoor Road,</addrLine>
  <addrLine>Oxford OX2 6RB,</addrLine>
  <addrLine>UK</addrLine>
</address>
```

Alternatively, an address may be encoded as a structure of more semantically rich elements. The class `model.addrPart` element class identifies a number of such possible components:

**<street>** contains a full street address including any name or number identifying a building as well as the name of the street or route on which it is located.

**<name>** (name, proper noun) contains a proper noun or noun phrase.

**<postCode>** (postal code) contains a numerical or alphanumeric code used as part of a postal address to simplify sorting or delivery of mail.

**<postBox>** (postal box or post office box) contains a number or other identifier for some postal delivery point other than a street address.

**model.nameLike** groups elements which name or refer to a person, place, or organization.

|                      |   |
|----------------------|---|
| model.nameLike.agent | groups elements which contain names of individuals or corporate bodies. |
| model.offsetLike     | groups elements which can appear only as part of a place name.          |
| model.persNamePart   | groups elements which form part of a personal name.                     |
| model.placeStateLike | groups elements which describe changing states of a place.              |

|      |  |
|------|--|
| idno | (identifier) supplies any form of identifier used to identify some object, such as a bibliographic item, a person, a title, an organization, etc. in a standardized way. |
| lang | (language name) contains the name of a language mentioned in etymological or other linguistic discussion.  |
| rs   | (referencing string) contains a general purpose name or referring string.  |

**model.persNamePart** groups elements which form part of a personal name.

|          |  |
|----------|--|
| addName  | (additional name) contains an additional name component, such as a nickname, epithet, or alias, or any other descriptive phrase used within a personal name.               |
| forename | contains a forename, given or baptismal name.  |
| genName  | (generational name component) contains a name component used to distinguish otherwise similar names on the basis of the relative ages or generations of the persons named. |
| nameLink | (name link) contains a connecting phrase or link used within a name but not regarded as part of it, such as <i>van der</i> or <i>of</i> .                                  |
| roleName | contains a name component which indicates that the referent has a particular role or position in society, such as an official title or rank.                               |
| surname  | contains a family (inherited) name, as opposed to a given, baptismal, or nick name.  |

**model.placeNamePart** groups elements which form part of a place name.

|            |  |
|------------|--|
| bloc       | contains the name of a geo-political unit consisting of two or more nation states or countries.  |
| country    | contains the name of a geo-political unit, such as a nation, country, colony, or commonwealth, larger than or administratively superior to a region and smaller than a bloc. |
| district   | contains the name of any kind of subdivision of a settlement, such as a parish, ward, or other administrative or geographic unit.  |
| geogName   | (geographical name) identifies a name associated with some geographical feature such as Windrush Valley or Mount Sinai.  |
| placeName  | contains an absolute or relative place name.   |
| region     | contains the name of an administrative unit such as a state, province, or county, larger than a settlement, but smaller than a country.                                      |
| settlement | contains the name of a settlement such as a city, town, or village identified as a single geo-political or administrative unit.  |

Any number of elements from the `model.addrPart` class may appear within an address and in any order. None of them is required.

Where code letters are commonly used in addresses (for example, to identify regions or countries) a useful practice is to supply the full name of the region or country as the content of the element, but to supply the abbreviatory code as the value of the global *n* attribute, so that (for example) an application preparing formatted labels can readily find the required information. Other components of addresses may be represented using the general-purpose `<name>` element or (when the additional module for names and dates is included) the more specialized elements provided for that purpose.

Using just the elements defined by the core module, the above address could thus be represented as follows:

```
<address>
  <street>110 Southmoor Road</street>
  <name type="city">Oxford</name>
  <postCode>OX2 6RB</postCode>
  <name type="country">United Kingdom</name>
</address>
```

The order of elements within an address is highly culture-specific, and is therefore unconstrained:

```
<address>
  <name type="org">Università di Bologna</name>
  <name type="country">Italy</name>
  <postCode>40126</postCode>
  <name type="city">Bologna</name>
  <street>via Marsala 24</street>
</address>
```

A telephone number (normally outside of the `<address>` element) might be tagged with an `<addrLine>` and `<ref>`, with the number itself appearing in the `tel:` namespace:

```
<addrLine>
  <ref target="tel:+1-201-555-0123">(201) 555 0123</ref>
</addrLine>
```

For further discussion of ways of regularizing the names of places, see section 3.5. *Names, Numbers, Dates, Abbreviations, and Addresses*. A full postal address may also include the name of the addressee, tagged as above using the general purpose `<name>` element.

When a schema includes the names and dates module discussed in chapter 13. *Names, Dates, People, and Places*, a large number of more specific elements such as `<country>` or `<settlement>` will be available from the class `model.addrPart`. The above example might then be encoded as follows:

```
<address>
  <street>110 Southmoor Road</street>
  <settlement>Oxford</settlement>
  <postCode>OX2 6RB</postCode>
  <country>United Kingdom</country>
</address>
```

### 3.5.3 Numbers and Measures

This section describes elements provided for the simple encoding of numbers and measurements and gives some indication of circumstances in which this may usefully be done. The following phrase level elements are provided for this purpose:

**<num>** (number) contains a number, written in any form.

**@type** indicates the type of numeric value.

**@value** supplies the value of the number in standard form.

**<measure>** contains a word or phrase referring to some quantity of an object or commodity, usually comprising a number, a unit, and a commodity name.

**@type** specifies the type of measurement in any convenient typology.

**<measureGrp>** (measure group) contains a group of dimensional specifications which relate to the same object, for example the height and width of a manuscript page.

Like names or abbreviations, numbers can occur virtually anywhere in a text. Numbers are special in that they can be written with either letters or digits (*twenty-one*, *xxi*, and *21*) and their presentation is language-dependent (e.g. English *5th* becomes Greek *5*; English *123,456.78* equals French *123.456,78*).

For many kinds of application, e.g. natural-language processing or machine translation, numbers are not regarded as 'lexical' in the same way as other parts of a text. For these and other applications, the **<num>** element provides a convenient method of distinguishing numbers from the surrounding text. For other kinds of application, numbers are only useful if normalized: here the **<num>** element is useful precisely because it provides a standardized way of representing a numerical value.

For example:

```
<num value="33">xxxiii</num>
<num type="cardinal" value="21">twenty-one</num>
<num type="percentage" value="10">ten percent</num>
<num type="percentage" value="10">10%</num>
<num type="ordinal" value="5">5th</num>
```

```
<num type="fraction" value="0.5">one half</num>
<num type="fraction" value="0.5">1/2</num>
```

Sometimes it may be desired to mark something as numerical which cannot be accurately normalized, for example an expression such as *dozens*; less frequently the number may be recognisable linguistically as such but may use a notation with which the encoder is unfamiliar. To help in these situations, the **<num>** element may also bear either or both of the following attributes from the **att.ranging** class:

**att.ranging** provides attributes for describing numerical ranges.

**@atLeast** gives a minimum estimated value for the approximate measurement.

**@atMost** gives a maximum estimated value for the approximate measurement.

In its fullest form, a *measure* consists of a number, a phrase expressing units of measure and a phrase expressing the commodity being measured, though not all of these components need be present in every case. It may be helpful to distinguish measures from surrounding text for two reasons. Firstly, a measure may be expressed using a particular notation or system of abbreviations which the encoder does not wish to regard as lexical. Secondly, a quantitative application may wish to distinguish and normalize the internal components of a measure, in order to perform calculations on them.

Consider, as an example of the first case, the following list of Celia's charms, in which the encoder has chosen to make explicit the measurements:

```
<div n="2">
  <list type="gloss">
    <label>Age</label>
    <item>Unimportant</item>
    <label>Head</label>
    <item>Small and round</item>
```

```

<label>Eyes</label>
<item>Green</item>
<label>Complexion</label>
<item>White</item>
<label>Hair</label>
<item>yellow</item>
<label>Features</label>
<item>Mobile</item>
<label>Neck</label>
<item>
  <measure>13¾" </measure>
</item>
<label>Upper arm</label>
<item>
  <measure>11" </measure>
</item>
<!--...-->
</list>
<!-- ... -->
</div>

```

In the same way, it may be convenient to mark representations of currency which might otherwise be misinterpreted as lexical:

```

<p>...the sum of
<measure type="currency">12s 6d</measure>...</p>

```

In general, normalization of a measure will require specification of one or more of its three parts: the quantity, the units, and possibly also the commodity being measured. This is accomplished by supplying values for the three attributes *quantity*, *unit*, and *commodity*, which are supplied by the `att.measurement` class:

**att.measurement** provides attributes to represent a regularized or normalized measurement.

*@quantity* specifies the number of the specified units that comprise the measurement

*@unit* indicates the units used for the measurement, usually using the standard symbol for the desired units.

*@commodity* indicates the substance that is being measured

With these attributes, the measurement of Celia's neck may be specified in a normalized form:

```

<measure quantity="13.75" unit="in">13¾" </measure>

```

Such techniques are particularly useful when representing historical data such as inventories:

```

<list>
  <item>
    <measure type="volume" quantity="2"
      unit="bag" commodity="hops">ii bags hops</measure>
  </item>
  <item>
    <measure type="volume" quantity="6"
      unit="truss" commodity="cloth">six trusses Woolen and linen goods</measure>
  </item>
  <item>

```

```

<measure type="weight" quantity="5"
  unit="ton" commodity="coal">5 tonnes coale</measure>
</item>
</list>

```

The `<measureGrp>` element is provided as a means of grouping several related measurements together, either because the measurement involves several dimensions (for example height and width) or to avoid the need to repeat all the normalizing attributes:

```

<measureGrp type="volume" unit="in">
  <measure type="height" quantity="14">xiv</measure>
  <measure type="width" quantity="5">v</measure>
  <measure type="depth" quantity="10">x</measure>
</measureGrp>

```

### 3.5.4 Dates and Times

Dates and times, like numbers, can appear in widely varying culture- and language-dependent forms, and can pose similar problems in automatic language processing. Such elements constitute the `model.dateLike` class, of which the default members are:

**<date>** contains a date in any format.

**<time>** contains a phrase defining a time of day in any format.

These elements have some additional attributes by virtue of being members of the `att.dateable` and `att.duration` classes which, in turn, are members of the `att.dateable.w3c` and `att.duration.w3c` classes. In particular, the *when* and *calendar* attributes will be discussed here:

**att.dateable.w3c** provides attributes for normalization of elements that contain dateable events conforming to the *W3C XML Schema Part 2: Datatypes Second Edition*.

*@when* supplies the value of the date or time in a standard form, e.g. yyyy-mm-dd.

**att.dateable** provides attributes for normalization of elements that contain dates, times, or dateable events.

*@calendar* indicates the system or calendar to which the date represented by the content of this element belongs.

Dates can occur virtually anywhere in a text, but in some contexts (e.g. bibliographic citations) their encoding is recommended or required rather than optional. Times can also appear anywhere but are generally optional.

Partial dates or times (e.g. *1990*, *September 1990*, *twelvish*) can be expressed in the *when* attribute by simply omitting a part of the value supplied. Imprecise dates or times (for example *early August*, *some time after ten and before twelve*) may be expressed as date or time ranges.

These mechanisms are useful primarily for fully specified dates or times known with certainty. If component parts of dates or times are to be marked up, or if a more complex analysis of the meaning of a temporal expression is required, the techniques described in chapter 13, *Names, Dates, People, and Places* should be used in preference to the simple method outlined here.

Where the certainty (i.e. reliability) of the date or time is in question, the encoder should record this fact using the mechanisms discussed in chapter 21, *Certainty, Precision, and Responsibility*. The same chapter also discusses various methods of recording the precision of numerical or temporal assertions.

The *when* attribute is a useful way of normalizing or disambiguating dates and times which can appear in many formats, as the following examples show:

```

<date when="1980-02-12">12/2/1980</date>

```

```
Given on the <date when="1977-06-12">Twelfth Day of June
in the Year of Our Lord One Thousand Nine Hundred and
Seventy-seven of the Republic the Two Hundredth and first
and of the University the Eighty-Sixth.</date>
```

The *when* attribute always supplies a normalized representation of the date given as content of the <date> element. The format used should be a valid W3C schema datatype.<sup>48</sup> Some typical examples follow:

```
<date when="2001">The year 2001</date>
<date when="2001-09">September 2001</date>
<date when="2001-09-11">11 Sep 01</date>
<date when="--09-11">9/11</date>
<date when="--09">September</date>
<date when="---11">Eleventh of the month</date>
<time when="08:48:00">8:48</time>
<date when="2001-09-11T12:48:00">Sept 11th, 12 minutes before 9 am</date>
```

Note in the last example the use of a normalized representation for the date string which includes a time: this example could thus equally well be tagged using the <time> element.

The following examples demonstrate the use of the <date> element to mark a period of time:

```
<p>Those five years –
<date from="1918" to="1923">1918 to 1923</date>
– had been, he suspected,
somehow very important.</p>
```

```
<p>The Eddic poems are preserved in a unique
manuscript (Codex Regius 2365) from
<date notBefore="1250" notAfter="1300">the second half of the
thirteenth century</date>, and <title>Hervarar
saga</title> dates from <date when="1300">around 1300</date>.</p>
```

The *calendar* attribute may be used to specify a date in any calendar system; if the *when* attribute is also supplied, it should specify the equivalent date in the Gregorian calendar.

---

<sup>48</sup>The datatypes are taken from the W3C Recommendation *XML Schema Part 2: Datatypes Second Edition*. The permitted datatypes are:

- date
- gYear
- gMonth
- gDay
- gYearMonth
- gMonthDay
- time
- dateTime

There is one exception: these Guidelines permit a time to be expressed as only a number of hours, or as a number of hours and minutes, as per ISO 8601:2004 section 4.2.2.3 and 4.3.3. The W3C *time* and *dateTime* datatypes require that the minutes and seconds be included in the normalized value if they are to be correctly processed for example when sorting.

### 3.5.5 Abbreviations and Their Expansions

It is sometimes desirable to mark abbreviations in the copy text, whether to trigger special processing for them, to provide the full form of the word or phrase abbreviated, or to allow for different possible expansions of the abbreviation. Abbreviations may be transcribed as they stand, or expanded; they may be left unmarked, or marked using these tags:

**<abbr>** (abbreviation) contains an abbreviation of any sort.

**<expan>** (expansion) contains the expansion of an abbreviation.

The **<abbr>** element is useful as a means of distinguishing semi-lexical items such as acronyms or jargon:

We can sum up the above discussion as follows:  
the identity of a **<abbr>CC</abbr>** is defined by that calibration of values which motivates the elements of its **<abbr>GSP</abbr>**; ...

Every manufacturer of **<abbr>3GL</abbr>** or **<abbr>4GL</abbr>** languages is currently nailing on **<abbr>00P</abbr>** extensions.

The *type* attribute may be used to distinguish types of abbreviation by their function:

```
<abbr type="title">Dr.</abbr>
<abbr type="initial">M.</abbr> Deegan is
the Director of the <abbr type="acronym">CTI</abbr> Centre for Textual Studies.
```

Abbreviations such as *Dr. M.* above may be treated as two abbreviations, as above, or as one:

```
<abbr>Dr. M.</abbr> Deegan is
the Director of the <abbr>CTI</abbr> Centre for Textual Studies.
```

The **<expan>** element may be used simply to record that an abbreviation has been silently expanded by the encoder, perhaps for reasons of house style or editorial policy. It should always include the whole of an abbreviated phrase or word. More usually however this will be combined with the **<abbr>** element inside a **<choice>** element to record both the abbreviation and its expansion:

```
the
<choice>
  <expan>World Wide Web Consortium</expan>
  <abbr>W3C</abbr>
</choice>
```

Nested abbreviations may also be handled in this way:

```
<choice>
  <abbr>RELAXNG</abbr>
  <expan>regular
    language for <choice>
      <abbr>XML</abbr>
      <expan>extensible markup
        language</expan>
    </choice>, next
  generation</expan>
</choice>
```

Abbreviation is a particularly important feature of manuscript and other source materials, the transcription of which needs more detailed treatment than is possible using these simple elements. A more detailed set of recommendations is discussed in 11.3.1. *Altered, Corrected, and Erroneous Texts*, which includes additional elements made available for the purpose by the `transcr` module.

### 3.6 Simple Links and Cross-References

Cross-references or links between one location in a document and one or more other locations, either in the same or different XML documents, may be encoded using the elements `<ptr>` and `<ref>`, as discussed in this section. These elements both ‘point’ from one location in a document, the place that the element itself appears, to another (or to several), specified by means of a *target* attribute, supplied by the `att.pointing` class:

**att.pointing** provides a set of attributes used by all elements which point to other elements by means of one or more URI references.

*@target* specifies the destination of the reference by supplying one or more URI References

Linkages of several other kinds are also provided for in these guidelines; see further chapter 16. *Linking, Segmentation, and Alignment*.

The value of the *target* attribute, wherever it appears, provides a way of pointing to some other element using a method standardized by the W3C consortium, and known as the *XPointer* mechanism. This permits a range of complexity, from the very simple (a reference to the value of the target element’s *xml:id* attribute) to the more complex usage of a full URI with embedded XPointers. For example, the source of the following paragraph looks something like this:

```
<p>...
The complete XPointer specification is managed by the W3C<note place="foot">
  <ptr target="http://www.w3.org/TR/xptr-framework/" />,
  <ptr target="http://www.w3.org/TR/xptr-element/" />,
  <ptr target="http://www.w3.org/TR/xptr-xmlns/" />, and
  <ptr target="http://www.w3.org/TR/xptr-xpointer/" />
</note>;
for a discussion of TEI schemes for XPointer, see
<ptr target="#eSATS"/>.</p>
<!--... -->
<div xml:id="eSATS">
<!--... -->
</div>
```

Alternatively, if no explicit link is to be encoded, but it is simply required to mark the phrase as a cross-reference, the `<ref>` element may be used without a *target* attribute.

For an introduction to the use of links in general, see 16. *Linking, Segmentation, and Alignment*. The complete XPointer specification is managed by the W3C<sup>49</sup>; for a discussion of TEI schemes for XPointer, see 16.2.4. *TEI XPointer Schemes*.

**<ptr>** (pointer) defines a pointer to another location.

**<ref>** (reference) defines a reference to another location, possibly modified by additional text or comment.

The elements `<ptr>` and `<ref>` are the default members of the phrase-level model class `model.ptrLike`. As members of the classes `att.pointing`, `att.typed`, `att.cReferencing`, and `att.internetMedia` they also carry the following attributes:

**att.pointing** provides a set of attributes used by all elements which point to other elements by means of one or more URI references.

*@target* specifies the destination of the reference by supplying one or more URI References

*@evaluate* specifies the intended meaning when the target of a pointer is itself a pointer.

**att.cReferencing** provides an attribute which may be used to supply a *canonical reference* as a means of identifying the target of a pointer.

<sup>49</sup><http://www.w3.org/TR/xptr-framework/>, <http://www.w3.org/TR/xptr-element/>, <http://www.w3.org/TR/xptr-xmlns/>, and <http://www.w3.org/TR/xptr-xpointer/>

`@cRef` (canonical reference) specifies the destination of the pointer by supplying a canonical reference expressed using the scheme defined in a `<refsDecl>` element in the TEI header

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

`@type` characterizes the element in some sense, using any convenient classification scheme or typology.

`@subtype` provides a sub-categorization of the element, if needed

**att.internetMedia** provides attributes for specifying the type of a computer resource using a standard taxonomy.

`@mimeType` (MIME media type) specifies the applicable multimedia internet mail extension (MIME) media type

The two elements may be used in the same way; the difference between them is simply that while the `<ptr>` element is empty, the `<ref>` element may contain phrases specifying, or describing more exactly, the target of a cross-reference, which form the content of the element. Since its content thus serves as a human-readable pointer, in the simplest case a `<ref>` element need not identify its target in any other way. For example:

See `<ref>`section 12 on page 34`</ref>`.

More usually, it will be desirable to identify the target of the cross-reference using either the *target* or the *cRef* attribute, so that processing software can access it directly, for example to implement a linkage, to generate an appropriate reference, or to give an error message if it cannot be found. Assuming that section 12 in the previous example has been tagged

```
<div1 xml:id="SEC12">
<!-- ... -->
</div1>
```

then the same cross-reference might more exactly be encoded as

See especially `<ref target="#SEC12">`section 12 on page 34`</ref>`.

If the cross-reference itself is to be generated according to a fixed pattern, or if no text is to appear in the body of the cross-reference, the `<ptr>` element would be used as follows:

See in particular `<ptr target="#SEC12"/>`.

The *cRef* attribute may be used to express the target of a cross reference using some canonical referencing scheme, such as those typically used for ancient texts. In this case, the referencing scheme must be defined using the `<cRefPattern>` element discussed below (3.10.4. *Declaring Reference Systems*); the definition it provides is used to translate the value of the *cRef* attribute into a conventional pointer value, such as one that might be supplied by the *target* attribute. It is an error to supply both *cRef* and *target* values.

When the *target* attribute is used, a cross reference may point to any number of locations simultaneously, simply by giving more than one identifier as the value of its *target* attribute. This may be particularly useful where an analytic index is to be encoded, as in the following example:

```
<list>
<item>Saints aid rejected in mel. <ptr target="#p299"/>
</item>
```

```

<item>Sallets censured <ptr target="#p143 #p144"/>
</item>
<item>Sanguine mel. signs <ptr target="#p263"/>
</item>
<item>Scilla or sea onion, a purger of mel. <ptr target="#p442"/>
</item>
</list>

```

Here the targets of the cross-references are simply page numbers; it is assumed that corresponding elements with identifiers p299, p143, etc. have been provided in the body of the text, for example as page breaks

```

<pb xml:id="p143"/>
...
<pb xml:id="p144"/>
...
<pb xml:id="p263"/>
...
<pb xml:id="p299"/>
...
<pb xml:id="p442"/>
...

```

A similar method may be used to link annotations on a text with the sigla used to encode their points of attachment in a text. For example:

```

annotated text <ref target="#a51" type="noteAnchor">51</ref>
<!-- ... -->
<note xml:id="a51" type="footnote">text of annotation</note>

```

The *type* attribute may be used, as elsewhere, to categorize the cross-reference according to any system of importance to the encoder. If bibliographic references require special processing (e.g. in order to provide a consistent short-form reference), they might be tagged thus:

```

Similar forms, often called
<term rend="ldquo rdquo">rewriting systems</term>, have a long history
among mathematicians, but the specific form of <ptr target="#fig22"/>
was first studied extensively by Chomsky <ptr type="bibliog" target="#chom59"/>.

<!-- ... -->
<figure xml:id="fig22">
  <graphic url="fig22.jpg"/>
</figure>
<!-- elsewhere, in the bibliography -->
<bibl xml:id="chom59">
<!-- citation for the book referenced above -->
</bibl>

```

The value *bibliog* for the *type* attribute on the second <ptr> element here might be used to indicate that the object being referenced here is a bibliographic entry rather than a simple cross-reference to an illustration, as is the first <ptr>. In either case, the value of the *target* attribute is a pointer to some other element.

The <ptr> and <ref> elements have many applications in addition to the simple cross-referencing facilities illustrated in this section. In conjunction with the analytic tools discussed in chapters 16. *Linking, Segmentation,*

and *Alignment*, 17. *Simple Analytic Mechanisms*, and 18. *Feature Structures*, they may be used to link analyses of a text to their object, to combine corresponding segments of a text, or to align segments of a text with a temporal or other axis or with each other.

Where the *target* attribute of `<ptr>` or `<ref>` points to an external resource available on the network, the *mimeType* attribute may be used to specify the mime type of that resource; this may be important for to enable appropriate processing. For example:

```
<p>The current version of the TEI Guidelines source
code is available in the TEI Sourceforge Repository;
<ref target="http://sourceforge.net/p/tei/code/HEAD/tree/trunk/P5/Source/guidelines-
en.xml"
mimeType="application/tei+xml">guidelines-en.xml</ref> is the root document used to
create the English version of these Guidelines.</p>
```

## 3.7 Lists

The following elements are provided for the encoding of lists, their constituent items, and the labels or headings associated with them:

**<list>** contains any sequence of items organized as a list.

**<item>** contains one component of a list.

**<label>** contains any label or heading used to identify part of a text, typically but not exclusively in a list or glossary.

**<head>** (heading) contains any type of heading, for example the title of a section, or the heading of a list, glossary, manuscript description, etc.

**<headLabel>** (heading for list labels) contains the heading for the label or term column in a glossary list or similar structured list.

**<headItem>** (heading for list items) contains the heading for the item or gloss column in a glossary list or similar structured list.

The `<list>` element should be used to mark any kind of *list*: numbered, lettered, bulleted, or unmarked. Lists formatted as such in the copy text should in general be encoded using this element, with an appropriate value for the *rend* attribute. Suggested values for *rend* include:

- *bulleted* (items preceded by bullets or similar markings)
- *inline* (items rendered within continuous prose, with no linebreaks)
- *numbered* (items preceded by numbers or letters)
- *simple* (items rendered as blocks, but with no bullet or number)

Some of these values may of course be combined; a list may be inline, but also be rendered with numbers. An example appears below. For more sophisticated and detailed description of list rendering, consider using the *style* attribute with Cascading Stylesheet properties and values, as described in the W3C's CSS Lists and Counters Module Level 3.

Each distinct item in the list should be encoded as a distinct `<item>` element. If the numbering or other identification for the items in a list is unremarkable and may be reconstructed by any processing program, no enumerator need be specified. If however an enumerator is retained in the encoded text, it may be supplied either by using the *n* attribute on the `<item>` element, or by using a `<label>` element. The following examples are thus equivalent:

```
I will add two facts, which have seldom occurred in
the composition of six, or even five quartos.
<list rend="inline numbered">
  <label>(1)</label>
  <item>My first rough manuscript, without any
    intermediate copy, has been sent to the press.</item>
  <label>(2)</label>
```

```
<item>Not a sheet has been seen by any human
  eyes, excepting those of the author and the printer:
  the faults and the merits are exclusively my own.</item>
</list>
```

```
I will add two facts, which have seldom occurred in
the composition of six, or even five quartos.
<list rend="inline numbered">
  <item n="1">My first rough manuscript, without any
    intermediate copy, has been sent to the press.</item>
  <item n="2">Not a sheet has been seen by any human
    eyes, excepting those of the author and the printer:
    the faults and the merits are exclusively my own.</item>
</list>
```

The two styles may not be mixed in the same list: if one item is preceded by a label, all must be.

A list need not necessarily be displayed in list format. For example, the following is a reasonable encoding of a list which (in the original) is simply printed as a single paragraph:

```
On those remote pages it is written that animals are
divided into <list rend="inline">
  <item n="a">those that belong to the Emperor, </item>
  <item n="b">embalmed ones, </item>
  <item n="c">those that are trained, </item>
  <item n="d">suckling pigs, </item>
  <item n="e">mermaids, </item>
  <item n="f">fabulous ones, </item>
  <item n="g">stray dogs, </item>
  <item n="h">those that are included in this classification, </item>
  <item n="i">those that tremble as if they were mad, </item>
  <item n="j">innumerable ones, </item>
  <item n="k">those drawn with a very fine camel's-hair brush, </item>
  <item n="l">others, </item>
  <item n="m">those that have just broken a flower vase, </item>
  <item n="n">those that resemble flies from a distance. </item>
</list>
```

A list may be given a heading or title, for which the <head> element should be used, as in the next example, which also demonstrates simple use of the <label> element to mark a tabular or glossary list in which each item is associated with a word or phrase rather than a numeric or alphabetic enumerator:

```
<list type="gloss">
  <head>Report of the conduct and progress of Ernest Pontifex.
    Upper Vth form – half term ending Midsummer 1851</head>
  <label>Classics</label>
  <item>Idle listless and unimproving</item>
  <label>Mathematics</label>
  <item>ditto</item>
  <label>Divinity</label>
  <item>ditto</item>
  <label>Conduct in house</label>
  <item>Orderly</item>
```

```

<label>General conduct</label>
<item>Not satisfactory, on account of his great
  unpunctuality and inattention to duties</item>
</list>

```

In such a list, the individual items have internal structure. In complex cases, where list items contain many components, the list is better treated as a *table*, on which see chapter 14. *Tables, Formulæ, Graphics and Notated Music*. A particularly important instance of the simple two-column table is the ‘glossary list’, which should be marked by the tag `<list type="gloss">`. In such lists, each `<label>` element contains a term and each `<item>` its gloss; it is a semantic error for a list tagged with `type="gloss"` not to have labels. For example:

```

<list type="gloss">
  <head>Unit Three – Vocabulary</head>
  <label xml:lang="la">acerbus, -a, -um </label>
  <item>bitter, harsh</item>
  <label xml:lang="la">ager, agrī, M. </label>
  <item>field</item>
  <label xml:lang="la">audiō, īre,
    īvī, ītus </label>
  <item>hear, listen (to)</item>
  <label xml:lang="la">bellum, -ī, N. </label>
  <item>war</item>
  <label xml:lang="la">bonus, -a, -um </label>
  <item>good</item>
</list>

```

Additionally, the `<term>` and `<gloss>` elements discussed in section 3.3.4. *Terms, Glosses, Equivalent, and Descriptions* might be used to make explicit the role that each column in the glossary list has, as follows:

```

<list type="gloss">
  <head>Unit Three – Vocabulary</head>
  <label>
    <term xml:lang="la">acerbus, -a, -um</term>
  </label>
  <item>
    <gloss>bitter, harsh</gloss>
  </item>
  <label>
    <term xml:lang="la">ager, agrī, M. </term>
  </label>
  <item>
    <gloss>field</gloss>
  </item>
  <label>
    <term xml:lang="la">audiō, -īre, -īvī, -ītus</term>
  </label>
  <item>
    <gloss>hear, listen (to)</gloss>
  </item>
  <label>
    <term xml:lang="la">bellum, -ī, N. </term>
  </label>
  <item>
    <gloss>war</gloss>
  </item>
</list>

```

```

</item>
<label>
  <term xml:lang="la">bonus, -a, -um</term>
</label>
<item>
  <gloss>good</gloss>
</item>
</list>

```

Note in the above examples the use of the global *xml:lang* attribute to specify on the <label> (or <term>) element what language the term is from. For further discussion of the *xml:lang* attribute see section 1.3.1.1. *Global Attributes*, and section vi.1 *Language Identification*. A more elaborate markup for this glossary would distinguish the headword forms from the grammatical information (principal parts and gender), perhaps using elements taken from 9. *Dictionaries*.

In addition to the <head> element used to supply a title or heading for the whole list, headings for the two columns of a glossary-style list may be specified using the two special elements <headLabel> and <headItem>:

The simple, straightforward statement of an idea is preferable to the use of a worn-out expression.

```

<list type="gloss">
  <headLabel>TRITE</headLabel>
  <headItem>SIMPLE, STRAIGHTFORWARD</headItem>
  <label>bury the hatchet </label>
  <item>stop fighting, make peace</item>
  <label>at loose ends </label>
  <item>disorganized</item>
  <label>on speaking terms </label>
  <item>friendly</item>
  <label>fair and square </label>
  <item>completely honest</item>
  <label>at death's door </label>
  <item>near death</item>
</list>

```

The elements <label>, <head>, <headLabel>, and <headItem> may contain only phrase-level elements. The <item> element however may contain paragraphs or other 'chunks', including other lists. In this example, a glossary list contains two items, each of which is itself a simple list:

```

<list type="gloss">
  <label>EVIL</label>
  <item>
    <list rend="bulleted">
      <item>I am cast upon a horrible desolate island, void
        of all hope of recovery.</item>
      <item>I am singled out and separated as it were from
        all the world to be miserable.</item>
      <item>I am divided from mankind – a solitaire; one
        banished from human society.</item>
    </list>
  </item>
  <label>GOOD</label>
  <item>
    <list rend="bulleted">
      <item>But I am alive; and not drowned, as all my
        ship's company were.</item>
    </list>
  </item>
</list>

```

```

<item>But I am singled out, too, from all the ship's
  crew, to be spared from death...</item>
<item>But I am not starved, and perishing on a barren place,
  affording no sustenances....</item>
</list>
</item>
</list>

```

Lists of different types may be nested to arbitrary depths in this way.

## 3.8 Notes, Annotation, and Indexing

### 3.8.1 Notes and Simple Annotation

The following element is provided for the encoding of discursive notes, whether already present in the copy text or supplied by the encoder:

**<note>** contains a note or annotation.

A note is any additional comment found in a text, marked in some way as being out of the main textual stream. All notes should be marked using the same tag, `<note>`, whether they appear as block notes in the main text area, at the foot of the page, at the end of the chapter or volume, in the margin, or in some other place.

Notes may be in a different hand or typeface, may be authorial or editorial, and may have been added later. Attributes may be used to specify these and other characteristics of notes, as detailed below.

A note is usually attached to a specific point or span within a text, which we term here its *point of attachment*. In conventional printed text, the point of attachment is represented by some siglum such as a star or cross, or a superscript digit.

When encoding such a text, it is conventional to replace this siglum by the content of the annotation, duly marked up with a `<note>` element. This may not always be possible for example with marginal notes, which may not be anchored to an exact location. For ease of processing, it may be adequate to position marginal notes before the relevant paragraph or other element. In printed texts, it is sometimes conventional to group notes together at the foot of the page on which their points of attachment appear. This practice is not generally recommended for TEI-encoded texts, since the pagination of a particular printed text is unlikely to be of structural significance. In some cases, however, it may be desirable to transcribe notes not at their point of attachment to the text but at their point of appearance, typically at the end of the volume, or the end of the chapter. In such cases, the *target* attribute of the `<note>` may be used to indicate the point of attachment. It is also possible to encode the point of attachment itself, using the `<ptr>` or `<ref>` element, pointing from that to the body of the `<note>` placed elsewhere.

In cases where the note is applied not to a point but to a span of text, not itself represented as a TEI element, the *target* attribute may use an appropriate pointer expression, for example using the `range()` function to specify the span of attachment.

For further discussion of pointing to points and spans in the text, see section 3.6. *Simple Links and Cross-References*.

In the following example, the *type* attribute is used to categorise the note as a gloss:

```

<l>The self-same moment I could pray</l>
<l>And from my neck so free</l>
<l>The albatross fell off, and sank</l>
<l>Like lead into the sea.
<note type="gloss" place="margin">The spell begins to break</note>
</l>

```

As the `<note>` appears within an `<l>` element, we may infer that its point of attachment is in the margin adjacent to the line in question. In the following version of the same text, however, it may be inferred that the note applies to the whole of the stanza:

```
<lg>
  <l>The self-same moment I could pray</l>
  <l>And from my neck so free</l>
  <l>The albatross fell off, and sank</l>
  <l>Like lead into the sea.</l>
  <note type="gloss" place="margin">The spell begins to break</note>
</lg>
```

This type of annotation, very common in the early printed texts which Coleridge may be presumed to be imitating in this case, may also be regarded as providing a heading or descriptive label for the passage concerned. The encoder may therefore prefer to use the <label> element to represent it, as in the following case:

```
<lg>
  <l>The self-same moment I could pray</l>
  <l>And from my neck so free</l>
  <l>The albatross fell off, and sank</l>
  <l>Like lead into the sea.</l>
  <label place="margin">The spell begins to break</label>
</lg>
```

In the following example, a note which appears at the foot of the page in the printed source is given at its point of attachment within the text. The global *n* attribute is used to indicate the note number:

```
Collections are ensembles of
distinct entities or objects of any sort.<note n="1" place="bottom">We
explain below why we use the uncommon term
<mentioned>collection</mentioned> instead of the expected
<mentioned>set</mentioned>. Our usage corresponds to the
<mentioned>aggregate</mentioned> of many mathematical writings and to
the sense of <mentioned>class</mentioned> found in older logical
writings.</note> The elements ...
```

In addition to transcribing notes already present in the copy text, researchers may wish to add their own notes or comments to it. The <note> element may be used for either purpose, but it will usually be advisable to distinguish the two categories. One way might be to use the *type* attribute shown above, categorizing notes as *authorial*, *editorial*, etc. Where notes derive from many sources, or where a more precise attribution is required, the *resp* attribute may be used to point to a definition of the person or other agency responsible for the content of the note.

As a simple example, an edition of the *Ancient Mariner* might include both Coleridge's original glosses and those of a modern commentator:

```
<lg>
<!-- ... -->
  <l>The self-same moment I could pray;
  <note place="margin" resp="#STC"
    type="gloss">The spell begins to break</note>
    <note place="bottom" resp="#JLL">The turning point of the poem...</note>
  </l>
</lg>
```

For this to be valid, the codes #JLL and #STC must point to some more information identifying the agency concerned. The syntax used is identical to that used for other cross-references, as discussed in 3.6. *Simple Links and Cross-References*; thus in this case, the TEI header for this text might contain a title statement like the following:

```

<titleStmt>
  <title>The Rime of the Ancient Mariner: an annotated edition</title>
  <author xml:id="STC">Samuel Taylor Coleridge</author>
  <editor xml:id="JLL">John Livingston Lowes</editor>
</titleStmt>

```

When annotating the electronic text by means of analytic notes in some structured vocabulary, e.g. to specify the topics or themes of a text, the `<span>` and `<interp>` elements may be more effective than the free form `<note>` element; these elements are available when the module for simple analysis is selected (see section 17.3. *Spans and Interpretations*).

### 3.8.2 Index Entries

The indexing of scholarly texts is a skilled activity, involving substantial amounts of human judgment and analysis. It should not therefore be assumed that simple searching and information retrieval software will be able to meet all the needs addressed by a well-crafted manual index, although it may complement them for example by providing free text search. The role of an index is to provide access via keywords and phrases which are not necessarily present in the text itself, but must be added by the skill of the indexer.

#### 3.8.2.1 Pre-existing Indexes

When encoding a pre-existing text, therefore, if such an index is present it may be advisable to retain it along with the text, rather than attempt to regenerate it automatically. Elements discussed elsewhere in these Guidelines may be used for this purpose. For example, the `<div1>` element or `<div>` element may be used to mark the section of the text containing the index and the `<list>` element might be used to mark the index itself, each entry being represented by an `<item>` element, possibly containing within it a series of `<ptr>` or `<ref>` elements, as follows:

```

<div type="index">
<!--...-->
  <list type="index">
    <item>Women, how cause of mel. <ref>193</ref>; their vanity in
      apparell taxed, <ref>527</ref>; their counterfeit tears
      <ref>547</ref>; their vices <ref>601</ref>, commended,
      <ref>624</ref>.</item>
    <item>Wormwood, good against mel. <ref>443</ref>
    </item>
    <item>World taxed, <ref>181</ref>
    </item>
    <item>Writers of the cure of mel. 295</item>
  </list>
<!--...-->
</div>

```

Note that this simple representation does not capture the nested structure of the first of these index entries. A more accurate representation might entail the use of nested lists like the following:

```

<item>Women,
<list>
  <item>how cause of mel. <ref>193</ref>;</item>
  <item>their vanity in apparell taxed, <ref>527</ref>;</item>
  <item>their counterfeit tears <ref>547</ref>;</item>
  <item>their vices
  <list>
    <item>
      <ref>601</ref>,</item>

```

```

    <item> commended, <ref>624</ref>.</item>
  </list>
</item>
</list>
</item>

```

The page references, encoded simply as <ref> elements above, might also include direct links to the appropriate location in the encoded text, using (for example) a target attribute to supply the identifier of an associated page break element:

```

<!-- in the text --><pb xml:id="P624"/>
<!-- start of page 624 -->
<!-- in the index -->
<ref target="#P624">624</ref>

```

For further discussion of this and alternative ways of encoding such links see the discussion in section 16. *Linking, Segmentation, and Alignment*. Note that similar methods may also be used to encode a table of contents, as further exemplified in section 4.5. *Front Matter*.

### 3.8.2.2 Auto-generated Indexes

It can also be useful, however, to generate a new index from a machine-readable text, whether the text is being written for the first time with the tags here defined, or as an addition to a text transcribed from some other source. Depending on the complexity of the text and its subject matter, such an automatically-generated index may not in itself satisfy all the needs of scholarly users. However it can assist a professional indexer to construct a fully adequate index, which might then be post-edited into the digital text, marked-up along the lines already suggested for preserving pre-existing index material.

Indexes generally contain both references to specific pages or sections and references to page ranges or sequences. The same element is used in either case:

**<index>** (index entry) marks a location to be indexed for whatever purpose.

Like the <interp> element described in 17.3. *Spans and Interpretations* this element may be used simply to provide descriptive or interpretive label of some kind for any location within a text, to be processed in any way by analytic software, but its main purpose is to facilitate the generation of an index for a printed version of the text. An <index> element may be placed anywhere within a text, between or within other elements. The headwords to be used when making up this index are given by the <term> elements within the <index> element. The location of the generated index might be specified by means of a processing instruction within the text, such as the following (the exact form of the PI is of course dependent on the application software in use):

```
<?tei indexplacement ?>
```

Alternatively, the special purpose <divGen> element might be used.

In the simplest case, a single headword is supplied by an <term> elements contained by an <index> element:

```

<p>The students understand procedures for Arabic lemmatisation
<index>
  <term>Lemmatization, Arabic</term>
</index>and are beginning to build parsers.</p>

```

The effect of this is to document an index entry for the term ‘Lemmatization, Arabic’, which when processed could reference the location of the original <index> element.

If the subject of Arabic lemmatization is treated at length in a text, then the index entry generated may need to reference a sequence of locations (e.g. page numbers). In such a case it will be necessary to identify the end of the relevant span of text as well as its starting point. This is most conveniently done by supplying an empty `<anchor>` element (as discussed in chapter 16. *Linking, Segmentation, and Alignment*) at the appropriate point and pointing to it from the `<index>` element by means of its `spanTo` attribute, as in this example:

```
<p>We now turn to the
topic of Arabic lemmatisation
<index spanTo="#ALAMEND">
  <term>Lemmatization, Arabic</term>
  </index> concerning which it is important to note [...]

<!-- much learned material omitted here -->
and now we can build our parser.<anchor xml:id="ALAMEND"/>
</p>
```

This would generate the same index entries as the previous example, but the reference would be to the whole span of text between the location of the `<index>` element and the location of the element identified by the code `ALAMEND`, rather than a single point, and thus might (for example) include a sequence of page numbers.

Although the position of the `<index>` element in the text provides the target location that will be specified in the generated index entry, no part of the text itself is used to construct that entry. Index terms appearing in the entry come solely from the content of `<term>` elements, which consequently may have to repeat words or phrases from the text proper. This need not be done verbatim, thus giving scope for normalization of spelling (as in the example above) or other modifications which may assist generation of an index in a desired form or sequence.

Sometimes, for example when index terms are taken from a different language or consist of mathematical formulae or other expressions, even a normalized form of an index term may be insufficient for an application to order it exactly as desired. The `sortKey` attribute may be used to address this problem, as in the following example:

```
<p>The @ operator
<index>
  <term sortKey="0000">@</term>
</index> precedes an
attribute name</p>
```

Here, an entry for the symbol `@` will appear in the index, but will be sorted alphabetically as if it were the string `0000`. This technique is also useful when an index entry is to contain some non-Unicode character or glyph represented by the `<g>` element discussed in chapter 5. *Characters, Glyphs, and Writing Modes*. In the following example, we assume that somewhere a definition for this glyph has been provided using the elements described in chapter 5. *Characters, Glyphs, and Writing Modes*, and given the code `PrinceGlyph`:

```
<char xml:id="PrinceGlyph">
<!-- definition of the glyph here -->
</char>
<p>The Artist formerly known as Prince <index>
  <term sortKey="Prince">
    <g ref="#PrinceGlyph"/>
  </term>
</index>...</p>
```

Note that if no value is supplied for the `sortKey` attribute, a sorting application should always use the content of the `<term>` element as a sort key.

It is common practice to compile more than one index for a given text. A biography of a poet, for example, may offer an index of references to poems by the subject of the study, another index of works by other writers, an index

of places or historical personages etc. The `indexName` attribute is used to assigning index terms and locations to one or more specific indexes:

```
<p>Sir John Ashford
<index indexName="INDEX-PERSONS">
  <term>Ashford, John</term>
</index> was,
coincidentally, born in
<index indexName="INDEX-PLACES">
  <term>Ashford
    (Kent)</term>
</index>Ashford...</p>
```

Multi-level indexing is particularly common in scholarly documents. For example, as well as entries such as *TEI*, or *markup*, an index may contain structured entries like *TEI*, *markup practices*, *index terms*, where a top level entry *TEI* is followed by a number of second-level subcategories, any or all of which may have a third-level list attached to them and so on. In order to reflect such a hierarchical index listing, `<index>` elements may be nested to the required depth. For example, suppose that we wish to make a structured index entry for ‘lemmatisation’ with subentries for ‘Arabic’, ‘Sanskrit’, etc. The example at the start of this section might then be encoded with nested `<index>` elements:

```
<p>The students understand procedures for Arabic lemmatisation
<index>
  <term>lemmatization</term>
  <index>
    <term>arabic</term>
  </index>
</index>
...</p>
```

The index entry from Burton's *Anatomy of Melancholy* quoted above might be generated in a similar way. To generate such an entry, the body of the text might include, at page 193, an `<index>` element such as

```
<index>
  <term>Women</term>
  <index>
    <term>how cause of mel.</term>
  </index>
</index>
```

. Similarly, page 601 of the body text would include an `<index>` element like the following:

```
<index>
  <term>Women</term>
  <index>
    <term>their vices</term>
  </index>
</index>
```

while the `<index>` element at page 624 would have a structure like the following:

```

<index>
  <term>Women</term>
  <index>
    <term>their vices</term>
    <index>
      <term>commended</term>
    </index>
  </index>
</index>

```

When processing such `<index>` elements, the duplication required to make the structure explicit will normally be removed, so as to produce entries like those quoted above. However, this is not required by the encoding recommended here.

As noted above, either a processing instruction or a `<divGen>` element may be used to mark the place at which an index generated from `<index>` elements should be inserted into the output of a processing program; typically but not necessarily this will be at some point within the back matter of the document. If the `<divGen>` element is used, then the *type* attribute should be used to specify which kind of index is to be generated, and its value should correspond with that of the *indexName* attribute on the relevant `<index>` elements.

```

<back>
  <div type="appendix">
    <head>Bibliography</head>
    <listBibl>
      <bibl> ... </bibl>
    </listBibl>
  </div>
  <divGen n="Index Nominum"
    type="INDEX-NAMES"/>
  <divGen n="Index Loci" type="INDEX-PLACES"/>
</back>

```

As this example shows, the global *n* attribute may also be used to specify a name or identifier for the generated index itself in the usual way. Any additional headings etc. required for the generated index must be specified as content of the `<divGen>` element.

```

<back>
  <divGen n="A1" type="INDEX-NAMES">
    <head>An Index of Names</head>
  </divGen>
</back>

```

If a processing instruction is used, then these parameters for the generated index may be supplied in some other way.

One final feature frequently found in manually-created indexes to printed works cannot readily be encoded by the means provided here, namely cross-references internal to the index term listing. For example, if all references to the TEI in a text have been indexed using the index term *Text Encoding Initiative*, it may also be helpful to include an entry under the term *TEI* containing some text such as ‘see Text Encoding Initiative’. Such internal cross-references must be added as part of the post-editing phase for an auto-generated index.

## 3.9 Graphics and Other Non-textual Components

Graphics, such as illustrations or diagrams, appear in many different kinds of text, and often with different purposes. Audio or video clips may also appear. In some cases, such media form an integral part of a text (indeed, some texts—comic books for example—may be almost entirely graphic); in others the graphic or video may be a kind of optional

extra. In some cases, the text may be incomprehensible unless the media is included; in others, the presence of the media adds little to the sense of the work. It will therefore be a matter of encoding policy as to whether or how media found in a source text are transferred to a new encoded version of the same. In documents which are 'born digital', media such as graphics and other non-textual components may be particularly salient, but their inclusion in an archival form of the document concerned remains an editorial decision.

Considered as structural components, media may be anchored to a particular point in the text, or they may *float* either completely freely, or within some defined scope, such as a chapter or section. Time-based media such as audio or video may need to be synchronized with particular parts of a written text. Media of all kinds often contain associated text such as a heading or label. These Guidelines provide the following different elements to indicate their appearance within a text:

**<figure>** groups elements representing or containing graphic information such as an illustration, formula, or figure.

**<media>** indicates the location of any form of external media such as an audio or video clip etc.

**<graphic>** indicates the location of a graphic or illustration, either forming part of a text, or providing an image of it.

**<binaryObject>** provides encoded binary data representing an inline graphic, audio, video or other object.

Media files may be encoded in a number of different ways:

- in some non-XML or binary format such as PNG, JPEG, MP3, MP4 etc.
- in an XML format such as SVG
- in a TEI XML format such as the notation for graphs and trees described in *19. Graphs, Networks, and Trees*

In the last two cases, the presence of the graphic will be indicated by an appropriate XML element, drawn from the SVG namespace in the second case, and its content will fully define the graphic to be produced. In the first case, however, one of the elements `<graphic>` or `<media>` is used to mark the presence of the graphic only and the visual content itself is stored outside the XML document at a location referenced by means of an *url* attribute. This attribute is provided by membership of these elements in the `att.resourced` class. Alternatively, if it is small, the media information may be embedded directly within the document using some suitable binary format such as Base64; in this case the `<binaryObject>` element may be used to contain it.

The elements `<graphic>`, `<media>`, and `<binaryObject>` are made available as members of the class `model.graphicLike` when this module is included in a schema. These elements are also members of the class `att.media`, from which they inherit the following attributes:

**att.internetMedia** provides attributes for specifying the type of a computer resource using a standard taxonomy.

**@mimeType** (MIME media type) specifies the applicable multimedia internet mail extension (MIME) media type

**att.media** provides attributes for specifying display and related properties of external media.

**@width** Where the media are displayed, indicates the display width

**@height** Where the media are displayed, indicates the display height

**@scale** Where the media are displayed, indicates a scale factor to be applied when generating the desired display size

For example, the following passage indicates that a copy of the image found in the source text may be recovered from the URL `zigzag2.png` and that this image is in PNG format:

```
<p>These were the four lines I moved in
through my first, second, third, and
fourth volumes. -- In the fifth volume
I have been very good, -- the precise
line I have described in it being this:
<graphic url="zigzag2.png"
  mimeType="image/png"/>
By which it appears, that except at the
curve, marked A. where I took a trip
```

```
to Navarre, -- and the indented curve B.
which is the short airing when I was
there with the Lady Baussiere and her
page, -- I have not taken the least frisk
...</p>
```

The media elements are phrase level elements which may be used anywhere that textual content is permitted, within but not between paragraphs or headings. In the following example, the encoder has decided to treat a specific printer's ornament as a heading:

```
<head>
  <graphic url="http://www.iath.virginia.edu/gants/Ornaments/Heads/hp-ral02.gif"/>
</head>
```

The `<figure>` element discussed in 14.4. *Specific Elements for Graphic Images* provides additional capabilities, for example the ability to combine a number of images into a hierarchically organized structure or a block of images. The `<figure>` element carries a *type* attribute, which can be used to distinguish different kinds of graphic component within a single work, for example, maps as opposed to illustrations. It also provides the ability to associate an image with additional information such as a heading or a description.

## 3.10 Reference Systems

By *reference system* we mean the system by which names or references are associated with particular passages of a text (e.g. *Ps. 23:3* for the third verse of Psalm 23 or *Amores 2.10.7* for Ovid's *Amores*, book 2, poem 10, line 7). Such names make it possible to mark a place within a text and enable other readers to find it again. A reference system may be based on structural units (chapters, paragraphs, sentences; stanza and verse), typographic units (page and line numbers), or divisions created specifically for reference purposes (chapter and verse in Biblical texts). Where one exists, the traditional reference system for a text should be preserved in an electronic transcript of it, if only to make it easier to compare electronic and non-electronic versions of the text.

Reference systems may be recorded in TEI-encoded texts in any of the following ways:

- where a reference system exists, and is based on the same logical structure as that of the text's markup, the reference for a passage may be recorded as the value of the global *xml:id* or *n* attribute on an appropriate tag, or may be constructed by combining attribute values from several levels of tags, as described below in section 3.10.1. *Using the xml:id and n Attributes.*
- where there is no pre-existing reference system, the global *xml:id* or *n* attributes may be used to construct one (e.g. collections and corpora created in electronic form), as described below in section 3.10.2. *Creating New Reference Systems.*
- where a reference system exists which is not based on the same logical structure as that of the text's markup (for example, one based on the page and line numbers of particular editions of the text rather than on the structural divisions of it), any of a variety of methods for encoding the logical structure representing the reference system may be employed, as described in chapter 20. *Non-hierarchical Structures.*
- where a reference system exists which does not correspond to any particular logical structure, or where the logical structure concerned is of no interest to the encoder except as a means of supporting the referencing system, then references may be encoded by means of `<milestone>` elements, which simply mark points in the text at which values in the reference system change, as described below in section 3.10.3. *Milestone Elements.*

The specific method used to record traditional or new reference systems for a text should be declared in the TEI header, as further described in section 3.10.4. *Declaring Reference Systems* and in section 16.2.5. *Canonical References.*

When a text has no pre-existing associated reference system of any kind, these Guidelines recommend as a minimum that at least the page boundaries of the source text be marked using one of the methods outlined in this

section. Retaining page breaks in the markup is also recommended for texts which have a detailed reference system of their own. Line breaks in prose texts may be, but need not be, tagged.<sup>50</sup>

### 3.10.1 Using the *xml:id* and *n* Attributes

When traditional reference schemes represent a hierarchical structuring of the text which mirrors that of the marked-up document, the *n* attribute defined for all elements may be used to indicate the traditional identifier of the relevant structural units. The *n* attribute may also be used to record the numbering of sections or list items in the copy text if the copy-text numbering is important for some reason, for example because the numbers are out of sequence.

For example, a traditional reference to Ovid's *Amores* might be *Amores 2.10.7*—book 2, poem 10, line 7. Book, poem, and line are structural units of the work and will therefore be tagged in any case. (See chapter 6. *Verse* for a discussion of structural units in verse collections.) In such cases, it is convenient to record traditional reference numbers of the structural units using the *n* attribute. The relevant tags for our example would be:

```
<div1 n="Amores" type="volume">
  <div2 n="1" type="book">
<!-- ... -->
  </div2>
  <div2 n="2" type="book">
    <div3 n="1" type="poem">
<!-- ... -->
    </div3>
    <div3 n="2" type="poem">
<!-- ... -->
    </div3>
<!-- ... -->
    <div3 n="10" type="poem">
      <l n="1"> ... </l>
      <l n="2"> ... </l>
<!-- ... -->
      <l n="7"> ... </l>
    </div3>
<!-- ... -->
  </div2>
<!-- ... -->
</div1>
```

One may also place the entire standard reference for each portion of the text into the appropriate value for the *n* attribute, though for obvious reasons this takes more space in the file:

```
<div1 n="Amores" type="volume">
  <div2 n="Amores 1" type="book">
<!-- ... -->
  </div2>
  <div2 n="Amores 2" type="book">
    <div3 n="Amores 2.1" type="poem">
<!-- ... -->
    </div3>
<!-- ... -->
    <div3 n="Amores 2.10" type="poem">
<!-- ... -->
      <l n="Amores 2.10.7"> ... </l>
<!-- ... -->
  </div2>
</div1>
```

<sup>50</sup>Many encoders find it convenient to retain the line breaks of the original during data entry, to simplify proofreading, but this may be done without inserting a tag for each line break of the original.

```

    </div3>
  <!-- ... -->
</div2>
<!-- ... -->
</div1>

```

If the names used by the traditional reference system can be formulated as identifiers, then the references can be given as values for the *xml:id* attribute; this requires that the reference be given without internal spaces, begin with a letter or underscore, and contain no characters other than letters, digits, hyphens, underscores, full stops, and the various combining and extender characters, as defined by the XML specification. Unlike values for the *n* attribute, values for the *xml:id* attribute must be unique throughout the document. Our example then looks like this:

```

<div1 n="Amores" type="volume">
  <div2 xml:id="am.1" type="book">
    <!-- ... -->
  </div2>
  <div2 xml:id="am.2" type="book">
    <div3 xml:id="am.2.1" type="poem">
      <!-- ... -->
    </div3>
    <!-- ... -->
    <div3 xml:id="am.2.10" type="poem">
      <!-- ... -->
      <l xml:id="am.2.10.7"> ... </l>
    </div3>
  </div2>
</div1>

```

To document the usage and to allow automatic processing of these standard references, it is recommended that the TEI header be used to declare whether standard references are recorded in the *n* or *xml:id* attributes and which elements may carry standard references or portions of them. For examples of declarations for the reference systems just shown, see section 3.10.4. *Declaring Reference Systems*.

Using the *n* attribute one can specify only a single standard referencing system, a limitation not without problems, since some editions may define structural units differently and thus create alternative reference systems. For example, another edition of the *Amores* considers poem 10 a continuation of poem 9, and therefore would specify the same line as *Amores* 2.9.31. In order to record both of these reference systems one could employ any of a variety of methods discussed in chapter 20. *Non-hierarchical Structures*.

### 3.10.2 Creating New Reference Systems

If a text has no canonical reference system of its own, a new custom reference system may be used.

The global attributes *n* and *xml:id* may be used to assign reference identifiers to segments of the text. Identifiers specified by either attribute apply to the entire element for which they are given. *xml:id* attributes must be unique within a single document, and *xml:id* values must begin with a letter. No such restrictions are made on the values of *n* attributes.

Determining a referencing system for a TEI encoding depends on many factors that may either be derived from textual structure, or influenced by extra-textual contingencies such as project and file management concerns. It is important, therefore, that the attribute used, the elements which can bear standard reference identifiers, and the method for constructing standard reference identifiers, should all be declared in the header as described in section 2.3.6. *The Reference System Declaration*.

The Guidelines do not recommend one specific method for creating new referencing systems; however, the rest of this section lists some possibly useful strategies.

## 3.10.2.1 Referencing system derived from markup

A new referencing system may be derived from the structure of the electronic text, specifically from the markup of the text. As with any reference system intended for long-term use, it is important to see the reference as an established, unchanging point in the text. Should the text be revised or rearranged, the reference-system identifiers associated with any section of text must stay with that section of text, even if it means the reference numbers fall out of sequence. (A new reference system may always be created beside the old one if out-of-sequence numbers must be avoided.)

A convenient method of mechanically generating unique values for *xml:id* or *n* attributes based on the structure of the document is to construct, for each element, a *domain-style address* comprising a series of components separated by full stops, with one component for each level of the document hierarchy. Two methods may be used. In the *typed path* form of identifier, each component in the identifier takes the form of an element identifier, a hyphen, and a number, for example p-2. The element name specifies what type of element is to be sought, and the number specifies which occurrence of that element type is to be selected. (The hyphen and number may be omitted if there is only one element of the given type.) In the *untyped path* form of identifier, each component consists of a number, indicating which element in the sequence of nodes at each level is to be selected. To make the resulting identifier a valid XML identifier, it may need to be prefixed with an unchanging alphabetic letter.

Identifiers generated with these methods should use the <text> element as their starting point, rather than the <TEI> or <body> elements. The <TEI> element may be taken as a starting point only if identifiers need to be generated for the <teiHeader>, which is not usually the case; using the <body> element as a root would prevent assignment of identifiers for the front and back matter. The component corresponding to the root element can be omitted from identifiers, if no confusion will result. In collections and corpora, the component corresponding to the root may be replaced by the unique identifier assigned to the text or sample.

In the following example, each element within the <text> element has been given a typed-path identifier as its *xml:id* value, and an untyped-path identifier as its *n* value; the latter are prefixed with the string AB, which may be imagined to be the general identifier for this text.

```
<text xml:id="Text-1" n="AB">
  <front xml:id="Front" n="AB.1">
    <div xml:id="Front.div-1" n="AB.1.1">
      <p> ... </p>
    </div>
    <titlePage xml:id="Front.titlePage"
      n="AB.1.2">
      <titlePart> ... </titlePart>
    </titlePage>
    <div xml:id="Front.div-2" n="AB.1.3">
      <p> ... </p>
    </div>
  </front>
  <body xml:id="Body" n="AB.2">
    <p xml:id="Body.p-1" n="AB.2.1"> ... </p>
    <p xml:id="Body.p-2" n="AB.2.2"> ... </p>
    <div xml:id="Body.div-1" n="AB.2.3">
      <head xml:id="Body.div-1.head"
        n="AB.2.3.1"> ... </head>
      <p xml:id="Body.div-1.p-1" n="AB.2.3.2"> ... </p>
      <p xml:id="Body.div-1.p-2" n="AB.2.3.3"> ... </p>
    </div>
    <div xml:id="Body.div-2" n="AB.2.4">
      <head xml:id="Body.div-2.head"
        n="AB.2.4.1"> ... </head>
      <p xml:id="Body.div-2.p-1" n="AB.2.4.2"> ... </p>
      <p xml:id="Body.div-2.p-2" n="AB.2.4.3"> ... </p>
    </div>
  </body>
</text>
```

```
</body>
</text>
```

The typed and untyped path methods are convenient, but are in no way required for anyone creating a reference system.

If the *xml:id* attribute is used to record the reference identifiers generated, each value should record the entire path. If the *n* attribute is used, each value may record either the entire path or only the subpath from the parent element. The attribute used, the elements which can bear standard reference identifiers, and the method for constructing standard reference identifiers, should all be declared in the header as described in section 2.3.6. *The Reference System Declaration*.

### 3.10.2.2 Referencing systems based on project conventions

A reference system may be based on an agreed project-specific convention for *xml:id* attributes. Every convention will have strengths and weaknesses and it is left to encoders to make a decision that enables them to locate information in their TEI document.

Here are some examples of referencing systems that have been used in TEI project:

- **Title-based identifiers:** identifiers constructed with a number of characters from the main document title, followed by an incremental number. E.g. HOL001, HOL002, etc. using a fixed number of digits; or without fixed digits: HOL1, HOL2, etc.
- **Based on markup, with prefix:** identifiers constructed on the markup itself, as described in the previous section. To facilitate uniqueness in a corpus, each identifier may be prefixed with the identifier of the root <TEI> element. E.g. RootID-Body-p-1.
- **Opaque identifiers:** computed identifiers using either a randomized algorithm or a universally unique identifier (UUID) algorithm. Note that XSLT's function `generate-id()` only guarantees identifier unique to the document being processed.

XML well-formedness requires only that *xml:id* attributes be unique within a single document. However, it is also worth keeping in mind that for operating with referencing systems across a corpus of TEI files it is helpful (or even necessary in some circumstances) to have unique identifiers across the whole corpus.

Values of *xml:id* may be either populated computationally or manually. In the latter case, it is advisable to put measures in place to avoid human error. Custom data types and Schematron rules may be defined in a customization ODD, and a check digit may be added to prevent unwanted changes.<sup>51</sup>

### 3.10.3 Milestone Elements

Where the desired reference system does not correspond to any particular structural hierarchy, or the document combines multiple structural hierarchies (as further discussed in 20. *Non-hierarchical Structures*), simpler though less expressive methods may be necessary. In such cases the simplest solution may be just to mark up changes in the reference system where they occur, by using one or more of the following *milestone* elements:

**<milestone>** marks a boundary point separating any kind of section of a text, typically but not necessarily indicating a point at which some part of a standard reference system changes, where the change is not represented by a structural element.

**<gb>** (gathering begins) marks the point in a transcribed codex at which a new gathering or quire begins.

**<pb>** (page break) marks the start of a new page in a paginated document.

**<lb>** (line break) marks the start of a new (typographic) line in some edition or version of a text.

**<cb>** (column break) marks the beginning of a new column of a text on a multi-column page.

These elements simply mark the points in a text at which some category in a reference system changes. They have no content but subdivide the text into regions, rather in the same way as milestones mark points along a road, thus implicitly dividing it into segments. The elements <gb>, <pb>, <cb>, and <lb> are specialized types of milestone, marking gathering, page, column, and line boundaries respectively. The global *n* attribute is used in each case to provide a value for the particular unit associated with this milestone (for example, the page or line number). Since

<sup>51</sup>A check digit is computed from the value of an identifier and appended to the value itself. If the identifier is changed, the check digit would therefore invalidate it.

it is not structural, validation of a reference system based on <milestone>s cannot readily be checked by an XML parser, so it will be the responsibility of the encoder or the application software to ensure that they are given in the correct order.

Milestone elements are often used as a simple means of capturing the original appearance of an early printed text, which will rarely coincide exactly with structural units, but they are generally useful wherever a text has two or more competing structures. For example, many English novels were first published as serial works, individual parts of which do not always contain a whole number of chapters. An encoder might decide to represent the chapter-based structure using <div1> elements, with <milestone> elements to mark the points at which individual parts end; or the reverse. Thus, an encoding in which chapters are regarded as more important than parts might encode some work in which chapter three begins in part one and is concluded in part two as follows:

```
<text>
  <body>
    <milestone unit="part" n="1"/>
    <div1 n="1" type="chapter">
      <p>
<!-- ... -->
      </p>
    </div1>
    <div1 n="2" type="chapter">
      <p>
<!-- ... -->
      </p>
    </div1>
    <div1 n="3" type="chapter">
      <p>
<!-- ... -->
      </p>
      <milestone unit="part" n="2"/>
      <p>
<!-- ... -->
      </p>
    </div1>
  </body>
</text>
```

An encoding of the same work in which parts are regarded as more important than chapters might begin as follows:

```
<text>
  <body>
    <div1 n="1" type="part">
      <milestone unit="chapter" n="1"/>
      <p>
<!-- ... -->
      </p>
      <milestone unit="chapter" n="2"/>
      <p>
<!-- ... -->
      </p>
      <milestone unit="chapter" n="3"/>
      <p>
<!-- ... -->
      </p>
    </div1>
  <div1 n="2" type="part">
```

```

    <p>
<!-- ... -->
    </p>
    <milestone unit="chapter" n="4"/>
    <p>
<!-- ... -->
    </p>
  </div1>
</body>
</text>

```

Similarly, when tagging dramatic verse one may wish to privilege stanzas and lines over speeches and speakers, particularly where speeches cross line and line group boundaries. One might also wish to mark changes in narrative voice in a prose text. In either case, a milestone tag may be used to indicate change of speaker:

```

<lg>
  <milestone unit="speaker" n="Man"/>
  <l>Oh what is this I cannot see</l>
  <l>With icy hands gets a hold on me</l>
  <milestone unit="speaker" n="Death"/>
  <l>Oh I am Death, none can excel</l>
  <l>I open the doors of heaven and hell</l>
</lg>

```

Milestone tags also make it possible to record the reference systems used in a number of different editions of the same work. The reference system of any one edition can be recreated from a text in which all are marked by simply ignoring all elements that do not specify that edition on their *ed* attribute.

As a simple example, assuming that edition E1 of some collection of poems regards the first two poems as constituting the first book, while edition E2 regards the first poem as prefatory, a markup scheme like the following might be adopted:

```

<milestone ed="E1" unit="work"/>
<milestone ed="E2" unit="work"/>
<milestone ed="E1" unit="book"/>
<milestone ed="E1" unit="poem"/>
<milestone ed="E2" unit="poem"/>
<milestone ed="E2" unit="book"/>
<milestone ed="E1" unit="poem"/>
<milestone ed="E2" unit="poem"/>

```

In this case no *n* value is specified, since the numbers rise predictably and the application can keep a count from the start of the document, if desired.

The value of the *n* attribute may but need not include the identifiers used for any larger sections. That is, either of the following styles is legitimate:

```

<milestone ed="E1" unit="work" n="Amores"/>
<milestone ed="E1" unit="book" n="1"/>
<milestone ed="E1" unit="poem" n="1"/>
<milestone ed="E1" unit="poem" n="2"/>
<milestone ed="E1" unit="book" n="2"/>

```

or

```

<milestone ed="E1" unit="work" n="Amores"/>
<milestone ed="E1" unit="book" n="1"/>
<milestone ed="E1" unit="poem" n="1.1"/>
<milestone ed="E1" unit="poem" n="1.2"/>
<milestone ed="E1" unit="book" n="2"/>

```

When using <milestone> tags, line numbers may be supplied for every line or only periodically (every fifth, every tenth line). The latter may be simpler; the former is more reliable.

The style of numbering used in the values of *n* is unrestricted: for the example above, I.i, I.ii, and I.iii could have been used equally well if preferred. The special value unnumbered should be reserved for marking sections of text which fall outside the normal numbering system (e.g. chapter heads, poem numbers, titles, or speaker attributions in a verse drama).

By default, there are no constraints on the values supplied for the *ed* attribute. If it is felt appropriate to enforce such a restriction, the techniques described in 23.3. *Personalization and Customization* may be used, for example to specify that the attribute must specify one of a predefined set of values.

See below, section 3.10.4. *Declaring Reference Systems*, for examples of declarations for the reference systems just shown.

Milestone elements may be used to mark any kind of shift in the properties associated with a piece of text, whether or not would normally be considered a reference system. For example, they may be used to mark changes in narrative voice in a prose text, or changes of speaker in a dramatic text, where these are not marked using structural elements such as <sp>, perhaps in order to avoid a clash of hierarchies.

As noted in 3.2.2. *Hyphenation* above, milestone elements such as <lb> or <pb> represent whitespace and are therefore by default assumed to occur between orthographic tokens in the text, where these are not otherwise indicated. By default it is reasonable to assume that words are not broken across page or line boundaries, and that therefore a sequence such as

```
...sed imp<lb>erator dixit...
```

should be tokenized as four words (*sed*, *imp*, *erator*, and *dixit*). The *break* attribute is provided to change the default assumption. To make explicit that *imperator* in the above example should be treated as a single word, a tagging such as the following is recommended:

```
...sed imp<lb break="no"/>erator dixit...
```

Where hyphenation appears before a line or page break, the encoder may or may not choose to record the fact, either explicitly using an appropriate Unicode character, or descriptively for example by means of the *rend* attribute; see further 3.2.2. *Hyphenation*.

### 3.10.4 Declaring Reference Systems

Whatever kind of reference system is used in an electronic text, it is recommended that the TEI header contain a description of its construction in the <refsDecl> element described in section 2.3.6. *The Reference System Declaration*. As described there, the declaration may consist either of a formal declaration using the <cRefPattern> element or an informal description in prose. The former is recommended because unlike prose it can be processed by software.

The three examples given in section 3.10.1. *Using the xml:id and n Attributes* would be declared as follows. The first example encodes the standard references for Ovid's *Amores* one level at a time, using the *n* attribute on the <div1>, <div2>, <div3>, and <l> tags. The header section for such an encoding should look something like this:

```

<encodingDesc>
  <refsDecl>
    <cRefPattern matchPattern="([^\s]+) ([0-9]+)\.([0-9]+)\.([0-9]+)"
      replacementPattern="#xpath(//div1[@n='$1']/div2[@n='$2']/div3[@n='$3']/l[@n='$4'])">
      <p>A canonical reference is assembled with
      <list>
        <item>the name of the <label>work</label>: the
        <att>n</att> of a <gi>div1</gi>,</item>
        <item>a space,</item>
        <item>the number of the <label>book</label>: the
        <att>n</att> of a child <gi>div2</gi>,</item>
        <item>a full stop</item>
        <item>the number of the <label>poem</label>: the
        <att>n</att> of a child <gi>div3</gi>,</item>
        <item>the line number: the <att>n</att> value of a
          child <gi>l</gi>
        </item>
      </list>
    </cRefPattern>
    <cRefPattern matchPattern="([^\s]+) ([0-9]+)\.([0-9]+)"
      replacementPattern="#xpath(//div1[@n='$1']/div2[@n='$2']/div3[@n='$3'])">
      <p>Same as above, but without the last component (full
        stop followed by the <gi>l</gi>'s <att>n</att>.</p>
    </cRefPattern>
    <cRefPattern matchPattern="([^\s]+) ([0-9]+)"
      replacementPattern="#xpath(//div1[@n='$1']/div2[@n='$2'])">
      <p>Same as above, but without the poem component (full
        stop followed by the <gi>div3</gi>'s <att>n</att>.</p>
    </cRefPattern>
  </refsDecl>
</encodingDesc>

```

The second example encodes the same reference system, again using the *n* attribute on the <div1>, <div2>, <div3>, and <l> tags, but giving the reference string in full on each tag. If canonical references are made only to lines, the reference system could be declared as follows:

```

<refsDecl>
  <cRefPattern matchPattern="([^\s]+ [0-9]+\.[0-9]+\.[0-9]+)"
    replacementPattern="#xpath(//l[@n='$1'])"/>
</refsDecl>

```

Since the entire regular expression is enclosed as a parenthetical subgroup, the entire canonical reference string is sought as the value of the *n* attribute on an <l> element.

In order to handle references to poems as well as to individual lines, the declaration for the reference system must be more complicated:

```

<refsDecl>
  <cRefPattern matchPattern="([^\s]+ [0-9]+\.[0-9]+\.[0-9]+)"
    replacementPattern="#xpath(//l[@n='$1'])"/>
  <cRefPattern matchPattern="([^\s]+ [0-9]+\.[0-9]+)"
    replacementPattern="#xpath(//div2[@n='$1'])"/>
</refsDecl>

```

This declaration indicates that the entire reference string must be sought as the value of the *n* attribute on a <div1>, <div2>, <div3>, or <l> element.

The third example encodes the same reference system, this time giving the entire reference string as the value of the *xml:id* attribute on the relevant tags. The reference system declaration for such an encoding could be:

```
<refsDecl>
  <cRefPattern matchPattern="(.*)"
    replacementPattern="#$1"/>
</refsDecl>
```

although in general there seems to be little advantage in this case: it is no more difficult to use a standard relative URI reference as the value of *target*.

Reference systems recorded by means of milestone tags can also be declared; the following prose description could be used to declare the example given in section 3.10.3. *Milestone Elements*.

```
<refsDecl>
  <p>Standard references to work, book, poem, and line may be
    constructed from the milestone tags in the text.</p>
</refsDecl>
```

Or in this way, using a formal declaration for this reference scheme derived from edition E1.

```
<refsDecl>
  <refState ed="E1" unit="work" delim=" "/>
  <refState ed="E1" unit="book" delim="."/>
  <refState ed="E1" unit="poem" delim=":"/>
  <refState ed="E1" unit="line"/>
</refsDecl>
```

## 3.11 Bibliographic Citations and References

Bibliographic references (that is, full descriptions of bibliographic items such as books, articles, films, broadcasts, songs, etc.) or pointers to them may appear at various places in a TEI text. They are required at several points within the TEI header's source description, as discussed in section 2.2.7. *The Source Description*; they may also appear within the body of a text, either singly (for example within a footnote), or collected together in a list as a distinct part of a text; detailed bibliographic descriptions of manuscript or other source materials may also be required. These Guidelines propose a number of specialized elements to encode such descriptions, which together constitute the `model.biblLike` class.

**model.biblLike** groups elements containing a bibliographic description.

|                         |  |
|-------------------------|--|
| <code>bibl</code>       | (bibliographic citation) contains a loosely-structured bibliographic citation of which the sub-components may or may not be explicitly tagged.                 |
| <code>biblFull</code>   | (fully-structured bibliographic citation) contains a fully-structured bibliographic citation, in which all components of the TEI file description are present. |
| <code>biblStruct</code> | (structured bibliographic citation) contains a structured bibliographic citation, in which only bibliographic sub-elements appear and in a specified order.    |
| <code>listBibl</code>   | (citation list) contains a list of bibliographic citations of any kind.  |
| <code>msDesc</code>     | (manuscript description) contains a description of a single identifiable manuscript or other text-bearing object.  |

Lists of such elements may also be encoded using the following element:

**<listBibl>** (citation list) contains a list of bibliographic citations of any kind.

In printed texts, the individual constituents of a bibliographic reference are conventionally marked off from each other and from the flow of text by such features as bracketing, italics, special punctuation conventions, underlining, etc. In electronic texts, such distinctions are also important, whether in order to produce acceptably formatted output or to facilitate intelligent retrieval processing,<sup>52</sup> quite apart from the need to distinguish the reference itself as a textual object with particular linguistic properties.

It should be emphasized that for references as for other textual features, the primary or sole consideration is not how the text should be formatted when it is printed. The distinctions permitted by the scheme outlined here may not necessarily be all that particular formatters or bibliographic styles require, although they should prove adequate to the needs of many such commonly used software systems.<sup>53</sup> The features distinguished and described below (in section 3.11.2. *Components of Bibliographic References*) constitute a set which has been useful for a wide range of bibliographic purposes and in many applications, and which moreover corresponds to a great extent with existing bibliographic and library cataloguing practice. For a fuller account of that practice as applied to electronic texts see section 2.2.7. *The Source Description*; for a brief mention of related library standards see section 2.8. *Note for Library Cataloguers*.

The most commonly used elements in the `model.biblLike` class are `<biblStruct>` and `<bibl>`. `<biblStruct>` will usually be easier to process mechanically than `<bibl>` because its structure is more constrained and predictable. It is suited to situations in which the objective is to represent bibliographic information for machine processing directly by other systems or after conversion to some other bibliographic markup formats such as BibTeXML or MODS. Punctuation delimiting the components of a print citation is not permitted directly within a `<biblStruct>` element; instead, the presence and order of child elements must be used to reconstruct the punctuation required by a particular style.

By contrast, `<bibl>` allows for considerable flexibility in that it can include both delimiting punctuation and unmarked-up text; and its constituents can also be ordered in any way. This makes it suitable for marking up bibliographies in existing documents, where it is considered important to preserve the form of references in the original document, while also distinguishing important pieces of information such as authors, dates, publishers, and so on. `<bibl>` may also be useful when encoding ‘born digital’ documents which require use of a specific style guide when rendering the content; its flexibility makes it easier to provide all the information for a reference in the exact sequence required by the target rendering, including any necessary punctuation and linking words, rather than using an XSLT stylesheet or similar to reorder and punctuate the data.

The third element in the `model.biblLike` class, `<biblFull>`, has a content model based on the `<fileDesc>` element of the TEI header. Both are based on the International Standard for Bibliographic Description (ISBD), which forms the basis of several national standards for bibliographic citations. The order of child elements in both `<biblFull>` and `<fileDesc>` corresponds to the order of bibliographic description ‘areas’ in ISBD with two minor exceptions. First, the `<extent>` element, corresponding to the *physical description area* in ISBD, appears just after the *publication, production, distribution, etc. area* in ISBD, not before it as in TEI. Second, `<biblFull>` and `<fileDesc>` use the child element `<publicationStmt>` to cover not only the *publication, production, distribution, etc. area* but also the *resource identifier and terms of availability area* associated with that publication. Despite these inconsistencies, users encoding citations and attempting to format them according to a standard that closely adheres to ISBD may find that `<biblFull>`, used with its child elements and without delimiting punctuation, provides an appropriate granularity of encoding with elements that can easily be rendered for the reader. However, it is important to note that some ISBD-derived citation formats (such as ANSI/NISO Z39.29 and FOCT 7.1) are not entirely conformant to ISBD either, since they may begin with a statement of authorship that does not map to the ISBD statement of responsibility.

### 3.11.1 Methods of Encoding Bibliographic References and Lists of References

The members of the `model.biblLike` class all share a number of possible component sub-elements. For the `<bibl>` and `<biblStruct>` elements, exactly the same sub-elements are concerned, and they are described together in section 3.11.2. *Components of Bibliographic References*; for the `<biblFull>` element, the sub-elements concerned are fully described in section 2.2. *The File Description*.

<sup>52</sup>For example, to distinguish *London* as an author’s name from *London* as a place of publication or as a component of a title.

<sup>53</sup>Among the bibliographic software systems and subsystems consulted in the design of the `<biblStruct>` structure were BibTeX, Scribe, and ProCite. The distinctions made by all three may be preserved in `<biblStruct>` structures, though the nature of their design prevents a simple one-to-one mapping from their data elements to TEI elements. For further information, see section 3.11.4. *Relationship to Other Bibliographic Schemes*.

Different levels of specific tagging may be appropriate in different situations. In some cases, it may be felt necessary to mark just the extent of the reference itself, with perhaps a few distinctions being made within it (for example, between the part of the reference which identifies a title or author and the rest). Such references, containing a mixture of text with specialized bibliographic elements, are regarded as <bibl> elements, and tagged accordingly. For example:

```
<p>A book which had a great influence on him
was <bibl>Tufte's <title>Envisioning
    Information</title>
</bibl>, although he may
never have actually read it.</p>
```

Indeed, some encoders may find it unnecessary to mark the bibliographic reference at all:

```
<p>A book which had a great influence on him
was Tufte's <title>Envisioning Information</title>,
although he may never have actually read it.</p>
```

Some bibliographic references are extremely elliptical, often only a string of the form *Baxter, 1983*. If no further details of Baxter's book are given in the source text and none is supplied by the encoder, then the reference thus given should be tagged as a <bibl>:

```
All of this is of course much more fully treated
in <bibl>Baxter, 1983</bibl>.
```

In general, however, normal modern bibliographic practice, and these Guidelines, distinguish between a bibliographic *reference*, which is a self-sufficient description of a bibliographic item, and a bibliographic *pointer*, which is a short-form citation (e.g. *Baxter, 1983*) which serves usually as a place-holder or pointer to a full long-form reference found elsewhere in the text. The usual encoding of short-form references such as *Baxter, 1983* is not as <bibl> elements but as cross-references to such elements; see section 3.11.3. *Bibliographic Pointers* below.

In cases where the encoder wishes to impose more structure on the bibliographic information, for example to make sure it conforms to a particular stylesheet or retrieval processor, the <biblStruct> element should be used. Note that several of the features in this and later examples are explained later in the current section.

```
<biblStruct>
  <monogr>
    <author>
      <persName>
        <forename>Edward</forename>
        <forename full="init">R.</forename>
        <surname>Tufte</surname>
      </persName>
      <idno type="scopus">6506403994</idno>
      <idno type="lcaf">http://id.loc.gov/authorities/names/n50012763.html</idno>
    </author>
    <title level="m">Envisioning Information</title>
    <imprint>
      <pubPlace>Cheshire, Conn.</pubPlace>
      <publisher>Graphics Press</publisher>
      <date when="1990"/>
    </imprint>
  </monogr>
</biblStruct>
```

A more complex and detailed bibliographic structure is provided by the `<biblFull>` element defined in the TEI header module. This element is provided as a means of embedding the file description of one existing digital text within that of another (see further section 2.2. *The File Description*); however, its use is not confined to digital texts, and it may be used in the same way as any other bibliographic element, as in this example:

```
<biblFull>
  <titleStmt>
    <title>Envisioning Information</title>
    <author>Tufte, Edward R[olf]</author>
  </titleStmt>
  <extent>126 pp.</extent>
  <publicationStmt>
    <publisher>Graphics Press</publisher>
    <pubPlace>Cheshire, Conn. USA</pubPlace>
    <date>1990</date>
  </publicationStmt>
</biblFull>
```

A list of bibliographic items, of whatever kind, may be treated in the same way as any other list (see section 3.7. *Lists*). Alternatively, the specialized `<listBibl>` element may be used. The difference between the two is that a `<list>` contains `<item>` elements, within which bibliographic elements (`<bibl>`, `<biblStruct>`, or `<biblFull>`) may appear, as well as other phrase- and paragraph-level elements, whereas the `<listBibl>` may contain only bibliographic elements, optionally preceded by a heading and a series of introductory paragraphs. For most purposes, good practice would usually require that a `<listBibl>` contain only one kind of bibliographic element, though the following example combines both fully structured `<biblStruct>` and informal `<bibl>` elements:

```
<listBibl>
  <head>Bibliography</head>
  <biblStruct xml:id="NELSON80">
    <analytic>
      <author>
        <persName>
          <surname>Nelson</surname>
          <forename>Theodore</forename>
          <forename>Holm</forename>
        </persName>
      </author>
      <title level="a">Replacing the printed word:
        a complete literary system</title>
    </analytic>
    <monogr>
      <title level="m">Information Processing '80: Proceedings of the IFIPS
        Congress, October 1980</title>
      <editor>
        <persName>
          <forename>Simon</forename>
          <forename>H.</forename>
          <surname>Lavington</surname>
        </persName>
      </editor>
      <imprint>
        <publisher>North-Holland</publisher>
        <pubPlace>Amsterdam</pubPlace>
        <date when="1980"/>
      </imprint>
    </monogr>
  </biblStruct>
</listBibl>
```

```

        <biblScope unit="pp" from="1013"
to="1023">1013–23</biblScope>
        </monogr>
        <note>Apparently a draft of section 4 of
        <title level="m">Literary Machines</title>.</note>
    </biblStruct>

    <bibl xml:id="NELSON88"><author><persName><forename>Ted</forename>
<surname>Nelson</surname></persName></author>:
<title level="u">Literary Machines</title> (privately published,
<date when="1987">1987</date>).</bibl>

    <bibl xml:id="BAXTER88"><author><persName><surname>Baxter</surname>,
<forename>Glen</forename></persName></author>:
<title level="m">Glen Baxter His Life: the years of struggle</title>
<pubPlace>London</pubPlace>: <publisher>Thames and Hudson</publisher>,
<date when="1988">1988</date>.</bibl>
</listBibl>

```

This example also demonstrates the way that bibliographical markup of authors, titles, dates etc. can be handled differently in <biblStruct>s and <bibl>s. In the two <bibl> items, the key information is marked up, but it is presented in an order which makes it suitable for direct rendering, with the punctuation included.

The <listBibl> element is most appropriate for a more formal bibliography. The same <bibl> or <biblStruct> elements may however be embedded within an ordinary list, thus allowing them to be mixed with running prose or presented informally, as in the following version of the same example:

```

<list>
  <head>Bibliography</head>
  <item>
    <bibl xml:id="NEL80">
      <author>Nelson, T. H.</author>
      <title level="a">Replacing the printed word:
        a complete literary system</title>.
      <title level="m">Information Processing '80:
        Proceedings of the IFIPS Congress, October 1980</title>.
      <editor>Simon H. Lavington</editor>
      <publisher>North-Holland</publisher>:
      <pubPlace>Amsterdam</pubPlace>,
      <date>1980</date>.
      <biblScope>pp 1013–23
      </biblScope>
      <note>Apparently a draft of section 4 of
      <title>Literary Machines</title>.</note>
    </bibl>
  </item>
  <item>
    <bibl xml:id="NEL88">Ted Nelson: <title>Literary Machines</title>
      (privately published, 1987)</bibl>
  </item>
  <item>
    <bibl xml:id="BAX88">
      <author>Baxter, Glen</author>
      <title>Glen Baxter His Life: the years of struggle</title>
      London: Thames and Hudson, 1988.
    </bibl>

```

```
</item>
</list>
```

### 3.11.2 Components of Bibliographic References

This section discusses commonly occurring components of bibliographic references and elements used for encoding them. They fall into four groups:

- elements for grouping components of the *analytic*, *monographic*, and *series* levels in a structured bibliographic reference
- titles of various kinds, and statements of intellectual responsibility (authorship, etc.)
- information relating to the publication, pagination, etc. of an item (most of these constitute the default members of the `model.biblPart` class)
- annotation, commentary, and further detail

The following sections describe the elements which may be used to represent such information within a `<bibl>` or `<biblStruct>` element. Within the former, elements from the `model.biblPart` class, other phrase-level elements, and plain text may be combined without other constraint; within the latter, such of these elements as exist for a given reference must be distinguished, and must also be presented in a specific order, discussed further below (section 3.11.2.9. *Order of Components within References*).

#### 3.11.2.1 Analytic, Monographic, and Series Levels

In common library practice a clear distinction is made between an individual item within a larger collection and a free-standing book, journal, or collection. Similarly a book in a series is distinguished sharply from the series within which it appears. An article forming part of a collection which itself appears in a series thus has a bibliographic description with three quite distinct levels of information:

1. the *analytic* level, giving the title, author, etc., of the article;
2. the *monographic* level, giving the title, editor, etc., of the collection;
3. the *series* level, giving the title of the series, possibly the names of its editors, etc., and the number of the volume within that series.

In the same way, an article in a journal requires at least two levels of information: the analytic level describing the article itself, and the monographic level describing the journal.

A different identifying number may be supplied for any of these three items, that is, for the analytic item, the monographic item, or the series.

Within `<bibl>`, these three levels may be distinguished simply by the use of the *level* attribute on `<title>`. They may also be distinguished through the practice of employing nested `<bibl>` elements. In this example, for instance, the monograph-level component of the reference is encapsulated in its own `<bibl>` within the main `<bibl>` for the article:

```
<bibl type="article"
  subtype="magazine_article" xml:id="beaupaire_1911">
  <author>
    <name>
      <surname>Beaupaire</surname>
      (<forename>Edmond</forename>)</name>
    </author>,
  <title level="a">A propos de la rue de la Femme-sans-Tête</title>,
  <bibl type="monogr">
    <title level="j">La Cité</title>,
    <date when="1911-01">janvier 1911</date>, pp. <biblScope unit="pp" from="5" to="17">5-
  17</biblScope>.
  </bibl>
</bibl>
```

Within <biblStruct>, the levels are distinguished by the use of the following distinct elements:

**<analytic>** (analytic level) contains bibliographic elements describing an item (e.g. an article or poem) published within a monograph or journal and not as an independent publication.

**<monogr>** (monographic level) contains bibliographic elements describing an item (e.g. a book or journal) published as an independent item (i.e. as a separate physical object).

**<series>** (series information) contains information about the series in which a book or other bibliographic item has appeared.

For purposes of TEI encoding, journals and anthologies are both treated as monographs; a journal title should thus be tagged as a <title level="j"> element within a <monogr> element. Individual articles in the journal or collected texts should be treated at the 'analytic' level. When an article has been printed in more than one journal or collection, the bibliographic reference may have more than one <monogr> element, each possibly followed by one or more <series> elements. A <series> element always relates to the most recently preceding <monogr> element. (Whether reprints of an article are treated in the same bibliographic reference or a separate one varies among different styles. Library lists typically use a different entry for each publication, while academic footnoting practice typically treats all publications of the same article in a single entry.)

The <biblScope> element is used to supply further information about the location of some part of a bibliographic reference. It specifies where to find the component in which it appears within the immediately preceding component of a different level.

In the following example, Schachter's article *Iolaos* appeared on pages 64 to 70 of a volume entitled *Herakles to Poseidon*, which was itself the second of a four volumes published together under the title *Cults of Boiotia*; this last title constituted the 38th volume in the series of *Bulletin of the Institute of Classical Studies Supplements*:

```
<biblStruct>
  <analytic>
    <author>Albert Schachter</author>
    <title level="a">Iolaos</title>
  </analytic>
  <monogr>
    <title level="m">Herakles to Poseidon</title>
    <imprint>
      <date>1986</date>
    </imprint>
    <biblScope unit="pp">64-70</biblScope>
  </monogr>
  <monogr>
    <title level="m">Cults of Boiotia</title>
    <imprint>
      <pubPlace>London</pubPlace>
    </imprint>
    <extent>4 vols.</extent>
    <biblScope unit="part">2</biblScope>
  </monogr>
  <series>
    <title level="s">Bulletin of the Institute of Classical Studies
      Supplements</title>
    <biblScope unit="vol">38</biblScope>
  </series>
</biblStruct>
```

In the following example, the article cited has been published twice, once in a journal (where it appeared in volume 40, on pages 3 -46 of the issue of October 1986) and once as a free-standing item, which appeared as number 11 of a German language series.

```

<biblStruct>
  <analytic>
    <author>
      <persName>
        <surname>Thaller</surname>
        <forename>Manfred</forename>
      </persName>
    </author>
    <title level="a">A Draft Proposal for a Standard for the

    <title level="s">Serie A: Historische Quellenkunden</title>
    <biblScope unit="vol">11</biblScope>
  </series>
</biblStruct>

```

The practice of analytic vs. monographic citation, as described here, should be distinguished from the practice of including within one citation a reference to another work, which the encoder considers to be related to in some way: see further 3.11.2.7. *Related Items* below.

If an identifier is available for the analytic item, it should be represented by means of an <idno> element placed within the <analytic> element, as in the following example where a DOI (Digital Object identifier) is supplied for the article in question.

```

<biblStruct>
  <analytic>
    <author>
      <forename>James</forename>
      <forename>H.</forename>
      <surname>Coombs</surname>
    </author>

    </imprint>
    <biblScope unit="vol">30</biblScope>
    <biblScope unit="issue">11</biblScope>
    <biblScope unit="pp">933-947</biblScope>
  </monogr>
  <ref type="url">http://xml.coverpages.org/coombs.html</ref>
</biblStruct>

```

Punctuation must not appear between the elements within a structured bibliographic entry encoded with <biblStruct> or <biblFull>, unless it is contained within the elements it delimits. When (as in most of the examples in this chapter) entries are encoded without any inter-element punctuation, they can be usually be processed more easily by rendering systems able to output bibliographic references in any of several styles.

Within a <bibl> however, it is possible and often convenient to include punctuation.

```

<bibl xml:id="NELSON_80">
  <author>
    <persName>
      <surname>Nelson</surname>,
      <forename>T.</forename>
      <forename>H.</forename>
    </persName>
  </author>
  <date when="1980">1980</date>.
  <title level="a">Replacing the printed word: a complete literary

    IFIPS Congress, October 1980</title>,
  ed.
  <editor>
    <persName>
      <forename>Simon</forename>
      <forename>H.</forename>
      <surname>Lavington</surname>
    </persName>
  </editor>
</bibl>

```

```

    </persName>
  </editor>,
<biblScope unit="pp">1013-23</biblScope>.
<pubPlace>Amsterdam</pubPlace>: <publisher>North-
  Holland</publisher>. (<note>Apparently a draft of section 4 of
  <ref target="#NELSON_88">
    <title level="m">Literary
      Machines</title>
  </ref>.</note>)
</bibl>

```

This example shows the components sequenced and punctuated according to the Chicago style, with all the relevant data items marked up appropriately. This markup approach can provide easy rendering, if only one styleguide is targeted, or an original source document uses a specific styleguide, while still allowing for automated recovery of key data items such as names of authors, titles etc.

### 3.11.2.2 Titles, Authors, and Editors

Bibliographic references typically include the title of the work being cited and the names of those intellectually responsible for it. For articles in journals or collections, such statements should appear both for the analytic and for the monographic level. The following elements are provided for tagging such elements:

**<title>** contains a title for any kind of work.

**<author>** in a bibliographic reference, contains the name(s) of an author, personal or corporate, of a work; for example in the same form as that provided by a recognized bibliographic name authority.

**<editor>** contains a secondary statement of responsibility for a bibliographic item, for example the name of an individual, institution or organization, (or of several such) acting as editor, compiler, translator, etc.

**<respStmt>** (statement of responsibility) supplies a statement of responsibility for the intellectual content of a text, edition, recording, or series, where the specialized elements for authors, editors, etc. do not suffice or do not apply. May also be used to encode information about individuals or organizations which have played a role in the production or distribution of a bibliographic work.

**<resp>** (responsibility) contains a phrase describing the nature of a person's intellectual responsibility, or an organization's role in the production or distribution of a work.

**<name>** (name, proper noun) contains a proper noun or noun phrase.

**<meeting>** contains the formalized descriptive title for a meeting or conference, for use in a bibliographic description for an item derived from such a meeting, or as a heading or preamble to publications emanating from it.

**<sponsor>** specifies the name of a sponsoring organization or institution.

**<funder>** (funding body) specifies the name of an individual, institution, or organization responsible for the funding of a project or text.

**<distributor>** supplies the name of a person or other agency responsible for the distribution of a text.

**<principal>** (principal researcher) supplies the name of the principal researcher responsible for the creation of an electronic text.

The elements **<author>**, **<editor>**, **<respStmt>**, **<meeting>**, **<sponsor>**, **<funder>**, and **<principal>** are the default members of the `model.respLike` class, a subclass of the `model.biblPart` class to which the constituents of the **<bibl>** element belong.

In bibliographic references, all titles should be tagged as such, whether analytic, monographic, or series titles. The single element **<title>** is used for all these cases. When it appears directly within an **<analytic>**, **<monogr>**, or **<series>** element, **<title>** is interpreted as belonging to the appropriate level. However, it is recommended that the *level* attribute be used to signal this explicitly.

It is a semantic error to give a value for the *level* attribute which is inconsistent with the context. The *level* value *a* implies the analytic level; the values *m*, *j*, and *u* imply the monographic level; the value *s* implies the series level. Note, however, that the semantic error occurs only if the nested title is directly enclosed by the **<analytic>**, **<monogr>**, or

<series> element; if it is enclosed only indirectly (i.e., nested more deeply), no semantic error need be present. For example, the analytic title may contain a monographic title, as in the following example:

```
<biblStruct>
  <analytic>
    <author ref="http://id.loc.gov/authorities/names/no2001067434">
      <persName>
        <forename>Lucy</forename>
        <forename>Allen</forename>
        <surname>Paton</surname>
      </persName>
    </author>
    <title>Notes on Manuscripts of the
    <title level="m" xml:lang="fr">Prophécies de Merlin</title>
    </title>
  </analytic>
  <monogr>
    <title level="j">PMLA</title>
    <imprint>
      <date>1913</date>
    </imprint>
    <biblScope unit="vol">8</biblScope>
    <biblScope unit="pp">122</biblScope>
  </monogr>
</biblStruct>
```

In this case, the analytic title ‘Notes on Manuscripts of the *Prophécies de Merlin*’ needs no *level* attribute because it is directly contained by an <analytic> element; the monographic title contained within it, ‘Prophécies de Merlin’, is not semantically erroneous because it is not directly contained by the <analytic> element.

In some bibliographic applications, it may prove useful to distinguish main titles from subordinate titles, parallel titles, etc. The *type* attribute is provided to allow this distinction to be recorded.

The following reference, from a national standard for bibliographic references, illustrates this type of analysis with its distinction between main and subordinate titles. Note that this uses the more flexible <bibl>, rather than the structured <biblStruct> element: consequently, there is no requirement to tag all the components of the reference (notably the authors).

```
<bibl>Saarikoski, Pirkko-Liisa, and Paavo Suomalainen,
<title level="a" type="main">Studies on the physiology of
  the hibernating hedgehog, 15</title>
<title level="a" type="sub">Effects of seasonal
  and temperature changes on the in vitro glycerol release from
  brown adipose tissue</title>
<title level="j">Ann. Acad. Sci. Fenn., Ser. A4</title>
<date>1972</date>
<biblScope unit="vol">187</biblScope>
<biblScope unit="pp" to="4">1-4</biblScope>
</bibl>
```

Slightly more complex is the distinction made below among main, subordinate, and parallel titles, in an example from the same source (p. 63). The punctuation and the bibliographic analysis are those given in ANSI Z39.29-1977; the punctuation is in the style prescribed by the International Standard Bibliographic Description (ISBD).<sup>54</sup> Again, it

<sup>54</sup>The analysis is not wholly unproblematic: as the text of the standard points out, the first subordinate title is subordinate only to the parallel title in French, while the second is subordinate to both the English main title and the French parallel title, without this relationship being made clear, either in the markup given in the example or in the reference structure offered by the standard.

is only because this example uses `<bibl>` rather than `<biblStruct>`, that specific punctuation may be included between the component elements of the reference.

```
<bibl>Tchaikovsky, Peter Ilich.
<title level="m" type="main">The swan lake ballet</title>
= <title level="m" type="parallel"
  xml:lang="fr">Le lac des cygnes</title>
: <title level="m" type="sub" xml:lang="fr">grand ballet en 4 actes</title>
: <title level="m" type="sub">op. 20</title>
[Score].
New York: Broude Brothers; [1951] (B.B. 59). vi, 685 p.</bibl>
```

The elements `<author>` and `<editor>` have fairly obvious significance for printed books and articles; for other kinds of bibliographic items their proper usage may be less obvious. The `<author>` element should be used for the person or agency with primary responsibility for a work's intellectual content, and the element `<editor>` for other people or agencies with some responsibility for that content, whether or not they are called 'editor'. An organization such as a radio or television station is usually accounted 'author' of a broadcast, for example, while the author of a government report will usually be the agency which produced it. A translator, illustrator, or compiler, may however be marked by means of the `<editor>` element, optionally using the *role* attribute to specify the nature of their responsibility more exactly.

Many bibliographic and Linked Data applications require disambiguation of author names using unique identifiers. Both the `<author>` and `<editor>` elements may contain one or more `<idno>` elements, to supply such identifiers. Alternatively, if only a single identifier is to be recorded, the *key* or *ref* attribute may be used, as further discussed in 3.5.1. *Referring Strings*.

For anyone else with responsibility for the work, the `<respStmt>` element should be used. The nature of the responsibility is indicated by means of a `<resp>` element, and the person, organization, etc. responsible by a `<name>`, `<persName>`, or `<orgName>` element. Strings such as 'unknown' may be encoded using the `<rs>` element. A `<respStmt>` should comprise either at least one of the four naming elements (`<name>`, `<persName>`, `<orgName>`, or `<rs>`) followed by one or more `<resp>` elements, or at least one `<resp>` element followed by one or more of the four naming elements.

Examples of secondary responsibility of this kind include the roles of illustrator, translator, encoder, and annotator. The `<respStmt>` element may also be used for editors, if it is desired to record the specific terms in which their role is described.

Examples of `<author>` and `<editor>` may be found in sections 3.11.1. *Methods of Encoding Bibliographic References and Lists of References*, and 3.11.2.1. *Analytic, Monographic, and Series Levels*; wherever `<author>` and `<editor>` may occur, the `<respStmt>` element may also occur. When one of these elements precedes or immediately follows a title, it applies to that title; when it follows an `<edition>` element or occurs within an edition statement, it applies to the edition in question.

In this example, the `<respStmt>` elements apply to the work as a whole, not merely to the first edition:

```
<bibl>
  <author>Lominandze, DG</author>.
  <title level="m">Cyclotron waves in plasma</title>.
  <respStmt>
    <resp>Translated by</resp>
    <name>AN. Dellis</name>
  </respStmt>;
  <respStmt>
    <resp>edited by</resp>
    <name>SM. Hamberger</name>
  </respStmt>.
  <edition>1st ed.</edition>
  <pubPlace>Oxford</pubPlace>;
  <publisher>Pergamon Press</publisher>,
```

```

<date>1981</date>.
<extent>206 p.</extent>
  <title level="s">International series in natural philosophy</title>.
<note place="inline">Translation of:
  <title xml:lang="ru-Latn" level="m">Ciklotronnye volny v
    plazme</title>.
  <idno type="isbn">ISBN 0-08-021680-3</idno>.
</note>
</bibl>

```

This example retains the original punctuation and editorial conventions of the source (ISO 690: 1987) and is therefore encoded using the <bibl> element.

In the following example, by contrast, the <respStmt> element applies to the edition, and not to the collection *per se* (Moser and Tervooren were not responsible for the first thirty-five printings). As is permissible within a <biblStruct> element, the component elements have been reordered from their appearance on the title page of the volume in order to ensure the correct relationship of the collection title, the edition statement, and the statement of responsibility.

```

<biblStruct>
  <monogr xml:lang="de">
    <title level="m">Des Minnesangs Frühling</title>
    <note place="inline">Mit 1 Faksimile</note>
    <edition>36., neugestaltete und erweiterte Auflage</edition>
    <respStmt>
      <resp>Unter Benutzung der Ausgaben von <name>Karl
        Lachmann</name> und <name>Moriz Haupt</name>, <name>Friedrich
        Vogt</name> und <name>Carl von Kraus</name> bearbeitet von</resp>
      <name>Hugo Moser</name>
      <name>Helmut Tervooren</name>
    </respStmt>
    <imprint>
      <pubPlace>Stuttgart</pubPlace>
      <publisher>S. Hirzel Verlag</publisher>
      <date>1977</date>
    </imprint>
    <biblScope unit="vol">I Texte</biblScope>
  </monogr>
</biblStruct>

```

The party with a particular responsibility for the intellectual content may vary over time. Likewise, a given individual's responsibility or role may change over time. These situations may be recorded with the <respStmt> element. For example, the following could be used when one proofreader took over for another.

```

<respStmt>
  <resp>proofreading</resp>
  <persName from="1994-02" to="1994-05">Ashley Cross</persName>
  <persName from="1994-06" to="1994-10">Loren Noveck</persName>
</respStmt>

```

The following example records the fact that one individual had two distinctly different intellectual responsibilities at different times.

```

<respStmt>
  <persName>Erica Dillon</persName>
  <resp when="2000-08">annotated uncredited citations</resp>
  <resp when="2001-03">encoded named entities</resp>
</respStmt>

```

Another form of ‘responsibility’ arises when a work is published as the outcome of a conference, workshop or similar meeting. The <meeting> element may be used to supply this information, as in the following example:

```

<biblStruct>
  <monogr>
    <title level="m">Proceedings of a workshop on corpus resources</title>
    <respStmt>
      <resp>Programme Organizer</resp>
      <name>Geoffrey Leech</name>
    </respStmt>
    <meeting>DTI Speech and Language Technology Club meeting, 3-4
      January 1990, Wadham College, Oxford</meeting>
    <imprint>
      <pubPlace>Oxford</pubPlace>
    </imprint>
  </monogr>
</biblStruct>

```

### 3.11.2.3 Document Identifiers

Many bibliographic references include identifiers for a work to help with precise identification of an appropriate document. For example, a book in the *Short Title Catalogue* could be referenced with its STC number:

```

<biblStruct>
  <monogr>
    <author>
      <forename>John</forename>
      <surname>Downname</surname>
    </author>
    <title type="short">Foure treatises tending to disswade all Christians from foure no
  lesse hainous then common sinnes</title>
    <idno type="stc2ndEd">7141</idno>
    <imprint>
      <pubPlace>At London</pubPlace>
      <publisher>Imprinted by Felix Kyngston, for William Welby, and are to be sold at
  his shop in Pauls Church-yard at the signe of the Greyhound</publisher>
      <date when="1609">1609</date>
    </imprint>
  </monogr>
</biblStruct>

```

However, some bibliographic references actually *require* identifiers of various types because they do not include a statement of the title and the names of those intellectually responsible for it. The following elements may be used for such purposes:

**<orgName>** (organization name) contains an organizational name.

**<idno>** (identifier) supplies any form of identifier used to identify some object, such as a bibliographic item, a person, a title, an organization, etc. in a standardized way.

**<classCode>** (classification code) contains the classification code used for this text in some standard classification system.

**<date>** contains a date in any format.

For example, a citation to a patent typically includes a country or organization code (a two-character code identifying a patent authority) and a serial number for the patent (whose structure varies by patent authority). The citation might also contain a *kind code* (which characterizes a particular publication for the patent and which corresponds to a specific stage in the patent procedure) and the date when the patent was filed with or published by the issuing authority. For bibliographic references to patents, the above elements may be used as follows:

- **<orgName>**, within **<authority>**, may be used to contain the code of the patent authority. The *type* attribute may be used to specify the type of patent authority (such as a national patent office or a supra-national patent organization).
- **<idno>** may be used to contain the serial number assigned by the corresponding patent authority.
- **<classCode>** may be used to contain the kind code of the patent document.
- **<date>** may be used to contain the date of the patent document. The *type* attribute may be used to specify whether this corresponds to the filing date of a patent application or the publication date of a patent publication.

The following reference illustrates an encoding for a patent publication which might be cited in print as "United States patent US 6,885,550 B1, issued April 26, 2005":

```
<biblStruct type="patent"
  status="publication">
  <monogr>
    <authority>
      <orgName type="national">US</orgName>
    </authority>
    <idno type="docNumber">6885550</idno>
    <imprint>
      <classCode scheme="http://www.uspto.gov/">B1</classCode>
      <date type="publicationDate"
        when="2005-04-26">April 26, 2005</date>
    </imprint>
  </monogr>
</biblStruct>
```

#### 3.11.2.4 Imprint, Size of a Document, and Reprint Information

By *imprint* is meant all the information relating to the publication of a work: the person or organization by whose authority and in whose name a bibliographic entity such as a book is made public or distributed (whether a commercial publisher or some other organization), the place and the date of publication. It may also include a full address for the publisher or organization. A full bibliographic references will usually also specify the number of pages in a print publication (or equivalent information for non-print materials), and possibly also the specific location of the material being cited within its containing publication. The following elements are provided to hold this information:

**<imprint>** groups information relating to the publication or distribution of a bibliographic item.

**<address>** contains a postal address, for example of a publisher, an organization, or an individual.

**<pubPlace>** (publication place) contains the name of the place where a bibliographic item was published.

**<publisher>** provides the name of the organization responsible for the publication or distribution of a bibliographic item.

**<date>** contains a date in any format.

**<extent>** describes the approximate size of a text stored on some carrier medium or of some other object, digital or non-digital, specified in any convenient units.

**<idno>** (identifier) supplies any form of identifier used to identify some object, such as a bibliographic item, a person, a title, an organization, etc. in a standardized way.

Members of the model classes `model.imprintPart` and `model.dateLike` may appear inside an **<imprint>** element in a specific location within a **<biblStruct>**, or alternatively, they may appear alongside any other bibliographic component inside a **<bibl>**.

**model.imprintPart** groups the bibliographic elements which occur inside imprints.

|             |  |
|-------------|--|
| biblScope   | (scope of bibliographic reference) defines the scope of a bibliographic reference, for example as a list of page numbers, or a named subdivision of a larger work. |
| distributor | supplies the name of a person or other agency responsible for the distribution of a text.  |
| publisher   | provides the name of the organization responsible for the publication or distribution of a bibliographic item.   |
| pubPlace    | (publication place) contains the name of the place where a bibliographic item was published.   |

**model.dateLike** groups elements containing temporal expressions.

|      |   |
|------|---|
| date | contains a date in any format.                          |
| time | contains a phrase defining a time of day in any format. |

For bibliographic purposes, usually only the place (or places) of publication are required, possibly including the name of the country, rather than a full address; the element <pubPlace> is provided for this purpose. Where however the full postal address is likely to be of importance in identifying or locating the bibliographic item concerned, it may be supplied and tagged using the <address> element described in section 3.5.2. *Addresses*. Alternatively, if desired, the <rs> or <name> elements described in section 3.5.1. *Referring Strings* may be used; this involves no claim that the information given is either a full address or the name of a city.

The name of the publisher of an item should be marked using the <publisher> element even if the item is made public ('published') by an organization other than a conventional publisher, as is frequently the case with technical reports:

```
<biblStruct>
  <monogr>
    <author>Nicholas, Charles K.</author>
    <author>Welsch, Lawrence A.</author>
    <title level="m">On the interchangeability of SGML and ODA</title>
    <idno type="NIST">NISTIR 4681</idno>
    <imprint>
      <pubPlace>Gaithersburg, MD</pubPlace>
      <publisher>National Institute of Standards and Technology
    </publisher>
      <date when="1992-01">January 1992</date>
    </imprint>
    <extent>19 pp.</extent>
  </monogr>
</biblStruct>
```

and with dissertations:

```
<biblStruct>
  <monogr>
    <author>Hansen, W.</author>
    <title level="u">Creation of hierarchic text
      with a computer display</title>
    <idno type="ANL">ANL-7818</idno>
    <note place="inline">Ph.D. dissertation</note>
    <imprint>
```

```

    <publisher>Dept. of Computer Science, Stanford Univ.</publisher>
    <pubPlace>Stanford, CA</pubPlace>
    <date when="1971-06">June 1971</date>
  </imprint>
</monogr>
</biblStruct>

```

In this second example, the <idno> element is used to provide the identifier allocated to the thesis by the Argonne National Laboratory. Since it applies to the monographic element, the <idno> should be provided as a direct child of the <monogr> element, rather than elsewhere in the <biblStruct> element.

The specialist elements <publisher> and <distributor> are provided to cover the most common roles related to the production and distribution of a bibliographical item, but other roles such as printer and bookseller may also need to be encoded, and <respStmt> is available inside <imprint> for this purpose.

When an item has been reprinted, especially reprinted without change from a specific earlier edition, the reprint may appear in a <monogr> element with only the <imprint> and other details of the reprint. In the following example, a microform reprint has been issued without any change in the title or authorship. The series statement here applies only to the second <monogr> element.

```

<biblStruct>
  <monogr>
    <author>Shirley, James</author>
    <title type="main">The gentlemen of Venice</title>
    <title type="sub">a tragi-comedie presented at the private
      house in Salisbury Court by Her Majesties servants</title>
    <note place="inline">[Microform]</note>
    <imprint>
      <pubPlace>London</pubPlace>
      <publisher>H. Moseley</publisher>
      <date>1655</date>
    </imprint>
    <extent>78 p.</extent>
  </monogr>
  <monogr>
    <imprint>
      <pubPlace>New York</pubPlace>
      <publisher>Readex Microprint</publisher>
      <date>1953</date>
    </imprint>
    <extent>1 microprint card, 23 x 15 cm.</extent>
  </monogr>
  <series>
    <title level="s">Three centuries of drama: English, 1642–1700</title>
  </series>
</biblStruct>

```

This encoding can be extended to the case of patent documents, where the same patent application is published, with or without changes, at different stages of the patenting procedure. In this case, the kind code and, optionally, the publication date characterize different publications of the same patent application during the procedure. For example:

```

<biblStruct type="patent"
  status="publication">
  <monogr>

```

```

<authority>
  <orgName type="national">EP</orgName>
</authority>
<idno type="docNumber">1558513</idno>
<imprint>
  <classCode scheme="http://www.epo.org/">A1</classCode>
  <date type="publicationDate"
    when="2005-08-03"/>
</imprint>
</monogr>
<monogr>
  <imprint>
    <classCode scheme="http://www.epo.org/">B1</classCode>
    <date type="publicationDate"
      when="2009-09-09"/>
  </imprint>
</monogr>
</biblStruct>

```

The above bibliographic reference discloses different publications of the patent EP1558513 during the patenting procedure. The first publication from 3 August 2005 has the kind code "A1" indicating that it is a published patent application comprising the European search report issued after carrying out the search at the European Patent Office, whereas the second publication from 9 September 2009 has the kind code "B1" indicating that it was published after the patent application has been granted.

An alternative way of handling the above situations would be to use the <relatedItem> element described in section 3.11.2.7. *Related Items* below.

### 3.11.2.5 Scopes and Ranges in Bibliographic Citations

Many bibliographic citations contain data limiting the citation to one or more volumes, issues, or pages, or to a name or number of a subdivision of the host work. These come in two varieties:

- the scope of a bibliographic reference (encoded using <biblScope>)
- the range of a work cited (encoded using <citedRange>)

Where it is desired to distinguish different classes of such information (volume number, page number, chapter number, etc.), the *unit* attribute may be used with any convenient typology (see the element definitions for <biblScope> and <citedRange> for some suggested values).

A scope of a bibliographic reference defines that the *entire work cited* may be found in particular volumes, issues, pages, etc. For example:

```

<biblStruct>
  <analytic>
    <author>
      <persName>
        <surname>Wrigley</surname>
        <forename full="init">E.</forename>
        <forename full="init">A.</forename>
      </persName>
    </author>
    <title level="a">Parish registers and the historian</title>
  </analytic>
  <monogr>
    <author>
      <persName>
        <surname>Steel</surname>
        <forename full="init">D.</forename>
      </persName>
    </author>
  </monogr>
</biblStruct>

```

```
    <forename full="init">J.</forename>
  </persName>
</author>
<author>
  <persName>
    <surname>Steel</surname>
    <forename full="init">A.</forename>
    <forename full="init">E.</forename>
    <forename full="init">F.</forename>
  </persName>
</author>
<title level="m">General sources of births, marriages and deaths before 1837</title>
<imprint>
  <pubPlace>London</pubPlace>
  <publisher>Society of Genealogists</publisher>
  <date when="1968"/>
</imprint>
<biblScope unit="pp" from="155" to="167">155–167</biblScope>
</monogr>
<series>
  <title level="s">National index of parish registers</title>
  <biblScope unit="vol">1</biblScope>
</series>
</biblStruct>
```

The *unit* attribute on <biblScope> is optional: both the following are legal examples:

```
<biblStruct>
  <analytic>
    <author>Boguraev, Branimir</author>
    <author>Neff, Mary</author>
    <title level="a">Text Representation, Dictionary Structure,
      and Lexical Knowledge</title>
  </analytic>
  <monogr>
    <title level="j">Literary & Linguistic Computing</title>
    <imprint>
      <date>1992</date>
    </imprint>
    <biblScope unit="vol">7</biblScope>
    <biblScope unit="issue">2</biblScope>
    <biblScope unit="pp">110-112</biblScope>
  </monogr>
</biblStruct>
```

```
<biblStruct>
  <analytic>
    <author>Chesnutt, David</author>
    <title level="a">Historical Editions in the States</title>
  </analytic>
  <monogr>
    <title level="j">Computers and the Humanities</title>
    <imprint>
```

```

    <date when="1991-12">(December, 1991):</date>
  </imprint>
  <biblScope>25.6</biblScope>
  <biblScope from="377" to="280">377–380</biblScope>
</monogr>
</biblStruct>

```

On the other hand, a cited range encodes that the author *cited only the portion* defined by this range. For example, a footnote following a quotation from page 378 of ‘Historical Editions in the States’ that includes a full bibliographic reference would be encoded using <biblStruct> as follows:

```

<biblStruct>
  <analytic>
    <author>Chesnutt, David</author>
    <title level="a">Historical Editions in the States</title>
  </analytic>
  <monogr>
    <title level="j">Computers and the Humanities</title>
    <imprint>
      <date when="1991-12">(December, 1991):</date>
    </imprint>
    <biblScope>25.6</biblScope>
    <biblScope unit="pp" from="377" to="280">377–380</biblScope>
  </monogr>
  <citedRange>378</citedRange>
</biblStruct>

```

### 3.11.2.6 Series Information

Series information may (in <bibl> elements) or must (in <biblStruct> elements) be enclosed in a <series> element or (in a <biblFull> element) a <seriesStmt> element. The title of the series may be tagged <title level="s">, the volume number <biblScope unit="vol">, and responsibility statements for the series (e.g. the name and affiliation of the editor, as in the example in section 3.11.2.1. *Analytic, Monographic, and Series Levels*) may be tagged <editor> or <respStmt>. Any identifier associated with the series itself should be marked using the <idno> element.

### 3.11.2.7 Related Items

In bibliographic parlance, a *related item* is any bibliographic item which, though related to that being defined, is distinct from it. The distinction between analytic and monographic items made above may be thought of as a special case of this kind of ‘related’ item. More usually however, the term is applied to such items as translations, continuations, different versions, parts, etc.

The element <relatedItem> is provided as a means of documenting such associated items:

<relatedItem> contains or references some other bibliographic item which is related to the present one in some specified manner, for example as a constituent or alternative version of it.

In the following example, the first <biblStruct> describes a facsimile edition, and the second describes the work of which it is a facsimile. The relation between the facsimile and its source is represented by means of a <relatedItem> within the first description, which points to the description of the source.

```

<biblStruct xml:id="bibl03">
  <monogr>
    <author>Swinburne, Algernon Charles</author>
    <title level="m">Swinburne's <title level="m">Atalanta in Calydon</title>: A Fac-
simile of the
      First Edition</title>
    <editor>Georges Lafourcade</editor>

```

```

    <imprint>
      <pubPlace>London</pubPlace>
      <publisher>Oxford UP</publisher>
      <date>1930</date>
    </imprint>
  </monogr>
  <relatedItem type="otherEdition">
    <ref target="#bibl04"/>
  </relatedItem>
</biblStruct>
<biblStruct xml:id="bibl04">
  <monogr>
    <author> Swinburne, Algernon Charles</author>
    <title level="m">Atalanta in Calydon</title>
    <imprint>
      <pubPlace>London</pubPlace>
      <publisher>Edward Moxon</publisher>
      <date>1865</date>
    </imprint>
  </monogr>
</biblStruct>

```

The <ref> element in the above example could be replaced by the referenced <biblStruct> itself since a <relatedItem> may contain any form of bibliographic reference. For example, one of the examples quoted above might also be encoded as follows:

```

<biblStruct>
  <monogr>
    <author>Shirley, James</author>
    <title type="main">The gentlemen of Venice</title>
    <imprint>
      <pubPlace>New York</pubPlace>
      <publisher>Readex Microprint</publisher>
      <date>1953</date>
    </imprint>
    <extent>1 microprint card, 23 x 15 cm.</extent>
  </monogr>
  <series>
    <title level="s">Three centuries of drama: English, 1642–1700</title>
  </series>
  <relatedItem type="otherEdition">
    <biblStruct>
      <monogr>
        <author>Shirley, James</author>
        <title type="main" level="m">The gentlemen of Venice</title>
        <title type="sub" level="m">a tragi-comedie presented at the private
          house in Salisbury Court by Her Majesties servants</title>
        <imprint>
          <pubPlace>London</pubPlace>
          <publisher>H. Moseley</publisher>
          <date when="1655">1655</date>
        </imprint>
        <extent>78 p.</extent>
      </monogr>
    </biblStruct>
  </relatedItem>
</biblStruct>

```

```
</relatedItem>
</biblStruct>
```

The *type* attribute should be used to indicate the relationship between the bibliographic item and any `<relatedItem>` it contains or points to. The relationships may be transitive (for example `translatedAs` or `reprintedFrom`) or non-transitive (for example `otherEdition`). The *subtype* attribute may be used to provide a more detailed classification, where this is appropriate. Some further examples follow:

```
<biblStruct>
  <monogr>
    <author>Tolkien, J.R.R.</author>
    <title level="m">Den hobbit</title>
    <title type="sub">aus dem Engleschen iwwersat</title>
    <editor role="translator">Henry Wickens</editor>
    <imprint>
      <pubPlace>Esch-sur-Sûre</pubPlace>
      <publisher>Op der Lay S. àr. L</publisher>
      <date>2002</date>
    </imprint>
  </monogr>
  <relatedItem type="translatedFrom">
    <bibl>
      <author>Tolkien, J.R.R.</author>
      <title level="m">The Hobbit</title>.
      <publisher>Collins</publisher>
      <date>1997</date>
    </bibl>
  </relatedItem>
</biblStruct>
```

In this example, a full bibliographic description of the edition used as source for the translation is provided within the content of the `<relatedItem>`. Alternatively this might be provided by means of a link, in which case the `<relatedItem>` would be empty:

```
<relatedItem type="translatedFrom"
  target="http://www.example.com/bibliography.xml#TOLK97"/>
```

### 3.11.2.8 Notes and Statement of Language

Explanatory notes about the publication of unusual items, the form of an item (e.g. *[Score]* or *[Microform]*), or its provenance (e.g. *translation of ...*) may be tagged using the `<note>` element. The same element may be used for any descriptive annotation of a bibliographic entry in a database.

**<note>** contains a note or annotation.

For example:

```
<bibl>
  <author>Coombs, James H., Allen H. Renear,
    and Steven J. DeRose.</author>
  <title level="a">Markup Systems and the Future of Scholarly
    Text Processing.</title>
  <title level="j">Communications of the ACM</title>
  <biblScope>30.11 (November 1987): 933–947.</biblScope>
  <note>Classic polemic supporting descriptive over procedural
```

```
markup in scholarly work.</note>
</bibl>
```

The <textLang> element may be used to record information about the languages used within a bibliographic item.

<textLang> (text language) describes the languages and writing systems identified within the bibliographic work being described, rather than its description.

@*mainLang* (main language) supplies a code which identifies the chief language used in the bibliographic work.

@*otherLangs* (other languages) one or more codes identifying any other languages used in the bibliographic work.

This element can take the form of a simple note such as:

```
<textLang>Latin, with some glosses in Anglo-Saxon and French</textLang>
```

However, it is generally recommended where feasible to use the *mainLang* attribute to record the chief language of the bibliographic item, and optionally the *otherLangs* to identify other languages used in the work. For example:

```
<textLang mainLang="la" otherLangs="ang fr">Latin, with some glosses in Anglo-Saxon and French</textLang>
```

The *mainLang* and *otherLangs* attributes should both provide language identifiers in the same form as used for *xml:lang* as described at *vi.1 Language Identification*. Where additional detail is needed correctly to describe a language, or to discuss its deployment in a given text, this should be done using the <langUsage> element in the TEI header, within which individual <language> elements document the languages used: see 2.4.2. *Language Usage*.

A description, in French, of a work predominantly in German, but also with some Latin might have a <textLang> like the following:

```
<textLang xml:lang="fr" mainLang="de"
otherLangs="la">allemand et latin</textLang>
```

For more information about the use of <textLang> in manuscript descriptions see: 10.6.6. *Languages and Writing Systems*.

### 3.11.2.9 Order of Components within References

The order of elements in <bibl> elements is not constrained.

In <biblStruct> elements, the <analytic> element, if it occurs, must come first, followed by one or more <monogr> and <series> elements, which may appear intermingled (as long as a <monogr> element comes first), and then zero or more of the following in any order: <note>, <witDetail>, <idno>, <ptr>, <ref>, <relatedItem>, and <citedRange>. Within <analytic>, the title(s), author(s), editor(s), and other statements of responsibility may appear in any order; it is recommended that all forms of the title be given together. Within <monogr>, the author, editor, and statements of responsibility may either come first or else follow the monographic title(s). Following these, the elements listed below, if present, must appear in the following order:

- <note>s on the publication (and <meeting> elements describing the conference, in the case of a proceedings volume)
- <edition> elements, each followed by any related <editor> or <respStmt> elements
- <imprint>
- <biblScope>

Within `<imprint>`, the elements allowed may appear in any order.

Finally, within the `<series>` information in a `<biblStruct>`, the sequence of elements is not constrained.

If more detailed structuring of a bibliographic description is required, the `<biblFull>` element should be used. This is not further described here, as its contents are essentially equivalent to those of the `<fileDesc>` element in the `<teiHeader>`, which is fully described in section 2.2. *The File Description*.

### 3.11.3 Bibliographic Pointers

References which are pointers to bibliographic items, of whatever kind, should be treated in the same way as other cross-references (see section 3.6. *Simple Links and Cross-References*). As discussed in that section, cross-referencing within TEI texts is in general represented by means of `<ptr>` or `<ref>` elements. A *target* attribute on these elements is used to supply an identifying value for the target of the cross-reference, which should be, in the case of bibliographic elements, a bibliographic reference of some kind. Where the form of the reference itself is unimportant, or may be reconstructed mechanically, or is not to be encoded, the `<ptr>` element is used, as in the following example:

```
As shown above (<ptr target="#NEL80"/>) ...
```

Where the form of the reference is important, or contains additional qualifying information which is to be kept but distinguished from the surrounding text, the `<ref>` element should be used, as in the following example:

```
Nelson claims <ref target="#NEL80">(ibid, passim)</ref> ...
```

It may be important to distinguish between the short form of a bibliographic reference and some qualifying or additional information. The latter should not appear within the scope of the `<ref>` element when this is the case, as for example in an application concerned to normalize bibliographic references:

```
Nelson claims (<ref target="#NEL80">Nelson [1980]</ref> pages 13–37) ...
```

The `<ref>` element may also be used to provide a reference to a copy of the bibliographic item itself, particularly if this is available online, as in the following example:

```
<biblStruct>
  <analytic>
    <author>
      <forename>Suzana</forename>
      <surname>Sukovic</surname>
    </author>
    <title level="a">Beyond the Scriptorium: The Role of the Library in Text
      Encoding</title>
  </analytic>
  <monogr>
    <title level="j">D-Lib</title>
    <ref type="url">http://www.dlib.org/dlib/january02/sukovic/01sukovic.html</ref>
    <imprint>
      <biblScope unit="vol">8</biblScope>
      <biblScope unit="issue">1</biblScope>
      <date>2002</date>
    </imprint>
  </monogr>
</biblStruct>
```

### 3.11.4 Relationship to Other Bibliographic Schemes

The bibliographic tagging defined here can capture the distinctions required by most bibliographic encoding systems; for the benefit of users of some commonly used systems, the following lists of equivalences are offered, showing the relationship of the markup defined here to the fields defined for bibliographic records in the Scribe, BibTeX, and ProCite systems.

Listed below are the equivalences between the various bibliographic fields defined for use in the Scribe and BibTeX systems of bibliographic databases and the elements defined in this module.<sup>55</sup> Elements and structures available in the module defined here which have no analogues in Scribe and BibTeX are not noted.

**address** tag as <placeName> or <address>

**annotate** tag as <note>

**author** tag as <author>

**booktitle** tag as <title level="m"> or <title> within <monogr>

**chapter** tag as <biblScope unit="chap">

**date** used only to record date entry was made in the bibliographic database; not supported

**edition** tag as <edition>

**editor** tag as <editor> or <respStmt>

**editors** tag as multiple <editor> or <respStmt> elements

**fullauthor** use the <reg> element, possibly inside a <choice> element, inside either an <author> or <name>

**fullorganization** use the <reg> element, possibly inside a <choice> element, inside a <name type="org">

**howpublished** tag as <note>, possibly using the form <note place="inline">

**institution** used only for issuer of technical reports; tag as <publisher>

**journal** tag as <title level="j"> or <title> within <monogr>

**key** used to specify an alternate sort key for the bibliographic item, for use instead of author's or editor's name; not supported

**meeting** tag as <meeting> or as <note>

**month** use <date>; if the date is not in a trivially parseable form, use the *when* attribute to provide a normalized equivalent in one of the format from *XML Schema Part 2: Datatypes Second Edition*

**note** tag as <note>

**number** tag as <biblScope unit="issue"> or <biblScope unit="number">; for technical report numbers, use <idno type="docno">

**organization** used only for sponsor of conference; use <name type="org"> within <respStmt> within <meeting> element

**pages** tag as <biblScope unit="pp">

**publisher** tag as <publisher>

**school** used only for institutions at which thesis work is done; tag as <publisher>

**series** tag as <title level="s"> or <title> within <series>

**title** tag as <title> in appropriate context or with appropriate *level* value

**volume** tag as <biblScope unit="vol">

**year** tag as <date>; if the date is not in a trivially parseable form, use the *when* attribute to provide an ISO-format equivalent

---

<sup>55</sup>The BibTeX scheme is intentionally compatible with that of Scribe, although it omits some fields used by Scribe. Hence only one list of fields is given here.

## 3.12 Passages of Verse or Drama

The following elements are included in the core module for the convenience of those encoding texts which include mixtures of prose, verse and drama.

- <l>** (verse line) contains a single, possibly incomplete, line of verse.
- <lg>** (line group) contains one or more verse lines functioning as a formal unit, e.g. a stanza, refrain, verse paragraph, etc.
- <sp>** (speech) contains an individual speech in a performance text, or a passage presented as such in a prose or verse text.
- <speaker>** contains a specialized form of heading or label, giving the name of one or more speakers in a dramatic text or fragment.
- <stage>** (stage direction) contains any kind of stage direction within a dramatic text or fragment.

Full details of other, more specialized, elements for the encoding of texts which are predominantly verse or drama are described in the appropriate chapter of part three (for verse, see the verse base described in chapter 6. *Verse*; for performance texts, see the drama base described in chapter 7. *Performance Texts*). In this section, we describe only the elements listed above, all of which can appear in any text, whichever of the three modes prose, verse, or drama may predominate in it.

### 3.12.1 Core Tags for Verse

Like other written texts, verse texts or poems may be hierarchically subdivided, for example into books or cantos. These structural subdivisions should be encoded using the general purpose `<div>` or `<div1>` (etc.) elements described below in chapters 4. *Default Text Structure* and 6. *Verse*. The fundamental unit of a verse text is the verse line rather than the paragraph, however.

The `<l>` element is used to mark up verse lines, that is metrical rather than typographic lines. In some modern or free verse, it may be hard to decide whether the typographic line is to be regarded as a verse line or not, but the distinction is quite clear for verse following regular metrical patterns. Where a metrical line is interrupted by a typographic line break, the encoder may choose to ignore the fact entirely or to use the empty `<lb>` (line break) element discussed in 3.10. *Reference Systems*. By convention, the start of a metrical line implies the start of a typographic line; hence there is no need to introduce an `<lb>` tag at the start of every `<l>` element, but only at places where a new typographic line starts within a metrical line, as in the following example:

```
<l>Of Mans First Disobedience, and<lb/> the Fruit</l>
<l>Of that Forbidden Tree, whose<lb/> mortal tast</l>
<l>Brought Death into the World,<lb/> and all our woe,</l>
<l>With loss of Eden, till one greater Man</l>
<l>Restore us, and regain the blissful Seat...</l>
```

In the original copy text, the presence of an ornamental capital at the start of the poem means that the measure is not wide enough to print the first four lines on four lines; instead each metrical line occupies two typographic lines, with a break at the point indicated. Note that this encoding makes no attempt to preserve information about the whitespace or indentation associated with either kind of line; if regarded as essential, this information would be recorded using the *rend* or *rendition* attributes discussed in 1.3.1.1. *Global Attributes*.

The `<l>` element should not be used to represent typographic lines in non-verse materials: if the line-breaking points in a prose text are considered important for analysis, they should be marked with the `<lb>` element. Alternatively, a neutral segmentation element such as `<seg>` or `<ab>` may be used; see further discussion of these elements in chapter 16. *Linking, Segmentation, and Alignment*. The `<l>` element is a member of the `model.lLike` class, which is a subclass of the `model.divPart` class, along with elements from the `model.pLike` (paragraph-like) class.

In some verse forms, regular groupings of lines are regarded as units of some kind, often identified by a regular verse scheme. In stichic verse and couplets, groups of lines analogous to paragraphs are often indicated by indentation. In other verse forms, lines are grouped into irregular sequences indicated simply by whitespace. The `<lg>` or line group element may be used to mark any such grouping of elements from the `model.lLike` class. As a member of the `att.typed` class, the `<lg>` element bears the following attributes:

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

`@type` characterizes the element in some sense, using any convenient classification scheme or typology.

`@subtype` provides a sub-categorization of the element, if needed

which may be used to further categorize the line group where this is felt desirable, as in the following example. This example also demonstrates the *rend* attribute to indicate whether or not a line is indented.

```
<lg>
  <l>Come fill up the Glass,</l>
  <l rend="indent">Round, round let it pass,</l>
  <l>'Till our Reason be lost in our Wine:</l>
  <l rend="indent">Leave Conscience's Rules</l>
  <l rend="indent">To Women and Fools,</l>
  <l>This only can make us divine.</l>
</lg>
<lg n="Chorus" type="refrain">
  <l>Then a Mohock, a Mohock I'll be,</l>
  <l>No Laws shall restrain</l>
  <l>Our Libertine Reign,</l>
  <l>We'll riot, drink on, and be free.</l>
</lg>
```

For some kinds of analysis, it may be useful to identify different kinds of line group within the same piece of verse. Such line groups may self-nest, in much the same way as the un-numbered `<div>` element described in chapter 4. *Default Text Structure*. For example:

```
<lg type="sonnet">
  <lg type="octet">
    <l>Thus speaks the Muse, and bends her brow severe:—</l>
    <l>“Did I, <name>Lætitia</name>, lend my choicest lays,</l>
    <l>And crown thy youthful head with freshest bays,</l>
    <l>That all the' expectance of thy full-grown year</l>
    <l>Should lie inert and fruitless? O revere</l>
    <l>Those sacred gifts whose meed is deathless praise,</l>
    <l>Whose potent charms the' enraptured soul can raise</l>
    <l>Far from the vapours of this earthly sphere!</l>
  </lg>
  <lg type="sestet">
    <l>Seize, seize the lyre! resume the lofty strain!</l>
    <l>'T is time, 't is time! hark how the nations round</l>
    <l>With jocund notes of liberty resound,—</l>
    <l>And thy own <name>Corsica</name> has burst her chain!</l>
    <l>O let the song to <name>Britain's</name> shores rebound,</l>
    <l rend="indent(-1)">Where Freedom's once-loved voice is heard,
      alas! in vain.”</l>
  </lg>
</lg>
```

It is often the case that verse line boundaries conflict with the boundaries of other structural elements. In the following example, the single verse line ‘A Workeman in't... welcome’ is interrupted by a stage direction:

```
<l>Thou fumblest <name>Eros</name>, and my Queenes a Squire</l>
<l>More tight at this, then thou: Dispatch. O Loue,</l>
<l>That thou couldst see my Warres to day, and knew'st</l>
```

```
<l>The Royall Occupation, thou should'st see</l>
<l part="I">A Workeman in't.</l>
<stage>Enter an Armed Soldier.</stage>
<l part="F">Good morrow to thee, welcome.</l>
```

In this encoding, the *part* attribute is used, as with `<div>`, to indicate that the last two `<l>` elements should be regarded as the initial and final parts of a single line, rather than as two lines.

The same technique may be used where verse lines are collected together into units such as verse paragraphs:

```
<lg n="6" type="para">
<!-- ... -->
  <l>Unprofitably travelling toward the grave,</l>
  <l>Like a false steward who hath much received</l>
  <l part="I">And renders nothing back.</l>
</lg>
<lg type="para" n="7">
  <l part="F">Was it for this</l>
  <l>That one, the fairest of all rivers, loved</l>
  <l>To blend his murmurs with my nurse's song,</l>
<!-- ... -->
</lg>
```

The *part* attribute may also be attached to an `<lg>` element to indicate that it is incomplete, for example because it forms part of a group that is divided between two speakers, as in the following example:

```
<sp>
  <speaker>First Voice</speaker>
  <lg type="stanza" part="I">
    <l>But why drives on that ship so fast</l>
    <l>Withouten wave or wind?</l>
  </lg>
</sp>
<sp>
  <speaker>Second Voice</speaker>
  <lg type="stanza" part="F">
    <l>The air is cut away before,</l>
    <l>And closes from behind.</l>
  </lg>
</sp>
```

For alternative methods of aligning groups of lines which do not form simple hierarchic groups, or which are discontinuous, see the more detailed discussion in chapter 16. *Linking, Segmentation, and Alignment*. For discussion of other elements and attributes specific to the encoding of verse, see chapter 6. *Verse*.

### 3.12.2 Core Tags for Drama

Like other written texts, dramatic and other *performance texts* such as cinema or TV scripts are often hierarchically organized, for example into acts and scenes. These structural subdivisions should be encoded using the general purpose `<div>` or `<div1>` (etc.) elements described below in chapters 4. *Default Text Structure* and 7. *Performance Texts*. Within these divisions, the body of a performance text typically consists of *speeches*, often prefixed by a phrase indicating who is speaking, and occasionally interspersed with stage directions of various kinds.

In the following simple example, each speech consists of a single paragraph:

```

<div2 n="I.2" type="scene">
  <head>Scene 2.</head>
  <stage type="setting">Peachum, Filch.</stage>
  <sp>
    <speaker>FILCH.</speaker>
    <p>Sir, Black Moll hath sent word her Trial comes on in
      the Afternoon, and she hopes you will order Matters
      so as to bring her off.</p>
  </sp>
  <sp>
    <speaker>PEACHUM.</speaker>
    <p>Why, she may plead her Belly at worst; to my
      Knowledge she hath taken care of that Security.
      But, as the Wench is very active and industrious,
      you may satisfy her that I'll soften the Evidence.</p>
  </sp>
  <sp>
    <speaker>FILCH.</speaker>
    <p>Tom Gagg, sir, is found guilty.</p>
  </sp>
</div2>

```

In the following example, each speech consists of a sequence of verse lines, some of them being marked as metrically incomplete:

```

<div1 n="I" type="Act">
  <head>ACT I</head>
  <div2 n="1" type="Scene">
    <head>SCENE I</head>
    <stage rend="italic">Enter Barnardo and Francisco,
      two Sentinels, at several doors</stage>
    <sp>
      <speaker>Barn</speaker>
      <l part="Y">Who's there?</l>
    </sp>
    <sp>
      <speaker>Fran</speaker>
      <l>Nay, answer me. Stand and unfold yourself.</l>
    </sp>
    <sp>
      <speaker>Barn</speaker>
      <l part="I">Long live the King!</l>
    </sp>
    <sp>
      <speaker>Fran</speaker>
      <l part="M">Barnardo?</l>
    </sp>
    <sp>
      <speaker>Barn</speaker>
      <l part="F">He.</l>
    </sp>
    <sp>
      <speaker>Fran</speaker>
      <l>You come most carefully upon your hour.</l>
    </sp>
  </div2>
</div1>

```

```

    <speaker>Barn</speaker>
    <l>'Tis now struck twelve. Get thee to bed, Francisco.</l>
  </sp>
  <sp>
    <speaker>Fran</speaker>
    <l>For this relief much thanks. 'Tis bitter cold,</l>
    <l part="I">And I am sick at heart.</l>
  </sp>
</div2>
</div1>

```

In some cases, as here in the First Quarto of *Hamlet*, the printed speaker attributions need to be supplemented by use of the *who* attribute; again, the lines are marked as complete or incomplete:

```

<stage>Enter two Centinels.
<add place="margin">Now call'd <name xml:id="barnardo">Bernardo</name> &
  <name xml:id="francisco">Francesco</name>.</add>
</stage>
<sp who="#francisco">
  <speaker>1.</speaker>
  <l part="Y">Stand: who is that?</l>
</sp>
<sp who="#barnardo">
  <speaker>2.</speaker>
  <l part="Y">Tis I.</l>
</sp>
<sp who="#francisco">
  <speaker>1.</speaker>
  <l>O you come most carefully vpon your watch,</l>
</sp>
<sp who="#barnardo">
  <speaker>2.</speaker>
  <l>And if you meete Marcellus and Horatio,</l>
  <l>The partners of my watch, bid them make haste.</l>
</sp>
<sp who="#francisco">
  <speaker>1.</speaker>
  <l part="Y">I will: See who goes there.</l>
</sp>
<stage>Enter Horatio and Marcellus.</stage>

```

By contrast with the preceding examples, the following encodes an early printed edition without making any assumption about which parts are prose or verse:

```

<div1 n="I" type="act">
  <div2 n="1" type="scene">
    <head rend="italic">Actus primus, Scena prima.</head>
    <stage rend="italic" type="setting">A tempestuous
      noise of Thunder and Lightning heard: Enter
      a Ship-master, and a Boteswaine.</stage>
    <sp>
      <speaker>Master.</speaker>
      <p>Bote-swaine.</p>
    </sp>
  </div2>
</div1>

```

```

<sp>
  <speaker>Botes.</speaker>
  <p>Heere Master: What cheere?</p>
</sp>
<sp>
  <speaker>Mast.</speaker>
  <p>Good: Speake to th' Mariners: fall
    too't, yarely, or we run our selues a ground,
    bestirre, bestirre. <stage type="move">Exit.</stage>
  </p>
</sp>
<stage type="move">Enter Mariners.</stage>
<sp>
  <speaker>Botes.</speaker>
  <p>Heigh my hearts, cheerely, cheerely my harts: yare,
    yare: Take in the toppe-sale: Tend to th' Masters whistle:
    Blow till thou burst thy winde, if roome e-nough.</p>
</sp>
</div2>
</div1>

```

The <sp> and <stage> elements should also be used to mark parts of a text otherwise in prose which are presented as if they were dialogue in a play. The following example is taken from a 19th century novel in which passages of narrative and passages of dialogue are mixed within the same chapter:

```

<sp>
  <speaker>The reverend Doctor Opimian</speaker>
  <p>I do not think I have named a single unpresentable fish.</p>
</sp>
<sp>

### 3.13 Overview of the Core Module

All the elements described in this chapter are provided by the `CORE` module.

**Module core: Elements common to all TEI documents**

- *Elements defined:* abbr add addrLine address analytic author bibl biblScope biblStruct binaryObject cb choice cit citedRange corr date del desc distinct divGen editor email emph expan foreign gap gb gloss graphic head headItem headLabel hi imprint index item l label lb lg list listBibl measure measureGrp media meeting mentioned milestone monogr name note num orig p pb postBox postCode ptr pubPlace publisher q quote ref reg relatedItem resp respStmt rs said series sic soCalled sp speaker stage street teiCorpus term textLang time title unclear
- *Classes defined:* att.milestoneUnit

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

## 4 Default Text Structure

This chapter describes the default high-level structure for TEI documents. A full TEI document combines metadata describing it, represented by a `<teiHeader>` element, with the document itself, represented by either a `<text>` element or one or more other elements taken from the `model.resourceLike` class, or the two in combination. This group of elements makes up a `<TEI>` element. The `<teiHeader>` element is specified by the `header` module, which is fully described in chapter 2. *The TEI Header*. The remainder of the present chapter describes the `<text>` element and its high-level constituents.

A variant on this basic form, the `<teiCorpus>`, is also defined for the representation of language corpora, or other collections of encoded texts. A `<teiCorpus>` consists of one or more complete `<TEI>` elements, each combining a `<teiHeader>` and a `<text>` which itself carries a `<teiHeader>`. This permits the encoder to distinguish metadata applicable to the whole collection of encoded texts, which is represented by the outermost `<teiHeader>`, from that applicable to each of the individual `<TEI>` elements within the corpus. Further information about the organization and encoding of language corpora is given in chapter 15. *Language Corpora*.

In summary, when the default structure module is included in a schema, the following elements are available for the representation of the outermost structure of a TEI document:

**<TEI>** (TEI document) contains a single TEI-conformant document, combining a single TEI header with one or more members of the `model.resourceLike` class. Multiple TEI elements may be combined to form a `<teiCorpus>` element.

`@version` specifies the major version number of the TEI Guidelines against which this document is valid.

**<teiCorpus>** contains the whole of a TEI encoded corpus, comprising a single corpus header and one or more TEI elements, each containing a single text header and a text.

**<teiHeader>** (TEI header) supplies descriptive and declarative metadata associated with a digital resource or set of resources.

**<text>** contains a single text of any kind, whether unitary or composite, for example a poem or drama, a collection of essays, a novel, a dictionary, or a corpus sample.

As noted above, the `<teiHeader>` element is formally declared in the `header` module (see chapter 2. *The TEI Header*). A TEI document may also contain elements from the `model.resourceLike` class (such as a collection of facsimile images, or a feature system declaration) if the appropriate module is included in a schema (see further 11.1. *Digital Facsimiles* and 18.11. *Feature System Declaration* respectively). By default, however, this class is not populated and hence only the elements `<TEI>`, `<text>`, and `<teiCorpus>` are available as major parts of a TEI document. These three elements are provided by the `textstructure` module described by the present chapter.

TEI texts may be regarded either as *unitary*, that is, forming an organic whole, or as *composite*, that is, consisting of several components which are in some important sense independent of each other. The distinction is not always entirely obvious: for example a collection of essays might be regarded as a single item in some circumstances, or as a number of distinct items in others. In such borderline cases, the encoder must choose whether to treat the text as unitary or composite; each may have advantages and disadvantages in a given situation.

Whether unitary or composite, the text is marked with the `<text>` tag and may contain front matter, a text body, and back matter. In unitary texts, the text body is tagged `<body>`; in composite texts, where the text body consists of a series of subordinate texts or groups, it is tagged `<group>`. The overall structure of any text, unitary or composite, is thus defined by the following elements:

**<front>** (front matter) contains any prefatory matter (headers, abstracts, title page, prefaces, dedications, etc.) found at the start of a document, before the main body.

**<body>** (text body) contains the whole body of a single unitary text, excluding any front or back matter.

**<group>** contains the body of a composite text, grouping together a sequence of distinct texts (or groups of such texts) which are regarded as a unit for some purpose, for example the collected works of an author, a sequence of prose essays, etc.

**<back>** (back matter) contains any appendixes, etc. following the main part of a text.

The overall structure of a unitary text is:

```
<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
```

```

<!-- ... -->
</teiHeader>
<text>
  <front>
<!-- front matter of copy text, if any, goes here -->
  </front>
  <body>
<!-- body of copy text goes here -->
  </body>
  <back>
<!-- back matter of copy text, if any, goes here -->
  </back>
</text>
</TEI>

```

The overall structure of a composite text made up of two unitary texts is:

```

<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
<!-- ... -->
  </teiHeader>
  <text>
    <front>
<!-- front matter for composite text -->
    </front>
    <group>
      <text>
        <front>
<!-- front matter of first unitary text, if any -->
        </front>
        <body>
<!-- body of first unitary text -->
        </body>
        <back>
<!-- back matter of first unitary text, if any -->
        </back>
      </text>
      <text>
        <body>
<!-- body of second unitary text -->
        </body>
      </text>
    </group>
    <back>
<!-- back matter for composite text, if any -->
    </back>
  </text>
</TEI>

```

Finally, a <floatingText> element is provided for the case where one text is embedded within another, but does not contribute to its hierarchical organization, for example because it interrupts it, or simply quoted within it. This is useful in such common literary contexts as the ‘play within a play’ or the narrative interrupted by other (often deeply nested) multiple narratives.

Each of these elements is further described in the remainder of this chapter. Elements <front> and <back> are further discussed in sections 4.5. *Front Matter* and 4.7. *Back Matter*. The <group> and <floatingText> elements, used for more complex or composite text structures, are further discussed in section 4.3. *Grouped and Floating Texts*.

Other textual elements, such as paragraphs, lists or phrases, which nest within these major structural elements, are discussed in chapter 3. *Elements Available in All TEI Documents*, in the case of elements which can appear in any kind of document, or elsewhere in the case of elements specific to particular kinds of document.

## 4.1 Divisions of the Body

In some texts, the body consists simply of a sequence of low-level structural items, referred to here as *components* or *component-level elements* (see section 1.3. *The TEI Class System*). Examples in prose texts include paragraphs or lists; in dramatic texts, speeches and stage directions; in dictionaries, dictionary entries. In other cases sequences of such elements will be grouped together hierarchically into textual divisions and subdivisions, such as chapters or sections. The names used for these structural subdivisions of texts vary with the genre and period of the text, or even at the whim of the author, editor, or publisher. For example, a major subdivision of an epic or of the Bible is generally called a ‘book’, that of a report is usually called a ‘part’ or ‘section’, that of a novel a ‘chapter’—unless it is an epistolary novel, in which case it may be called a ‘letter’. Even texts which are not organized as linear prose narratives, or not as narratives at all, will frequently be subdivided in a similar way: a drama into ‘acts’ and ‘scenes’; a reference book into ‘sections’; a diary or day book into ‘entries’; a newspaper into ‘issues’ and ‘sections’, and so forth.

Because of this variety, these Guidelines propose that all such textual divisions be regarded as occurrences of the same neutrally named elements, with an attribute *type* used to categorize elements independently of their hierarchic level. Two alternative styles are provided for the marking of these neutral divisions: *numbered* and *un-numbered*. Numbered divisions are named <div1>, <div2>, etc., where the number indicates the depth of this particular division within the hierarchy, the largest such division being ‘div1’, any subdivision within it being ‘div2’, any further sub-sub-division being ‘div3’ and so on. Un-numbered divisions are simply named <div>, and allowed to nest recursively to indicate their hierarchic depth. The two styles must *not* be combined within a single <front>, <body>, or <back> element.

### 4.1.1 Un-numbered Divisions

The following element is used to identify textual subdivisions in the un-numbered style:

**<div>** (text division) contains a subdivision of the front, body, or back of a text.

As a member of the class **att.typed**, this element has the following additional attributes:

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

**@type** characterizes the element in some sense, using any convenient classification scheme or typology.

**@subtype** provides a sub-categorization of the element, if needed

Using this style, the body of a text containing two parts, each composed of two chapters, might be represented as follows:

```
<body>
  <div type="part" n="1">
    <div type="chapter" n="1">
<!-- text of part 1, chapter 1 -->
    </div>
    <div type="chapter" n="2">
<!-- text of part 1, chapter 2 -->
    </div>
  </div>
  <div type="part" n="2">
    <div n="1" type="chapter">
<!-- text of part 2, chapter 1 -->
    </div>
    <div n="2" type="chapter">
<!-- text of part 2, chapter 2 -->
    </div>
  </div>
</body>
```

### 4.1.2 Numbered Divisions

The following elements are used to identify textual subdivisions in the numbered style:

- <div1>** (level-1 text division) contains a first-level subdivision of the front, body, or back of a text.
- <div2>** (level-2 text division) contains a second-level subdivision of the front, body, or back of a text.
- <div3>** (level-3 text division) contains a third-level subdivision of the front, body, or back of a text.
- <div4>** (level-4 text division) contains a fourth-level subdivision of the front, body, or back of a text.
- <div5>** (level-5 text division) contains a fifth-level subdivision of the front, body, or back of a text.
- <div6>** (level-6 text division) contains a sixth-level subdivision of the front, body, or back of a text.
- <div7>** (level-7 text division) contains the smallest possible subdivision of the front, body or back of a text, larger than a paragraph.

As members of the class `att.typed` these elements all bear the following additional attributes:

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

`@type` characterizes the element in some sense, using any convenient classification scheme or typology.

`@subtype` provides a sub-categorization of the element, if needed

The largest possible subdivision of the body is `<div1>` element and the smallest possible `<div7>`. If numbered divisions are in use, a division at any one level (say, `<div3>`), may contain only numbered divisions at the next lowest level (in this case, `<div4>`).

Using this style, the body of a text containing two parts, each composed of two chapters, might be represented as follows:

```
<body>
  <div1 type="part" n="1">
    <div2 type="chapter" n="1">
<!-- text of part 1, chapter 1 -->
    </div2>
    <div2 type="chapter" n="2">
<!-- text of part 1, chapter 2 -->
    </div2>
  </div1>
  <div1 type="part" n="2">
    <div2 n="1" type="chapter">
<!-- text of part 2, chapter 1 -->
    </div2>
    <div2 n="2" type="chapter">
<!-- text of part 2, chapter 2 -->
    </div2>
  </div1>
</body>
```

### 4.1.3 Numbered or Un-numbered?

Within the same `<front>`, `<body>`, or `<back>` element, all hierarchic subdivisions must be marked using either nested `<div>` elements, or `<div1>`, `<div2>` etc. elements nested as appropriate; the two styles must *not* be mixed.

The choice between numbered and un-numbered divisions will depend to some extent on the complexity of the material: un-numbered divisions allow for an arbitrary depth of nesting, while numbered divisions limit the depth of the tree which can be constructed. Where divisions at different levels should be processed differently (for example to ensure that chapters, but not sections, begin on a new page), numbered divisions slightly simplify the task of defining the desired processing for each level, though this distinction could also be made by supplying this information on the `type` attribute of an un-numbered `<div>`. Some software may find numbered divisions easier to process, as there is no need to maintain knowledge of the whole document structure in order to know the level at which a division occurs; such software may, however, find it difficult to cope with some other aspects of the TEI scheme. On the other hand, in a collection of many works it may prove difficult or impossible to ensure that the same numbered division

always corresponds with the same type of textual feature: a ‘chapter’ may be at level 1 in one work and level 3 in another.

Whichever style is used, the global *n* and *xml:id* attributes (section 1.3.1.1. *Global Attributes*) may be used to provide reference strings or labels for each division of a text, where appropriate. Such labels should be provided for each section which is regarded as significant for referencing purposes (on reference systems, see further section 3.10. *Reference Systems*).

As indicated above, the *type* and *subtype* attributes provided by the `att.typed` class may be used to provide a name or description for the division. Typical values might be ‘book’, ‘chapter’, ‘section’, ‘part’, or (for verse texts) ‘book’, ‘canto’, ‘stanza’, or (for dramatic texts) ‘act’, ‘scene’. The following extended example uses numbered divisions to indicate the structure of a novel, and illustrates the use of the attributes discussed above. It also uses some elements discussed in section 4.2. *Elements Common to All Divisions* and the `<p>` element discussed in section 3.1. *Paragraphs*.

```
<div1 type="book" n="I" xml:id="JA0100">
  <head>Book I.</head>
  <div2 type="chapter" n="1" xml:id="JA0101">
    <head>Of writing lives in general, and particularly of Pamela, with a word
      by the bye of Colley Cibber and others.</head>
    <p>It is a trite but true observation, that examples work more forcibly on
      the mind than precepts: ... </p>
  <!-- remainder of chapter 1 here -->
</div2>
  <div2 type="chapter" n="2" xml:id="JA0102">
    <head>Of Mr. Joseph Andrews, his birth, parentage, education, and great
      endowments; with a word or two concerning ancestors.</head>
    <p>Mr. Joseph Andrews, the hero of our ensuing history, was esteemed to
      be the only son of Gaffar and Gammar Andrews, and brother to the
      illustrious Pamela, whose virtue is at present so famous ... </p>
  <!-- remainder of chapter 2 here -->
</div2>
<!-- remaining chapters of Book 1 here -->
  <trailer>The end of the first Book</trailer>
</div1>
<div1 type="book" n="II" xml:id="JA0200">
  <head>Book II</head>
  <div2 type="chapter" n="1" xml:id="JA0201">
    <head>Of divisions in authors</head>
    <p>There are certain mysteries or secrets in all trades, from the highest
      to the lowest, from that of <term>prime-ministering</term>, to this of
      <term>authoring</term>, which are seldom discovered unless to members of
      the same calling ... </p>
    <p>I will dismiss this chapter with the following observation: that it
      becomes an author generally to divide a book, as it does a butcher to
      joint his meat, for such assistance is of great help to both the reader
      and the carver. And now having indulged myself a little I will endeavour
      to indulge the curiosity of my reader, who is no doubt impatient to know
      what he will find in the subsequent chapters of this book.</p>
  </div2>
  <div2 type="chapter" n="2" xml:id="JA0202">
    <head>A surprising instance of Mr. Adams's short memory, with the
      unfortunate consequences which it brought on Joseph.
    </head>
    <p>Mr. Adams and Joseph were now ready to depart different ways ... </p>
  </div2>
</div1>
```

As an alternative (or complement) to this use of the *type* attribute to characterize neutrally named division elements, the modification mechanisms discussed in section 23.3. *Personalization and Customization* may be used to

define new elements such as `<chapter>`, `<part>`, etc. To make this simpler, a single member model class is defined for each of the neutrally named division elements: `model.divLike` (containing `<div>`), `model.div1Like` (containing `<div1>`), `model.div2Like` (containing `<div2>`), etc. For example, suppose that the body of a text consists of a series of diary entries, each of which is potentially divided into entries for the morning and the afternoon. This might be represented in any of the following ways. First, using the un-numbered style:

```
<body>
  <div type="entry" n="1">
    <div type="morning" n="1.1">
      <p>[...]</p>
    </div>
    <div type="afternoon" n="1.2">
      <p>[...]</p>
    </div>
  </div>
  <div type="entry" n="2">
    <div type="morning" n="2.1">
      <p>[...]</p>
    </div>
    <div type="afternoon" n="2.2">
      <p>[...]</p>
    </div>
  </div>
<!-- .....>
</body>
```

Equivalently, using the numbered style:

```
<body>
  <div1 type="entry" n="1">
    <div2 type="morning" n="1.1">
      <p>[...]</p>
    </div2>
    <div2 type="afternoon" n="1.2">
      <p>[...]</p>
    </div2>
  </div1>
  <div1 type="entry" n="2">
    <div2 type="morning" n="2.1">
      <p>[...]</p>
    </div2>
    <div2 type="afternoon" n="2.2">
      <p>[...]</p>
    </div2>
  </div1>
<!-- .....>
</body>
```

Now, assuming a customization in which a new element `<diaryEntry>` has been added to the `model.divLike` class:

```
<body
  xmlns:my="http://www.example.org/ns/nonTEI">
  <my:diaryEntry type="entry" n="1">
```

```

<my:diaryEntry type="morning" n="1.1">
  <p>[...]</p>
</my:diaryEntry>
<my:diaryEntry type="afternoon" n="1.2">
  <p>[...]</p>
</my:diaryEntry>
</my:diaryEntry>
<my:diaryEntry type="entry" n="1">
  <my:diaryEntry type="morning" n="1.1">
    <p>[...]</p>
  </my:diaryEntry>
  <my:diaryEntry type="afternoon" n="1.2">
    <p>[...]</p>
  </my:diaryEntry>
</my:diaryEntry>
<!-- ... -->
</body>

```

And finally, assuming a customization in which three new elements have been added: `<diaryEntry>` to the `model.div1Like` class, and `<amEntry>` and `<pmEntry>` both to the `model.div2Like` class:

```

<body
  xmlns:my="http://www.example.org/ns/nonTEI">
  <p>
<!-- ... -->
  </p>
  <my:diaryEntry type="entry" n="1">
    <my:amEntry type="morning" n="1.1">
      <p>[...]</p>
    </my:amEntry>
    <my:pmEntry type="afternoon" n="1.2">
      <p>[...]</p>
    </my:pmEntry>
  </my:diaryEntry>
  <my:diaryEntry type="entry" n="1">
    <my:amEntry type="morning" n="1.1">
      <p>[...]</p>
    </my:amEntry>
    <my:pmEntry type="afternoon" n="1.1">
      <p>[...]</p>
    </my:pmEntry>
  </my:diaryEntry>
<!-- ... -->
</body>

```

More information about the customization techniques exemplified here is provided in 23.3. *Personalization and Customization*.

#### 4.1.4 Partial and Composite Divisions

In most situations, the textual subdivisions marked by `<div>` or `<div1>` (etc.) elements will be both complete and identically organized with reference to the original source. For some purposes however, in particular where dealing with unusually large or unusually small texts, encoders may find it convenient to present as textual divisions sequences of text which are incomplete with reference to the original text, or which are in fact an ad hoc agglomeration of tiny texts. Moreover, in some kinds of texts it is difficult or impossible to determine the order in which individual subdivisions should be combined to form the next higher level of subdivision, as noted below.

To overcome these problems, the following additional attributes are defined for all elements in the `att.divLike` class:

**att.divLike** provides attributes common to all elements which behave in the same way as divisions.

`@org` (organization) specifies how the content of the division is organized.

`@sample` indicates whether this division is a sample of the original source and if so, from which part.

**att.fragmentable** provides an attribute for representing fragmentation of a structural element, typically as a consequence of some overlapping hierarchy.

`@part` specifies whether or not its parent element is fragmented in some way, typically by some other overlapping structure: for example a speech which is divided between two or more verse stanzas, a paragraph which is split across a page division, a verse line which is divided between two speakers.

For example, an encoder might choose to transcribe only the first two thousand words of each chapter from a novel. In such a case, each chapter might conveniently be regarded as a partial division, and tagged with a `<div>` element in the following form:

```
<div n="xx" sample="initial" part="Y"
  type="chapter">
  <p> ... </p>
</div>
```

where `xx` represents a number for the chapter, and the `part` attribute takes the value `Y` to indicate that this division is incomplete in some respect. Other possible values for this attribute indicate whether material has been omitted initially (`I`), finally (`F`), or in the middle (`M`) of the division, while the `<gap>` element (3.4.3. *Additions, Deletions, and Omissions*) may be used to indicate exactly where material has been omitted:

```
<div n="xx" part="M" type="chapter">
  <p> ... </p>
  <gap extent="2" reason="sampling"/>
  <p> ... </p>
</div>
```

The `<samplingDecl>` element in the TEI header should also be used to record the principles underlying the selection of incomplete samples, as further described in section 2.3.2. *The Sampling Declaration*.

The following example demonstrates how a newspaper column composed of very short unrelated snippets may be encoded using these attributes:

```
<div1 type="storylist" org="composite">
  <head>News in brief</head>
  <div2 type="story">
    <head>Police deny <soCalled>losing</soCalled> bomb</head>
    <p>Scotland Yard yesterday denied claims in the Sunday
      Express that anti-terrorist officers trailing an IRA van
      loaded with explosives in north London had lost track of
      it 10 days ago.</p>
  </div2>
  <div2 type="story">
    <head>Hotel blaze</head>
    <p>Nearly 200 guests were evacuated before dawn
      yesterday after fire broke out at the Scandic
      Crown hotel in the Royal Mile, Edinburgh.</p>
  </div2>
</div1>
```

```

</div2>
<div2 type="story">
  <head>Test match split</head>
  <p>Test Match Special next summer will be split
    between Radio 5 and Radio 3, after protests this
    year that it disrupted Radio 3's music schedule.</p>
</div2>
</div1>

```

The *org* attribute on the <div1> element is used here to indicate that individual stories in this group, marked here as <div2>, are really quite independent of each other, although they are all marked as subdivisions of the whole group. They can be read in any order without affecting the sense of the piece; indeed, in some cases, divisions of this nature are printed in such a way as to make it impossible to determine the order in which they are intended to be read. Individual stories can be added or removed without affecting the existing components.

This method of encoding composite texts as composite divisions has some limitations compared with the more general and powerful mechanisms discussed in section 4.3.1. *Grouped Texts*. However, it may be preferable in some circumstances, notably where the individual texts are very small.

## 4.2 Elements Common to All Divisions

The divisions of any kind of text may sometimes begin with a brief heading or descriptive title, with or without a byline, an epigraph or brief quotation, or a salutation such as one finds at the start of a letter. They may also conclude with a brief trailer, byline, postscript, or signature. Many of these (e.g. a byline) may appear either at the start or at the end of a text division proper.

To support this heterogeneity, the TEI architecture defines five classes, all of which are populated by this module:

**model.divTop** groups elements appearing at the beginning of a text division.

|                  |   |
|------------------|---|
| model.divTopPart | groups elements which can occur only at the beginning of a text division.       |
| model.divWrapper | groups elements which can appear at either top or bottom of a textual division. |

**model.divBottom** groups elements appearing at the end of a text division.

|                     |   |
|---------------------|---|
| model.divBottomPart | groups elements which can occur only at the end of a text division.             |
| model.divWrapper    | groups elements which can appear at either top or bottom of a textual division. |

**model.divTopPart** groups elements which can occur only at the beginning of a text division.

|                |   |
|----------------|---|
| model.headLike | groups elements used to provide a title or heading at the start of a text division. |
|----------------|---|

opener groups together dateline, byline, salutation, and similar phrases appearing as a preliminary group at the start of a division, especially of a letter.

signed (signature) contains the closing salutation, etc., appended to a foreword, dedicatory epistle, or other division of a text.

**model.divBottomPart** groups elements which can occur only at the end of a text division.

closer groups together salutations, datelines, and similar phrases appearing as a final group at the end of a division, especially of a letter.

|            |   |
|------------|---|
| postscript | contains a postscript, e.g. to a letter.  |
| signed     | (signature) contains the closing salutation, etc., appended to a foreword, dedicatory epistle, or other division of a text. |
| trailer    | contains a closing title or footer appearing at the end of a division of a text.  |

**model.divWrapper** groups elements which can appear at either top or bottom of a textual division.

|           |   |
|-----------|---|
| argument  | contains a formal list or prose description of the topics addressed by a subdivision of a text.   |
| byline    | contains the primary statement of responsibility given for a work on its title page or at the head or end of the work.  |
| dateline  | contains a brief description of the place, date, time, etc. of production of a letter, newspaper story, or other work, prefixed or suffixed to it as a kind of heading or trailer.                                    |
| docAuthor | (document author) contains the name of the author of the document, as given on the title page (often but not always contained in a byline).   |
| docDate   | (document date) contains the date of a document, as given on a title page or in a dateline.   |
| epigraph  | contains a quotation, anonymous or attributed, appearing at the start or end of a section or on a title page.   |
| meeting   | contains the formalized descriptive title for a meeting or conference, for use in a bibliographic description for an item derived from such a meeting, or as a heading or preamble to publications emanating from it. |
| salute    | (salutation) contains a salutation or greeting prefixed to a foreword, dedicatory epistle, or other division of a text, or the salutation in the closing of a letter, preface, etc.                                   |

### 4.2.1 Headings and Trailers

The `<head>` element is used to identify a heading prefixed to the start of any textual division, at any level. A given division may contain more than one such element, as in the following example:

```
<div1 n="Etym">
  <head>Etymology</head>
  <head>(Supplied by a late consumptive usher to a
    grammar school)</head>
  <p>The pale Usher – threadbare in coat, heart,
    body and brain; I see him now. He was ever
    dusting his old lexicons and grammars, ...</p>
</div1>
```

Unlike some other markup schemes, the TEI scheme does *not* require that headings attached to textual subdivisions at different hierarchic levels have different identifiers. All kinds of heading are marked identically using the `<head>` tag; the type or level of heading intended is implied by the immediate parent of the `<head>` element, which may for example be a `<div1>`, `<div2>`, etc., an un-numbered `<div>`, or any member of the `model.listLike` class. However, as with `<div>` elements, the encoder may choose to extend the `model.headLike` class of which `<head>` is the sole member to include other such elements if required.

In certain kinds of text (notably newspapers), there may be a need to categorize individual headings within the sequence at the start of a division, for example as ‘main’ headings, or ‘detail’ headings: this may readily be done using the *type* or *subtype* attribute. Specific elements are provided for certain kinds of heading-like features, (notably `<byline>`, `<dateline>`, and `<salute>`; see further section 4.2.2. *Openers and Closers*), but the *type* or *subtype* attributes must be used to discriminate among other forms of heading. These attributes are provided, as elsewhere, by the `att.typed` attribute class of which the `<head>` element is a member.

In the following example, taken from a British newspaper, the lead story and its associated headlines have been encoded as a `<div>` element, with appropriate `model.divTop` elements attached:

```

<div type="story">
  <head rend="underlined" type="sub">President pledges safeguards for 2,400 British
    troops in Bosnia</head>
  <head rend="scream" type="main">Major agrees to enforced no-fly zone</head>
  <byline>By George Jones, Political Editor, in Washington</byline>
  <p>Greater Western intervention in the conflict in
    former Yugoslavia was pledged by President Bush ...</p>
</div>

```

In older writings, the headings or *incipits* may be longer than in modern works. When heading-like material appears in the middle of a text, the encoder must decide whether or not to treat it as the start of a new division. If the phrase in question appears to be more closely connected with what follows than with what precedes it, then it may be regarded as a heading and tagged as the <head> of a new <div> element. If it appears to be simply inserted or superimposed—as for example the kind of ‘pull quotes’ often found in newspapers or magazines, then the <quote>, <q>, or <cit> element may be more appropriate.

The <trailer> element, which can appear at the end of a division only, is used to mark any heading-like feature appearing in this position, as in this example:

```

<div type="book" n="I">
  <head>In the name of Christ here begins the
    first book of the ecclesiastical history of Georgius Florentinus,
    known as Gregory, Bishop of Tours.</head>
  <div>
    <head>Chapter Headings</head>
    <list>
      <item>
<!-- chapter head -->
      </item>
<!-- further chapter heads omitted -->
    </list>
  </div>
  <div>
    <head>In the name of Christ here begins Book I of the history.</head>
    <p>Proposing as I do ...</p>
    <p>From the Passion of our Lord until the death of Saint Martin four
      hundred and twelve years passed.</p>
    <trailer>Here ends the first Book, which covers five thousand, five
      hundred and ninety-six years from the beginning of the world down
      to the death of Saint Martin.</trailer>
  </div>
</div>

```

## 4.2.2 Openers and Closers

In addition to headings of various kinds, divisions sometimes include more or less formulaic opening or closing passages, typically conveying such information as the name and address of the person to whom the division is addressed, the place or time of its production, a salutation or exhortation to the reader, and so on. Divisions in epistolary form are particularly liable to include such features. Additional elements for the detailed encoding of personal names, dates, and places are provided in chapter 13, *Names, Dates, People, and Places*. For simple cases, the following elements should be adequate:

**<byline>** contains the primary statement of responsibility given for a work on its title page or at the head or end of the work.

**<dateline>** contains a brief description of the place, date, time, etc. of production of a letter, newspaper story, or other work, prefixed or suffixed to it as a kind of heading or trailer.

**<salute>** (salutation) contains a salutation or greeting prefixed to a foreword, dedicatory epistle, or other division of a text, or the salutation in the closing of a letter, preface, etc.

**<signed>** (signature) contains the closing salutation, etc., appended to a foreword, dedicatory epistle, or other division of a text.

The **<byline>** and **<dateline>** elements are used to encode headings which identify the authorship and provenance of a division. Although the terminology derives from newspaper usage, there is no implication that **<dateline>** or **<byline>** elements apply only to newspaper texts. The following example illustrates use of the **<dateline>** and **<signed>** elements at the end of the preface to a novel:

```
<div type="preface">
  <head>To Henry Hope.</head>
  <p>It is not because this volume was conceived and partly
    executed amid the glades and galleries of the Deepdene,
    that I have inscribed it with your name. ... I shall find a
    reflex to their efforts in your own generous spirit and
    enlightened mind.
  </p>
  <closer>
    <signed xml:lang="el">D.</signed>
    <dateline>Grosvenor Gate, May-Day, 1844</dateline>
  </closer>
</div>
```

Where a sequence of such elements appear together, either at the beginning or end of an element, it may be convenient to group them together using one of the following elements:

**<opener>** groups together dateline, byline, salutation, and similar phrases appearing as a preliminary group at the start of a division, especially of a letter.

**<closer>** groups together salutations, datelines, and similar phrases appearing as a final group at the end of a division, especially of a letter.

The following examples demonstrate the use of the **<opener>** and **<closer>** grouping elements:

```
<div type="narrative" n="6">
  <head>Sixth Narrative</head>
  <head>contributed by Sergeant Cuff</head>
  <div type="fragment" n="6.1">
    <opener>
      <dateline>
        <name type="place">Dorking, Surrey,</name>
        <date>July 30th, 1849</date>
      </dateline>
      <salute>To <name>Franklin Blake, Esq.</name> Sir, -</salute>
    </opener>
    <p>I beg to apologize for the delay that has occurred in the
      production of the Report, with which I engaged to furnish you.
      I have waited to make it a complete Report ...</p>
    <closer>
      <salute>I have the honour to remain, dear sir, your
        obedient servant </salute>
      <signed>
        <name>RICHARD CUFF</name> (late sergeant in the
          Detective Force, Scotland Yard, London). </signed>
    </closer>
  </div>
</div>
```

```

<div type="letter" n="14">
  <head>Letter XIV: Miss Clarissa Harlowe to Miss Howe</head>
  <opener>
    <dateline>Thursday evening, March 2.</dateline>
  </opener>
  <p>On Hannah's depositing my long letter ...</p>
  <p>An interruption obliges me to conclude myself
    in some hurry, as well as fright, what I must ever be,</p>
  <closer>
    <salute>Yours more than my own,</salute>
    <signed>Clarissa Harlowe</signed>
  </closer>
</div>

```

For further discussion of the encoding of dates and of names of persons and places, see section 3.5.4. *Dates and Times* and chapter 13. *Names, Dates, People, and Places*.

### 4.2.3 Arguments, Epigraphs, and Postscripts

The <argument> element may be used to encode the prefatory list of topics sometimes found at the start of a chapter or other division. It is most conveniently encoded as a list, since this allows each item to be distinguished, but may also simply be presented as a paragraph. The following are thus both equally valid ways of encoding the same argument:

```

<div type="chap" n="6">
  <argument>
    <p>Kingston – Instructive remarks on early English history
      – Instructive observations on carved oak and life in general
      – Sad case of Stivvings, junior – Musings on antiquity
      – I forget that I am steering – Interesting result
      – Hampton Court Maze – Harris as a guide.</p>
  </argument>
  <p>It was a glorious morning, late spring or early summer, as you
    care to take it ...</p>
</div>

```

```

<div type="chap" n="6">
  <argument>
    <list type="inline">
      <item>Kingston</item>
      <item>Instructive remarks on early English history</item>
      <item>Instructive observations on carved oak and life in
        general</item>
      <item>Sad case of Stivvings, junior</item>
      <item>Musings on antiquity</item>
      <item>I forget that I am steering</item>
      <item>Interesting result</item>
      <item>Hampton Court Maze</item>
      <item>Harris as a guide.</item>
    </list>
  </argument>
  <p>It was a glorious morning, late spring or early summer, as you
    care to take it ...</p>
</div>

```

An *epigraph* is a quotation from some other work, a saying, or a motto, appearing on a title page, or at the start of a division. It may be encoded using the special-purpose <epigraph> element, as in the following example:

```
<titlePage>
  <docAuthor>E. M. Forster</docAuthor>
  <docTitle>
    <titlePart>Howards End</titlePart>
  </docTitle>
  <epigraph>
    <q>Only connect...</q>
  </epigraph>
</titlePage>
```

When an epigraph contains a quotation, this may often be associated with a bibliographic reference. In such cases, it is recommended additionally to group the quotation and its source together using the <cit> element, as in the following example:

```
<div n="19" type="chap">
  <head>Chapter 19</head>
  <epigraph>
    <cit>
      <quote>I pity the man who can travel
        from Dan to Beersheba, and say <q>'Tis all
          barren;</q> and so is all the world to him
          who will not cultivate the fruits it offers.
      </quote>
      <bibl>Sterne: Sentimental Journey.</bibl>
    </cit>
  </epigraph>
  <p>To say that Deronda was romantic would be to
    misrepresent him: but under his calm and somewhat
    self-repressed exterior ...</p>
</div>
```

For discussion of quotations appearing other than as epigraphs refer to section 3.3.3. *Quotation*.

A *postscript* is a passage added after the signature of a letter or, less frequently, the main portion of the body of a book, article, or essay. In English a postscript is often abbreviated as *P.S.* or *PS*, and postscripts are often introduced by labels with one of these abbreviations, as in the following example.

```
<div type="letter">
  <opener>
    <dateline>
      <placeName>Newport</placeName>
      <date when="1761-05-27">May ye 27th 1761</date>
    </dateline>
    <salute>Gentlemen</salute>
  </opener>
  <p>Capt Stoddard's Business
  <lb/>calling him to Providence, have
  <lb/>got him to look at Hopkins brigantine
  <lb/>& if can agree to Purchase her, shall
  <lb/>be much oblig'd for your further
  <lb/>assistance herein, & will acquiesce with
  <lb/>whatever you & he shall Contract
```

```
<lb/>for – I Thank you for your
<lb/>
  <unclear>Line</unclear> respecting the brigantine & Beg
<lb/>leave to Recommend the Bearer
<lb/>to you for your advice & Friendship
<lb/>in this matter</p>
<closer>
  <salute>I am your most humble servant</salute>
  <signed>Joseph Wanton Jr</signed>
</closer>
<postscript>
  <label>P.S.</label>
  <p>I have Mollases, Sugar,
  <lb/>Coffee & Rum, which
  <lb/>will Exchange with you
  <lb/>for Candles or Oyl</p>
</postscript>
</div>
```

#### 4.2.4 Content of Textual Divisions

Other than elements from the `model.divWrapper`, `model.divTop`, or `model.divBottom` classes, every textual division (numbered or un-numbered) consists of a sequence of ungrouped `macro.component` elements (see 1.3. *The TEI Class System*). The actual elements available will depend on the modules in use; in all cases, at least the component-level structural elements defined in the core will be available (paragraphs, lists, dramatic speeches, verse lines and line groups etc.). If the drama module has been selected, then other component- or phrase- level items specialized for performance texts (for example, cast lists or camera angles) will be available, as defined in chapter 7. *Performance Texts*) will be available. If the dictionary module is in use, then dictionary entries, related entries, etc. (as defined in chapter 9. *Dictionaries*) will also be available; if the module for transcribed speech is in use, then utterances, pauses, vocals, kinesics, etc., as defined in chapter 8.3. *Elements Unique to Spoken Texts* will be available; and so on.

Where a text contains low-level elements from more than one module these may appear at any point; there is no requirement that elements from the same module be kept together.

### 4.3 Grouped and Floating Texts

The `<group>` element discussed in 4.3.1. *Grouped Texts* should be used to represent a collection of independent texts which is to be regarded as a single unit for processing or other purposes. The `<floatingText>` element discussed in 4.3.2. *Floating Texts* should be used to represent an independent text which interrupts the text containing it at any point but after which the surrounding text resumes.

**<group>** contains the body of a composite text, grouping together a sequence of distinct texts (or groups of such texts) which are regarded as a unit for some purpose, for example the collected works of an author, a sequence of prose essays, etc.

**<floatingText>** contains a single text of any kind, whether unitary or composite, which interrupts the text containing it at any point and after which the surrounding text resumes.

#### 4.3.1 Grouped Texts

Examples of composite texts which should be represented using the `<group>` element include anthologies and other collections. The presence of common front matter referring to the whole collection, possibly in addition to front matter relating to each individual text, is a good indication that a given text might usefully be encoded in this way; this structure may be found useful in other circumstances too.

For example, the overall structure of a collection of short stories might be encoded as follows:

```

<text>
  <front>
    <docTitle>
      <titlePart> The Adventures of Sherlock Holmes
    </titlePart>
    </docTitle>
    <docImprint>First published in <title>The Strand</title>
      between July 1891 and December 1892</docImprint>
    <!-- any other front matter specific to this collection -->
  </front>
  <group>
    <text>
      <front>
        <head rend="italic">Adventures of Sherlock
          Holmes</head>
        <docTitle>
          <titlePart>Adventure I. --</titlePart>
          <titlePart>A Scandal in Bohemia</titlePart>
        </docTitle>
        <byline>By A. Conan Doyle.</byline>
      </front>
      <body>
        <p>To Sherlock Holmes she is always
          <emph>the</emph> woman. ... </p>
        <!-- remainder of A Scandal in Bohemia here -->
      </body>
    </text>
    <text>
      <front>
        <head rend="italic">Adventures of Sherlock Holmes</head>
        <docTitle>
          <titlePart>Adventure II. --</titlePart>
          <titlePart>The Red-Headed League</titlePart>
        </docTitle>
        <byline>By A. Conan Doyle.</byline>
      </front>
      <body>
        <p>I had called upon my friend, Mr. Sherlock Holmes, one day
          in the autumn of last year and found him in deep conversation
          with a very stout, florid-faced, elderly gentleman with fiery red hair ...
        </p>
        <!-- remainder of The Red Headed League here -->
      </body>
    </text>
    <text>
      <front>
        <head rend="italic">Adventures of Sherlock Holmes</head>
        <docTitle>
          <titlePart>Adventure XII. --</titlePart>
          <titlePart>The Adventure of the Copper Beeches</titlePart>
        </docTitle>
        <byline>By A. Conan Doyle.</byline>
      </front>
      <body>
        <p>
          <q>To the man who loves art for its
            own sake,</q> remarked Sherlock Holmes ...
        </p>
      </body>
    </text>
  </group>
</text>

```

```

<!-- remainder of The Copper Beeches here -->
        ... she is now the head of a private school
        at Walsall, where I believe that she has
        met with considerable success.</p>
    </body>
</text>
<!-- end of The Copper Beeches -->
</group>
</text>
<!-- end of the Adventures of Sherlock Holmes -->

```

A text which is a member of a group may itself contain groups. This is quite common in collections of verse, but may happen in any kind of text. As an example, consider the overall structure of a typical collection, such as the *Muses Library* edition of Crashaw's poetry. Following a critical introduction and table of contents, this work contains the following major sections:

- *Steps to the Temple* (a collection of verse first published in 1648)
- *Carmen deo Nostro* (a second collection, published in 1652)
- *The Delights of the Muses* (a third collection, published in 1648)
- *Posthumous Poems, I* (a collection of fragments all taken from a single manuscript)
- *Posthumous Poems, II* (a further collection of fragments, taken from a different manuscript)

Each of the three collections published in Crashaw's lifetime has a reasonable claim to be considered as a text in its own right, and may therefore be encoded as such. It is rather more arbitrary as to whether the two posthumous collections should be treated as two groups, following the practice of the *Muses Library* edition. An encoder might elect to combine the two into a single group or simply to treat each fragment as an ungrouped unitary text.

The *Muses Library* edition reprints the whole of each of the three original collections, including their original front matter (title pages, dedications etc.). These should be encoded using the <front> element and its constituents (on which see further section 4.5. *Front Matter*), while the body of each collection should be encoded as a single <group> element. Each individual poem within the collections should be encoded as a distinct <text> element. The beginning of the whole collection would thus appear as follows (for further discussion of the use of the elements <div> and <lg> for textual subdivision of verse, see section 3.12.1. *Core Tags for Verse* and chapter 6. *Verse*):

```

<text>
  <front>
    <titlePage>
      <docTitle>
        <titlePart>The poems of Richard Crashaw</titlePart>
      </docTitle>
      <byline>Edited by J.R. Tutin</byline>
    </titlePage>
    <div type="preface">
      <head>Editor's Note</head>
      <p>A few words are necessary ... </p>
    </div>
  </front>

  </group>
</text>
</group>
<back>
<!-- back matter for the whole collection -->
</back>
</text>

```

The <group> element may be used in this way to encode any kind of collection of which the constituents are regarded by the encoder as texts in their own right. Examples include anthologies or collections of verse or prose by multiple authors, florilegia, or commonplace books, journals, day books, etc. As a fairly typical example, we consider *The Norton Book of Travel*, an anthology edited by Paul Fussell and published in 1987 by W. W. Norton. This work comprises the following major sections:

1. Front matter (title page, acknowledgments, introductory essay)
2. The Beginnings
3. The Eighteenth Century and the Grand Tour
4. The Heyday
5. Touristic Tendencies
6. Post Tourism
7. Back matter (permissions list, index)

Each titled section listed above comprises a group of extracts or complete texts from writers of a given historical period, preceded by an introductory essay. For example, the second group listed above contains, inter alia, the following:

1. Prefatory essay
2. Five letters by Lady Mary Wortley Montagu
3. An extract from Swift's *Gulliver's Travels*
4. Two poems by Alexander Pope
5. Two extracts from Boswell's Journal
6. A poem by William Blake

Each group of writings by a single author is preceded by a brief biographical notice. Some of the extracts are quite lengthy, containing several chapters or other divisions; others are quite short. As the above list indicates, the texts included range across all kinds of material: verse, prose, journals and letters.

The easiest way of encoding such an anthology is to treat each individual extract as a text in its own right. A sequence of texts by a single author, together with the biographical note preceding it, can then be treated as a single <group> element within the larger <group> formed by the section. The sequence of single or composite texts making up a single section of the work is likewise treated, together with its prefatory essay, as a single <group> within the work. Schematically:

```

<text>
<!-- the whole anthology -->
  <front>
<!-- title page, acknowledgments, introductory essay -->
  </front>
  <group>
<!-- body of anthology starts here -->
  <group>
    <head>The Beginnings</head>
<!-- sequence of texts or groups -->
  </group>
  <group>
<!-- The Eighteenth Century and the Grand Tour -->
    <text>
<!-- prefatory essay by editor -->
    </text>
    <group>
<!-- Section on Lady Mary Wortley Montagu starts -->
    <text>
<!-- biographical notice by editor -->
    </text>
    <text>
<!-- first letter -->
    </text>
    <text>
<!-- second letter -->
    </text>
    <!-- ... -->
    </group>
<!-- end of Montagu section -->
    <text>
<!-- single text by Jonathan Swift starts -->
    <front>
<!-- biographical notice by editor -->
    </front>
    <body/>
    </text>
<!-- end of Swift section -->
    <group>
<!-- Section on Alexander Pope starts -->
    <text>
<!-- biographical notice by editor -->
    </text>
    <text>
<!-- first poem -->
    </text>
    <text>
<!-- second poem -->
    </text>
    </group>
<!-- end of Pope section -->
    <!-- ... -->
  </group>
<!-- end of 18th century section -->
  <group>
    <head>The Heyday</head>
<!-- texts and subgroups -->

```

```

    </group>
  <!-- ... -->
  </group>
  <!-- end of the anthology proper -->
  <back>
  <!-- back matter for anthology -->
  </back>
</text>

```

Note that the editor's introductory essays on each author may be treated as texts in their own right (as the essays on Lady Mary Wortley Montagu and Alexander Pope have been treated above), or as front matter to the embedded text, as the essay on Swift has been. The treatment in the example is intentionally inconsistent, to allow comparison of the two approaches. Consistency can be imposed either by treating the Swift section as a <group> containing one text by Swift and one by the editor, or by treating the Montagu and Pope sections as <text> elements containing the editor's essays as front matter. Marked in the second way, the Pope section of the book would look like this:

```

<text>
  <!-- Section on Alexander Pope starts -->
  <front>
  <!-- biographical notice by editor -->
  </front>
  <group>
    <text>
  <!-- first poem -->
    </text>
    <text>
  <!-- second poem -->
    </text>
  </group>
</text>
<!-- end of Pope section-->

```

The essays on 'The Eighteenth Century and the Grand Tour' and other larger sections could also be tagged as 'front' matter in the same way, by treating the larger sections as <text> elements rather than <group> elements.

Where, as in this case, an anthology contains different kinds of text (for example, mixtures of prose and drama, or transcribed speech and dictionary entries, or letters and verse), the elements to be encoded will of course be drawn from more than one module. The elements provided by the core module described in chapter 3. *Elements Available in All TEI Documents* should however prove adequate for most simple purposes, where prose, drama, and verse are combined in a single collection.

For anthologies of short extracts such as commonplace books, it may often be preferable to regard each extract not as a text in its own right but simply as a quotation or <cit> element. The following component-level elements may be used to encode quotations of this kind:

**<cit>** (cited quotation) contains a quotation from some other document, together with a bibliographic reference to its source. In a dictionary it may contain an example text with at least one occurrence of the word form, used in the sense being described, or a translation of the headword, or an example.

**<quote>** (quotation) contains a phrase or passage attributed by the narrator or author to some agency external to the text.

For example, the chapter of 'extracts' which appears in the front matter of Melville's *Moby Dick* might be encoded as follows:

```

<div n="2" type="chap">
  <head>Extracts</head>

```

```

<head>(Supplied by a sub-sub-Librarian)</head>
<p>It will be seen that this mere painstaking burrower and
  grubworm of a poor devil of a Sub-Sub appears to have gone
  through the long Vaticans and street-stalls of the earth,
  picking up whatever random allusions to whales he could
  anyways find ...
  Here ye strike but splintered hearts together – there,
  ye shall strike unsplinterable glasses!</p>
<p>
  <cit>
    <quote>And God created great whales.</quote>
    <bibl>Genesis</bibl>
  </cit>
  <cit>
    <quote>
      <l>Leviathan maketh a path to shine after him;</l>
      <l>One would think the deep to be hoary.</l>
    </quote>
    <bibl>Job</bibl>
  </cit>
  <cit>
    <quote>By art is created that great Leviathan,
      called a Commonwealth or State – (in Latin,
    <mentioned xml:lang="la">civitas</mentioned>), which
      is but an artificial man.</quote>
    <bibl>Opening sentence of Hobbes's Leviathan</bibl>
  </cit>
</p>
</div>

```

For more information on the use of the `<quote>` and `<bibl>` elements, see sections 3.3.3. *Quotation* and 3.11. *Bibliographic Citations and References* respectively.

### 4.3.2 Floating Texts

An important characteristic of the unitary or composite text structures discussed so far is that they can be regarded as forming what is mathematically known as a *tesselation* covering the whole of the available text (or text division) at each hierarchic level. Just as an XML document has a single root element containing a single tree, each node of which forms a properly nested sub-tree, so it seems natural to think of the internal structure of a text as decomposable hierarchically into subparts, each of which is a properly nested subtree. While this is undoubtedly true of a large number of documents, it is not true of all. In particular, it is not true of texts which are only partly tessellated at a given level. For example, if a text A is contained by text B in such a way that part of B precedes A and part follows it, we cannot tessellate the whole of B. In such a case, we say that text A is a ‘floating’ text.

The `<floatingText>` element is a member of the `model.divPart` class, and can thus appear within any division level element in the same way as a paragraph. For example, texts such as the *Decameron* or the *Arabian Nights* might be regarded as containing many floating texts embedded within another single text, the framing narrative, rather than as groups of discrete texts in which the fragments of framing narrative are regarded as front or back matter.

As an example, we consider an 18th century text *The Lining to the Patch-Work Screen*, by Jane Barker (1726). This lengthy narrative contains nearly a hundred distinct ‘tales’ embedded (as the title suggests) in a single patchwork. The work begins by introducing the central character, Galecia, but within a few pages launches into a distinct narrative, the story of Captain Manly:

```

<p>Galecia one Evening setting alone in her Chamber by a clear Fire,
  and a clean Hearth [...] reflected on the Providence of our
  All-wise and Gracious Creator [...] </p>

```

```

<p>She was thus ruminating, when a Gentleman enter'd the Room, the
Door being a jar [...] calling for a Candle, she beg'd a thousand
Pardons, engaged him to sit down, and let her know, what had so long
conceal'd him from her Correspondence.
</p>
<pb n="5"/>
<floatingText>
  <body>
    <head>The Story of <hi>Captain Manly</hi>
    </head>
    <p>Dear Galecia, said he, though you partly know the loose, or rather
      lewd Life that I led in my Youth; yet I can't forbear relating part of
      it to you by way of Abhorrence...

<!-- Captain Manly's story here -->
      I had lost and spent all I had in the World; in which I verified the
      Old Proverb, That a Rolling Stone never gathers Moss,
    </p>
  </body>
</floatingText>
<pb n="37"/>

```

Following the conclusion of Captain Manly's tale, we are returned to Galecia, and almost immediately after that into two further stories. However, the Galecia narrative returns between each of the texts, which is why we choose to represent them as <floatingText>s:

```

<p>The Gentleman having finish'd his Story, Galecia waited on him to
the Stairs-head; and at her return, casting her Eyes on the Table, she
saw lying there an old dirty rumbled Book, and found in it the
following story: </p>
<floatingText>
  <body>
    <p>IN the time of the Holy War when
      Christians from all parts went into the Holy Land to oppose the Turks;
      Amongst these there was a certain English Knight...</p>
<!-- rest of story here -->
    <p>The King graciously pardoned the Knight; Richard was kindly receiv'd
      into his Convent, and all things went on in good order: But from hence
      came the Proverb, We must not strike <hi>Robert</hi> for
      <hi>Richard.</hi>
    </p>
  </body>
</floatingText>
<pb n="43"/>
<p>By this time Galecia's Maid brought up her Supper; after which she
cast her Eyes again on the foresaid little Book, where she found the
following Story, which she read through before she went to bed.
</p>
<floatingText>
  <body>
    <head>The Cause of the Moors Overrunning
    <hi>Spain</hi>
    </head>
    <p>King —— of Spain at his Death, committed the Government of his
      Kingdom to his Brother Don —— till his little Son should come of
      Age ...</p>

```

```

<p>Thus the little Story ended, without telling what Misery
  befel the King and Kingdom, by the Moors, who over ran the Country for
  many Years after. To which, we may well apply the Proverb,
  <quote>
    <l>Who drives the Devil's Stages,</l>
    <l>Deserves the Devil's Wages</l>
  </quote>
</p>
</body>
</floatingText>
<p>The reading this Trifle of a Story detained Galecia from her Rest
beyond her usual Hour; for she slept so sound the next Morning, that
she did not rise, till a Lady's Footman came to tell her, that his
Lady and another or two were coming to breakfast with her...
</p>

```

In other multi-narrative texts, the individual nested tales may have greater significance than the framing narratives, and it may therefore be preferable to treat the fragments of framing narrative as front or back matter associated with each nested tale. This is commonly done, for example, in texts such as Chaucer's *Canterbury Tales*, where each tale is typically presented with front matter in which the teller of the tale is introduced, and back matter in which the pilgrims comment on it.

It is important to distinguish between the uses of `<floatingText>` and `<quote>`. Whereas the semantics of `<quote>` suggest that its content derives from a source external to the current text, `<floatingText>` carries no such implication and is simply used whenever the richer content model that it provides is required to support the markup of a part of a text that is presented as a discrete 'inclusion.' In some cases, such inclusions could be considered external (e.g., enclosures, attachments, etc.); often however, as in the examples above, the included text bears no signs of emanating from outside.

`<floatingText>` and `<quote>` may be used in combination. For a text with rich internal structure that is quoted at length, `<floatingText>` might be used within `<quote>`. Also, like a unitary text, `<floatingText>` may include one or more quoted sections, each marked with a `<quote>` element.

## 4.4 Virtual Divisions

Where the whole of a division can be automatically generated, for example because it is derived from another part of this or another document, an encoder may prefer not to represent it explicitly but instead simply mark its location by means of a processing instruction, or by using the special purpose `<divGen>` element:

**<divGen>** (automatically generated text division) indicates the location at which a textual division generated automatically by a text-processing application is to appear.

This element is made available by the `model.divGenLike` class of which it is the sole element. The `<divGen>` element is a member of the `att.typed` class, from which it inherits the `type` and `subtype` attributes. It may appear wherever a `<div>` or `<div1>` (`<div2>`, etc.) element may appear.

For example, if the table of contents (toc) for a given work is simply derived by copying the first `<head>` element from each `<div>` element in a text, it might be more easily encoded as follows:

```
<divGen type="toc"/>
```

Similarly, in a digital edition combining a transcribed version of some text with a translated version of it, it may be desired to represent the transcript, the translation, and an aligned version of the two as three distinct divisions. This could be achieved by an encoding like the following:

```
<div>
<!-- transcript here-->
```

```

</div>
<div>
<!-- translation here -->
</div>
<divGen type="alignment"/>

```

The processing to be carried out when a <divGen> element is rendered will be determined by the application program or stylesheet in use: the function of the TEI markup is simply to identify the location at which the virtual division is to be generated, and also to provide some information about the kind of division to be generated. As such it may be regarded as a special kind of processing instruction, and could equally well be represented by one.

## 4.5 Front Matter

By *front matter* we mean distinct sections of a text (usually, but not necessarily, a printed one), prefixed to it by way of introduction or identification as a part of its production. Features such as title pages or prefaces are clear examples; a less definite case might be the prologue attached to a play. The front matter of an encoded text should not be confused with the TEI header described in chapter 2. *The TEI Header*, which serves as a kind of front matter for the computer file itself, not the text it encodes.

An encoder may choose simply to ignore the front matter in a text, if the original presentation of the work is of no interest, or for other reasons; alternatively some or all components of the front matter may be thought worth including with the text as components of the <front> element.<sup>56</sup> With the exception of the title page, (on which see section 4.6. *Title Pages*), front matter should be encoded using the same elements as the rest of a text. As with the divisions of the text body, no other specific tags are proposed here for the various kinds of subdivision which may appear within front matter: instead either numbered or un-numbered <div> elements may be used. The following suggested values<sup>57</sup> for the *type* attribute may be used to distinguish various kinds of division characteristic of front matter:

**preface** A foreword or preface addressed to the reader in which the author or publisher explains the content, purpose, or origin of the text.

**ack** A formal declaration of acknowledgment by the author in which persons and institutions are thanked for their part in the creation of a text.

**dedication** A formal offering or dedication of a text to one or more persons or institutions by the author.

**abstract** A summary of the content of a text as continuous prose.

**contents** A table of contents, specifying the structure of a work and listing its constituents. The <list> element should be used to mark its structure.

**frontispiece** A pictorial frontispiece, possibly including some text.

The following extended example demonstrates how various parts of the front matter of a text may be encoded. The front part begins with a title page, which is presented in section 4.6. *Title Pages* below. This is followed by a dedication and a preface, each of which is encoded as a distinct <div>:

```

<div type="dedication">
  <p>To my parents, Ida and Max Fish</p>
</div>
<div type="preface">
  <head>Preface</head>
  <p>The answer this book gives to its title question is <q>there is
    and there isn't</q>.</p>
  <p>Chapters 1–12 have been previously published in the

```

<sup>56</sup>This decision should be recorded in the <samplingDecl> element of the header.

<sup>57</sup>As with all lists of 'suggested values' for attributes, it is recommended that software written to handle TEI-conformant texts be prepared to recognize and handle these values when they occur, without limiting the user to the values in this list.

```

    following journals and collections:
<list>
  <item>chapters 1 and 3 in <title>New literary History</title>
  </item>
  <item>chapter 10 in <title>Boundary II</title> (1980)</item>
</list>.
  I am grateful for permission to reprint.</p>
<signed>S.F.</signed>
</div>

```

The front matter concludes with another <div> element, shown in the next example, this time containing a table of contents, which contains a <list> element (as described in section 3.7. *Lists*). Note the use of the <ptr> element to provide page-references: the implication here is that the target identifiers supplied (fish1, fish2, etc.) will correspond with identifiers used for the <div> elements containing chapters of the text itself. (For the <ptr> element, see 3.6. *Simple Links and Cross-References*.)

```

<div type="contents">
  <head>Contents</head>
  <list>
    <item>Introduction, or How I stopped Worrying and Learned to Love
      Interpretation <ptr target="#fish1"/>
    </item>
    <item>
      <list>
        <head>Part One: Literature in the Reader</head>
        <item n="1">Literature in the Reader: Affective Stylistics
          <ptr target="#fish2"/>
        </item>
        <item n="2">What is Stylistics and Why Are They Saying Such
          Terrible Things About It? <ptr target="#fish3"/>
        </item>
      </list>
    </item>
  </list>
</div>
<div xml:id="fish1">
  <head>Introduction</head>
  <!-- ... -->
</div>
<div xml:id="fish2">
  <head>Literature in the Reader</head>
  <!-- ... -->
</div>
<div xml:id="fish3">
  <head>What is stylistics?</head>
  <!-- ... -->
</div>

```

Alternatively, the pointers in the index might link to the page breaks at which a chapter begins, assuming that these have been included in the markup:

```

<!-- ... --><item n="1">Literature in the Reader: Affective Stylistics
<ref target="#fish-p24">24</ref>
</item>

```

```

<!-- ... -->
<div type="chapter">
  <head>Literature in the Reader</head>
  <pb xml:id="fish-p24"/>
<!-- ... -->
</div>
<!-- ... -->

```

The following example uses numbered divisions to mark up the front matter of a medieval text. Note that in this case no title page in the modern sense occurs; the title is simply given as a heading at the start of the front matter. Note also the use of the *type* attribute on the <div> elements to indicate document elements comparatively unusual in modern books such as the initial prayer:

```

<front>
  <div1 type="incipit">
    <p>Here bygynnip a book of contemplacyon, þe whiche
      is clepyd <title>þE CLOWDE OF VNKNOWYNG</title>,
      in þe whiche a soule is onyd wip GOD.</p>
  </div1>
  <div1 type="prayer">
    <head>Here biginneþ þe preyer on þe prologe.</head>
    <p>God, unto whom alle hertes ben open, & unto whome alle wille
      spekib, & unto whom no priue þing is hid: I beseche
      þee so for to clense þe entent of myn hert wip þe
      unspekable 3ift of þi grace, þat I may parfiteliche
      loue þee & worpilich preise þee. Amen.</p>
  </div1>
  <div1 type="preface">
    <head>Here biginneþ þe prolog.</head>
    <p>In þe name of þe Fader & of þe Sone &
      of þe Holy Goost.</p>
    <p>I charge þee & I beseche þee, wip as moche
      power & vertewe as þe bonde of charite is sufficient
      to suffre, what-so-euer þou be þat þis book schalt
      haue in possession ...</p>
  </div1>
  <div1 type="contents">
    <head>Here biginneþ a table of þe chapitres.</head>
    <list>
      <label>þe first chapitre </label>
      <item>Of foure degrees of Cristen mens leuing; & of þe
        cours of his cleping þat þis book was maad vnto.</item>
      <label>þe secound chapitre</label>
      <item>A schort stering to meeknes & to þe werk of þis
        book</item>
      <label>þe fiue and seuenti chapitre</label>
      <item>Of somme certein tokenes bi þe whiche a man may proue
        wheper he be clepid of God to worche in þis werk.</item>
    </list>
    <trailer>& here eendeþ þe table of þe chapitres.</trailer>
  </div1>
</front>

```

If, however, the table of contents can be automatically generated from the remainder of the text, it may be preferable simply to mark its presence, either by means of an empty <divGen> element or by using an appropriate processing instruction.

## 4.6 Title Pages

Detailed analysis of the title page and other *preliminaries* of older printed books and manuscripts is of major importance in descriptive bibliography and the cataloguing of printed books; such analysis may require a rather more detailed module than that proposed here. The following elements are suggested as a means of encoding the major features of most title pages:

- <titlePage>** (title page) contains the title page of a text, appearing within the front or back matter.
- <docTitle>** (document title) contains the title of a document, including all its constituents, as given on a title page.
- <titlePart>** contains a subsection or division of the title of a work, as indicated on a title page.  
@*type* specifies the role of this subdivision of the title.
- <argument>** contains a formal list or prose description of the topics addressed by a subdivision of a text.
- <byline>** contains the primary statement of responsibility given for a work on its title page or at the head or end of the work.
- <docAuthor>** (document author) contains the name of the author of the document, as given on the title page (often but not always contained in a byline).
- <epigraph>** contains a quotation, anonymous or attributed, appearing at the start or end of a section or on a title page.
- <imprimatur>** contains a formal statement authorizing the publication of a work, sometimes required to appear on a title page or its verso.
- <docEdition>** (document edition) contains an edition statement as presented on a title page of a document.
- <docImprint>** (document imprint) contains the imprint statement (place and date of publication, publisher name), as given (usually) at the foot of a title page.
- <docDate>** (document date) contains the date of a document, as given on a title page or in a dateline.
- <graphic>** indicates the location of a graphic or illustration, either forming part of a text, or providing an image of it.

Together with the <figure> element described in chapter 14. *Tables, Formulæ, Graphics and Notated Music*, these elements constitute the `model.titlepagePart` class. Any number of elements from this class can appear grouped together within a <titlePage> element. The <figure> element is included so as to enable encoders to record the presence of complex non-textual material on a title page. For simple cases such as printers' ornaments or illustrations the <graphic> element discussed in section 3.9. *Graphics and Other Non-textual Components* should be adequate.

The elements listed above, together with the <head> element, also constitute the class `model.pLike.front`. The elements in this class can appear within a minimal <front> element without any need to group them together and encode a complete title page.

Encoders wishing to add new elements to either class may do so using the methods described in section 23.3. *Personalization and Customization*. Two examples of the use of these elements follow. First, the title page of the work discussed earlier in this section:

```
<front>
  <titlePage>
    <docTitle>
      <titlePart type="main">Is There a Text in This Class?</titlePart>
      <titlePart type="sub">The Authority of Interpretive Communities</titlePart>
    </docTitle>
    <docAuthor>Stanley Fish</docAuthor>
    <docImprint>
      <publisher>Harvard University Press</publisher>
      <pubPlace>Cambridge, Massachusetts</pubPlace>
      <pubPlace>London, England</pubPlace>
    </docImprint>
  </titlePage>
</front>
```

Second, a characteristically verbose 17th century example. Note the use of the <lb> tag to mark the line breaks of the original where necessary:

```
<titlePage>
  <docTitle>
    <titlePart type="main">THE
    <lb/>Pilgrim's Progress
    <lb/>FROM
    <lb/>THIS WORLD,
    <lb/>TO
    <lb/>That which is to come:</titlePart>
    <titlePart type="sub">Delivered under the Similitude of a
    <lb/>DREAM</titlePart>
    <titlePart type="desc">Wherein is Discovered,
    <lb/>The manner of his setting out,
    <lb/>His Dangerous Journey; And safe
    <lb/>Arrival at the Desired Countrey.</titlePart>
  </docTitle>
  <epigraph>
    <cit>
      <quote>I have used Similitudes,</quote>
      <bibl>Hos. 12.10</bibl>
    </cit>
  </epigraph>
  <byline>By <docAuthor>John Bunyan</docAuthor>.</byline>
  <imprimatur>Licensed and Entred according to Order.</imprimatur>
  <docImprint>
    <pubPlace>LONDON,</pubPlace>
    Printed for <name>Nath. Ponder</name>
    <lb/>at the <name>Peacock</name> in the <name>Poultry</name>
    <lb/>near <name>Cornhil</name>, <docDate>1678</docDate>.
  </docImprint>
</titlePage>
```

Where, as here, it is considered important to encode salient features of the way a title page was originally rendered, the techniques exemplified in 2.3.4. *The Tagging Declaration* may also be useful.

Where title pages are encoded, their physical rendition is often of considerable importance. One approach to this requirement would be to use the <seg> tag, described in chapter 16. *Linking, Segmentation, and Alignment*, to segment the typographic content of each part of the title page, and then use the global *rend* attribute to specify its rendition. Another would be to use a module specialized for the description of typographic entities such as pages, lines, rules, etc., bearing special-purpose attributes to describe line-height, leading, degree of kerning, font, etc. Further discussion of these problems is provided in chapter 11. *Representation of Primary Sources*.

## 4.7 Back Matter

Conventions vary as to which elements are grouped as back matter and which as front. For example, some books place the table of contents at the front, and others at the back. Even title pages may appear at the back of a book as well as at the front. The content model for <back> and <front> elements are therefore identical.

The following suggested values may be used for the *type* attribute on all division elements, in order to distinguish various kinds of division characteristic of back matter:

**appendix** An ancillary self-contained section of a work, often providing additional but in some sense extra-canonical text.

**glossary** A list of terms associated with definition texts ('glosses'): this should be encoded as a <list type="gloss"> (see section 3.7. *Lists*).

**notes** A section in which textual or other kinds of notes are gathered together.

**bibliogr** A list of bibliographic citations: this should be encoded as a <listBibl> (see section 3.11. *Bibliographic Citations and References*).

**index** Any form of index to the work.

**colophon** A statement appearing at the end of a book describing the conditions of its physical production.

No additional elements are proposed for the encoding of back matter at present. Some characteristic examples follow; first, an index (for the case in which a printed index is of sufficient interest to merit transcription):

```
<back>
  <div type="index">
    <head>Index</head>
    <list type="index">
      <item>Actors, public, paid for the contempt attending
        their profession, <ref>263</ref>
      </item>
      <item>Africa, cause assigned for the barbarous state of
        the interior parts of that continent, <ref>125</ref>
      </item>
      <item>Agriculture
      <list type="indexentry">
        <item>ancient policy of Europe unfavourable to, <ref>371</ref>
        </item>
        <item>artificers necessary to carry it on, <ref>481</ref>
        </item>
        <item>cattle and tillage mutually improve each other, <ref>325</ref>
        </item>
        <item>wealth arising from more solid than that which proceeds
          from commerce <ref>520</ref>
        </item>
      </list>
      </item>
      <item>Alehouses, not the efficient cause of drunkenness, <ref>461</ref>
      </item>
    </list>
  </div>
</back>
```

Note that if the page breaks in the original source have also been explicitly encoded, and given identifiers, the references to them in the above index can more usefully be recorded as links. For example, assuming that the encoding of page 461 of the original source starts like this:

```
<pb xml:id="P461"/>
```

then the last item above might be encoded more usefully in either of the following forms:

```
<item>Alehouses, not
the efficient cause of drunkenness, <ref target="#P461">461</ref>
</item>
<item>Alehouses, not the efficient cause of drunkenness, <ptr target="#P461"/>
</item>
```

Next, a back-matter division in epistolary form:

```

<back>
  <div type="letter">
    <head>A letter written to his wife, founde with this booke
      after his death.</head>
    <p>The remembrance of the many wrongs offred thee, and thy
      unreproued vertues, adde greater sorrow to my miserable state,
      than I can utter or thou conceiue. ...
      ... yet trust I in the world to come to find mercie, by the
      merites of my Saiuour to whom I commend thee, and commit
      my soule.</p>
    <signed>Thy repentant husband for his disloyaltie,
    <name>Robert Greene.</name>
    </signed>

## 4.8 Module for Default Text Structure

The module described by the present chapter has the following components:

Module textstructure: Default text structure

- *Elements defined:* TEI argument back body byline closer dateline div div1 div2 div3 div4 div5 div6 div7 docAuthor docDate docEdition docImprint docTitle epigraph floatingText front group imprimatur opener postscript salute signed text titlePage titlePart trailer

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*

## 5 Characters, Glyphs, and Writing Modes

Chapter *vi Languages and Character Sets* introduced the fundamental notions of language identification and character representation in an encoded TEI document. In this chapter we discuss some additional issues relating to the way that written language is represented in a TEI document. In sections 5.1. *Is Your Journey Really Necessary?* and 5.2. *Markup Constructs for Representation of Characters and Glyphs* we introduce markup which may be used to represent and document non-standard characters, that is, written symbols for which no codepoint exists in Unicode. The same markup may be used to annotate existing characters according to their visual or other properties, and thus process them as distinct glyphs (see section 5.3. *Annotating Characters*), or to define new characters or glyphs (section 5.4. *Adding New Characters*). We also provide recommendations concerning the Unicode Private Use Area (5.5. *How to Use Code Points from the Private Use Area*). Finally, in section 5.6. *Writing Modes* we discuss ways of documenting the writing mode used in a source text, that is, the directionality of the script, the orientation of individual characters, and related questions.

### 5.1 Is Your Journey Really Necessary?

Despite the availability of Unicode, text encoders still sometimes find that the published repertoire of available characters is inadequate to their needs. This is particularly the case when dealing with ancient languages, for which encoding standards do not yet exist, or where an encoder wishes to represent variant forms of a character or *glyphs*. The module defined by this chapter provides a mechanism to satisfy that need, while retaining compatibility with standards.

When encoders encounter some graphical unit in a document which is to be represented electronically, the first issue to be resolved should be ‘Is this really a different character?’ To determine whether a particular graphical unit is a character or not, see *vi.2.2 Terminology and Key Concepts*.

If the unit is indeed determined to be a character, the next question should be ‘Has this character been encoded already?’ In order to determine whether a character has been encoded, encoders should follow the following steps:

1. Check the Unicode web site at <http://www.unicode.org>, in particular the page “Where is my Character?”, and the associated character code charts. Alternatively, users can check the latest published version of *The Unicode Standard* (Unicode Consortium (2006)), though the web site is often more up to date than the printed version, and should be checked for preference.

The pictures (‘glyphs’) in the Unicode code charts are only meant to be representative, not definitive. If a specific form of an already encoded character is required for a project, refer to the guidelines contained below under *Annotating Characters*. Remember that your encoded document may be rendered on a system which has different fonts from yours: if the specific form of a character is important to you, then you should document it.

2. Check the Proposed New Characters web page (<http://unicode.org/alloc/Pipeline.html>) to see whether the character is in line for approval.
3. Ask on the Unicode email list (<http://www.unicode.org/consortium/distlist.html>) to see whether a proposal is pending, or to determine whether this character is considered eligible for addition to the Unicode Standard.

Since there are now close to 100,000 characters in Unicode, chances are good that what you need is already there, but it might not be easy to find, since it might have a different name in Unicode. Look again, this time at other sites, for example <http://www.eki.ee/letter/>, which also provide searches based on scripts and languages. Take care, however, that all the properties of what seems to be a relevant character are consistent with those of the character you are looking for. For example, if your character is definitely a digit, but the properties of the best match you can find for it say that it is a letter, you may have a character not yet defined in Unicode.

In general, it is advisable to avoid Unicode characters generally described as presentation forms.<sup>58</sup> However, if the character you are looking for is being used in a notation (rather than as part of the orthography of a language) then it is quite acceptable to select characters from the Mathematical Operators block, provided that they have the appropriate properties (i.e. **So**: Symbol, Other; or **Sm**: Symbol, Math).

An encoded character may be precomposed or it may be formed from base characters and combining diacritical marks. Either will suffice for a character to be “found” as an encoded character.

<sup>58</sup>Specifically, characters in the Unicode blocks Alphabetic Presentation Forms, Arabic Presentation Forms-A, Arabic Presentation Forms-B, Letterlike Symbols, and Number Forms.

If there are several possible Unicode characters to choose amongst, it is good practice to consult other colleagues and practitioners to see whether a consensus has emerged in favour of one or other of them.

If, however, no suitable form of your character seems to exist, the next question will be: ‘Does the graphical unit in question represent a variant form of a known character, or does it represent a completely unencoded character?’ If the character is determined to be missing from the Unicode Standard, it would be helpful to submit the new character for inclusion (see <http://unicode.org/pending/proposals.html>).

These guidelines will help you proceed once you have identified a given graphical unit as either a variant or an unencoded character. Determining this will require knowledge of the contents of the document that you have. The first case will be called *annotation* of a character, while the second case will be called *adding* of a new character. How to handle graphical units that represent variants will be discussed below (5.3. *Annotating Characters*) while the problem of representing new characters will be dealt with in section 5.4. *Adding New Characters*.

While there is some overlap between these requirements, distinct specialized markup constructs have been created for each of these cases. These constructs are presented in section 5.2. *Markup Constructs for Representation of Characters and Glyphs* below.

## 5.2 Markup Constructs for Representation of Characters and Glyphs

An XML document can, in principle, contain any defined Unicode character. The standard allows these characters to be represented either directly, using an appropriate encoding (UTF-8 by default), or indirectly by means of a *numeric character reference* (NCR), such as `&#196;` (A-umlaut). The encoder can also restrict the range of characters which are represented directly in a document (or part of it) by adding a suitable encoding declaration. For example, if a document begins with the declaration `<?xml encoding="iso-8859-1" ?>` any Unicode characters which are not in the ISO-8859-1 character set must be represented by NCRs.

The *gaiji* module defined by this chapter adds a further way of representing specific characters and glyphs in a document. (*Gaiji* is from Japanese 外字, meaning *external characters*.) This allows the encoder to distinguish characters and glyphs which Unicode regards as identical, to add new nonstandard characters or glyphs, and to represent Unicode characters not available in the document encoding by an alternative means.

The mechanism provided here consists functionally of two parts:

1. an element `<g>`, which serves as a proxy for new characters or glyphs
2. elements `<char>` and `<glyph>`, providing information about such characters or glyphs; these elements are stored in the `<charDecl>` element in the header.

When the *gaiji* module is included in a schema, the `<charDecl>` element is added to the `model.encodingDescPart` class, and the `<g>` element is added to the phrase class. These elements and their components are documented in the rest of this section.

The Unicode standard defines properties for all the characters it defines in the Unicode Character Database, knowledge of which is usually built into text processing systems. If the character represented by the `<g>` element does not exist in Unicode at all, its properties are not available. If the character represented is an existing Unicode character, but is not available in the document character set recognized by a given text processing system, it may also be convenient to have access to its properties in the same way. The `<char>` element makes it possible to store properties for use by such applications in a standard way.

The list of attributes (properties) for characters is modelled on those in the Unicode Character Database, which distinguishes *normative* and *informative* character properties. Additional, non-Unicode, properties may also be supplied. Since the list of properties will vary with different versions of the Unicode Standard, there may not be an exact correspondence between them and the list of properties defined in these Guidelines.

Usage examples for these elements are given below at 5.3. *Annotating Characters* and 5.4. *Adding New Characters*.

The *gaiji* module itself is formally defined in section 5.10. *Formal Definition* below. It declares the following additional elements:

**<charDecl>** (character declarations) provides information about nonstandard characters and glyphs.

**<g>** (character or glyph) represents a glyph, or a non-standard character.

*@ref* points to a description of the character or glyph intended.

The `<charDecl>` element is a member of the class `model.encodingDescPart`, and thus becomes available within `<encodingDesc>` when this module is included in a schema. The `<g>` element is the only member of the

class `model.gLike`: this class is referenced as an alternative to plain text in almost every element which contains plain text, thus permitting the `<g>` element also to appear at such places when this module is included in a schema.

The following elements may appear within a `<charDecl>` element:

**<desc>** (description) contains a brief description of the object documented by its parent element, including its intended usage, purpose, or application where this is appropriate.

**<char>** (character) provides descriptive information about a character.

**<glyph>** (character glyph) provides descriptive information about a character glyph.

The `<char>` and `<glyph>` elements have similar contents and are used in similar ways, but their functions are different. The `<char>` element is provided to define a character which is not available in the current document character set, for whatever reason, as stated above. The `<glyph>` element is used to annotate a character that has already been defined somewhere (either in the document character set, or through a `<char>` element) by providing a specific glyph that shows how a character appeared in the original document. This is necessary since Unicode code points refer not to a single, specific glyph shape of a character, but rather to a set of glyphs, any of which may be used to render the code point in question; in some cases they can differ considerably.

The `<glyph>` element is provided for cases where the encoder wants to specify a specific glyph (or family of glyphs) out of all possible glyphs. Unfortunately, due to the way Unicode has been defined, there are cases where several glyphs that logically belong together have been given separate code points, especially in the blocks defining East Asian characters. In such cases, `<glyph>` elements can also be used to express the view that these apparently distinct characters are to be regarded as instances of the same character (see further 5.3. *Annotating Characters*).

The Unicode Standard recommends naming conventions which should be followed strictly where the intention is to annotate an existing Unicode character, and which may also be used as a model when creating new names for characters or glyphs<sup>59</sup>. For convenience of processing, the following distinct elements are proposed for naming characters and glyphs:

**<charName>** (character name) contains the name of a character, expressed following Unicode conventions.

**<glyphName>** (character glyph name) contains the name of a glyph, expressed following Unicode conventions for character names.

Within both `<char>` and `<glyph>`, the following elements are available:

**<gloss>** identifies a phrase or word used to provide a gloss or definition for some other word or phrase.

**<charProp>** (character property) provides a name and value for some property of the parent character or glyph.

**<desc>** (description) contains a brief description of the object documented by its parent element, including its intended usage, purpose, or application where this is appropriate.

**<mapping>** (character mapping) contains one or more characters which are related to the parent character or glyph in some respect, as specified by the *type* attribute.

**<figure>** groups elements representing or containing graphic information such as an illustration, formula, or figure.

**<note>** contains a note or annotation.

Four of these elements (`<gloss>`, `<desc>`, `<figure>`, and `<note>`) are defined by other TEI modules, and their usage here is no different from their usage elsewhere. The `<figure>` element, however, is used here only to link to an image of the character or glyph under discussion, or to contain a representation of it in SVG. The `<figure>` element may contain more than one `<graphic>` element, for example to provide images with different resolution, or in different formats, or may itself be repeated. As elsewhere, the *contentType* attribute of `<graphic>` should be used to specify the format of the image.

The `<mapping>` element is similar to the standard TEI `<equiv>` element. While the latter is used to express correspondence relationships between TEI concepts or elements and those in other systems or ontologies, the former is used to express any kind of relationship between the character or glyph under discussion and characters or glyphs defined elsewhere. It may contain any Unicode character, or a `<g>` element linked to some other `<char>` or `<glyph>` element, if, for example, the intention is to express an association between two non-standard characters. The type

<sup>59</sup>It should be noted, however, that this naming convention cannot meaningfully be applied to East Asian characters; the typical Unicode descriptions for these characters take the form 'CJK Unified Ideograph U+4E00', where U+4E00 is simply the Unicode code point value of the character in question. In cases where no Unicode code point exists, there is little hope of finding a name that helps to identify the character. Names should therefore be constructed in a way meaningful to local practice, for example by using a reference number from a well-known character dictionary or a project-specific serial number.

of association is indicated by the *type* attribute, which may take such values as **exact** for exact equivalences, **uppercase** for uppercase equivalences, **lowercase** for lowercase equivalences, **standard** for standardized forms, and **simplified** for simplified characters, etc., as in the following example:

```
<charDecl>
  <char xml:id="aenl">
    <charName>LATIN LETTER ENLARGED SMALL A</charName>
    <charProp>
      <localName>entity</localName>
      <value>aenl</value>
    </charProp>
    <mapping type="standard">a</mapping>
  </char>
</charDecl>
```

The mapping element may also be used to represent a mapping of the character or (more likely) glyph under discussion onto a character from the private use area as in this example:

```
<charDecl>
  <glyph xml:id="z103">
    <glyphName>LATIN LETTER Z WITH TWO STROKES</glyphName>
    <mapping type="standard">Z</mapping>
    <mapping type="PUA">U+E304</mapping>
  </glyph>
</charDecl>
```

A more precise documentation of the properties of any character or glyph may be supplied using the generic `<charProp>` element described in the next section. Despite its name, this element may be used for either characters or glyphs.

### 5.2.1 Character Properties

The Unicode Standard documents ‘ideal’ characters, defined by reference to a number of *properties* (or attribute-value pairs) which they are said to possess. For example, a lowercase letter is said to have the value **Lu** for the property **general-category**. The Standard distinguishes between *normative* properties (i.e. properties which form part of the definition of a given character), and *informative* or *additional* properties which are not normative. It also allows for the addition of new properties, and (in some circumstances) alteration of the values currently assigned to certain properties. When making such modifications, great care should be taken not to override standard informative properties for characters which already exist in the Unicode Standard, as documented in Freytag (2006).

The `<charProp>` element allows an encoder to supply information about a character or glyph. Where the information concerned relates to a property which has already been identified in the Unicode Standard, encoders are urged to use the appropriate Unicode property name.

The following elements are used to record character properties:

**<unicodeName>** (unicode property name) contains the name of a registered Unicode normative or informative property.

**<localName>** (locally-defined property name) contains a locally defined name for some property.

**<value>** contains a single value for some property, attribute, or other analysis.

For each property, the encoder must supply either a `<unicodeName>` or a `<localName>`, followed by a `<value>`.

For convenience, we list here some of the normative character properties and their values. For full information, refer to chapter 4 of *The Unicode Standard*, or the online documentation of the Unicode Character Database.

**general-category** The general category (described in the Unicode Standard chapter 4 section 5) is an assignment to some major classes and subclasses of characters. Suggested values for this property are listed here:

|    |                   |
|----|-------------------|
| Lu | Letter, uppercase |
|----|-------------------|

|    |                            |
|----|----------------------------|
| Ll | Letter, lowercase          |
| Lt | Letter, titlecase          |
| Lm | Letter, modifier           |
| Lo | Letter, other              |
| Mn | Mark, nonspacing           |
| Mc | Mark, spacing combining    |
| Me | Mark, enclosing            |
| Nd | Number, decimal digit      |
| Nl | Number, letter             |
| No | Number, other              |
| Pc | Punctuation, connector     |
| Pd | Punctuation, dash          |
| Ps | Punctuation, open          |
| Pe | Punctuation, close         |
| Pi | Punctuation, initial quote |
| Pf | Punctuation, final quote   |
| Po | Punctuation, other         |
| Sm | Symbol, math               |
| Sc | Symbol, currency           |
| Sk | Symbol, modifier           |
| So | Symbol, other              |
| Zs | Separator, space           |
| Zl | Separator, line            |
| Zp | Separator, paragraph       |
| Cc | Other, control             |
| Cf | Other, format              |
| Cs | Other, surrogate           |
| Co | Other, private use         |
| Cn | Other, not assigned        |

**directional-category** This property applies to all Unicode characters. It governs the application of the algorithm for bi-directional behaviour, as further specified in Unicode Annex 9, *The Bidirectional Algorithm*. The following 19 different values are currently defined for this property in Davis et al (2006):

|     |                            |
|-----|----------------------------|
| L   | left to right              |
| LRE | left to right embedding    |
| LRO | left to right override     |
| R   | right to left              |
| AL  | right to left Arabic       |
| RLE | right to left embedding    |
| RLO | right to left override     |
| PDF | Pop Directional Format     |
| EN  | European Number            |
| ES  | European Number Separator  |
| ET  | European Number Terminator |
| AN  | Arabic Number              |
| CS  | Common Number Separator    |
| NSM | Non-spacing Mark           |
| BN  | Boundary Neutral           |
| B   | Paragraph separator        |
| S   | Segment separator          |
| WS  | Whitespace                 |
| ON  | Other neutrals             |

**canonical-combining-class** This property exists for characters that are not used independently, but in combination with other characters, for example the strokes making up CJK (Chinese, Japanese, and Korean) characters. It records a class for these characters, which is used to determine how they interact typographically. The following values are defined in the Unicode Standard: (see Unicode Character Database: Canonical Combining Class Values); these were taken from version 5.0:

|     |   |
|-----|---|
| 0   | Spacing, split, enclosing, reordrant, and Tibetan subjoined |
| 1   | Overlays and interior                                       |
| 7   | Nuktas  |
| 8   | Hiragana/Katakana voicing marks                             |
| 9   | Viramas   |
| 10  | Start of fixed position classes                             |
| 199 | End of fixed position classes                               |
| 200 | Below left attached   |
| 202 | Below attached  |
| 204 | Below right attached  |
| 208 | Left attached (reordrant around single base character)      |
| 210 | Right attached  |
| 212 | Above left attached   |
| 214 | Above attached  |
| 216 | Above right attached  |
| 218 | Below left  |
| 220 | Below   |
| 222 | Below right   |
| 224 | Left (reordrant around single base character)               |
| 226 | Right   |
| 228 | Above left  |
| 230 | Above   |
| 232 | Above right   |
| 233 | Double below  |
| 234 | Double above  |
| 240 | Below (iota subscript)                                      |

**character-decomposition-mapping** This property is defined for characters, which may be decomposed, for example to a canonical form plus a typographic variation of some kind. For such characters the Unicode standard specifies both a decomposition type and a decomposition mapping (i.e. another Unicode character to which this one may be mapped in the way specified by the decomposition type). The following types of mapping are defined in the Unicode Standard:

|          |   |
|----------|---|
| font     | A font variant (e.g. a blackletter form)      |
| noBreak  | A no-break version of a space or hyphen       |
| initial  | An initial presentation form (Arabic)         |
| medial   | A medial presentation form (Arabic)           |
| final    | A final presentation form (Arabic)            |
| isolated | An isolated presentation form (Arabic)        |
| circle   | An encircled form                             |
| super    | A superscript form                            |
| sub      | A subscript form                              |
| vertical | A vertical layout presentation form           |
| wide     | A wide (or zenkaku) compatibility character   |
| narrow   | A narrow (or hankaku) compatibility character |
| small    | A small variant form (CNS compatibility)      |
| square   | A CJK squared font variant                    |
| fraction | A vulgar fraction form                        |

compat

Otherwise-unspecified compatibility character

**numeric-value** This property applies for any character which expresses any kind of numeric value. Its value is the intended value in decimal notation.

**mirrored** The mirrored character property is used to properly render characters such as U+0028, **OPENING PARENTHESIS** independent of the text direction: it has the value **Y** (character is mirrored) or **N** (code is not mirrored).

The Unicode Standard also defines a set of informative (but non-normative) properties for Unicode characters. If encoders want to provide such properties, they may be included using the suggested Unicode name, tagged using the `<unicodeName>` element. However, encoders may also supply other locally-defined properties, which must be named using the `<localName>` element to distinguish them. If a Unicode name exists for a given property, it should however always be preferred to a locally defined name. Locally defined names should be used only for properties which are not specified by the Unicode Standard.

## 5.3 Annotating Characters

Annotation of a character becomes necessary when it is desired to distinguish it on the basis of certain aspects (typically, its graphical appearance) only. In a manuscript, for example, where distinctly different forms of the letter "r" can be recognized, it might be useful to distinguish them for analytic purposes, quite distinct from the need to provide an accurate representation of the page. A digital facsimile, particularly one linked to a transcribed and encoded version of the text, will always provide a superior visual representation (for information on how to link a digital facsimile to a transcribed text see *11.1. Digital Facsimiles*), but cannot be used to support arguments based on the distribution of such different forms. Character annotation as described here provides a solution to this problem.<sup>60</sup>

Assuming that we wish to distinguish the variant glyphs from the standard representation for the character concerned, we will need to define distinct `<glyph>` elements, one for each of the forms of the letter we wish to distinguish:

```
<charDecl>
  <glyph xml:id="r1">
    <glyphName>LATIN SMALL LETTER R WITH ONE FUNNY STROKE</glyphName>
    <charProp>
      <localName>entity</localName>
      <value>r1</value>
    </charProp>
    <figure>
      <graphic url="r1img.png"/>
    </figure>
  </glyph>
  <glyph xml:id="r2">
    <glyphName>LATIN SMALL LETTER R WITH TWO FUNNY STROKES</glyphName>
    <charProp>
      <localName>entity</localName>
      <value>r2</value>
    </charProp>
    <figure>
      <graphic url="r2img.png"/>
    </figure>
  </glyph>
</charDecl>
```

With these definitions in place, occurrences of these two special "r"s in the text can be annotated using the element `<g>`:

<sup>60</sup>It should be kept in mind that any kind of text encoding is an abstraction and an interpretation of the text at hand, which will not necessarily be useful in reproducing an exact facsimile of the appearance of a manuscript.

```
<p>Wo<g ref="#r1">r</g>ds in this
manusc<g ref="#r2">r</g>ipt are sometimes
written in a funny way.</p>
```

As can be seen in this example, the <glyph> element pointed to from the <g> element will be interpreted as an annotation on the content of the element <g>. This mechanism can be used to represent common manuscript abbreviations or ligatures, as in the following examples:

```
<p> ... <g ref="#Filig">Fi</g>lthy riches...</p>
<!-- in the charDecl -->
<glyph xml:id="Filig">
  <glyphName>LATIN UPPER F AND LATIN LOWER I LIGATURE</glyphName>
  <figure>
    <graphic url="Filig.png"/>
  </figure>
</glyph>
```

```
<p> ... <abbr>
  <g ref="#per">per</g>
</abbr> ardua</p>
<!-- in the charDecl -->
<glyph xml:id="per">
  <glyphName>LATIN ABBREVIATION PER</glyphName>
  <figure>
    <graphic url="per.png"/>
  </figure>
</glyph>
```

(In fact the Unicode Standard does provide a character to represent the **Fi** ligature; the encoder may however prefer not to use it in order to simplify other text processing operations, such as indexing).

With this markup in place, it will be possible to write programs to analyze the distribution of the different letters "r" as well as produce more 'faithful' renderings of the original. It will also be possible to produce normalized versions by simply ignoring the annotation pointed to by the element <g>.

For brevity of encoding, it may be preferred to predefine internal entities such as the following:

```
<!ENTITY r1 '<g ref="#r1">r</g>' >
<!ENTITY r2 '<g ref="#r2">r</g>' >
```

which would enable the same material to be encoded as follows:

```
<p>Wo&r1;ds in this manusc&r2;ipt are
sometimes written in a funny way.</p>
```

The same technique may be used to represent particular abbreviation marks as well as to represent other characters or glyphs. For example, if we believe that the r-with-one-funny-stroke is being used as an abbreviation for **receipt**, this might be represented as follows:

```
<abbr>&r1;</abbr>
```

Note however that this technique employs markup objects to provide a link between a character in the document and some annotation on that character. Therefore, it cannot be used in places where such markup constructs are not allowed, notably in attribute values.

Since the need to use these constructs to annotate or define characters occurs frequently in Chinese, Korean, and Japanese documents, here are some issues that are specific to these documents. There are two slightly different versions of the problem. In the first case, due to the way Unicode is defined, there are occasions when more than one glyph is defined for a character. In such an occasion, one might want to retain the character as used, but add information in a way so that a normalizer (for search or indexing operations) could take advantage of this information. To achieve this, we simply define within a `<charDecl>` element a `<glyph>` that has two `<mapping>` elements, as shown here:

```
<charDecl>
  <glyph xml:id="u8aaa">
    <mapping type="Unicode">説</mapping>
    <mapping type="standard">説</mapping>
  </glyph>
</charDecl>
```

The first of these `<mapping>`s, of type `Unicode`, simply maps our glyph to the code point where Unicode defined it. The other one, of type `standard`, encodes the fact that in our view, this glyph is a variation of the standard character given in the content of the element. We could then use this `<glyph>` element's unique identifier `u8aaa` to refer to it from within a text as follows.

```
<g ref="#u8aaa">説</g>
```

A slightly different, but related problem occurs when we have multiple variants, none of which has been defined in Unicode. In this case, we need to define one as a new character using `<char>`, and the others as glyphs using `<glyph>`.

```
<charDecl>
  <char xml:id="newchar1">
<!-- more properties here -->
  </char>
  <glyph xml:id="varofnewchar1">
<!-- more properties here -->
    <mapping type="standard">
      <g ref="#newchar1"/>
    </mapping>
  </glyph>
</charDecl>
```

The `<char>` defines a new character, while the `<glyph>` element then defines a variant glyph of this newly defined character. Additional properties should be specified in order to make these both identifiable.

## 5.4 Adding New Characters

The creation of additional characters for use in text encoding is quite similar to the annotation of existing characters. The same element `<g>` is used to provide a link from the character instance in the text to a character definition provided within the `<charDecl>` element. This character definition takes the form of a `<char>` element. The element `<g>` itself will usually be empty, but could contain a code point from the Private Use Area (PUA) of the

Unicode Standard, which is an area set aside for the very purpose of privately adding new characters to a document. Recommendations on how to use such PUA characters are given in the following section.

In some circumstances, it may be desirable to provide a single precomposed form of a character that is encoded in Unicode only as a sequence of code points. For example, in Medieval Nordic material, a character looking like a lowercase letter Y with a dot and an acute-accent above it may be encountered so frequently that the encoder wishes to treat it as a single precomposed character with one single coded value. In the transcription concerned, the encoder enters this letter as `&ydotacute;`, which when the transcription is processed can then be expanded in one of three ways, depending on the mapping in force. The entity reference might be translated into the sequence of corresponding Unicode code points or into some locally-defined PUA character (say `&#xE0A4;`) for local processing only. Both these options have disadvantages; the former loses the fact that the sequence of composed characters is regarded as a single object; the second is not reliably portable. Therefore, the recommended representation is to use the `<g>` element defined by the module defined in this chapter:

```
<g ref="#ydotacute"/>
```

. This makes it possible for the encoder to provide useful documentation for the particular character or glyph so referenced:

```
<char xml:id="ydotacute">
  <charName>LATIN SMALL LETTER Y WITH DOT ABOVE AND
    ACUTE</charName>
  <charProp>
    <localName>entity</localName>
    <value>ydotacute</value>
  </charProp>
  <mapping type="composed">&#x0079;&#x0307;&#x0301;</mapping>
  <mapping type="PUA">U+E0A4</mapping>
</char>
```

This definition specifies the mapping between this composed character and the individual Unicode-defined code points which make it up. It also supplies a single locally-defined property ('entity') for the character concerned, the purpose of which is to supply a recommended character entity name for the character.

Under certain circumstances, Chinese Han characters can be written within a circle. Rather than considering this as simply an aspect of the rendering, an encoder may wish to treat such circled characters as entirely distinct derived characters. For a given character (say that represented by the numeric-character reference `&#x4EBA;`) the circled variant might conveniently be represented as

```
<g ref="#U4EBA-circled"/>
```

, which references a definition such as the following:

```
<char xml:id="U4EBA-circled">
  <charName>CIRCLED IDEOGRAPH</charName>
  <charProp>
    <unicodeName>character-decomposition-mapping</unicodeName>
    <value>circle</value>
  </charProp>
  <charProp>
    <localName>daikanwa</localName>
    <value>36</value>
  </charProp>
```

```

<mapping type="standard"> &#x4EBA;
</mapping>
<mapping type="PUA"> &#xE000;
</mapping>
</char>

```

In this example, the ‘circled ideograph’ character has been defined with two mappings, and with two properties. The two properties are the Unicode-defined character-decomposition which specifies that this is a circled character, using the appropriate terminology (see 5.2.1. *Character Properties* above) and a locally defined property known as ‘daikanwa’. The two mappings indicate firstly that the standard form of this character is the character `&#x4EBA;`, and secondly that the character used to represent this character locally is the PUA character `&#xE000;`. For convenience of local processing this PUA character may in fact appear as content of the `<g>` element. In general, however, the `<g>` element will be empty.

## 5.5 How to Use Code Points from the Private Use Area

The developers of the Unicode Standard have set aside an area of the codespace for the private use of software vendors, user groups, or individuals. As of this writing (Unicode 5.0), there are around 137,000 code points available in this area, which should be enough for most needs. No code point assignments will be made to this area by standard bodies and only some very basic default properties have been assigned (which may be overridden where necessary by the mechanism outlined in this chapter). Therefore, unlike all other code points defined by the Unicode Standard, PUA code points should *not* be used directly in documents intended for blind interchange.

In the two previous examples, we mentioned that the variant characters concerned might well be assigned specific code points from the PUA. This might, for example, facilitate the use of a particular font which displays the desired character at this code point in the local processing environment. Since however this assignment would be valid only on the local site, documents containing such code points are unsuitable for blind interchange. During the process of preparing such documents for interchange, any PUA code points should be replaced by an appropriate use of the `<g>` element, such as `<g ref="#xxxx">`, thus associating the character required with the documentation of it provided by the referenced `<char>` element. The PUA character used during the preparation of the document might be recorded in the `<char>` element, as shown in the example in 5.4. *Adding New Characters*, or retained as content of the `<g>` element. However, since there is no requirement that the same PUA character be used to represent it at the receiving site, and since it may well be the case that this other site has already made an assignment of some other character to the original PUA code point, it is best practice to remove the locally-defined PUA character. It is to be expected that a further translation into the local processing environment at the receiving site will be necessary to handle such characters, during which variant letters can be converted to hitherto unused code points on the basis of the information provided in the `<char>` element.

This mechanism is rather weak in cases where DOM trees or parsed XML fragments are exchanged, which may increasingly be the case. The best an application can do here is to treat any occurrence of a PUA character only in the context of the local document and use the properties provided through the `<char>` element as a handle to the character in other contexts.

In the fullness of time, a character may become standardized, and thus assigned a specific code point outside the PUA. Documents which have been encoded using the mechanism must at the least ensure that this changed code point is recorded within the relevant `<char>` element; it will however normally be simpler to remove the `<char>` element and replace all occurrences of `<g>` elements which reference it by occurrences of the newly coded character.

## 5.6 Writing Modes

The scripts used for writing human languages vary not only in the glyphs they use, but also in the way (or ways) that those glyphs are arranged on the writing surface. For the majority of modern languages, writing is arranged as a series of lines which are to be read from top to bottom. Within each line, individual characters are frequently presented from left to right (English, Russian, Greek), but there are also several widely-used scripts which run right-to-left (Arabic, Hebrew). Writing in which the lines of glyphs are presented vertically and read from right to left is also often encountered, notably in older East Asian scripts (Sinitic characters, Japanese Kana, Korean Hangul, Vietnamese *chữ nôm*). In many cases, a language normally uses the same *writing mode* (we use this term to refer to the orientation of individual glyphs within a line and the order in which glyphs and lines should be read), but

there are exceptions in which the same language may appear in different modes, for example either vertically or horizontally. Many East Asian scripts were traditionally written from top to bottom within the line, with their lines sequenced from right to left. Although modern Japanese, Chinese, and Korean are often written horizontally, the traditional vertical writing mode is still widely used. There are also comparatively rare cases of ancient scripts written with lines running left to right, each line being read top to bottom (Ancient Uighur, classical Mongolian and Manchu), or scripts such as Ogham where the writing direction may start from the bottom left and run around the edge of an inscribed object.

When different languages are combined, it is possible that different writing modes will be needed: for example, in Hebrew text, running right to left, sequences of Latin digits still run left to right. When different writing modes are available for the same language, it may be that different glyphs will be preferred when the script is used in different modes. For example, when Japanese is written horizontally, the Unicode character U+3001, the 'ideographic comma', is used in preference to Unicode character U+FE11, the vertical mode comma. This ensures that the comma appears in the correct position relative to the surrounding glyphs. Even for scripts which are usually written in exactly the same way, different writing modes may be encountered in particular contexts; for example when a language using Roman script is embedded within vertically-organized Chinese text, it may sometimes be displayed vertically and sometimes horizontally. The writing mode may also vary in response to layout constraints such as those imposed by a complex table, where column or row labels may be written vertically or diagonally to make the most effective use of available space, just as it may vary in response to the size and shape of the carrier in the case of a monumental inscription.

For many, perhaps most, TEI documents there may be no need to encode the writing mode explicitly, even in so-called "mixed mode" texts containing passages written in languages which use different writing modes. Modern printed texts in most European languages, for instance, may be expected to use left-to-right/top-to-bottom directionality; while Arabic or Hebrew texts are expected to run right-to-left/top-to-bottom. In a TEI document, language and script are explicitly stated in the markup using the attribute *xml:lang*; this indication will usually imply a particular default writing mode. Even where this attribute is not used, passages in different scripts will use different Unicode characters, and will thus imply a particular default writing mode.

Consider the case of an English text containing a few Arabic words :

The Arabic term `قلم رصاص` means "pencil".

A correct TEI encoding might read as follows:

```
<s xml:lang="en">The Arabic term  
<term xml:lang="ar">قلم رصاص</term> means "pencil".</s>
```

We might assume that it is the presence of the *xml:lang* attribute with value ar that causes processing software to display the Arabic from right to left, but in fact, this is not the case. The order in which the Arabic characters appear when rendered would be the same, even if the markup were not present:

```
<s>The Arabic term قلم رصاص means "pencil".</s>
```

This is because Arabic glyphs are always displayed right to left, even when they appear within a left-to-right English sentence. Like most other codepoints in the Unicode standard, they have a specific directionality setting which helps any rendering software determine how they should be ordered. The Latin glyph "a" has a strong left-to-right bidirectionality setting, as do the digits 0 to 9; the Hebrew א (alef) is strongly right-to-left. Of course, some glyphs (common punctuation marks such as the period or comma for example) have weak or neutral settings because they may appear in several contexts.

The Unicode Bidirectional Algorithm (Unicode Consortium, 2013) defines a number of rules enabling software to render sequences of characters which have differing directionality properties in a predictable and reliable way,

using only those properties.<sup>61</sup> It should be remembered however that individual sequences of characters are always stored in a file in the order in which they should be read, irrespective of the order in which the characters making up a sequence should be displayed or rendered. For example, in a RTL language such as Hebrew, the first character in a file will be that which is displayed at the rightmost end of the first line of text.

An encoder wishing to document or to control the order in which sequences of characters in a TEI document are displayed will usually do so by segmenting the text into sequences presented in the desired order and specifying an appropriate language code for each. In situations where this approach may result in ambiguity or lack of precision, or if the encoder wishes to record directional information explicitly in their encoding, we recommend using the global `@style` attribute to supply detail about the writing mode applicable to the content of any element. The *style* attribute (discussed in 1.3.1.1.3. *Rendition Indicators*) permits use of any formatting language; for these purposes however, we recommend use of CSS, which now includes a Writing Modes module<sup>62</sup> which permits direct specification of a number of useful properties associated with writing modes, notably `direction` (`ltr` or `rtl`); `writing-mode` (`horizontal-tb`, `vertical-rl`, or `vertical-lr`); and `text-orientation` (`mixed`, `upright`, `sideways` ...) as well as properties affecting the behaviour of the unicode-bidi (bidirectional) algorithm. We discuss and exemplify how these properties may be used below.

The global TEI *style* attribute applies to the element on which it is specified (and in most cases, its descendants). Rather than specify it on every element, it will often be more efficient to express sets of commonly-used styling rules as `<rendition>` elements in the `<teiHeader>` and then point to them using the global *rendition* attribute, as further discussed in 2.3.4.1. *Rendition*. Although the CSS specifications are mainly used to provide instructions for software when rendering a digital text, they also provide a useful means of describing the visual properties of a pre-existing document in a formal and standardized way.

The next section presents some examples of how CSS can be used to describe a variety of writing modes. A full description of the appearance of a document will probably include many other properties of course.

## 5.7 Examples of Different Writing Modes

The CSS recommendations provides several properties which can be used to encode aspects of the "writing mode". The most useful of these is the property "writing-mode" which may be used to specify a reading-order for both characters within a single line and lines within a single block of text. The property "text-orientation" may also used to indicate the orientation of individual characters with respect to the line, and the property "direction" to determine the reading order of characters within a line only. We give some examples of each below.

### 5.7.1 Vertical Writing Modes

The `writing-mode` property is particularly useful for languages which can be written in different writing modes, such as Chinese and Japanese. Its possible values include `horizontal-tb`, `vertical-rl` and `vertical-lr`. Each value has two components: 'horizontal' or 'vertical' specifies the inline writing direction, while the second component specifies the direction in which lines in a block, and blocks in a sequence are arranged: from top to bottom (as in most European languages, in which lines and paragraphs are arranged from top to bottom on a page), from right to left (as in the case of Japanese written vertically), or left-to-right (as in the case of Mongolian).

The following example shows three versions of the same poem: first in Japanese, written top to bottom; next in *romaji* (Japanese in Latin script); and finally in an English translation.

We might encode this as follows:

```
<div>
  <lg xml:lang="ja"
    style="writing-mode: vertical-rl">
    <l>古池や</l>
    <l>蛙</l>
```

<sup>61</sup>Because this algorithm may not always give the desired result, Unicode also provides a set of "directional formatting characters" ([http://www.unicode.org/reports/tr9/#Directional\\_Formatting\\_Codes](http://www.unicode.org/reports/tr9/#Directional_Formatting_Codes)). These additional codepoints can be used to signal to rendering software that a specific directionality setting should be turned on or off. However, in the case of documents encoded in XML, there is no need to use such characters, and in fact the W3C explicitly advises against it. "In (X)HTML and XML do not use the paired Unicode bidi formatting code characters where equivalent markup is available." (<http://www.w3.org/International/questions/qa-bidi-controls>)

<sup>62</sup>At the time of writing, this W3C module has the status of a candidate recommendation: see further Ishi (eds.) (2014)

Figure 2: Taken from p.42 of *Haiku: Japanese Art and Poetry*.<sup>200</sup> Judith Patt, Michiko Warkentyne (calligraphy) and Barry Till. 2010.

```

<l>飛び込む</l>
<l>水の音</l>
</lg>
<lg xml:lang="ja-Latn"
  style="writing-mode: horizontal-tb">
  <l>furu ike ya</l>
  <l>kawazu tobikomu</l>
  <l>mizu no oto</l>
</lg>
<lg xml:lang="en">
  <l>Old pond,</l>
  <l>and a frog dives in</l>
  <l>"Splash"!!</l>
</lg>
</div>

```

For the sake of simplicity, we have not attempted to capture in this encoding such aspects as the indenting of lines in the first Japanese version, or the central alignment of the other two versions, nor any other renditional features such as font weight or size etc. The Japanese transcription has `writing-mode: vertical-rl`, which is required because Japanese may be written either in this mode or horizontally. The transcription in romaji uses the attribute `xml:lang` to supply a value of `ja-Latn`, indicating Japanese written in Latin script. Its `style` attribute specifies a horizontal writing mode; this may seem superfluous, but vertically-written romaji is not unknown.

### 5.7.2 Vertical Text with Embedded Horizontal Text

When Japanese is written vertically, the glyph orientation remains the same as when it is written horizontally. In other words, glyphs are not rotated (although as noted above some different glyphs may be used for some characters, in particular for punctuation which needs to be positioned differently in vertical and in horizontal text). However, it is very common for languages written vertically to have embedded runs of text from languages which are normally written horizontally. This raises the issue of the orientation of the glyphs from the horizontal language. Are they written upright, as they would normally appear in horizontal text runs, or are they rotated? Consider this fragment from a Japanese article about the Indonesian language, which takes the form of a glossary list:

The text-orientation property allows us to indicate whether or not glyphs are rotated. In the following example, we have indicated that the list uses a `vertical-rl` writing mode, but that the orientation of individual glyphs may vary:

```

<list type="gloss" xml:lang="ja"
  style="writing-mode: vertical-rl; text-orientation: mixed">
  <label xml:lang="id">hampir</label>
  <item>「近い、ほとんど」</item>
  <label xml:lang="id">baru</label>
  <item>「新しい、ばかい」</item>
<!-- ... -->
</list>

```

The rule `text-orientation: mixed` specifies that ‘characters from horizontal-only scripts are set sideways, i.e. 90° clockwise from their standard orientation in horizontal text. Characters from vertical scripts are set with their intrinsic orientation’ (fantasai 2014). Since the default value for `text-orientation` is `mixed`, this rule is not strictly required. However, if the Indonesian glyphs (which are roman characters) had been set vertically, like this:

then an encoding like the following could be used to make this explicit:

```

<list type="gloss" xml:lang="ja"
  style="writing-mode: vertical-rl; text-orientation: upright">
  <label xml:lang="id">hampir</label>

```

hampir 「近い、ほとんど」  
baru 「新しい、ばかり」  
ada 「ある・いる」  
akan 「(未来)」  
hendak 「欲する」  
mau 「欲する」

Figure 3: Detail from p.62 of *XXXXXXXXXX*". *XXXX*. 1985. *XXXXXXXXXX II*. *XXXXXXXXXX* 11.

b a r u 「新  
h a m p i r 「近  
しい、ばかり」  
近い、ほとんど」

Figure 4: Fragment of previous image with Indonesian glyphs upright.

```

<item>「近い、ほとんど」</item>
<label xml:lang="id">baru</label>
<item>「新しい、ばかい」</item>
<!--... -->
</list>

```

The rule `text-orientation: upright` specifies that ‘characters from horizontal-only scripts are rendered upright, i.e. in their standard horizontal orientation. Characters from vertical scripts are set with their intrinsic orientation and shaped normally’ (fantasai 2014).

### 5.7.3 Vertical Orientation in Horizontal Scripts

It is not unusual to see text from horizontal languages written vertically even where no vertically-written script is involved. This example is a fragment from a table of information about agricultural development on Vancouver Island, written in 1855:

|           | Acres of land in Farms |            | Value of Farms & Implements |                             |              |        |
|-----------|------------------------|------------|-----------------------------|-----------------------------|--------------|--------|
|           | Improved               | Unimproved | Cash Value of Farms         | Value of Farming Implements | all ordinary | Horses |
| Soko      | 60                     | 940        | 4000                        | 2000                        |              | 16     |
| Metchosen | 60                     | 340        | 1600                        | 120                         |              | 10     |
| Agneton   | 70                     | 392        | 1000                        | 100                         |              | 10     |
| James Bay | 12                     | .          | 3500                        | .                           |              | 5      |
| Fairfield | 90                     | 328        | 3300                        | 200                         |              | 10     |
| Rock Bay  | 60                     | 43         | "                           | .                           |              | 7      |

Figure 5: Enclosure with *Despatch to London* 10048, CO 305/6, p. 131v from <http://bcgenesis.uvic.ca/getDoc.htm?id=V55116.scx>

Four of the subheading cells in this fragment contain English text written vertically, bottom-to-top, to conserve space on the page. To describe this sort of phenomenon, we can use the `text-orientation` property again:

```
text-orientation: mixed | upright | sideways-right | sideways-left | sideways
| use-glyph-orientation
```

For full details on this property, we refer the reader to the CSS Writing Modes specification. For the present example, we will make use only of the ‘sideways-left’ value, which ‘causes text to be set as if in a horizontal layout, but rotated 90° counter-clockwise.’ We might encode the third of the four cells containing vertical text like this:

```
<cell style="writing-mode: vertical-lr; text-orientation: sideways-left">
  <lb/>Cash Value
<lb/>of
<lb/>Farms
</cell>
```

The `writing-mode` property captures the fact that the script is written vertically, and its lines are to be read from left to right (so the line containing ‘of’ is to the right of that containing ‘Cash value’), while the `text-orientation` value encodes the orientation (rotated 90° counter-clockwise). We might also add `text-align: center` to the style, to express the fact that the text is centrally-aligned.

#### 5.7.4 Bottom-to-top Writing

Of the rather small number of scripts which appear to be written bottom-to-top, perhaps the best-known is Ogham, an alphabet used mainly to write Archaic Irish. Ogham is typically found inscribed along the edge of a standing stone, starting at its base. The CSS Writing Modes specification does not explicitly distinguish between vertical scripts which are written top-to-bottom and those which are written bottom-to-top. Instead, such bottom-to-top scripts are best treated as left-to-right horizontal scripts, oriented vertically because of the constraints of the medium on which they are inscribed. Such scripts are analogous to the vertical English text-runs in the table cells in the example above, and can be handled in exactly the same manner (`writing-mode: vertical-lr; text-orientation: sideways-left`). In cases where writing follows a curved path (such as Ogham running around the edge of a stone), a meticulous encoder might resort to the use of SVG to describe the path, rather than treating the phenomenon as a writing mode.

#### 5.7.5 Mixed Horizontal Directionality

Returning to our previous simple example

The Arabic term رصاص قلم means "pencil".

we could use the `direction` property to make directionality explicit:

```
direction: ltr | rtl
```

```
<s xml:lang="en" style="direction: ltr">The Arabic term
<term xml:lang="ar"
  style="direction: rtl; unicode-bidi: embed">رصاص قلم />رصاص<term> means "pencil".</s>
```

The use of the `direction` property to record the observed directionality of the text is unambiguous, even though it is (as we noted above) superfluous. The use of the `unicode-bidi` property here may require some explanation. By default this property has the value ‘normal’, the effect of which in this context would be to ignore any value supplied for the `direction` property. The CSS Writing Modes specification stipulates that the `direction` property ‘has no effect on bidi reordering when specified on inline boxes whose `unicode-bidi` property’s value is ‘normal’, because the element does not open an additional level of embedding with respect to the bidirectional algorithm.’

Mixed horizontal directionality is very common in languages such as Arabic and Hebrew, particularly when numbers (which are always given LTR) or phrases from LTR languages are embedded. It is not impossible, though quite unusual, for ambiguities to arise in such situations, which may give rise to the parts of a document being

displayed in unexpected ways that do not correspond to the natural reading order. A more detailed discussion of this issue from an HTML perspective is provided by a W3C Internationalization Working Group report *Inline markup and bidirectional text in HTML*.

### 5.7.6 Summary

For most texts, information about text directionality need not be explicitly encoded in a TEI text, either because it follows unambiguously from *xml:lang* values, or because it can be expected to be handled unequivocally by the Unicode Bidi Algorithm. Where it is considered important to encode such information, properties and values taken from the CSS Writing Modes module may be used by means of the global TEI *style* attribute (or using the TEI *<rendition>* element, linked with the *rendition* attribute). Most phenomena can be well described in this way; of those which cannot, other approaches based on the CSS Transforms module are presented in the next section.

## 5.8 Text Rotation

In what follows, we examine a range of textual phenomena which in some ways appear very similar to those examined above, and even overlap with them. We can categorize these as text transformation features, and suggest some strategies for encoding them based on the properties detailed in the CSS Transforms (Fraser et al 2013) specification. This CSS module provides a complex array of properties, values and functions which can be used to rotate, skew, translate and otherwise transform textual and graphical objects. We can borrow this vocabulary in order to describe textual phenomena in a precise manner.

We begin with a simple example of a rotational transform:

Here a block of text has been rotated around its z-axis. This is clearly not a ‘writing mode’; the writing mode for this text is horizontal, left to right. Furthermore, even if we wished to treat this as a writing mode, we could not do so, because there is no way to use writing modes properties to describe an text orientation which is angled at 45 degrees; no human languages are consistently written in this orientation. It is more appropriate to treat this as a rotational transformation. We can do this using two properties: **transform** and **transform-origin**. (Both of these properties have quite complex value sets, and we will not look at all of them here. See the specification for full details.)

The **transform** property takes as its value one or more of the transform functions, one of which is the function **rotateZ()**:

```
<ab style="transform:rotateZ(-45deg)">TEI-C.ORG</ab>
```

Any rotation must take place clockwise around an axis positioned relative to the element being rotated, and the **transform-origin** property can be used to specify the pivot point. By default, the value of **transform-origin** is ‘50% 50%’, the point at the centre of the element, but these values can be changed to reflect rotation around a different origin point. (The TEI *<zone>* element also bears an attribute *rotate* which can specify rotation in degrees around the z-axis, but it is not available for any other element.)

A block of text may also be rotated about either of its other axes. For example, this shows rotation around the Y (vertical) axis:

```
<ab style="transform:rotateY(45deg)">TEI-C.ORG</ab>
```

These are obviously trivial examples, but similar features do appear in historical texts. George Herbert's *The Temple* includes two stanzas headed 'Easter Wings' which are both normally printed in a rotated form so that they represent a pair of wings:

This could be encoded thus:

```
<lg style="transform:rotateZ(90deg)">
  <l>My tender age in forrow did beginne:</l>
  <l>And ftill with fickneffes and fhome</l>
<!-- ... -->
</lg>
```

We might also argue that this is in fact a vertical writing mode by supplying `writing-mode: vertical-rl; text-orientation: sideways-right` as the value for the *style* attribute in the preceding example.

Rotation is also useful as a method of handling a true writing mode which is not covered by the CSS Writing Modes: *boustrophedon*. This is a writing mode common in inscriptions in Latin, Greek and other languages, in which alternate lines run from left to right and from right to left<sup>63</sup>. Right-to-left lines in boustrophedon have another unexpected feature: their glyphs are reversed, so that these lines appear as 'mirror writing', as in the following ancient Greek inscription:

This might be transcribed as follows (ignoring word boundaries for the moment):

```
<ab>
  <lb/>HEPMONTINA
<lb/>
  <seg style="rotateY(180deg)">ΚΑΘΕΟΝΠΟΤΘΕΜ</seg>
  <lb/>ΕΝΟΣΥΕΝΕΑΦ
<lb/>
  <seg style="rotateY(180deg)">ΘΙΥΕΝΘΙΤΙΕΚΚ</seg>
  <lb/>ΡΕΤΑΙΑΣΟΝΑ
<lb/>
  <seg style="rotateY(180deg)">ΣΙΜΟΣΟΤΤΑΙΕ</seg>
  <lb/>ΑΣΣΑΙ
</ab>
```

The 180-degree rotation around the Y (vertical) axis here describes what is happening in the RTL line in boustrophedon; the order of glyphs is reversed, and so is their individual orientation (in fact, we see them 'from

<sup>63</sup>The name is taken from the Greek βουστροφηδόν, meaning 'ox-turning' from βούς (an ox) and στροφή ('turn'); that is, turning as an ox does when pulling a plough.

Figure 6: Page 35 of George Herbert's *The Temple* (1633), from a copy in the Folger Library.

Figure 7: Leaden plaque bearing an inquiry by Hermon from the oracular precinct at Dodona. (L.H. Jeffery Archive)

the back', as it were). `<seg>` elements have been used here because these are clearly not 'lines' in the sense of poetic lines; the text is continuous prose, and linebreaks are incidental.

There are obviously some unsatisfactory aspects of this manner of encoding boustrophedon. In the inscription above, some words run across linebreaks, so if we wished to tag both words and the right-to-left phenomena, one hierarchy would have to be privileged over the other. By using a transform function rather than a writing mode property, we are apparently suggesting that boustrophedon is not in fact a writing mode, whereas it clearly is. But the CSS Writing Modes specification does not provide support for boustrophedon, because it is a rather obscure historical phenomenon; using a rotational transform is one practical alternative.

## 5.9 Caveat

As with other parts of the CSS specification, the intended effect of CSS Transforms properties and values is defined with reference to a specific Visual formatting model; the language is designed to describe how an HTML document should be formatted. This is not, of course, the case for the TEI, which lacks any explicit processing or formatting model, and attempts to define objects as far as possible without consideration of their visual appearance. As long as the properties and values from the CSS Transforms module are used as a convenient, well-specified descriptive language to capture features of a text, without any expectation of using them directly and reliably for rendering, this is not particularly problematic. CSS provides a useful and well-defined vocabulary to describe many aspects of the appearance of source texts, benefitting particularly from the clarity of definition provided by the specification. However, if there is any expectation of using this information to render a text in a predictable and accurate way, it will be essential to provide enough styling information throughout the document hierarchy to resolve all ambiguities with regard to size, positioning, block status, etc. before any element undergoes a transform operation.

## 5.10 Formal Definition

The gaiji module described in this chapter makes available the following components:

**Module gaiji: Character and glyph documentation**

- *Elements defined:* char charDecl charName charProp g glyph glyphName localName mapping unicodeName value

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

## 6 Verse

This module is intended for use when encoding texts which are entirely or predominantly in verse, and for which the elements for encoding verse structure already provided by the core module are inadequate.

The tags described in section 3.12.1. *Core Tags for Verse* include elements for the encoding of verse lines and line groups such as stanzas: these are available for any TEI document, irrespective of the module it uses. Like the modules for prose and for drama, the module for verse additionally makes use of the module defined in chapter 4. *Default Text Structure* to define the basic formal structure of a text, in terms of <front>, <body> and <back> elements and the text-division elements into which these may be subdivided.

The module for verse extends the facilities provided by these modules in the following ways:

- a special purpose <caesura> element is provided, to allow for segmentation of the verse line (see section 6.2. *Components of the Verse Line*)
- a set of attributes is provided for the encoding of rhyme scheme and metrical information (see sections 6.4. *Rhyme and Metrical Analysis* and 6.5. *Rhyme*)
- a special purpose <rhyme> element is provided to support simple analysis of rhyming words (see section 6.5. *Rhyme*)

### 6.1 Structural Divisions of Verse Texts

Like other kinds of text, texts written in verse may be of widely differing lengths and structures. A complete poem, no matter how short, may be treated as a free-standing text, and encoded in the same way as a distinct prose text. A group of poems functioning as a single unit may be encoded either as a <group> or as a <text>, depending on the encoder's view of the text. For further discussion, including an example encoding for a verse anthology, see chapter 4. *Default Text Structure*.

Many poems consist only of ungrouped lines. This short poem by Emily Dickinson is a simple case:

```
<text>
  <front>
    <head>1755</head>
  </front>
  <body>
    <l>To make a prairie it takes a clover and one bee,</l>
    <l>One clover, and a bee,</l>
    <l>And revery.</l>
    <l>The revery alone will do,</l>
    <l>If bees are few.</l>
  </body>
</text>
```

Often, however, lines are grouped, formally or informally, into stanzas, verse paragraphs, etc. The <lg> element defined in the core tag set (in section 3.12.1. *Core Tags for Verse*) may be used for all such groupings. It may thus serve for informal groupings of lines such as those of the following example from Allen Ginsberg:

```
<text>
  <body>
    <head>My Alba</head>
    <lg>
      <l>Now that I've wasted</l>
      <l>five years in Manhattan</l>
      <l>life decaying</l>
      <l>talent a blank</l>
    </lg>
    <lg>
      <l>talking disconnected</l>
      <l>patient and mental</l>
    </lg>
  </body>
</text>
```

```

    <l>sliderule and number</l>
    <l>machine on a desk</l>
  </lg>
</body>
</text>

```

It may also be used to mark the verse paragraphs into which longer poems are often divided, as in the following example from Samuel Taylor Coleridge's *Frost at Midnight*:

```

<lg>
  <l>The Frost performs its secret ministry,</l>
  <l>Unhelped by any wind. ...</l>
  <l>Whose puny flaps and freaks the idling Spirit</l>
  <l>By its own moods interprets, every where</l>
  <l>Echo or mirror seeking of itself,</l>
  <l part="I">And makes a toy of Thought.</l>
</lg>
<lg>
  <l part="F">But O! how oft,</l>
  <l>How oft, at school, with most believing mind</l>
  <l>Presageful, have I gazed upon the bars,</l>
  <l>To watch that fluttering <hi>stranger</hi>! ... </l>
</lg>
<lg>
  <l>Dear Babe, that sleepest cradled by my side,</l>
</lg>

```

Note, in the above example, the use of the *part* attribute on the `<l>` element, where a verse line is broken between two line groups, as discussed in section 3.12.1. *Core Tags for Verse*.

Most typically, however, the `<lg>` element is used to mark the highly regular line groups which characterize stanzaic and similar verse forms, as in the following example from Chaucer:

```

<lg>
  <l>Sire Thopas was a doghty swayn;</l>
  <l>White was his face as payndemayn,</l>
  <l>His lippes rede as rose;</l>
  <l>His rode is lyk scarlet in grayn,</l>
  <l>And I yow telle in good certayn,</l>
  <l>He hadde a semely nose.</l>
</lg>
<lg>
  <l>His heer, his ber was lyk saffroun,</l>
  <l>That to his girdel raughte adoun;</l>
</lg>

```

Like other text-division elements, `<lg>` elements may be nested hierarchically. For example, one particularly common English stanzaic form consists of a quatrain or sestet followed by a couplet. The `<lg>` element may be used to encode both the stanza and its components, as in the following example from Byron:

```

<lg type="stanza">
  <lg type="sestet">
    <l>In the first year of Freedom's second dawn</l>

```

```

<l>Died George the Third; although no tyrant, one</l>
<l>Who shielded tyrants, till each sense withdrawn</l>
<l>Left him nor mental nor external sun:</l>
<l>A better farmer ne'er brushed dew from lawn,</l>
<l>A worse king never left a realm undone!</l>
</lg>
<lg type="couplet">
  <l>He died – but left his subjects still behind,</l>
  <l>One half as mad – and t'other no less blind.</l>
</lg>
</lg>

```

Note the use of the *type* attribute to name the type of unit encoded by the <lg> element; this attribute is common to all members of the `att.divLike` class (see section 4.1.1. *Un-numbered Divisions*).<sup>64</sup> When used on <lg>, the *type* attribute is intended solely for conventional names of different classes of text block. For systematic analysis of metrical and rhyme schemes, use the *met* and *rhyme* attributes, for which see below, section 6.4. *Rhyme and Metrical Analysis*.

As a further example, consider the Shakespearean sonnet. This may be divided into two parts: a concluding couplet, and a body of twelve lines, itself subdivided into three quatrains:

```

<text>
  <body>
    <lg>
      <lg type="quatrain">
        <l>My Mistres eyes are nothing like the Sunne,</l>
        <l>Currall is farre more red, then her lips red</l>
        <l>If snow be white, why then her brests are dun:</l>
        <l>If haire be wiers, black wiers grown on her head:</l>
      </lg>
      <lg type="quatrain">
        <l>I have seene Roses damaskt, red and white,</l>
        <l>But no such Roses see I in her cheekes,</l>
        <l>And in some perfumes is there more delight,</l>
        <l>Then in the breath that from my Mistres reekes.</l>
      </lg>
      <lg type="quatrain">
        <l>I love to heare her speake, yet well I know,</l>
        <l>That Musicke hath a farre more pleasing sound:</l>
        <l>I graunt I never saw a goddesse goe,</l>
        <l>My Mistres when shee walkes treads on the ground.</l>
      </lg>
    </lg>
    <lg type="couplet">
      <l>And yet by heaven I think my love as rare,</l>
      <l>As any she beli'd with false compare.</l>
    </lg>
  </body>
</text>

```

Particularly lengthy poetic texts are often subdivided into units larger than stanzas or paragraphs, which may themselves be subdivided. Spenser's *Faery Queene*, for example, consists of twelve 'books' each of which contains a prologue followed by twelve 'cantos'. Each prologue and each canto consists of nine-line 'stanzas', each of which follows the same regular pattern. Other examples in the same tradition are easy to find.

<sup>64</sup>For discussion of other attributes of this class, see 4.1.4. *Partial and Composite Divisions*.

Large structures of this kind are most conveniently represented by `<div>` or `<div1>` elements, as described in section 4.1. *Divisions of the Body*. Thus the start of the *Faerie Queene* might be encoded as follows:

```
<body>
  <div n="I" type="book">
    <div n="1" type="canto">
      <lg n="I.1.1" type="stanza">
        <l>A Gentle Knight was pricking on the plain</l>
        <l>Y cladd in mightie armes and silver shielde,</l>
      </lg>
    </div>
  </div>
</body>
```

The encoder must choose at which point in the hierarchy of structural units to introduce `<lg>` elements rather than a yet smaller `<div>` element: it would (for example) also be possible to encode the above example as follows:

```
<body>
  <div n="I" type="book">
    <div n="I.1" type="canto">
      <div n="I.1.1" type="stanza">
        <l>A gentle knight was pricking on the plain</l>
        <l>Ycladd in mightie armes and silver shielde,</l>
      </div>
    </div>
  </div>
</body>
```

One reason for using `<div>` rather than `<lg>` elements is that the former may contain non-metrical elements, such as epigraphs or dedications and other members of the `model.divTop` class, whereas `<lg>` elements may contain only headings or metrical lines.

## 6.2 Components of the Verse Line

It is often convenient for various kinds of analysis to encode subdivisions of verse lines. The general purpose `<seg>` element defined in the tag set for segmentation and alignment (section 16.3. *Blocks, Segments, and Anchors*) is provided for this purpose:

`<seg>` (arbitrary segment) represents any segmentation of text below the ‘chunk’ level.

To use this element together with the module for verse, the module for segmentation and alignment must also be enabled as further described in section 1.2. *Defining a TEI Schema*.

In Old and Middle English alliterative verse, individual verse lines are typically split into half lines. The `<seg>` element may be used to mark these explicitly, as in the following example from Langland's *Piers Plowman*:

```
<l>
  <seg>In a somer
    seson,</seg>
  <seg>whan softe was the sonne,</seg>
</l>
<l>
  <seg>I shoop me into shroudes</seg>
  <seg>as I a sheep were,</seg>
</l>
<l>
  <seg>In habite as an heremite </seg>
```

```

<seg>unholy of werkes,</seg>
</l>
<l>
  <seg>Went wide in this world </seg>
  <seg>wondres to here.</seg>
</l>

```

The <seg> element can be nested hierarchically, in the same way as the <lg> element, down to whatever level of detailed structure is required. In the following example, the line has been divided into *feet*, each of which has been further subdivided into syllables.<sup>65</sup>

```

<l>
  <seg type="foot">
    <seg type="syll">Ar</seg>
    <seg type="syll">ma </seg>
    <seg type="syll">vi</seg>
  </seg>
  <seg type="foot">
    <seg type="syll">rum</seg>
    <seg type="syll">que </seg>
    <seg type="syll">ca</seg>
  </seg>
  <seg type="foot">
    <seg type="syll">no </seg>
    <seg type="syll">Tro</seg>
  </seg>
  <seg type="foot">
    <seg type="syll">iae </seg>
    <seg type="syll">qui </seg>
  </seg>
  <seg type="foot">
    <seg type="syll">pri</seg>
    <seg type="syll">mus </seg>
    <seg type="syll">ab </seg>
  </seg>
  <seg type="foot">
    <seg type="syll">or</seg>
    <seg type="syll">is </seg>
  </seg>
</l>

```

The <seg> element may be used to identify any subcomponent of a line which has content; its type attribute may characterize such units in any way appropriate to the needs of the encoder. For the specific case of labeling each foot with its formal type ('dactyl', 'spondee', etc.), and each syllable with its metrical or prosodic status (syllables bearing primary or secondary stress, long syllables, short syllables), however, the specialized attributes *met* and *real* are defined, which provide a more systematic framework than the *type* attribute; see section 6.4. *Rhyme and Metrical Analysis* below.

In classical verse, a hexameter like that above may also be formally divided into two *cola* or 'hemistiches'. This example provides a typical case, in that the boundary of the first colon falls in the middle of one of the feet (between the syllables 'no' and 'Tro'). If both kinds of segmentation are required, the *part* attribute might be used to mark the overlapping structure as follows.

<sup>65</sup> As elsewhere in these Guidelines, this example has been formatted for clarity of exposition rather than correct display. Note in particular that whether an XML processor retains whitespace within the <seg> element or not (this can be configured by means of the *xml:space* attribute) this example will still require additional processing, since whitespace should be retained for the lower level <seg> elements (those of type *syll*) but not for the higher level one (those of type *foot*).

```

<l>
  <seg type="hemistich">
    <seg type="foot">
      <seg type="syll">Ar</seg>
      <seg type="syll">ma </seg>
      <seg type="syll">vi</seg>
    </seg>
    <seg type="foot">
      <seg type="syll">rum</seg>
      <seg type="syll">que </seg>
      <seg type="syll">ca</seg>
    </seg>
    <seg type="foot" part="I">
      <seg type="syll">no </seg>
    </seg>
  </seg>
  <seg type="hemistich">
    <seg type="foot" part="F">
      <seg type="syll">Tro</seg>
    </seg>
    <seg type="foot">
      <seg type="syll">iae </seg>
      <seg type="syll">qui </seg>
    </seg>
  </seg>
</l>

```

Instead of using the *part* attribute on the `<seg>` element, it might be simpler just to mark the point at which the caesura occurs. An additional element is provided for analyses of this kind, in which what is to be marked are points 'between the words', which have some significance within a verse line:

**<caesura>** marks the point at which a metrical line may be divided.

In classical prosody, the *caesura*, which occurs within a foot, is distinguished from a *diaeresis*, which occurs on a foot boundary (not to be confused with the division of a diphthong into two syllables, or the diacritic symbol used to indicate such division, each of which is also termed *diaeresis*). This distinction is rarely made nowadays, the term *caesura* being used for any division irrespective of foot boundaries. No special-purpose **<diaeresis>** element is therefore provided.

As an example of the `<caesura>` element, we refer again to the example from Langland. An encoder might choose simply to record the location of the caesura within each line, rather than encoding each half-line as a segment in its own right, as follows:

```

<l>In a somer seson,
<caesura/> whan softe was the sonne, </l>
<l>I shoop me into shroudes <caesura/> as I a sheep were, </l>
<l>In habite as an heremite <caesura/> unholy of werkes, </l>
<l>Went wide in this world <caesura/> wondres to here. </l>

```

Logically, the opposite of caesura might be considered to be *enjambement*. When the `verse` module is included in a schema, an additional class called `att.enjamb` is defined as follows:

**att.enjamb** (enjambement) provides an attribute which may be used to indicate enjambement of the parent element.

`@enjamb` (enjambement) indicates that the end of a verse line is marked by enjambement.

The following lines demonstrate the use of the *enjamb* attribute to mark places where there is a discrepancy between the boundaries of the `<l>` elements and the syntactic structure of the verse (a discrepancy of some significance in some schools of verse):

```
<l enjamb="y">Un astrologue, un jour, se laissa choir</l>
<l>Au fond d'un puits.</l>
```

## 6.3 Encoding Textual Structures Across Verses

It is possible that certain textual structures may span multiple lines of verse, either by incorporating more than one, or by crossing line hierarchy. This is common, for example, when lines contain reported thought or speech (i.e. `<said>`), or other forms of quotation (i.e. `<q>`). For these cases, it is recommended practice to fragment and reconstruct the elements representing the textual structures.

The following example from Margaret Cavendish's *Nature's Pictures* shows speech encoded across two lines reconstructed by chaining elements with *prev* and *next* attributes:

```
<lg type="couplet">
  <l>
    <said xml:id="eg1-said1"
      next="#eg1-said2">Our lives</said>, faid he,
    <said xml:id="eg1-said2"
      next="#eg1-said3" prev="#eg1-said1">wee'll give before we yield</said>,
  </l>
  <l>
    <said xml:id="eg1-said3"
      prev="#eg1-said2">Wee'll win your battles, or dye in the field</said>.
  </l>
</lg>
```

Alternatively, the elements may be reconstructed with stand-off markup using the element `<join>`:

```
<lg type="couplet">
  <l>
    <seg xml:id="eg2-said1">Our lives</seg>, faid he,
    <seg xml:id="eg2-said2">wee'll give before we yield</seg>,
  </l>
  <l>
    <seg xml:id="eg2-said3">Wee'll win your battles, or dye in the field</seg>.
  </l>
</lg>
<!-- Elsewhere in the document -->
<p>
  <join result="said" scope="root"
    target="#eg2-said1 #eg2-said2 #eg2-said3"/>
</p>
```

A more general discussion of these and other strategies to deal with fragmentation and reconstruction appears in section 20.3. *Fragmentation and Reconstitution of Virtual Elements*.

## 6.4 Rhyme and Metrical Analysis

When the module for verse is in use, the following additional attributes are available to record information about rhyme and metrical form:

**att.metrical** defines a set of attributes which certain elements may use to represent metrical information.

*@met* (metrical structure, conventional) contains a user-specified encoding for the conventional metrical structure of the element.

`@real` (metrical structure, realized) contains a user-specified encoding for the actual realization of the conventional metrical structure applicable to the element.

`@rhyme` (rhyme scheme) specifies the rhyme scheme applicable to a group of verse lines.

These attributes may be attached to the `<lg>` element, or to the higher-level text-division elements `<div>`, `<div1>`, etc. In general, the attributes should be specified at the highest level possible; they may not however be specifiable at the highest level if some of the subdivisions of a text are in prose and others in verse. All these attributes may also be attached to the `<l>` and `<seg>` elements, but the default notation for the *rhyme* attribute has no defined meaning when specified on `<l>` or `<seg>`. The value for these attributes may take any form desired by the encoder, but the nature of the notation used will determine how well the attribute values can be processed by automatic means.

The primary function of the metrical attributes is to encode the conventional metrical or rhyming structure within which the poet is working, rather than the actual prosodic realization of each line; the latter can be recorded using the *real* attribute, as further discussed below. A simple mechanism is also provided for recording the actual realization of a rhyme pattern; see 6.5. *Rhyme*.

### 6.4.1 Sample Metrical Analyses

As a simple example of the use of these attributes, consider the following lines from Pope's 'Essay on Criticism':

```
<div type="book" n="1" met="-+|-+|-+|-+|-+/"
  rhyme="aa">
  <lg n="1" type="paragraph">
    <l>'Tis hard to say, if greater Want of Skill</l>
    <l>Appear in <hi>Writing</hi> or in <hi>Judging</hi> ill;</l>
    <l>But, of the two, less dang'rous is th'Offence,</l>
    <l>To tire our <hi>Patience</hi>, than mis-lead our <hi>Sense</hi>:</l>
  </lg>
</div>
```

This text is written entirely in *heroic couplets*; each line is an iambic pentameter (which, using a common notation, can be described with the formula `-+|-+|-+|-+|-+|`, each `-` denoting a metrically unstressed syllable, each `+` a metrically stressed one, each `|` a foot boundary, and the `/` a line-end), and the couplets rhyme (which can be represented with the conventional formula *aa*).

Because both rhyme pattern and metrical form are consistent throughout the poem, they may be conveniently specified on the `<div>` element; the values given for the attributes will be inherited by any metrical unit contained within the `<div>` elements of this poem, and must be interpreted in the appropriate way.

Since the notation used in the *met*, *real*, and *rhyme* attributes is user-defined, no binding description can be given of its details or of how its interpretation must proceed. (A default notation is provided for the *rhyme* attribute, which however the encoder can replace with another; see section 6.5. *Rhyme*.) It is expected, however, that software should be able to support these attributes in useful ways; the more intelligent the software is, and the more knowledge of metrics is built into it, the better it will be able to support these attributes. In the extract given above, for example, the *met* and *rhyme* attribute values specified on the `<div>` element are inherited directly by the `<lg>` elements nested within it. Since the *met* value specifies the metrical form of a single verse line, the structure of the `<lg>` as a whole is understood to involve as many repetitions of the pattern as there are lines in the verse paragraph. The same attribute value, when inherited in turn by the `<l>` element, must be understood *not* to repeat. With sufficiently sophisticated software, segments within the line might even be understood as inheriting precisely that portion of the formula which applies to the segment in question; this will, however, be easier to accomplish for some languages than for others.

The *rhyme* attribute in this example uses the default notation to specify a rhyme scheme applicable only to pairs of lines. As elsewhere, the default notation for the *rhyme* attribute has no meaning for metrical units at the line level or below. In verse forms where line-internal rhyme is structurally significant, e.g. in some skaldic poetry, the default notation is incapable of expressing the required information, since the rhyme pattern may need to be specified for units smaller than the line. In such cases, a user-specified rhyme notation must be substituted for the default notation, or else the rhyme pattern must be described using some alternative method (e.g. by using the `<link>` mechanism described below).

The precise semantics of the *met* attribute and the inferences which software is expected or able to draw from it, are implementation-dependent; so are the semantics and processing of the *rhyme* attribute, when user-specified notations are used.

A formal definition of the significance of each component of the pattern given as the value of the *met* attribute may be provided in the <metDecl> element within the <encodingDesc> element in the TEI header (see section 6.6. *Metrical Notation Declaration*). The encoder is free to invent any notation appropriate to his or her analytic needs, provided that it is adequately documented in this element. The notation may define metrical components using invented or traditional names (such as ‘iamb’ or ‘hexameter’) or in terms of basic units such as codes for stressed or unstressed syllables, or a combination of the two.

The *real* (for ‘realization’) attribute may optionally be specified to indicate any deviation from the pattern defined by the *met* attribute which the encoder wishes to record. By default, the *real* attribute has the same value as the *met* attribute on the same element; it is only necessary to provide an explicit value when the realization differs in some way from the abstract metrical pattern. The tension between conventional metrical pattern and its realization may thus be recorded explicitly. For example, many readers of the above passage would stress the word ‘But’ at the beginning of the third line rather than the word ‘of’ following it, as the metrical pattern would normally require. This variation might be encoded as follows:

```
<l real="+-|-+|-+|-+|-+>But, of the two, ...</l>
```

Where the *real* attribute is used to over-ride the default or conventional metrical pattern, it applies only to the element on which it is specified. The default pattern for any subsequent lines is unaffected.

As it happens, this particular kind of variation is very common in the English iambic pentameter—it even has a name: *trochaic substitution*—an encoder might therefore choose to regard this not as an instance of a variant realization, but as an instance of a variant metrical form:

```
<l met="+-|-+|-+|-+|-+>But, of the two,  
...</l>
```

Alternatively, a different metrical notation might be defined, in which this kind of variation was permitted throughout the text.

In choosing whether to over-ride a metrical specification in this way or by using the *real* attribute, the encoder is required to determine whether the change is a systematic or conventional one (as in this example) or an occasional variation, perhaps for local effect. In the following example, from Goethe's ‘Auf dem See’, the variation is a matter of local realization:

```
<lg type="chevy-chase-stanza"  
  met="-+--+--+/-+--++" rhyme="ababcdcd">  
  <l n="1"> Und frische Nahrung, neues Blut</l>  
  <l n="2" real="+--+--+> Saug' ich aus freier Welt;</l>  
  <l n="3" real="+--+--+> Wie ist Natur so hold und gut,</l>  
  <l n="4" real="---+--+> Die mich am Busen hält!</l>  
  <l n="5"> Die Welle wieget unsern Kahn</l>  
  <l n="6"> Im Rudertakt hinauf,</l>  
  <l n="7"> Und Berge, wolkg himmelan,</l>  
  <l n="8"> Begegnen unserm Lauf.</l>  
</lg>
```

On the other hand, the famous inserted alexandrine in Pope's ‘Essay on Criticism’, might be encoded as follows:

```
<l n="356"> A  
needless alexandrine ends the song, </l>
```

```
<l n="357" met="-+|-+|-+|-+|-+|-+"
  real="++|-+|-+|-+|-+|-+"> That, like a wounded
snake, drags its slow length along. </l>
```

Here the *met* attribute indicates that a different metrical convention (the alexandrine) is in force, while the *real* attribute indicates that there is a variation from that convention. As with many other aspects of metrical analysis, however, this is of necessity an entirely interpretive judgment.

### 6.4.2 Segment-Level versus Line-level Tagging

The examples given so far have encoded information about the realization of metrical conventions at the level of the whole verse-line. This has obvious advantages of simplicity, but the disadvantage that any deviation from metrical convention is not marked at its precise point of occurrence in the text. Greater precision may be achieved, but only at the cost of marking deviant metrical units explicitly. This may be done with the `<seg>` element, giving the variant realization as the value of the *real* attribute on that element. Using this method, the example given immediately above might be encoded as follows:

```
<l n="356"> A need<seg type="foot" n="2" real="--">less a</seg>alexandrine ends the
song,</l>
<l n="357" met="-+|-+|-+|-+|-+|-+">
  <seg n="1" real="++"> That, like </seg> a wounded snake, <seg n="4" real="+-"> drags
its </seg>
  <seg n="5" real="++"> slow length </seg> along.
</l>
```

The marking of the foot boundaries with the symbol | in the *met* attribute value of the `<l>` element allows the human reader, or a sufficiently intelligent software program, to isolate the correct portion of that attribute value as the default value for the same attribute on the `<seg>` elements for feet, namely `-+`. It is of course up to the encoder to decide whether or not to include the *n* attribute of `<seg>` here, and whether or not also to tag the feet in the line in which there is no deviation from the metrical convention. The ability of software to infer which foot is being marked, if not all are tagged, will depend heavily on the language of the text and the knowledge of prosody built into the software; the fuller and more explicit the markup, the easier it will be for software to handle it. It may prove useful, however, to mark metrical deviations in the manner shown, even if the available software is not sufficiently intelligent to scan lines without aid from the markup. Human readers who are interested in prosody may well be able to exploit the markup in useful ways even with less sophisticated software.

There are circumstances where it may also be useful to use the *met* attribute of `<seg>`. If we wish to identify the exact location of the different types of foot in the first line of Virgil's *Aeneid*, the text could be encoded as follows (for simplicity's sake the caesura has been omitted):

```
<l>
  <seg type="foot" met="+--">Arma vi</seg>
  <seg met="+--">rumque ca</seg>
  <seg met="++">no Tro</seg>
  <seg met="++">iae qui </seg>
  <seg met="+--">primus ab</seg>
  <seg met="++"> oris</seg>
</l>
```

An appropriate value of the *met* attribute might also be supplied on the enclosing `<div>` element, to indicate that each foot may be made up of a dactyl or a spondee, so that the values given here for *met* at the level of the foot may be considered a series of local variations on this fundamental pattern; in cases like this, of course, the local variations may also be considered aspects of realization rather than of convention, in which case the *real* attribute may be used instead of *met*, if desired.

### 6.4.3 Metrical Analysis of Stanzaic Verse

The method described above may be used to encode quite complex verse forms, for instance various kinds of fixed-form stanzas. Let us take one of Dante's canzoni, in which each stanza except the last has the same combination of eleven-syllable and seven-syllable lines, and the same rhyme scheme:

```
<div type="canzone"
  met="E/E/S/E/S/E/S/E/S/E/S/S/E/S/E/S/S/E/E" rhyme="abbcacbdceeffghhgg">
  <lg n="1" type="stanza">
    <l n="1">Doglia mi reca nello core ardire</l>
  </lg>
</div>
```

Here the *met* attribute specifies a metrical pattern for each of the twenty-one lines making up a stanza of the *canzone*. Each stanza inherits this definition from the parent <div> element. The *rhyme* attribute specifies a rhyme scheme for each stanza, in the same way.

In the metrical notation used here, the letter E represents a line containing nine syllables which may or may not be metrically prominent, a tenth which is prominent and an optional non-prominent eleventh syllable. The letter 'S' is used to represent a line containing five syllables which may or may not be metrically prominent, a sixth which is prominent and an optional non-prominent seventh syllable. A suitable definition for this notation might be given by a <metDecl> element like the following:

```
<metDecl type="met" pattern="((E|S)/)+">
  <metSym value="E" terminal="false">xxxxxxxxx+o</metSym>
  <metSym value="S" terminal="false">xxxxx+o</metSym>
  <metSym value="x">metrically prominent or non-prominent</metSym>
  <metSym value="+">metrically prominent</metSym>
  <metSym value="o">optional non prominent</metSym>
  <metSym value="/">line division</metSym>
</metDecl>
```

As noted above, the metrical pattern specified on the <div> applies to each <lg> (stanza) element contained within the <div>. In fact however, after seven stanzas of this type, there is a final stanza, known as a *commiato* or envoi, which follows a different metrical and rhyming scheme. The solution to this problem is simply to specify a new *met* attribute on the eighth stanza itself, which will override the default value inherited from parent <div>, as follows:

```
<div met="[...]">
  <lg>
    <l> ... </l>
  </lg>
  <lg type="commiato"
    met="E/S/S/E/S/E/S/S/E/E" rhyme="abbcdeedd">
    <l n="1">Canzone, presso di qui è una donna</l>
  </lg>
</div>
```

Note that, in the same way as for the *real* attribute, over-riding of this kind does not affect subsequent elements at the same hierarchic level. Any <lg> element following the *commiato* above would be assumed to use the same metrical and rhyming scheme as the one preceding the *commiato*. Moreover, although it is quite regular (in the sense that the last stanza of each *canzone* is a *commiato*), the over-riding must be specified for each case.

## 6.5 Rhyme

The *rhyme* attribute is used to specify the rhyme pattern of a verse form. It should not be confused with the <rhyme> element, which is used to mark the actual rhyming word or words:

**<rhyme>** marks the rhyming part of a metrical line.

Like the *met* attribute, the *rhyme* attribute can be used with a user-specified notation documented by the **<metDecl>** element in the TEI header. Unlike *met*, however, the *rhyme* attribute has a default notation; if this default notation is used, no **<metDecl>** element need be given.

The default notation for rhyme offers the ability to record patterns of rhyming lines, using the traditional notation in which distinct letters stand for rhyming lines. For a work in rhyming couplets, like the Pope example above, the *rhyme* attribute simply specifies *aa*, indicating that pairs of adjacent lines rhyme with each other. For a slightly more complex scheme, applicable to groups of four lines, in which lines 1 and 3 rhyme, as do lines 2 and 4, this attribute would have the value *abab*. The traditional Spenserian stanza has the pattern *ababbcbcc*, indicating that within each nine line stanza, lines 1 and 3 rhyme with each other, as do lines 2, 4, 5 and 7, and lines 6, 8 and 9.

Non-rhyming lines within such a group may be represented using a hyphen or an *x*, as in the following example:

```
<lg rhyme="aa-a">
  <l>Why, all the Saints and Sages who discuss'd</l>
  <l>Of the Two Worlds so learnedly, are thrust</l>
  <l>Like foolish Prophets forth; their Words to Scorn</l>
  <l>Are scatter'd, and their Mouths are stopt with Dust. </l>
</lg>
```

The **<rhyme>** element may be used to mark the words (or parts of words) which rhyme according to a predefined pattern:

```
<lg type="couplet" rhyme="aa">
  <l>Outside in the distance a wildcat did <rhyme>growl</rhyme>
  </l>
  <l>Two riders were approaching and the wind began to <rhyme>howl</rhyme>
  </l>
</lg>
```

The *label* attribute is used to specify which parts of a rhyme scheme a given set of rhyming words represent:

```
<lg type="quatrain" rhyme="abab">
  <l>I wander thro' each charter'd <rhyme label="a">street</rhyme>,</l>
  <l>Near where the charter'd Thames does <rhyme label="b">flow</rhyme>,</l>
  <l>And mark in every face I <rhyme label="a">meet</rhyme>
  </l>
  <l>Marks of weakness, marks of <rhyme label="b">woe</rhyme>.</l>
</lg>
<lg rhyme="abab">
  <l>In every cry of every <rhyme label="a">Man</rhyme>
  </l>
  <l>In every Infant's cry of <rhyme label="b">fear</rhyme>,</l>
  <l>In every voice, in every <rhyme label="a">ban</rhyme>,</l>
  <l>The mind-forg'd manacles I <rhyme label="b">hear</rhyme>.</l>
</lg>
```

Within a given scope, all **<rhyme>** elements with the same value for their *label* attribute are assumed to rhyme with each other: thus, in the above example, the two rhymes labelled *a* in the first stanza rhyme with each other, but not necessarily with those labelled *a* in the second stanza. The scope is defined by the nearest ancestor element for which the *rhyme* attribute has been supplied.

The **<rhyme>** element can appear anywhere within a verse line, and not necessarily around a single word. It can thus be used to mark quite complex internal rhyming schemes, as in the following example:

```

<lg rhyme="ABCCBBA">
  <l>The sunlight on the <rhymer label="A">garden</rhymer>
  </l>
  <l>
    <rhymer label="A">Harden</rhymer>s and grows <rhymer label="B">cold</rhymer>,</l>
  <l>We cannot cage the <rhymer label="C">minute</rhymer>
  </l>
  <l>Wi<rhymer label="C">thin it</rhymer>s nets of <rhymer label="B">gold</rhymer>
  </l>
  <l>When all is <rhymer label="B">told</rhymer>
  </l>
  <l>We cannot beg for <rhymer label="A">pardon</rhymer>.</l>
</lg>

```

This mechanism, although reasonably simple for simple cases, may not be appropriate for more complex applications. In general, rhyme may be considered as a special form of ‘correspondence’, and hence encoded using the mechanisms defined for that purpose in section 16.4. *Correspondence and Alignment*. Similar considerations apply to other metrical features such as alliteration or assonance.

To use the correspondence mechanisms to represent the complex rhyming pattern of the above example, each <rhymer> element must be given a unique identifier, as follows:

```

<lg rhyme="AB-BBA">
  <l>The sunlight on the <rhymer xml:id="V-A1">garden</rhymer>
  </l>
  <l>
    <rhymer xml:id="V-A2">Harden</rhymer>s and grows <rhymer xml:id="V-B1">cold,</rhymer>
  </l>
  <l>We cannot cage the <rhymer xml:id="V-C1">minute</rhymer>
  </l>
  <l>Wi<rhymer xml:id="V-C2">thin it</rhymer>s nets of <rhymer xml:id="V-B2">gold</rhymer>
  </l>
  <l>When all is <rhymer xml:id="V-B3">told</rhymer>
  </l>
  <l>We cannot beg for <rhymer xml:id="V-A3">pardon</rhymer>.</l>
</lg>

```

Now that each rhyming word, or part-word, has been tagged and allocated an arbitrary identifier, the general purpose <link> element may be used to indicate which of the <rhymer> elements share the same rhyme, as follows:

```

<linkGrp type="rhyme">
  <link target="#V-A1 #V-A2 #V-A3"/>
  <link target="#V-B1 #V-B2 #V-B3"/>
  <link target="#V-C1 #V-C2"/>
</linkGrp>

```

For further discussion of the <link> and <linkGrp> element, see section 16.4. *Correspondence and Alignment*.

The <rhymer> and <caesura> phrase level elements are made available by the `model.lPart` class when the module defined by this chapter is included in a schema.

## 6.6 Metrical Notation Declaration

When the module defined in this chapter is included in a schema, a specialized element is optionally available in the <encodingDesc> element of the TEI header to document the metrical notation used in marking up a text.

**<metDecl>** (metrical notation declaration) documents the notation employed to represent a metrical pattern when this is specified as the value of a *met*, *real*, or *rhyme* attribute on any structural element of a metrical text (e.g. <lg>, <l>, or <seg>).

**@pattern** (regular expression pattern) specifies a regular expression defining any value that is legal for this notation.

**<metSym>** (metrical notation symbol) documents the intended significance of a particular character or character sequence within a metrical notation, either explicitly or in terms of other symbol elements in the same metDecl.

**@value** specifies the character or character sequence being documented.

**@terminal** specifies whether the symbol is defined in terms of other symbols (*terminal* is set to false) or in prose (*terminal* is set to true).

As with other components of the header, metrical notation may be specified either formally or informally. In a formal specification, every symbol used in the metrical notation must be documented by a corresponding <metSym> element; in an informal one, only a brief prose description of the way in which the notation is used need be given. In either case, the optional *pattern* attribute may be used to supply a regular expression which a processor can use to validate expressions in the intended notation. The following constraints apply:

- if *pattern* is supplied, any notation used which does not conform to it should be regarded as invalid
- if any <metSym> is defined, then any notation using undefined symbols should be regarded as invalid
- if both *pattern* and *symbol* are defined, then every symbol appearing explicitly within *pattern* must be defined
- symbols which are not matched by *pattern* may be defined within a <metDecl> element

As a simple example, consider the case of the notation in which metrical prominence, metrical feet, and line boundaries are all to be encoded. Legal specifications in this notation may be written for any sequence of metrically prominent or non-prominent features, optionally separated by foot or metrical line boundaries at arbitrary points. Assuming that the symbol *1* is used for metrical prominence, *0* for non-prominence, *|* for foot boundary and */* for line boundary, then the following declaration achieves this object:

```
<metDecl pattern="((1|0)+\|?/?)*">
  <metSym value="1">metrical prominence</metSym>
  <metSym value="0">metrical non-prominence</metSym>
  <metSym value="|">foot boundary</metSym>
  <metSym value="/">metrical line boundary</metSym>
</metDecl>
```

The same notation might also be specified less formally, as follows:

```
<metDecl>
  <p>Metrically prominent syllables are marked '1' and other syllables '0'. Foot divisions are marked by a vertical bar, and line divisions with a solidus.</p>
  <p>This notation may be applied to any metrical unit, of any size (including, for example, individual feet as well as groups of lines).</p>
</metDecl>
```

Note that in this case, because the *pattern* attribute has not been supplied, no processor can validate *met* attribute values within the text which use this metrical notation.

For more complex cases, it will often be more convenient to define a notation incrementally. The *terminal* attribute should be used to indicate for a given symbol whether or not it may be re-defined in terms of other symbols used within the same notation. For example, here is a notation for encoding classical metres, in which symbols are provided for the most common types of foot. These symbols are themselves documented within the same notation, in terms of more primitive long and short syllables:

```

<metDecl pattern="[DTIS3A]+">
  <metSym n="dactyl" value="D"
    terminal="false">-oo</metSym>
  <metSym n="trochee" value="T"
    terminal="false">-o</metSym>
  <metSym n="iamb" value="I" terminal="false">o-</metSym>
  <metSym n="spondee" value="S"
    terminal="false">--</metSym>
  <metSym n="tribrach" value="3"
    terminal="false">ooo</metSym>
  <metSym n="anapaest" value="A"
    terminal="false">oo-</metSym>
  <metSym value="o">short syllable</metSym>
  <metSym value="-">long syllable</metSym>
</metDecl>

```

Note here the use of the global *n* attribute to supply an additional name for the symbols being documented.

Where an encoder wishes to use more than one different pattern for metrical notation, multiple `<metDecl>` elements may be included in the `<encodingDesc>`, each supplied with an *xml:id*. The *decls* attribute may be used in the text of the document to specify which `<metDecl>` is in force at a particular point in the text. In this example, two `<metDecl>`s are defined in the header, one with an English verse pattern and one with a French pattern. In the body of the document, there are two `<div>` elements, one declaring the English pattern and one the French:

```

<encodingDesc>
  <!-- ... -->
  <metDecl xml:id="md_en" type="met"
    pattern="((SU|US)USUSUSUS/)">
    <metSym value="S">stressed syllable</metSym>
    <metSym value="U">unstressed syllable</metSym>
    <metSym value="/">metrical line boundary</metSym>
  </metDecl>
  <metDecl xml:id="md_fr" type="met"
    pattern="(AAAAAT|AAAAT(A)?)">
    <metSym value="T">syllabe tonique</metSym>
    <metSym value="A">syllabe atone</metSym>
    <metSym value="|">pause métrique</metSym>
  </metDecl>
  <!-- ... -->
</encodingDesc>
  <!-- ... -->
<body>
  <div decls="#md_en">
    <lg>
      <l>
<!-- ... -->
      </l>
<!-- ... -->
    </lg>
  </div>
  <div decls="#md_fr">
    <lg>
      <l>
<!-- ... -->
      </l>
<!-- ... -->
    </lg>
  </div>

```

```

</lg>
</div>
</body>

```

## 6.7 Encoding Procedures for Other Verse Features

A number of procedures that may be of particular concern to encoders of verse texts are dealt with elsewhere in these guidelines. Some aspects of layout and physical appearance, especially important in the case of free verse, are dealt with in chapter 11. *Representation of Primary Sources*. Some initial recommendations for the encoding of phonetic or prosodic transcripts, which may be helpful in the analysis of sound structures in poetry, are to be found in chapter 8. *Transcriptions of Speech*; it may also be found convenient to use standard entity names (those proposed for the International Phonetic Alphabet suggest themselves) to mark positions of suprasegmentals such as primary and secondary stress, or other aspects of accentual structure.

As already indicated, chapter 16. *Linking, Segmentation, and Alignment* contains much which will be found useful for the aligning of multiple levels of commentary and structure within verse analysis. Encoders of verse (as of other types of literary text) will frequently wish to attach identifying labels to portions of text that are not part of a system of hierarchical divisions, may overlap with one another, and/or may be discontinuous; for instance passages associated with particular characters, themes, images, allusions, topoi, styles, or modes of narration. Much of the computerized analysis of verse seems likely to require dividing texts up into blocks in this way. The `<span>` element discussed in 17.3. *Spans and Interpretations* provides the means for doing this. Finally, the procedures for the tagging of feature structures, described in chapter 18. *Feature Structures*, provide a powerful means of encoding a wide variety of aspects of verse literature, including not only the metrical structures discussed above, but also such stylistic and rhetorical features as metaphor.

For other features it must for the time being be left to encoders to devise their own terminology. Elements such as `<metaphor tenor="..." vehicle="..."> ... </metaphor>` might well suggest themselves; but given the problems of definition involved, and the great richness of modern metaphor theory, it is clear that any such format, if predefined by these Guidelines, would have seemed objectionable to some and excessively restrictive to many. Leaving the choice of tagging terminology to individual encoders carries with it one vital corollary, however: the encoder must be utterly explicit, in the TEI header, about the methods of tagging used and the criteria and definitions on which they rest. Where no formal elements are currently proposed, such information may readily be given as simple prose description within the `<encodingDesc>` element defined in section 2.3. *The Encoding Description*.

## 6.8 Module for Verse

The module described in this chapter makes available the following components:

**Module verse: Verse structures**

- *Elements defined:* caesura metDecl metSym rhyme
- *Classes defined:* att.enjamb att.metrical

The selection and combination of modules to form a TEI schema is described in 1.2. *Defining a TEI Schema*.

## 7 Performance Texts

This module is intended for use when encoding printed dramatic texts, screen plays or radio scripts, and written transcriptions of any other form of performance.

Section 7.1. *Front and Back Matter* discusses elements such as cast lists, which can appear only in the front or back matter of printed dramatic texts. Section 7.2. *The Body of a Performance Text* discusses the structural components of performance texts: these include major structural divisions such as acts and scenes (section 7.2.1. *Major Structural Divisions*); individual speeches (section 7.2.2. *Speeches and Speakers*); groups of speeches (section 7.2.3. *Grouped Speeches*); stage directions (section 7.2.4. *Stage Directions*); and the elements making up individual speeches (section 7.2.5. *Speech Contents*). Section 7.2.6. *Embedded Structures* discusses ways of encoding units which cross the simple hierarchic structure so far defined, such as embedded songs or masques. Finally, section 7.3. *Other Types of Performance Text* discusses a small number of additional elements characteristic of screen plays and radio or television scripts, as well as some elements for representing technical stage directions such as lighting or blocking.

The default structure for dramatic texts is similar to that defined by chapter 4. *Default Text Structure*, as further discussed in section 7.2.1. *Major Structural Divisions*.

Two element classes are used by this module. The `model.frontPart.drama` class supplies specialized elements which can appear only in the front or back matter of performance texts. The `model.stageLike` class supplies a set of elements for stage directions and similar items such as camera movements, which can occur between or within speeches.

### 7.1 Front and Back Matter

In dramatic texts, as in all TEI-conformant documents, the header element is followed by a `<text>` element, which contains optional front and back matter, and either a `<body>` or else a `<group>` of nested `<text>` elements. For more information on these, see chapter 4. *Default Text Structure*.

The `<front>` and `<back>` elements are most likely to be of use when encoding preliminary materials in published performance texts. When the module defined by this chapter is included in a schema, the following additional elements not generally found in other forms of text become available as part of the front or back matter:

- `<performance>`** contains a section of front or back matter describing how a dramatic piece is to be performed in general or how it was performed on some specific occasion.
- `<prologue>`** contains the prologue to a drama, typically spoken by an actor out of character, possibly in association with a particular performance or venue.
- `<epilogue>`** contains the epilogue to a drama, typically spoken by an actor out of character, possibly in association with a particular performance or venue.
- `<set>`** (setting) contains a description of the setting, time, locale, appearance, etc., of the action of a play, typically found in the front matter of a printed performance text (not a stage direction).
- `<castList>`** (cast list) contains a single cast list or dramatis personae.

Elements for encoding each of these specific kinds of front matter are discussed in the remainder of this section, in the order given above. In addition, the front matter of dramatic texts may include the same elements as that of any other kind of text, notably title pages and various kinds of text division, as discussed in section 4.5. *Front Matter*. The encoder may choose to ignore the specialized elements discussed in this section and instead use constructions of the type `<div type="performance">` or `<div1 type="set">`.

Most other material in the front matter of a performance text will be marked with the default text structure elements described in chapter 4. *Default Text Structure*. For example, the title page, dedication, other commendatory material, preface, etc., in a printed text should be encoded using `<div>` or `<div1>` elements, containing headings, paragraphs, and other core tags.

#### 7.1.1 The Set Element

A special form of note describing the setting of a dramatic text (that is, the time and place of its action) is sometimes found in the front matter.

- `<set>`** (setting) contains a description of the setting, time, locale, appearance, etc., of the action of a play, typically found in the front matter of a printed performance text (not a stage direction).

Descriptions of the setting may also appear as initial stage directions in the body of the play, but such descriptions should be marked as stage directions, not `<set>`. The `<set>` element should be used only where the description forms part of the front matter, as in the following examples:

```

<front>
  <castList>
    <castItem> ... </castItem>
  </castList>
  <set>
    <p>The action of the play is set in Chicago's
      Southside, sometime between World War II and the
      present.</p>
  </set>
</front>

```

```

<front>
  <titlePage type="half-title">
    <docTitle>
      <titlePart>Peer Gynt</titlePart>
    </docTitle>
  </titlePage>
  <div type="copyright_page"/>
  <div type="Contents"/>
  <div type="Introduction"/>
  <div type="note">

      </castItem>
    </castList>
  </div>
  <set>
    <p>The action, which opens in the beginning of the nineteenth
      century, and ends around the 1860s, takes place partly in
      Gudbrandsdalen, and on the mountains around it, partly on the coast
      of Morocco, in the desert of Sahara, in a madhouse at Cairo, at sea,
      etc.</p>
  </set>
  <performance>
    <p>
<!-- ... -->
    </p>
  </performance>
</front>

```

### 7.1.2 Prologues and Epilogues

Many plays in the Western tradition include in their front matter a prologue, spoken by an actor, generally not in character. Similar speeches often also occur at the end of the play, as epilogues. The elements `<prologue>` and `<epilogue>` are provided for the encoding of such features within the front or back matter, where appropriate.

**<prologue>** contains the prologue to a drama, typically spoken by an actor out of character, possibly in association with a particular performance or venue.

**<epilogue>** contains the epilogue to a drama, typically spoken by an actor out of character, possibly in association with a particular performance or venue.

A prologue may be encoded just like a distinct poem, as in the following example:

```
<front>
  <prologue>
    <head>Prologue, spoken by <name>Mr. Hart</name>
    </head>
    <l>Poets like Cudgel'd Bullys, never do</l>
    <l>At first, or second blow, submit to you;</l>
    <l>But will provoke you still, and ne're have done,</l>
    <l>Till you are weary first, with laying on:</l>
    <l>We patiently you see, give up to you,</l>
    <l>Our Poets, Virgins, nay our Matrons too.</l>
  </prologue>
  <castList>
    <head>The Persons</head>
    <castItem> ... </castItem>
  </castList>
  <set>
    <head>The SCENE</head>
    <p>London</p>
  </set>
</front>
```

A prologue or epilogue may also be encoded as a speech, using the <sp> element described in section 3.12.2. *Core Tags for Drama*. This is particularly appropriate where stage directions, etc., are involved, as in the following example:

```
<epilogue>
  <head>Written by <name>Colley Cibber, Esq</name>
    and spoken by <name>Mrs. Cibber</name>
  </head>
  <sp>
    <lg type="stanza">
      <l>Since Fate has robb'd me of the hapless Youth,</l>
      <l>For whom my heart had hoarded up its truth;</l>
      <l>By all the Laws of Love and Honour, now,</l>
      <l>I'm free again to chuse, – and one of you</l>
    </lg>
    <lg type="stanza">
      <l>Suppose I search the sober Gallery; – No,</l>
      <l>There's none but Prentices – & Cuckolds all a row:</l>
      <l>And these, I doubt, are those that make 'em so.</l>
    </lg>
    <stage>Pointing to the Boxes.</stage>
    <lg type="stanza">
      <l>'Tis very well, enjoy the jest:</l>
    </lg>
  </sp>
</epilogue>
```

In cases where the prologue or epilogue is clearly a significant part of the dramatic action, it may be preferable to include it in the body of a text, rather than in the front or back matter. In such cases, the encoder (and theatrical tradition) will determine whether or not to regard it as a new scene or division, or simply the final speech in the play. In the First Folio version of Shakespeare's *Tempest*, for example, Prospero's final speech is clearly marked off as a distinct textual unit by the headings and layout of the page, and might therefore be encoded as back matter:

```

<text>
  <body>
    <div1 type="scene">
      <sp>
        <l part="Y">I'll deliver all,</l>
        <l>And promise you calme Seas, auspicious gales,</l>
        <l>Be free and fare thou well: please you, draw neere.</l>
        <stage>Exeunt omnes.</stage>
      </sp>
    </div1>
  </body>
  <back>
    <epilogue>
      <head>Epilogue, spoken by Prospero.</head>
      <sp>
        <l>Now my Charmes are all ore-throwne,</l>
        <l>And what strength I have's mine owne</l>
        <l>As you from crimes would pardon'd be,</l>
        <l>Let your Indulgence set me free.</l>
      </sp>
      <stage>Exit</stage>
    </epilogue>
    <set>
      <p>The Scene, an un-inhabited Island.</p>
    </set>
    <castList>
      <head>Names of the Actors.</head>
      <castItem>Alonso, K. of Naples</castItem>
      <castItem>Sebastian, his Brother.</castItem>
      <castItem>Prospero, the right Duke of Millaine.</castItem>
    </castList>
    <trailer>FINIS</trailer>
  </back>
</text>

```

In many modern editions, the editors have chosen to regard Prospero's speech as a part of the preceding scene:

```

<sp>
  <speaker>Prospero</speaker>
  <l part="Y">I'll deliver all,</l>
  <l>And promise you calm seas, auspicious gales,</l>
  <l>Be free and fare thou well. <stage type="exit">Exit Ariel</stage>
  Please you, draw near. <stage type="exit">Exeunt all but Prospero</stage>
  <note place="margin">Epilogue</note>
</l>
  <l>Now my charms are all o'erthrown,</l>
  <l>And what strength I have's mine own</l>
  <l>As you from crimes would pardoned be,</l>
  <l>Let your indulgence set me free.</l>
</sp>
<stage type="mix">He awaits applause, then exit.</stage>

```

### 7.1.3 Records of Performances

Performance texts are not only printed in books to be read, they are also performed. It is common practice therefore to include within the front matter of a printed dramatic text some brief account of particular performances, using the following element:

**<performance>** contains a section of front or back matter describing how a dramatic piece is to be performed in general or how it was performed on some specific occasion.

The **<performance>** element may be used to group any and all information relating to the actual performance of a play or screenplay, whether it specifies how the play should be performed in general or how it was performed in practice on some occasion.

Performance information may include complex structures such as cast lists, or paragraphs describing the date and location of a performance, details about the setting portrayed in the performance and so forth. (See the discussion of these specialized structures in section 7.1. *Front and Back Matter* above.) If information for more than one performance is being recorded, then more than one **<performance>** element should be used, wherever possible.

Names of persons, places, and dates of particular significance within the performance record may be explicitly marked using the general purpose **<name>**, **<rs type="place">** and **<date>** elements described in section 3.5.4. *Dates and Times*. No particular elements for such features as stagehouses, directors, etc., are proposed at this time.

For example:

```
<performance>
  <head>Death of a Salesman</head>
  <p>A New Play by Arthur Miller</p>
  <p>Staged by Elia Kazan</p>
  <castList>
    <head>Cast</head>
    <note rend="small type flush left"
      place="inline">(in order of appearance)</note>
    <castItem>
      <role>Willy Loman</role>
      <actor>Lee J. Cobb</actor>
    </castItem>
    <castItem>
      <role>Linda</role>
      <actor>Mildred Dunnock</actor>
    </castItem>
    <castItem>
      <role>Biff</role>
      <actor>Arthur Kennedy</actor>
    </castItem>
    <castItem>
      <role>Happy</role>
      <actor>Cameron Mitchell</actor>
    </castItem>
  <!-- ... -->
</castList>
  <p>The setting and lighting were designed by
  <name>Jo Mielziner</name>.</p>
  <p>The incidental music was composed by <name>Alex North</name>.</p>
  <p>The costumes were designed by <name>Julia Sze</name>.</p>
  <p>Presented by <name rend="unmarked">Kermit Bloomgarden</name>
  and <name rend="unmarked">Walter Fried</name> at the
  <rs type="place">Morosco Theatre in New York</rs> on
  <date when="1949-02-10">February 10, 1949</date>.</p>
</performance>
```

Or:

```
<performance>
  <p>La Machine Infernale a été
  représentée pour la première fois au
```

```

<rs type="place-theatre">théâtre Louis-Jouvet</rs>
  <rs type="place-theatre">(Comédie des
    Champs-élysées)</rs>
  <date>le 10 avril 1934</date>,
  avec les décors et les costumes de
  <name>Christian Bérard.</name> ... </p>
</performance>

```

#### 7.1.4 Cast Lists

A *cast list* is a specialized form of list, conventionally found at the start or end of a play, usually listing all the speaking and non-speaking roles in the play, often with additional description (‘Cataplasma, a maker of Periwiggies and Attires’) or the name of an actor or actress (‘Old Lady Squeamish. Mrs Rutter’). Cast lists may be encoded with the general purpose `<list>` element described in section 3.7. *Lists*, but for more detailed work the following specialized elements are provided:

**<castList>** (cast list) contains a single cast list or *dramatis personae*.

**<castGroup>** (cast list grouping) groups one or more individual `castItem` elements within a cast list.

**<castItem>** (cast list item) contains a single entry within a cast list, describing either a single role or a list of non-speaking roles.

`@type` characterizes the cast item.

A `<castItem>` element may contain any mixture of elements taken from the `model.castItemPart` class, members of which (when this module is included) are:

**<role>** contains the name of a dramatic role, as given in a cast list.

**<roleDesc>** (role description) describes a character's role in a drama.

**<actor>** contains the name of an actor appearing within a cast list.

Cast lists often have an internal structure of their own; it is quite usual to find, for example, nobility and commoners, or male and female roles, presented in different groups or sublists. Roles are also often grouped together by their function, for example:

- Sons of Cato:
  - Portius
  - Marcus

A cast list relating to a specific performance may be accompanied by notes about the time or place of that performance, indicating (for example) the name of the theatre where the play was first presented, the name of the producer or director, and so forth. When the cast list relates to a specific performance, it should be embedded within a `<performance>` element (see section 7.1.3. *Records of Performances*), as in the following example:

```

<performance>
  <p>The first performance in Great Britain of <title>Waiting for
    Godot</title> was given at the Arts Theatre, London, on
    <date when="1955-08-03">3rd August 1955</date>. It was directed by
    <name>Peter Hall</name>, and the décor was by <name>Peter
    Snow</name>. The cast was as follows:</p>
  <castList>
    <castItem>Estragon: Peter Woodthorpe</castItem>
    <castItem>Vladimir: Paul Daneman</castItem>
    <castItem> ... </castItem>
  </castList>
</performance>

```

In this example, the `<castItem>` elements have no substructure. If desired, however, their components may be more finely distinguished using the elements `<role>`, `<roleDesc>`, and `<actor>`. For example, the second cast item above might be encoded as follows:

```
<castItem>
  <role xml:id="vlad">Vladimir</role>:
<actor>Paul Daneman</actor>
</castItem>
```

The global *xml:id* attribute may be used to specify a unique identifier for the `<role>` element, where it is desired to link speeches within the text explicitly to the role, using the *who* attribute, as further discussed in section 7.2.2. *Speeches and Speakers* below.

The occasionally lengthy descriptions of a role sometimes found in written play scripts may be marked using the `<roleDesc>` element, as in the following example:

```
<castItem>
  <role>Tom Thumb the Great</role>
  <roleDesc>a little hero with a great soul, something violent in his
    temper, which is a little abated by his love for Huncamunca</roleDesc>
  <actor>Young Verhuyk</actor>
</castItem>
```

For non-speaking or un-named roles, a `<castItem>` may contain a `<roleDesc>` without an accompanying `<role>`, for example

```
<castItem>
  <roleDesc>Costermonger</roleDesc>
</castItem>
```

When a list of such minor roles is given together, the *type* attribute of the `<castItem>` should indicate that it contains more than one role, by taking a value such as *list*. The encoder may or may not elect to encode each separate constituent within such a composite `<castItem>`. Thus, either of the following is acceptable:

```
<castItem type="list">Constables, Drawer, Turnkey, etc.</castItem>
<castItem type="list">
  <roleDesc>Constables,</roleDesc>
  <roleDesc>Drawer,</roleDesc>
  <roleDesc>Turnkey,</roleDesc>
  etc.
</castItem>
```

A group of cast items forming a distinct subdivision of a cast list may be marked as such by using the special purpose `<castGroup>` element. The *rend* attribute may be used to indicate whether this grouping is indicated in the text by layout alone (i.e. the use of whitespace), by long braces or by some other means. A `<castGroup>` may contain an optional heading (represented as usual by a `<head>` element) followed by a series of `<castItem>` elements:

```
<castGroup rend="braced">
  <head>friends of Mathias</head>
  <castItem>
    <role>Walter</role>
    <actor>Mr Frank Hall</actor>
  </castItem>
  <castItem>
    <role>Hans</role>
```

```

    <actor>Mr F.W. Irish</actor>
  </castItem>
</castGroup>

```

Alternatively, the encoder may prefer to regard the phrase ‘friends of Mathias’ as a role description, and encode the above example as follows:

```

<castGroup rend="braced">
  <roleDesc>friends of Mathias</roleDesc>
  <castItem>
    <role>Walter</role>
    <actor>Mr Frank Hall</actor>
  </castItem>
  <castItem>
    <role>Hans</role>
    <actor>Mr F.W. Irish</actor>
  </castItem>
</castGroup>

```

This version has the advantage that all role descriptions are treated alike, rather than in some cases being treated as headings. On the other hand there are also cases, such as the following, where the role description does function more like a heading:

```

<castList>
  <castGroup>
    <head rend="braced">Mendicants</head>
    <castItem>
      <role>Aafaa</role>
      <actor>Femi Johnson</actor>
    </castItem>
    <castItem>
      <role>Blindman</role>
      <actor>Femi Osofisan</actor>
    </castItem>
    <castItem>
      <role>Goyi</role>
      <actor>Wale Ogunyemi</actor>
    </castItem>
    <castItem>
      <role>Cripple</role>
      <actor>Tunji Oyelana</actor>
    </castItem>
  </castGroup>
  <castItem>
    <role>Si Bero</role>
    <roleDesc>Sister to Dr Bero</roleDesc>
    <actor>Deolo Adedoyin</actor>
  </castItem>
  <castGroup>
    <head rend="braced">Two old women</head>
    <castItem>
      <role>Iya Agba</role>
      <actor>Nguba Agolia</actor>
    </castItem>
  </castGroup>
</castList>

```

```

    <castItem>
      <role>Iya Mate</role>
      <actor>Bopo George</actor>
    </castItem>
  </castGroup>
  <castItem>
    <role>Dr Bero</role>
    <roleDesc>Specialist</roleDesc>
    <actor>Nat Okoro</actor>
  </castItem>
  <castItem>
    <role>Priest</role>
    <actor>Gbenga Sonuga</actor>
  </castItem>
  <castItem>
    <role>The old man</role>
    <roleDesc>Bero's father</roleDesc>
    <actor>Dapo Adelugba</actor>
  </castItem>
</castList>

```

## 7.2 The Body of a Performance Text

The body of a performance text may be divided into structural units, variously called acts, scenes, stasima, entr'actes, etc. All such formal divisions should be encoded using an appropriate text-division element (<div>, <div1>, <div2>, etc.), as further discussed in section 7.2.1. *Major Structural Divisions*. Whether divided up into such units or not, all performance texts consist of sequences of speeches (see 7.2.2. *Speeches and Speakers*) and stage directions (see 7.2.4. *Stage Directions*). In musical performances, it is also common to identify groups of speeches which act as a single unit, sometimes called a *number*; such units typically float within the structural hierarchy at the same level as speeches preceding or following them and cannot therefore be treated as text-divisions. (see 7.2.3. *Grouped Speeches*). Speeches will generally consist of a sequence of *chunk*-level items: paragraphs, verse lines, stanzas, or (in case of uncertainty as to whether something is verse or prose) <ab> elements (see 7.2.5. *Speech Contents*).

The boundaries of formal units such as verse lines or paragraphs do not always coincide with speech boundaries. Units such as songs may be discontinuous or shared among several speakers. As described below in section 7.2.6. *Embedded Structures*, such fragmentation may be encoded in a relatively simple fashion using the linkage and aggregation mechanisms defined in chapter 16. *Linking, Segmentation, and Alignment*.

### 7.2.1 Major Structural Divisions

Large divisions in drama such as acts, scenes, stasima, or entr'actes are indicated by numbered or unnumbered <div> elements, as described in section 4.1. *Divisions of the Body*. The *type* and *n* attributes may be used to define the type of division being marked, and to provide a name or number for it, as in the following example:

```

<body>
  <div1 type="scene" n="1">
    <head>Night–Faust's Study (i)</head>
  </div1>
  <div1 type="scene" n="2">
    <head>Outside the City Gate</head>
  </div1>
</body>

```

Where the largest divisions of a performance text are themselves subdivided, most obviously in the case of plays traditionally divided into acts and scenes, further nested text-division elements may be used, as in this example:

```

<body>
  <div1 type="act" n="1">
    <head>Act One</head>
    <div2 type="scene" n="1">
      <stage>Pa Ubu, Ma Ubu</stage>
      <sp>
        <speaker>Pa Ubu</speaker>
        <p>Pschitt!</p>
      </sp>
    </div2>
    <div2 type="scene" n="2">
      <stage>A room in Pa Ubu's house, where a magnificent
        collation is set out</stage>
    </div2>
  </div1>
  <div1 type="act" n="2">
    <head>Act Two</head>
    <div2 type="scene" n="1">
      <head>Scene One</head>
    </div2>
    <div2 type="scene" n="2">
      <head>Scene Two</head>
    </div2>
  </div1>
</body>

```

In the example above, the `<div2>` element has been used to represent the ‘French scene’ convention, (where the entrance of each new set of characters is marked as a distinct unit in the text) and the `<div1>` element to represent the acts into which the play is divided. The elements chosen are determined only by the hierarchic position of these units in the text as a whole. If the text had no acts, but only scenes, then the scenes might be represented by `<div1>` elements. Equally, if a play is divided only into ‘acts’, with no smaller subdivisions, then the `<div1>` element might be used to represent acts. The *type* should be used, as above, to make explicit the name associated with a particular category of subdivision.

As an alternative to the use of numbered divisions, the encoder may represent all subdivisions with the same element, the unnumbered `<div>`. The second act in the above example would then be represented as follows:

```

<div type="act" n="2">
  <head>Act Two</head>
  <div type="scene" n="1">
    <head>Scene One</head>
  </div>
  <div type="scene" n="2">
    <head>Scene Two</head>
  </div>
</div>

```

For further discussion of the use of numbered and unnumbered divisions, see section 4.1. *Divisions of the Body*.

### 7.2.2 Speeches and Speakers

The following elements are used to identify speeches and speakers in a performance text:

**<sp>** (speech) contains an individual speech in a performance text, or a passage presented as such in a prose or verse text.

**<speaker>** contains a specialized form of heading or label, giving the name of one or more speakers in a dramatic text or fragment.

As noted above, the structure of many performance texts may be analysed as multiply hierarchic: a scene of a verse play, for example, may be divided into speeches and, at the same time, into verse lines. The end of a line may or may not coincide with the end of a speech, and vice versa. Other structures, such as songs, may be discontinuous or split up over several speeches. For some purposes it will be appropriate to regard the verse-structure as the fundamental organizing principle of the text, and for others the speech structure; in some cases, the choice between the two may be arbitrary. The discussion in the remainder of this chapter assumes that it is the speech-based hierarchy which most prominently determines the structure of performance texts, but the same mechanisms could be employed to encode a view of a performance text in which individual speeches were entirely subordinate to the formal units of prose and verse. For more detailed discussion and examples of various treatments of this fundamental issue, refer to chapter 20. *Non-hierarchical Structures*.

The *who* attribute and the `<speaker>` element are both used to indicate the speaker or speakers of a speech, but in rather different ways. The `<speaker>` element is used to encode the word or phrase actually used within the source text to indicate the speaker: it may contain any string or prefix, and may be thought of as a highly specialized form of stage direction. The *who* attribute however contains one or more pointer values, each of which indicates one or more other XML elements documenting the character to whom the speech is assigned. Typically, this attribute might point to a `<person>` element in the TEI header 15.2.2. *The Participant Description*, to a `<role>` element in the cast list 7.1.4. *Cast Lists*, or even to some external source such as an online handbook of dramatic roles. The most usual case is that the pointer value supplied (prefixed by a sharp sign) corresponds with the value of an *xml:id* attribute, used elsewhere in the document to identify a particular element, as in the following examples:

```
<castList>
  <castItem>
    <role xml:id="menae">Menaechmus</role>
  </castItem>
  <castItem>
    <role xml:id="penic">Peniculus</role>
  </castItem>
</castList>
<sp who="#menae">
  <speaker>Menaechmus</speaker>
  <l>Responde, adulescens, quaeso, quid nomen tibist?</l>
</sp>
<sp who="#penic">
  <speaker>Peniculus</speaker>
  <l>Etiam derides, quasi nomen non noveris?</l>
</sp>
<sp who="#menae">
  <speaker>Menaechmus</speaker>
  <l>Non edepol ego te, quot sciam, umquam ante hunc diem</l>
  <l>Vidi neque novi; ...</l>
</sp>
```

If present, a `<speaker>` element may only appear as the first part of an `<sp>` element. The distinction between the `<speaker>` element and the *who* attribute makes it possible to encode uniformly characters whose names are not indicated in a uniform fashion throughout the play, or characters who appear in disguise, as in the following examples:

```
<castList>
  <castItem>
    <role xml:id="hh">Henry Higgins</role>
  </castItem>
</castList>
<sp who="#hh">
  <speaker>The Notetaker</speaker>
```

```
<p> ... </p>
</sp>
```

If the speaker attributions are completely regular (and may thus be reconstructed mechanically from the values given for the *who* attribute), or are of no interest for the encoder of the text (as might be the case with editorially supplied attributions in older texts), then the `<speaker>` element need not be used; the former example above then might look like this:

```
<castList>
  <castItem>
    <role xml:id="menaechmus">Menaechmus</role>
  </castItem>
  <castItem>
    <role xml:id="peniculus">Peniculus</role>
  </castItem>
</castList>
<sp who="#menaechmus">
  <l>Responde, adulescens, quaeso, quid nomen tibist?</l>
</sp>
<sp who="#peniculus">
  <l>Etiam derides, quasi nomen non noveris?</l>
</sp>
<sp who="#menaechmus">
  <l>Non edepol ego te, quot sciam, umquam ante hunc diem</l>
  <l>Vidi neque novi; ...</l>
</sp>
```

More than one identifier may be listed as value for the *who* attribute if the speech is spoken by more than one person, as in the following example:

```
<castList>
  <castItem>
    <role xml:id="nan">Nano</role>
  </castItem>
  <castItem>
    <role xml:id="cas">Castrone</role>
  </castItem>
</castList>
<stage>Nano and Castrone sing</stage>
<sp who="#nan #cas">
  <l>Fools, they are the only nation</l>
  <l>Worth men's envy or admiration</l>
</sp>
```

The `<sp>` and `<speaker>` elements are both declared within the core module (see section 3.12. *Passages of Verse or Drama*).

### 7.2.3 Grouped Speeches

This module makes available the following additional element for handling groups of speeches:

**<spGrp>** (speech group) contains a group of speeches or songs in a performance text presented in a source as constituting a single unit or ‘number’.

The `<spGrp>` element is intended for cases where the characters in a performance launch into something which might be regarded almost as a kind of separate structural division, typically associated with its own heading or

numbering system, but which ‘floats’ in the text, at the same hierarchic level as speeches preceding or following it. Such units are often numbered, titled, and visually presented as distinct objects within the text. Here is a typical example from a well-known American musical comedy:

```
<spGrp type="number" n="3">
  <head>By Strauss : performed by Georges Guetary, Gene Kelly, and Oscar
    Levant</head>
  <sp>
    <speaker>HENRI BAUREL</speaker>
    <lg>
      <l>The waltzes of Mittel Europa </l>
      <l>They charm you and warm you within </l>
      <l>While each day discloses </l>
      <l>What Broadway composes </l>
      <l>Is emptiness pounding on tin.</l>
    </lg>
  </sp>
  <sp xml:lang="de">
    <speaker>JERRY MULLIGAN: ADAM COOK:</speaker>
    <lg>
      <l>Mein Herr! </l>
      <l>Mein Herr!</l>
      <l>Bitte, bitte!</l>
      <l>Denke, danke!</l>
      <l>Aufwiedersehen! Aufwiedersehen!</l>
    </lg>
  </sp>
  <sp>
    <speaker>HENRI BAUREL:</speaker>
    <lg>
      <l>How can I be civil </l>
      <l>When hearing this drivel? </l>
      <l>It's only for night-clubbing souses. </l>
      <l>Oh give me the free 'n easy </l>
      <l>Waltz that is Viennes-y </l>
      <l>And go tell the band</l>
      <l>If they want a hand</l>
      <l>The waltz must be Strauss's</l>
    </lg>
  </sp>
  <sp>
    <speaker>ALL</speaker>
    <lg>
      <l>Ya ya ya </l>
      <l>Give me oom pah pah...</l>
    </lg>
  </sp>
<!-- ... -->
</spGrp>
```

### 7.2.4 Stage Directions

Both between and within the speeches of a written performance text, it is normal practice to include a wide variety of descriptive directions to indicate non-verbal action. The following elements are provided to represent these:

**<stage>** (stage direction) contains any kind of stage direction within a dramatic text or fragment.

@*type* indicates the kind of stage direction.

**<move>** (movement) marks the actual entrance or exit of one or more characters on stage.

**@type** characterizes the movement, for example as an entrance or exit.

**@where** specifies the direction of a stage movement.

**@perf** (performance) identifies the performance or performances in which this movement occurred as specified by pointing to one or more <performance> elements.

A satisfactory typology of stage directions is difficult to define. Certain basic types such as ‘entrance’, ‘exit’, ‘setting’, ‘delivery’, are easily identified. But the list is not a closed one, and it is not uncommon to mix types within a single direction. No closed set of values for the *type* attribute is therefore proposed at the present time, though some suggested values are indicated in the list below, which also indicates the range of possibilities.

```
<stage type="setting">The throne descends.</stage>
<stage type="setting">Music</stage>
<stage type="entrance">Enter Husband as being thrown off his horse.</stage>
<stage type="exit">Exit pursued by a bear.</stage>
<stage type="business">He quickly takes the stone out.</stage>
<stage type="delivery">To Lussurioso.</stage>
<stage type="delivery">Aside.</stage>
<stage type="delivery">Not knowing what to say.</stage>
<stage type="costume">Disguised as Ansaldo.</stage>
<stage type="location">At a window.</stage>
<stage type="novelistic">Having had enough, and embarrassed
for the family.</stage>
```

The meaning of the values used for the *type* attribute on <stage> elements may be defined within the <tagUsage> element of the TEI header (described in section 2.3.4. *The Tagging Declaration*). For example:

```
<tagUsage gi="stage">This element is used for all stage directions,
editorial or authorial. The type attribute on this element takes
one or more of the following values:
<list type="gloss">
  <label>setting</label>
  <item>describes the set</item>
  <label>blocking</label>
  <item>describes movement across stage, position, etc.</item>
  <label>business</label>
  <item>describes movement other than blocking</item>
  <label>delivery</label>
  <item>describes how the line is said</item>
  <label>motivation</label>
  <item>describes character's emotional state or through line</item>
</list>
</tagUsage>
```

This approach is purely documentary; in a real project it would generally be more effective to define the range of permitted values explicitly within the project's schema specification, using the techniques described in chapter 23.3. *Personalization and Customization*. For example, a specification like the following might be used to produce a schema in which the *type* attribute of the <stage> element is permitted to take only the values listed above:

```
<schemaSpec ident="myDrama">
  <moduleRef key="core"/>
  <moduleRef key="tei"/>
  <moduleRef key="structure"/>
  <moduleRef key="header"/>
  <moduleRef key="drama"/>
```

```

<elementSpec ident="stage" mode="change">
  <attList>
    <attDef ident="type" mode="replace">
      <valList type="closed">
        <valItem ident="setting">
          <desc>describes the set</desc>
        </valItem>
        <valItem ident="blocking">
          <desc>describes movement across stage, position, etc.</desc>
        </valItem>
        <valItem ident="business">
          <desc>describes movement other than blocking</desc>
        </valItem>
        <valItem ident="delivery">
          <desc>describes how the line is said</desc>
        </valItem>
        <valItem ident="motivation">
          <desc>describes character's emotional state or through line</desc>
        </valItem>
      </valList>
    </attDef>
  </attList>
</elementSpec>
</schemaSpec>

```

The <stage> element may appear both between and within <sp> elements. It may contain a mixture of phrase level elements, possibly combined into paragraphs, as in the following example:

```

<div1 n="1" type="act">
  <stage type="setting">
    <p>Scene. – A room furnished comfortably and
      tastefully but not extravagantly ...
      The floor is carpeted and a fire burns in the stove.
      It is winter.</p>
    <p>A bell rings in the hall; shortly afterwards the
      door is heard to open. Enter NORA humming a tune ...</p>
  </stage>
  <sp>
    <speaker>Nora</speaker>
    <p>Hide the Christmas Tree carefully, Helen. Be sure the
      children do not see it till this evening, when it is
      dressed. <stage type="delivery">To the PORTER taking
        out her purse</stage> How much?</p>
  </sp>
</div1>

```

The <stage> element may also be used in non-theatrical texts, to mark sound effects or musical effects, etc., as further discussed in section 7.3. *Other Types of Performance Text*.

The <move> element is intended to help overcome the fact that the stage directions of a printed text may often not provide full information about either the intended or the actual movement of actors on stage. It may be used to keep track of entrances and exits in detail, so as to know which characters are on stage at which time. Its attributes permit a relatively formal specification for movements of characters, using user-defined codes to identify the characters involved (the *who* attribute), the direction of the movement (*type* attribute), and optionally which part of the stage is involved (*where* attribute). For stage-historical purposes, a *perf* attribute is also provided; this allows the recording of different <move> elements as taken in different performances of the same text.

The `<move>` element should be located at the position in the text where the move is presumed to take place. This will often coincide with a stage direction, as in the following simple example:

```
<castList>
  <castItem>
    <role xml:id="bella">Bellafront</role>
  </castItem>
</castList>
<stage type="entrance">
  <move who="#bella" type="enter"/>
  Enter Bellafront mad.
</stage>
```

The `<move>` element can however appear independently of a stage direction, as in the following example:

```
<castList>
  <castItem>
    <role xml:id="lm">Lady Macbeth</role>
  </castItem>
  <castItem>
    <role xml:id="g1">First Gentleman</role>
  </castItem>
<!-- ... -->
</castList>
<sp who="#g1">
  <speaker>Gent.</speaker>
  <p>Neither to you, nor any one; having no witness
    to confirm my speech. <move who="#lm" type="enter" where="C"/>
    Lo you! here she comes. This is her very guise; and,
    upon my life, fast asleep.</p>
</sp>
```

### 7.2.5 Speech Contents

The actual speeches of a dramatic text may be composed of running text, which must be formally organized into paragraphs, in the case of prose (see section 3.1. *Paragraphs*), verse lines or line groups in that of verse (see section 3.12. *Passages of Verse or Drama*), or `<seg>` elements, in case of doubt as to whether the material should be treated as verse or prose. The following elements, all of which are defined in the core, are particularly useful when marking units of prose or verse within speeches:

- <p>** (paragraph) marks paragraphs in prose.
- <lb>** (line break) marks the start of a new (typographic) line in some edition or version of a text.
- <l>** (verse line) contains a single, possibly incomplete, line of verse.
- <lg>** (line group) contains one or more verse lines functioning as a formal unit, e.g. a stanza, refrain, verse paragraph, etc.

Like other milestone elements, the element `<lb>` additionally bears the attributes `ed` and `edRef`, from its membership in the class `att.edition`:

**att.edition** provides attributes identifying the source edition from which some encoded feature derives.

**@ed** (edition) supplies a sigil or other arbitrary identifier for the source edition in which the associated feature (for example, a page, column, or line break) occurs at this point in the text.

**@edRef** (edition reference) provides a pointer to the source edition in which the associated feature (for example, a page, column, or line break) occurs at this point in the text.

As a member of the classes `att.typed` and `att.divLike`, the `<lg>` element also bears the following attributes:

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

*@type* characterizes the element in some sense, using any convenient classification scheme or typology.

*@subtype* provides a sub-categorization of the element, if needed

**att.divLike** provides attributes common to all elements which behave in the same way as divisions.

*@org* (organization) specifies how the content of the division is organized.

*@sample* indicates whether this division is a sample of the original source and if so, from which part.

**att.fragmentable** provides an attribute for representing fragmentation of a structural element, typically as a consequence of some overlapping hierarchy.

*@part* specifies whether or not its parent element is fragmented in some way, typically by some other overlapping structure: for example a speech which is divided between two or more verse stanzas, a paragraph which is split across a page division, a verse line which is divided between two speakers.

When the *verse* module is included in a schema, the elements *<l>* and *<lg>* also gain additional attributes through their membership of the class *att.metrical*:

**att.metrical** defines a set of attributes which certain elements may use to represent metrical information.

*@met* (metrical structure, conventional) contains a user-specified encoding for the conventional metrical structure of the element.

*@rhyme* (rhyme scheme) specifies the rhyme scheme applicable to a group of verse lines.

In many texts, prose and verse may be inextricably mingled; particularly in earlier printed texts, prose may be printed as verse or verse as prose, or it may be impossible to distinguish the two. In cases of doubt, an encoder may prefer to tag the dubious material consistently as verse, to tag it all as prose, to follow the typography of the source text, or to use the neutral *<ab>* element to contain the speech itself. When this question arises, the *<tagUsage>* element in the *<encodingDesc>* element of the header may be used to record explicitly what policy has been adopted.

Even where they can reliably be distinguished, a single speech may frequently contain a mixture of prose (marked as *<p>*) and verse (marked as *<l>* or—if stanzaic—*<lg>*).

The *part* attribute which both *<l>* and *<lg>* elements inherit from the *att.fragmentable* class provides one simple way of indicating where the boundaries of a speech and of a verse line or line group do not coincide. The encoder may simply indicate that a line or line group is metrically incomplete by specifying the value Y or N, as in the following example:

```
<sp>
  <speaker>Face</speaker>
  <l part="N">You most
    notorious whelp, you insolent slave</l>
  <l part="Y">Dare you do this?</l>
</sp>
<sp>
  <speaker>Subtle</speaker>
  <l part="Y">Yes faith, yes faith.</l>
</sp>
<sp>
  <speaker>Face</speaker>
  <l part="Y">Why! Who</l>
  <l part="Y">Am I, my mongrel? Who am I?</l>
</sp>
<sp>
  <speaker>Subtle</speaker>
  <l part="Y">I'll tell you,</l>
<!-- ... -->
</sp>
```

Alternatively, where the fragments of the line or line group are consecutive in the text (though possibly interrupted by stage directions), the values I (initial), M (medial), and F (final) may be used to indicate how metrical lines are constituted:

```
<sp>
  <speaker>Face</speaker>
  <l>You most
    notorious whelp, you insolent slave</l>
  <l part="I">Dare you do this?</l>
</sp>
<sp>
  <speaker>Subtle</speaker>
  <l part="M">Yes faith, yes faith.</l>
</sp>
<sp>
  <speaker>Face</speaker>
  <l part="F">Why! Who</l>
  <l part="I">Am I, my mongrel? Who am I?</l>
</sp>
<sp>
  <speaker>Subtle</speaker>
  <l part="F">I'll tell you,</l>
<!-- ... -->
</sp>
```

In dramatic texts, the <lg> or line group element is most often of use for the encoding of songs and other stanzaic material. Line groups may be fragmented across speakers in the same way as individual lines, and the same set of attributes may be used to record this fact. The element <spGrp> is provided in order to simplify the situation, very common in performances, where performance of a single entity, such as a song, is shared amongst several performers, as in the following example:

```
<spGrp>
  <head>Song – Sir Joseph</head>
  <sp>
    <l>I am the monarch of the sea,</l>
    <l>The ruler of the Queen's Navee.</l>
    <l>Whose praise Great Britain loudly chants.</l>
  </sp>
  <sp>
    <speaker>Cousin Hebe</speaker>
    <l>And we are his sisters and his cousins and his aunts!</l>
  </sp>
  <sp>
    <speaker>Rel.</speaker>
    <l>And we are his sisters and his cousins and his aunts!</l>
  </sp>
<!-- ... -->
</spGrp>
```

This encoding however does not indicate that the three lines of Sir Joseph's song and the two lines following it together constitute a single verse stanza. This can be indicated by using the *part* attribute, as follows:

```
<spGrp>
  <head>Song – Sir Joseph</head>
```

```

<sp>
  <lg part="I">
    <l>I am the monarch of the sea,</l>
    <l>The ruler of the Queen's Navee.</l>
    <l>Whose praise Great Britain loudly chants.</l>
  </lg>
</sp>
<sp>
  <speaker>Cousin Hebe</speaker>
  <lg part="M">
    <l>And we are his sisters and his cousins and his aunts!</l>
  </lg>
</sp>
<sp>
  <speaker>Rel.</speaker>
  <lg part="F">
    <l>And we are his sisters and his cousins and his aunts!</l>
  </lg>
</sp>
<!-- ... -->
</spGrp>

```

### 7.2.6 Embedded Structures

Although primarily composed of speeches, performance texts often contain other structural units such as songs or strophes which are shared among different speakers. More generally, complex nested structures of plays within plays, interpolated masques, or interludes are far from uncommon. In more modern material, comparably complex structural devices such as flashback or nested playback are equally frequent. In all kinds of performance material, it may be necessary to indicate several actions which are happening simultaneously.

A number of different devices are available within the TEI scheme to support these complexities in the general case. Texts may be composite or self-nesting (see section 4.3.1. *Grouped Texts*) and multiple hierarchies may be defined (see chapter 20. *Non-hierarchical Structures*). The TEI encoding scheme provides a variety of linking mechanisms, which may be used to indicate temporal alignment and aggregation of fragmented structures. In this section we provide a few specific examples of the application of these techniques to performance texts:

- the use of the <floatingText> element
- the use of the *part* attribute on fragmentary <lg> elements
- the use of the *next* and *prev* attributes on fragments of embedded structures to join them into a larger whole
- the use of the <join> element to define a 'virtual element' composed of the fragments indicated

When the whole of a song appears within a single speech, it may require no special treatment if it is considered to form a part of the speech:

```

<sp>
  <speaker>Kelly</speaker>
  <stage>(calmly).</stage>
  <p>Aha, so you've bad minds along with th' love of gain.
    You thry to pin on others th' dirty decorations that
    may be hangin' on your own coats.</p>
  <stage>(He points, one after the other at Conroy, Bull,
    and Flagonson. Liling)</stage>
  <lg type="song">
    <l>Who were you with last night?</l>
    <l>Who were you with last night?</l>
    <l>Will you tell your missus when you go home</l>
    <l>Who you were with last night?</l>
  </lg>

```

```

</lg>
</sp>
<sp>
  <speaker>Flagonson</speaker>
  <stage>(in anguished indignation).</stage>
  <p>This is more than a hurt to us: this hits at the
    decency of the whole nation!</p>
</sp>

```

If however, the song is to be regarded as forming a distinct item, perhaps with its own front and back matter, it may be better to regard it as a floating text:

```

<sp>
  <speaker>Kelly</speaker>
  <stage>(calmly).</stage>
  <p>Aha, so you've bad minds along with ...</p>
</sp>
<stage>(He points, one after the other at Conroy, Bull,
and Flagonson. Liltng):</stage>
<floatingText>
  <front>
    <titlePart>Kelly's Song</titlePart>
  </front>
  <body>
    <l>Who were you with last night?</l>
    <l>Who were you with last night?</l>
    <l>Will you tell your missus when you go home</l>
    <l>Who you were with last night?</l>
  </body>
</floatingText>

```

When an embedded structure extends across more than one <sp> element, each of its constituent parts must be regarded as a distinct fragment; the problem then facing the encoder is to reconstitute the interrupted whole in some way.

As already noted above, the <spGrp> element may be used to group together consecutive speeches which are grouped together in some way, for example constituting a single song. Alternatively the *part* attribute, typically used to indicate that an <l> element contains a partial, not a complete, verse line, may also be used on the <lg> element, to indicate that the line group is partial rather than complete, thus:

```

<sp>
  <speaker>Kelly</speaker>
  <stage>(wheeling quietly in his semi-dance,
    as he goes out):</stage>
  <lg type="stanza" part="I">
    <l>Goodbye to holy souls left here,</l>
    <l>Goodbye to man an' fairy;</l>
  </lg>
</sp>
<sp>
  <speaker>Widda Machree</speaker>
  <stage>(wheeling quietly in her semi-dance,
    as she goes out):</stage>
  <lg type="stanza" part="F">
    <l>Goodbye to all of Leicester Square,</l>

```

```

    <l>An' the long way to Tipperary.</l>
  </lg>
</sp>

```

When the fragments of a song are separated by other intervening dialogue, or even when not, they may be linked together with the *next* and *prev* attributes defined in section 16.7. *Aggregation*. For example, the line groups making up Ophelia's song might be encoded as follows:

```

<div1 n="4" type="act">
  <div2 n="5" type="scene">
    <stage>Elsinore. A room in the Castle.</stage>
    <stage type="setting">Enter Ophelia, distracted.</stage>
    <sp>
      <speaker>Ophelia</speaker>
      <p>Where is the beauteous Majesty of Denmark?</p>
    </sp>
    <sp>
      <speaker>Queen</speaker>
      <p>How now, Ophelia?</p>
    </sp>
    <sp>
      <speaker>Ophelia</speaker>
      <stage>Singing</stage>
      <lg next="#Tl2" xml:id="Tl1" type="song"
        part="Y">
        <l>How should I your true-love know</l>
        <l>From another one?</l>
        <l>By his cockle hat and staff</l>
        <l>And his sandal shoon.</l>
      </lg>
    </sp>
    <sp>
      <speaker>Queen</speaker>
      <p>Alas, sweet lady, what imports this song?</p>
    </sp>
    <sp>
      <speaker>Ophelia</speaker>
      <p>Say you? Nay, pray you mark.</p>
      <stage>Sings</stage>
      <lg prev="#Tl1" xml:id="Tl2" type="song"
        part="Y">
        <l>He is dead and gone, lady,</l>
        <l>He is dead and gone;</l>
        <l>At his head a grass-green turf,</l>
        <l>At his heels a stone.</l>
      </lg>
      <p>O, ho!</p>
    </sp>
  </div2>
</div1>

```

The *next* and *prev* attributes are discussed in section 16.7. *Aggregation*: they form part of the module for alignment and linking; this module must therefore be included in a schema if they are to be used, as further discussed in section 1.2. *Defining a TEI Schema*.

The fragments of Ophelia's song might also be linked together using the <join> mechanism described in section 16.7. *Aggregation*. The <join> element is specifically intended to encode the fact that several discontinuous elements of the text together form one 'virtual' element. Using this mechanism, the example might be encoded as follows:

```
<text>
  <body>
    <div1 n="4" type="act">
      <div2 n="5" type="scene">
        <stage type="setting">Elsinore. A room in the Castle.</stage>
        <sp>
          <speaker>Queen</speaker>
          <p>How now, Ophelia?</p>
        </sp>
        <sp>
          <speaker>Ophelia</speaker>
          <stage type="delivery">Singing</stage>
          <lg xml:id="TL1" type="song" part="Y">
            <l>How should I your true-love know</l>
            <l>From another one?</l>
            <l>By his cockle hat and staff</l>
            <l>And his sandal shoon.</l>
          </lg>
        </sp>
        <sp>
          <speaker>Queen</speaker>
          <p>Alas, sweet lady, what imports this song?</p>
        </sp>
        <sp>
          <speaker>Ophelia</speaker>
          <p>Say you? Nay, pray you mark.</p>
          <stage type="delivery">Sings</stage>
          <lg xml:id="TL2" type="song" part="Y">
            <l>He is dead and gone, lady,</l>
            <l>He is dead and gone;</l>
            <l>At his head a grass-green turf,</l>
            <l>At his heels a stone.</l>
          </lg>
          <p>O, ho!</p>
          <join type="lg" target="#TL1 #TL2"/>
        </sp>
      </div2>
    </div1>
  </body>
</text>
```

The location of the <join> element is not significant; here it has been placed shortly after the conclusion of the song, in order to have it close to the fragments it unifies.

Like the *next* and *prev* attributes, the <join> element requires the additional module for linking, which is selected as shown above.

### 7.2.7 Simultaneous Action

In printed or written versions of performance texts, a variety of techniques may be used to indicate the temporal alignment of speeches or actions. Speeches may be printed vertically aligned on the page, or braced together; stage directions (e.g. 'Speaking at the same time') are also often used. In operatic or musical works in particular, the need to indicate timing and alignment of individual parts of a song may lead to very complex layout.

One simple method of indicating the temporal alignment of speeches or actions is to use the <spGrp> element discussed in section 7.2.3. *Grouped Speeches*, with an *type* attribute to specify the reason for grouping, as in the following example:

```
<sp>
  <speaker>Mangan</speaker>
  <stage type="delivery">wildly</stage>
  <p>Look here: I'm going to take off all my clothes.</p>
  <stage type="action">he begins tearing off his coat.</stage>
</sp>
<spGrp type="simultaneous" rend="braced">
  <sp>
    <speaker>Lady Utterword</speaker>
    <p>Mr Mangan!</p>
  </sp>
  <sp>
    <speaker>Captain Shotover</speaker>
    <p>Whats that?</p>
  </sp>
  <sp>
    <speaker>Hector</speaker>

  <stage type="action">catching his arm and stopping him</stage>
  <p>Alfred: for shame! Are you mad?</p>
</sp>
```

In the original, the stage direction ‘in consternation’ is printed opposite a brace grouping all four speeches, indicating that all four characters speak at once, and that the stage direction applies to all of them. Rather than attempting to represent the appearance of the source, this example encoding represents its presumed meaning: the <stage> element is placed arbitrarily after the last relevant speech, and the four speeches with which it is to be associated are grouped by means of the <spGrp> element. The *rend* attribute is used to specify the fact that the three speeches were grouped by the brace in the copy text. Producing a readable version of the text which simulates the original printed effect may however require more complex markup and processing.

More powerful and more precise mechanisms for temporal alignment are defined in chapter 8. *Transcriptions of Speech*. These would be appropriate for encodings the focus of which is on the actual performance of a text rather than its structure or formal properties. The module described in that chapter includes a large number of other detailed proposals for the encoding of such features as voice quality, prosody, etc., which might be relevant to such a treatment of performance texts.

## 7.3 Other Types of Performance Text

Most of the elements and structures identified thus far are derived from traditional theatrical texts. Although other performance texts, such as screenplays or radio scripts, have not been discussed specifically, they can be encoded using the elements and structures listed above. Encoders may however find it convenient to use, as well, the additional specialized elements discussed in this section. For scripts containing very detailed technical information, the <tech> element discussed in section 7.3.1. *Technical Information* may also be useful.

Like other texts, screenplays and television or radio scripts may be divided into text divisions marked with <div> or <div1>, etc. Within units corresponding with the traditional ‘act’ and ‘scene’, further subdivisions or sequences

may be identified, composed of individual ‘shots’, each associated with a single camera angle and setting. Shots and sequences should be encoded using an appropriate text-division element (i.e., a `<div3>` element if numbered division elements are in use and the next largest unit is a `<div2>`, or a `<div>` element if un-numbered divisions are in use) specifying sequence or shot as the value of the *type* attribute, as appropriate.

It is normal practice in screenplays and radio scripts to distinguish directions concerning camera angles, sound effects, etc., from other forms of stage direction. Such texts also generally include far more detailed specifications of what the audience actually sees: descriptions of actions and background, etc. Scripts derived from cinema and television productions may also include texts displayed as captions superimposed on the action. All of these may be encoded using the general purpose `<stage>` element discussed in section 7.2.4. *Stage Directions*, and distinguished by means of its *type* attribute. Alternatively, or in addition, the following more specific elements may be used, where clear distinctions can be made:

**<view>** describes the visual context of some part of a screen play in terms of what the spectator sees, generally independent of any dialogue.

**<camera>** describes a particular camera angle or viewpoint in a screen play.

**<caption>** contains the text of a caption or other text displayed as part of a film script or screenplay.

**<sound>** describes a sound effect or musical sequence specified within a screen play or radio script.

*@type* categorizes the sound in some respect, e.g. as music, special effect, etc.

*@discrete* indicates whether the sound overlaps the surrounding speeches or interrupts them.

Some examples of the use of these elements follow:

```
<camera>Angle on Olivia.</camera>
<view>Ryan's wife, standing nervously alone on the sidelines,
biting her lip. She's scared and she shows it.</view>
```

Where particular words or phrases within a direction are emphasized (by change of typeface or use of capital letters), an appropriate phrase-level element may be used to indicate the fact, as in the following examples, where certain words in the original are given in small capitals:

```
<view>George glances at the window--and freezes.
<camera>New angle--shock cut</camera> Out the window
the body of a dead man suddenly slams into
<hi>frame</hi>. He dangles grotesquely,
held up by his coat caught on a protruding bolt.
George gasps. The train <hi>whistle</hi> screams.</view>
```

```
<view>Ext. TV control van--Early morning.
The <name>T.V. announcer</name> from the Ryan interview
stands near the Control Van, the lake in b.g.</view>
<sp>
  <speaker>T.V. Announcer</speaker>
  <p>Several years ago, Jack Ryan was a highly
    successful hydroplane racer ...</p>
</sp>
```

All of these elements, like other stage directions, can appear both within and between speeches.

```
<sp>
  <speaker>TV Announcer V0</speaker>
  <p>Working with Ryan are his two coworkers--
```

```

    Strut Bowman, the mechanical engineer-
<view>
  <camera>Angle on Strut</camera>
    standing in the tow boat, walkie-talkie in hand,
    watching Ryan carefully.</view>
  -and Roger Dalton, a rocket
    systems analyst, and one of the scientists
    from the Jet Propulsion Lab ...</p>
</sp>

```

```

<sp>
  <speaker>Benjy</speaker>
  <p>Now to business.</p>
</sp>
<sp>
  <speaker>Ford and Zaphod</speaker>
  <p>To business.</p>
</sp>
<sound>Glasses clink.</sound>
<sp>
  <speaker>Benjy</speaker>
  <p>I beg your pardon?</p>
</sp>
<sp>
  <speaker>Ford</speaker>
  <p>I'm sorry, I thought you were proposing a toast.</p>
</sp>

```

```

<camera>Zoom in to overlay showing some stock film
of hansom cabs galloping past.</camera>
<caption>London, 1895.</caption>
<caption>The residence of Mr Oscar Wilde.</caption>
<sound>Suitably classy music starts.</sound>
<view>Mix through to Wilde's drawing room. A crowd of suitably
dressed folk are engaged in typically brilliant conversation,
laughing affectedly and drinking champagne.</view>
<sp>
  <speaker>Prince of Wales</speaker>
  <p>My congratulations, Wilde. Your latest play is a great success.</p>
</sp>

```

### 7.3.1 Technical Information

Traditional stage scripts may contain additional technical information about such production-related factors as lighting, 'blocking' (that is, detailed notes on actors' movements), or props required at particular points. More technical information about intended production effects may also appear in published versions of screenplays or movie scripts. Where these are presented simply as marginal notes, they may be encoded using the general-purpose `<note>` element defined in section 3.8. *Notes, Annotation, and Indexing*. Alternatively, they may be formally distinguished from other stage directions by using the specialized `<tech>` element:

**<tech>** (technical stage direction) describes a special-purpose stage direction that is not meant for the actors.

`@type` categorizes the technical stage direction.

*@perf* (performance) points to one or more <performance> elements documenting the performance or performances to which this technical direction applies.

Like stage directions, <tech> elements can appear anywhere within a speech or between speeches.

## 7.4 Module for Performance Texts

The module described in this chapter makes available the following components:

**Module drama: Performance texts**

- *Elements defined:* actor camera caption castGroup castItem castList epilogue move performance prologue role roleDesc set sound spGrp tech view

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

## 8 Transcriptions of Speech

The module described in this chapter is intended for use with a wide variety of transcribed spoken material. It should be stressed, however, that the present proposals are not intended to support unmodified every variety of research undertaken upon spoken material now or in the future; some discourse analysts, some phonologists, and doubtless others may wish to extend the scheme presented here to express more precisely the set of distinctions they wish to draw in their transcriptions. Speech regarded as a purely acoustic phenomenon may well require different methods from those outlined here, as may speech regarded solely as a process of social interaction.

This chapter begins with a discussion of some of the problems commonly encountered in transcribing spoken language (section 8.1. *General Considerations and Overview*). Section 8.2. *Documenting the Source of Transcribed Speech* documents some additional TEI header elements which may be used to document the recording or other source from which transcribed text is taken. Section 8.3. *Elements Unique to Spoken Texts* describes the basic structural elements provided by this module. Finally, section 8.4. *Elements Defined Elsewhere* of this chapter reviews further problems specific to the encoding of spoken language, demonstrating how mechanisms and elements discussed elsewhere in these Guidelines may be applied to them.

### 8.1 General Considerations and Overview

There is great variation in the ways different researchers have chosen to represent speech using the written medium.<sup>66</sup> This reflects the special difficulties which apply to the encoding or *transcription* of speech. Speech varies according to a large number of dimensions, many of which have no counterpart in writing (for example, tempo, loudness, pitch, etc.). The audibility of speech recorded in natural communication situations is often less than perfect, affecting the accuracy of the transcription. Spoken material may be transcribed in the course of linguistic, acoustic, anthropological, psychological, ethnographic, journalistic, or many other types of research. Even in the same field, the interests and theoretical perspectives of different transcribers may lead them to prefer different levels of detail in the transcript and different styles of visual display. The production and comprehension of speech are intimately bound up with the situation in which speech occurs, far more so than is the case for written texts. A speech transcript must therefore include some contextual features; determining which are relevant is not always simple. Moreover, the ethical problems in recording and making public what was produced in a private setting and intended for a limited audience are more frequently encountered in dealing with spoken texts than with written ones.

Speech also poses difficult structural problems. Unlike a written text, a speech event takes place in time. Its beginning and end may be hard to determine and its internal composition difficult to define. Most researchers agree that the utterances or *turns* of individual speakers form an important structural component in most kinds of speech, but these are rarely as well-behaved (in the structural sense) as paragraphs or other analogous units in written texts: speakers frequently interrupt each other, use gestures as well as words, leave remarks unfinished and so on. Speech itself, though it may be represented as words, frequently contains items such as vocalized pauses which, although only semi-lexical, have immense importance in the analysis of spoken text. Even non-vocal elements such as gestures may be regarded as forming a component of spoken text for some analytic purposes. Below the level of the individual utterance, speech may be segmented into units defined by phonological, prosodic, or syntactic phenomena; no clear agreement exists, however, even as to appropriate names for such segments.

Spoken texts transcribed according to the guidelines presented here are organized as follows. The overall structure of a TEI spoken text is identical to that of any other TEI text: the <TEI> element for a spoken text contains a <teiHeader> element, followed by a <text> element. Even texts primarily composed of transcribed speech may also include conventional front and back matter, and may even be organized into divisions like printed texts.

We may say, therefore, that these Guidelines regard transcribed speech as being composed of arbitrary high-level units called *texts*. A spoken <text> might typically be a conversation between a small number of people, a lecture, a broadcast TV item, or a similar event. Each such unit has associated with it a <teiHeader> providing detailed contextual information such as the source of the transcript, the identity of the participants, whether the speech is scripted or spontaneous, the physical and social setting in which the discourse takes place and a range of other aspects. Details of the header in general are provided in chapter 2. *The TEI Header*; the particular elements it provides for use with spoken texts are described below (8.2. *Documenting the Source of Transcribed Speech*). Details concerning additional elements which may be used for the documentation of participant and contextual information are given in 15.2. *Contextual Information*.

---

<sup>66</sup>For a discussion of several of these see Edwards and Lampert (eds.) (1993); Johansson (1994); and Johansson et al. (1991).

Defining the bounds of a spoken text is frequently a matter of arbitrary convention or convenience. In public or semi-public contexts, a text may be regarded as synonymous with, for example, a *lecture*, a *broadcast item*, a *meeting*, etc. In informal or private contexts, a text may be simply a conversation involving a specific group of participants. Alternatively, researchers may elect to define spoken texts solely in terms of their duration in time or length in words. By default, these Guidelines assume of a text only that:

- it is internally cohesive,
- it is describable by a single header, and
- it represents a single stretch of time with no significant discontinuities.

Deviation from these assumptions may be specified (for example, the *org* attribute on the `<text>` element may take the value *compos* to specify that the components of the text are discrete) but is not recommended.

Within a `<text>` it may be necessary to identify subdivisions of various kinds, if only for convenience of handling. The neutral `<div>` element discussed in section 4.1. *Divisions of the Body* is recommended for this purpose. It may be found useful also for representing subdivisions relating to discourse structure, speech act theory, transactional analysis, etc., provided only that these divisions are hierarchically well-behaved. Where they are not, as is often the case, the mechanisms discussed in chapters 16. *Linking, Segmentation, and Alignment* and 20. *Non-hierarchical Structures* may be used.

A spoken text may contain any of the following components:

- utterances
- pauses
- vocalized but non-lexical phenomena such as coughs
- kinesic (non-verbal, non-lexical) phenomena such as gestures
- entirely non-linguistic incidents occurring during and possibly influencing the course of speech
- writing, regarded as a special class of incident in that it can be transcribed, for example captions or overheads displayed during a lecture
- shifts or changes in vocal quality

Elements to represent all of these features of spoken language are discussed in section 8.3. *Elements Unique to Spoken Texts* below.

An utterance (tagged `<u>`) may contain lexical items interspersed with pauses and non-lexical vocal sounds; during an utterance, non-linguistic incidents may occur and written materials may be presented. The `<u>` element can thus contain any of the other elements listed, interspersed with a transcription of the lexical items of the utterance; the other elements may all appear between utterances or next to each other, but except for `<writing>` they do not contain any other elements nor any data.

A spoken text itself may be without substructure, that is, it may consist simply of units such as utterances or pauses, not grouped together in any way, or it may be subdivided. If the notion of what constitutes a ‘text’ in spoken discourse is inevitably rather an arbitrary one, the notion of formal subdivisions within such a ‘text’ may appear even more debatable. Nevertheless, such divisions may be useful for such types of discourse as debates, broadcasts, etc., where structural subdivisions can easily be identified, or more generally wherever it is desired to aggregate utterances or other parts of a transcript into units smaller than a complete ‘text’. Examples might include ‘conversations’ or ‘discourse fragments’, or more narrowly, ‘that part of the conversation where topic x was discussed’, provided only that the set of all such divisions is coextensive with the text.

Each such division of a spoken text should be represented by the numbered or unnumbered `<div>` elements defined in chapter 4. *Default Text Structure*. For some detailed kinds of analysis a hierarchy of such divisions may be found useful; nested `<div>` elements may be used for this purpose, as in the following example showing how a collection made up of transcribed ‘sound bites’ taken from speeches given by a politician on different occasions might be encoded. Each extract is regarded as a distinct `<div>`, nested within a single composite `<div>` as follows:

```
<div type="soundbites"
  subtype="conservative" org="composite">
  <div sample="medial"/>
  <div sample="medial"/>
```

```
<div sample="initial"/>
</div>
```

As a member of the class `att.declaring`, the `<div>` element may also carry a `decls` attribute, for use where the divisions of a text do not all share the same set of the contextual declarations specified in the TEI header. (See further section 15.3. *Associating Contextual Information with a Text*).

## 8.2 Documenting the Source of Transcribed Speech

Where a computer file is derived from a spoken text rather than a written one, it will usually be desirable to record additional information about the recording or broadcast which constitutes its source. Several additional elements are provided for this purpose within the source description component of the TEI header:

**<scriptStmt>** (script statement) contains a citation giving details of the script used for a spoken text.

**<recordingStmt>** (recording statement) describes a set of recordings used as the basis for transcription of a spoken text.

**<recording>** (recording event) provides details of an audio or video recording event used as the source of a spoken text, either directly or from a public broadcast.

`@type` the kind of recording.

**<transcriptionDesc>** describes the set of transcription conventions used, particularly for spoken material.

`@ident` supplies an identifier for the encoding convention, independent of any version number.

`@version` supplies a version number for the encoding conventions used, if any.

As a member of the `att.duration` class, the `<recording>` element inherits the following attribute:

**att.duration.w3c** provides attributes for recording normalized temporal durations.

`@dur` (duration) indicates the length of this element in time.

Note that detailed information about the participants or setting of an interview or other transcript of spoken language should be recorded in the appropriate division of the profile description, discussed in chapter 15. *Language Corpora*, rather than as part of the source description. The source description is used to hold information only about the source from which the transcribed speech was taken, for example, any script being read and any technical details of how the recording was produced. If the source was a previously-created transcript, it should be treated in the same way as any other source text.

The `<scriptStmt>` element should be used where it is known that one or more of the participants in a spoken text is speaking from a previously prepared script. The script itself should be documented in the same way as any other written text, using one of the three citation tags mentioned above. Utterances or groups of utterances may be linked to the script concerned by means of the `decls` attribute, described in section 15.3. *Associating Contextual Information with a Text*.

```
<sourceDesc>
  <scriptStmt xml:id="CNN12">
    <bibl>
      <author>CNN Network News</author>
      <title>News headlines</title>
      <date when="1991-06-12">12 Jun 91</date>
    </bibl>
  </scriptStmt>
</sourceDesc>
```

The `<recordingStmt>` is used to group together information relating to the recordings from which the spoken text was transcribed. The element may contain either a prose description or, more helpfully, one or more `<recording>` elements, each corresponding with a particular recording. The linkage between utterances or groups of utterances and the relevant recording statement is made by means of the `decls` attribute, described in section 15.3. *Associating Contextual Information with a Text*.

The `<recording>` element should be used to provide a description of how and by whom a recording was made. This information may be provided in the form of a prose description, within which such items as statements of responsibility, names, places, and dates may be identified using the appropriate phrase-level tags. Alternatively, a selection of elements from the `model.recordingPart` class may be provided. This element class makes available the following elements:

**<date>** contains a date in any format.

**<time>** contains a phrase defining a time of day in any format.

**<respStmt>** (statement of responsibility) supplies a statement of responsibility for the intellectual content of a text, edition, recording, or series, where the specialized elements for authors, editors, etc. do not suffice or do not apply. May also be used to encode information about individuals or organizations which have played a role in the production or distribution of a bibliographic work.

**<equipment>** provides technical details of the equipment and media used for an audio or video recording used as the source for a spoken text.

**<broadcast>** describes a broadcast used as the source of a spoken text.

Specialized collections may wish to add further sub-elements to these major components. These elements should be used only for information relating to the recording process itself; information about the setting or participants (for example) is recorded elsewhere: see sections 15.2.3. *The Setting Description* and 15.2.2. *The Participant Description*.

```
<recordingStmt>
  <recording type="video">
    <p>U-matic recording made by college audio-visual department staff,
      available as PAL-standard VHS transfer or sound-only cassette</p>
  </recording>
</recordingStmt>
```

```
<recordingStmt>
  <recording type="audio" dur="P30M">
    <respStmt>
      <resp>Location recording by</resp>
      <name>Sound Services Ltd.</name>
    </respStmt>
    <equipment>
      <p>Multiple close microphones mixed down to stereo Digital
        Audio Tape, standard play, 44.1 KHz sampling frequency</p>
    </equipment>
    <date>12 Jan 1987</date>
  </recording>
</recordingStmt>
```

```
<recordingStmt>
  <recording type="audio" dur="P15M"
    xml:id="rec-3001">
    <date>14 Feb 2001</date>
  </recording>
  <recording type="audio" dur="P15M"
    xml:id="rec-3002">
    <date>17 Feb 2001</date>
  </recording>
  <recording type="audio" dur="P15M"
    xml:id="rec-3003">
```

```
<date>22 Feb 2001</date>
</recording>
</recordingStmt>
```

When a recording has been made from a public broadcast, details of the broadcast itself should be supplied within the <recording> element, as a nested <broadcast> element. A broadcast is closely analogous to a publication and the <broadcast> element should therefore contain one or the other of the bibliographic citation elements <bibl>, <biblStruct>, or <biblFull>. The broadcasting agency responsible for a broadcast is regarded as its author, while other participants (for example interviewers, interviewees, script writers, directors, producers, etc.) should be specified using the <respStmt> or <editor> element with an appropriate <resp> (see further section 3.11. *Bibliographic Citations and References*).

```
<recording type="audio" dur="P10M">
  <equipment>
    <p>Recorded from FM Radio to digital tape</p>
  </equipment>
  <broadcast>
    <bibl>
      <title>Interview on foreign policy</title>
      <author>BBC Radio 5</author>
      <respStmt>
        <resp>interviewer</resp>
        <name>Robin Day</name>
      </respStmt>
      <respStmt>
        <resp>interviewee</resp>
        <name>Margaret Thatcher</name>
      </respStmt>
      <series>
        <title>The World Tonight</title>
      </series>
      <note>First broadcast on <date when="1989-11-27">27 Nov 1989</date>
      </note>
    </bibl>
  </broadcast>
</recording>
```

When a broadcast contains several distinct recordings (for example a compilation), additional <recording> elements may be further nested within the <broadcast> element.

```
<recording dur="P100M">
  <broadcast>
    <recording/>
  </broadcast>
</recording>
```

The <transcriptionDesc> element can be used to document the particular transcription conventions (use of space, punctuation, special characters etc.) used in making the transcription. A number of sets of such conventions have been defined within particular research communities, or by users of particular transcription tools. The attributes *ident* and *version* may be used to refer to such conventions in a machine tractable way, where this is appropriate.

```
<transcriptionDesc ident="HIAT"
  version="2004"/>
```

## 8.3 Elements Unique to Spoken Texts

The following elements characterize spoken texts, transcribed according to these Guidelines:

**<u>** (utterance) contains a stretch of speech usually preceded and followed by silence or by a change of speaker.

**<pause>** marks a pause either between or within utterances.

**<vocal>** marks any vocalized but not necessarily lexical phenomenon, for example voiced pauses, non-lexical backchannels, etc.

**<kinesic>** marks any communicative phenomenon, not necessarily vocalized, for example a gesture, frown, etc.

**<incident>** marks any phenomenon or occurrence, not necessarily vocalized or communicative, for example incidental noises or other events affecting communication.

**<writing>** contains a passage of written text revealed to participants in the course of a spoken text.

**<shift>** marks the point at which some paralinguistic feature of a series of utterances by any one speaker changes.

The `<u>` element may appear directly within a spoken text, and may contain any of the others; the others may also appear directly (for example, a `<vocal>` may appear between two utterances) but cannot contain a `<u>` element. In terms of the basic TEI model, therefore, we regard the `<u>` element as analogous to a paragraph, and the others as analogous to ‘phrase’ elements, but with the important difference that they can exist either as siblings or as children of utterances. The class `model.divPart.spoken` provides the `<u>` element; the class `model.global.spoken` provides the six other elements listed above.

As members of the `att.ascribed` class, all of these elements share the following attribute:

**att.ascribed** provides attributes for elements representing speech or action that can be ascribed to a specific individual.

`@who` indicates the person, or group of people, to whom the element content is ascribed.

As members of the `att.typed`, `att.timed` and `att.duration` classes, all of these elements except `<shift>` share the following attribute:

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

`@type` characterizes the element in some sense, using any convenient classification scheme or typology.

`@subtype` provides a sub-categorization of the element, if needed

**att.timed** provides attributes common to those elements which have a duration in time, expressed either absolutely or by reference to an alignment map.

`@start` indicates the location within a temporal alignment at which this element begins.

`@end` indicates the location within a temporal alignment at which this element ends.

**att.duration.w3c** provides attributes for recording normalized temporal durations.

`@dur` (duration) indicates the length of this element in time.

Each of these elements is further discussed and specified in sections 8.3.1. *Utterances* to 8.3.4. *Writing*.

We can show the relationship between four of these constituents of speech using the features *eventive*, *communicative*, *anthropophonic* (for sounds produced by the human vocal apparatus), and *lexical*:

|           | eventive | communicative | anthropophonic | lexical |
|-----------|----------|---------------|----------------|---------|
| incident  | +        | -             | -              | -       |
| kinesic   | +        | +             | -              | -       |
| vocal     | +        | +             | +              | -       |
| utterance | +        | +             | +              | +       |

The differences are not always clear-cut. Among *incidents* might be included actions like slamming the door, which can certainly be communicative. *Vocals* include coughing and sneezing, which are usually involuntary noises. Equally, the distinction between utterances and vocals is not always clear, although for many analytic purposes it will be convenient to regard them as distinct. Individual scholars may differ in the way borderlines are drawn and should declare their definitions in the <editorialDecl> element of the header (see 2.3.3. *The Editorial Practices Declaration*).

The following short extract exemplifies several of these elements. It is recorded from a text originally transcribed in the CHILDES format.<sup>67</sup> Each utterance is encoded using a <u> element (see section 8.3.1. *Utterances*). The speakers are defined using the <listPerson> element discussed in 13.3.2. *The Person Element* and each is given a unique identifier also used to identify their speech. Pauses marked by the transcriber are indicated using the <pause> element (see section 8.3.2. *Pausing*). Non-verbal vocal effects such as the child's meowing are indicated either with orthographic transcriptions or with the <vocal> element, and entirely non-linguistic but significant incidents such as the sound of the toy cat are represented by the <incident> elements (see section 8.3.3. *Vocal, Kinesic, Incident*).

```
<u who="#mar">you
never <pause/> take this cat for show and tell
<pause/> meow meow</u>
<u who="#ros">yeah well I dont want to</u>
<incident>
  <desc>toy cat has bell in tail which continues to make a tinkling sound</desc>
</incident>
<vocal who="#mar">
  <desc>meows</desc>
</vocal>
<u who="#ros">because it is so old</u>
<u who="#mar">how <choice>
  <orig>bout</orig>
  <reg>about</reg>
</choice>
  <emph>your</emph> cat <pause/>yours is <emph>new</emph>
  <kinesic>
    <desc>shows Father the cat</desc>
  </kinesic>
</u>
<u trans="pause" who="#fat">thats <pause/> darling</u>
<u who="#mar">
  <seg>no <emph>mine</emph> isnt old</seg>
  <seg>mine is just um a little dirty</seg>
</u>
<!-- ... -->
<listPerson>
  <person xml:id="mar">
<!-- ... -->
  </person>
  <person xml:id="ros">
<!-- ... -->
  </person>
  <person xml:id="fat">
<!-- ... -->
  </person>
</listPerson>
```

This example also uses some elements common to all TEI texts, notably the <reg> tag for editorial regularization. Unusually stressed syllables have been encoded with the <emph> element. The <seg> element has also been used to segment the last utterance. Further discussion of all of such options is provided in section 8.4. *Elements Defined Elsewhere*.

<sup>67</sup>The original is a conversation between two children and their parents, recorded in 1987, and discussed in MacWhinney (1988)

Contextual information is of particular importance in spoken texts, and should be provided by the TEI header of a text. In general, all of the information in a header is understood to be relevant to the whole of the associated text. The element `<u>` as a member of the `att.declaring` class, may however specify a different context by means of the `decls` attribute (see further section 15.3. *Associating Contextual Information with a Text*).

### 8.3.1 Utterances

Each distinct *utterance* in a spoken text is represented by a `<u>` element, described as follows:

**<u>** (utterance) contains a stretch of speech usually preceded and followed by silence or by a change of speaker.

**@*trans*** (transition) indicates the nature of the transition between this utterance and the previous one.

Use of the *who* attribute to associate the utterance with a particular speaker is recommended but not required. Its use implies as a further requirement that all speakers be identified by a `<person>` or `<personGrp>` element in the TEI header (see section 15.2.2. *The Participant Description*), but it may also point to another external source of information about the speaker. Where utterances or other parts of the transcription cannot be attributed with confidence to any particular participant or group of participants, the encoder may choose to create `<personGrp>` elements with *xml:id* attributes such as *various* or *unknown*, and perhaps give the root `<listPerson>` element an *xml:id* value of *all*, then point to those as appropriate using *who*.

The *trans* attribute is provided as a means of characterizing the transition from one utterance to the next at a simpler level of detail than that provided by the temporal alignment mechanism discussed in section 16.5. *Synchronization*. The value specified applies to the transition from the preceding utterance into the utterance bearing the attribute. For example:<sup>68</sup>

```
<u xml:id="ts_a1" who="#a">Have you heard the</u>
<u xml:id="ts_b1" trans="latching" who="#b">the election results? yes</u>
<u xml:id="ts_a2" trans="pause" who="#a">it's a disaster</u>
<u xml:id="ts_b2" trans="overlap" who="#b">it's a miracle</u>
```

In this example, utterance `ts_b1` latches on to utterance `ts_a1`, while there is a marked pause between `ts_b1` and `ts_a2`. `ts_b2` and `ts_a2` overlap, but by an unspecified amount. For ways of providing a more precise indication of the degree of overlap, see section 8.4.2. *Synchronization and Overlap*.

An utterance may contain either running text, or text within which other basic structural elements are nested. Where such nesting occurs, the *who* attribute is considered to be inherited for the elements `<pause>`, `<vocal>`, `<shift>` and `<kinesic>`; that is, a pause or shift (etc.) within an utterance is regarded as being produced by that speaker only, while a pause between utterances applies to all speakers.

Occasionally, an utterance may seem to contain other utterances, for example where one speaker interrupts himself, or when another speaker produces a 'back-channel' while they are still speaking. The present version of these Guidelines does not support nesting of one `<u>` element within another. The transcriber must therefore decide whether such interruptions constitute a change of utterance, or whether other elements may be used. In the case of self-interruption, the `<shift>` element may be used to show that the speaker has changed the quality of their speech:

```
<u who="#a">Listen to this <shift new="reading"/>The government is
confident, he said, that the current economic problems will be
completely overcome by June<shift new="normal"/> what nonsense</u>
```

Alternatively the `<incident>` element described in section 8.3.3. *Vocal, Kinesic, Incident* might be used, without transcribing the read material:

<sup>68</sup>For the most part, the examples in this chapter use no sentence punctuation except to mark the rising intonation often found in interrogative statements; for further discussion, see section 8.4.3. *Regularization of Word Forms*.

```
<u who="#a">Listen to this
<incident>
  <desc>reads aloud from newspaper</desc>
</incident> what
nonsense</u>
```

Often, back-channelling is only semi-lexicalized and may therefore be represented using the `<vocal>` element:

```
<u who="#a">So what could I have done <vocal who="#b">
  <desc>tut-tutting</desc>
</vocal> about it anyway?</u>
```

Where this is not possible, it is simplest to regard the back-channel as a distinct utterance.

### 8.3.2 Pausing

Speakers differ very much in their rhythm and in particular in the amount of time they leave between words. The following element is provided to mark occasions where the transcriber judges that speech has been paused, irrespective of the actual amount of silence:

**<pause>** marks a pause either between or within utterances.

A pause contained by an utterance applies to the speaker of that utterance. A pause between utterances applies to all speakers. The *type* attribute may be used to categorize the pause, for example as short, medium, or long; alternatively the attribute *dur* may be used to indicate its length more exactly, as in the following example:

```
<u>0kay <pause dur="PT2M"/>U-m<pause dur="PT75S"/>the scene opens up
<pause dur="PT50S"/> with <pause dur="PT20S"/> um <pause dur="PT145S"/> you see
a tree okay?</u>
```

If detailed synchronization of pausing with other vocal phenomena is required, the alignment mechanism defined at section 16.5. *Synchronization* and discussed informally below should be used. Note that the *trans* attribute mentioned in the previous section may also be used to characterize the degree of pausing between (but not within) utterances.

### 8.3.3 Vocal, Kinesic, Incident

The presence of non-transcribed semi-lexical or non-lexical phenomena either between or within utterances may be indicated with the following three elements.

**<vocal>** marks any vocalized but not necessarily lexical phenomenon, for example voiced pauses, non-lexical backchannels, etc.

**<kinesic>** marks any communicative phenomenon, not necessarily vocalized, for example a gesture, frown, etc.

**<incident>** marks any phenomenon or occurrence, not necessarily vocalized or communicative, for example incidental noises or other events affecting communication.

The *who* attribute should be used to specify the person or group responsible for a `<vocal>`, `<kinesic>`, or `<incident>` which is contained within an utterance, if this differs from that of the enclosing utterance. The attribute must be supplied for a `<vocal>`, `<kinesic>`, or `<incident>` which is not contained within an utterance.

The *iterated* attribute may be used to indicate that the vocal, kinesic, or incident is repeated, for example laughter as opposed to laugh. These should both be distinguished from laughing, where what is being encoded is a shift in voice quality. For this last case, the `<shift>` element discussed in section 8.3.6. *Shifts* should be used.

A child `<desc>` element may be used to supply a conventional representation for the phenomenon, for example:

**non-lexical** burp, click, cough, exhale, giggle, gulp, inhale, laugh, sneeze, sniff, snort, sob, swallow, throat, yawn

**semi-lexical** ah, aha, aw, eh, ehm, er, erm, hmm, huh, mm, mmhm, oh, ooh, oops, phew, tsk, uh, uh-huh, uh-uh, um, urgh, yup

Researchers may prefer to regard some semi-lexical phenomena as ‘words’ within the bounds of the <u> element. See further the discussion at section 8.4.3. *Regularization of Word Forms* below. As for all basic categories, the definition should be made clear in the <encodingDesc> element of the TEI header.

Some typical examples follow:

```
<u who="#jan">This is just delicious</u>
<incident>
  <desc>telephone rings</desc>
</incident>
<u who="#ann">I'll get it</u>
<u who="#tom">I used to <vocal>
  <desc>cough</desc>
</vocal> smoke a lot</u>
<u who="#bob">
  <vocal>
    <desc>sniffs</desc>
  </vocal>He thinks he's tough
</u>
<vocal who="#ann">
  <desc>snorts</desc>
</vocal>
<!-- ... -->
<listPerson>
  <person xml:id="ann">
<!-- ... -->
  </person>
  <person xml:id="bob">
<!-- ... -->
  </person>
  <person xml:id="jan">
<!-- ... -->
  </person>
  <person xml:id="kim">
<!-- ... -->
  </person>
  <person xml:id="tom">
<!-- ... -->
  </person>
</listPerson>
```

Note that Ann's snorting could equally well be encoded as follows:

```
<u who="#ann">
  <vocal>
    <desc>snorts</desc>
  </vocal>
</u>
```

The extent to which encoding of incidents or kinesics is included in a transcription will depend entirely on the purpose for which the transcription was made. As elsewhere, this will depend on the particular research agenda and the extent to which their presence is felt to be significant for the interpretation of spoken interactions.

### 8.3.4 Writing

Written text may also be encountered when speech is transcribed, for example in a television broadcast or cinema performance, or where one participant shows written text to another. The <writing> element may be used to distinguish such written elements from the spoken text in which they are embedded.

**<writing>** contains a passage of written text revealed to participants in the course of a spoken text.

*@gradual* indicates whether the writing is revealed all at once or gradually.

**att.source** provides attributes for pointing to the source of a bibliographic reference.

For example, if speaker A in the breakfast table conversation in section 8.3.1. *Utterances* above had simply shown the newspaper passage to her interlocutor instead of reading it, the interaction might have been encoded as follows:

```
<u who="#a">look at this</u>
<writing who="#a" type="newspaper"
  gradual="false">Government claims economic problems
<soCalled>over by June</soCalled>
</writing>
<u who="#a">what nonsense!</u>
```

If the source of the writing being displayed is known, bibliographic information about it may be stored in a `<listBibl>` within the `<sourceDesc>` element of the TEI header, and then pointed to using the *source* attribute. For example, in the following imaginary example, a lecturer displays two different versions of the same passage of text:

```
<sourceDesc>
<!-- .....
```

### 8.3.5 Temporal Information

As noted above, utterances, vocals, pauses, kinesics, incidents, and writing elements all inherit attributes providing information about their position in time from the classes **att.timed** and **att.duration**. These attributes can be used to link parts of the transcription very exactly with points on a timeline, or simply to indicate their duration. Note that if *start* and *end* point to `<when>` elements whose temporal distance from each other is specified in a timeline, then *dur* is ignored.

The `<anchor>` element (see 16.4. *Correspondence and Alignment*) may be used as an alternative means of aligning the start and end of timed elements, and is required when the temporal alignment involves points within an element.

For further discussion of temporal alignment and synchronization see 8.4.2. *Synchronization and Overlap* below.

### 8.3.6 Shifts

A common requirement in transcribing spoken language is to mark positions at which a variety of prosodic features change. Many paralinguistic features (pitch, prominence, loudness, etc.) characterize stretches of speech which are not co-extensive with utterances or any of the other units discussed so far. One simple method of encoding such units is simply to mark their boundaries. An empty element called `<shift>` is provided for this purpose.

**<shift>** marks the point at which some paralinguistic feature of a series of utterances by any one speaker changes.

*@feature* a paralinguistic feature.

*@new* specifies the new state of the paralinguistic feature specified.

A `<shift>` element may appear within an utterance or a segment to mark a significant change in the particular feature defined by its attributes, which is then understood to apply to all subsequent utterances for the same speaker, unless

changed by a new shift for the same feature in the same speaker. Intervening utterances by other speakers do not normally carry the same feature. For example:

```
<u>
  <shift feature="loud" new="f"/>Elizabeth
</u>
<u>Yes</u>
<u>
  <shift feature="loud" new="normal"/>Come and try this <pause/>
  <shift feature="loud" new="ff"/>come on
</u>
```

In this example, the word *Elizabeth* is spoken loudly, the words *Yes* and *Come and try this* with normal volume, and the words *come on* very loudly.

The values proposed here for the *feature* attribute are based on those used by the Survey of English Usage (see further Rose 1990); this list may be revised or supplemented using the methods outlined in section 23.3. *Personalization and Customization*.

The *new* attribute specifies the new state of the feature following the shift. If this attribute has the special value *normal*, the implication is that the feature concerned ceases to be remarkable at this point.

A list of suggested values for each of the features proposed follows:

- tempo
  - a allegro (fast)
  - aa very fast
  - acc accelerando (getting faster)
  - l lento (slow)
  - ll very slow
  - rall rallentando (getting slower)
- loud (for loudness):
  - f forte (loud)
  - ff very loud
  - cresc crescendo (getting louder)
  - p piano (soft)
  - pp very soft
  - dimin diminuendo (getting softer)
- pitch (for pitch range):
  - high high pitch-range
  - low low pitch-range
  - wide wide pitch-range
  - narrow narrow pitch-range
  - asc ascending
  - desc descending
  - monot monotonous
  - scand scandent, each succeeding syllable higher than the last, generally ending in a falling tone
- tension:

**sl** slurred

**lax** lax, a little slurred

**ten** tense

**pr** very precise

**st** staccato, every stressed syllable being doubly stressed

**leg** legato, every syllable receiving more or less equal stress

- rhythm:

**rh** beatable rhythm

**arrh** arrhythmic, particularly halting

**spr** spiky rising, with markedly higher unstressed syllables

**spf** spiky falling, with markedly lower unstressed syllables

**glr** glissando rising, like spiky rising but the unstressed syllables, usually several, also rise in pitch relative to each other

**glf** glissando falling, like spiky falling but with the unstressed syllables also falling in pitch relative to each other

- voice (for voice quality):

**whisp** whisper

**breath** breathy

**husk** husky

**creak** creaky

**fals** falsetto

**reson** resonant

**giggle** unvoiced laugh or giggle

**laugh** voiced laugh

**trem** tremulous

**sob** sobbing

**yawn** yawning

**sigh** sighing

A full definition of the sense of the values provided for each feature may be provided either in the encoding description section of the text header (see section 2.3. *The Encoding Description*) or as part of a TEI customization, as described in section 23.3. *Personalization and Customization*.

## 8.4 Elements Defined Elsewhere

This section describes the following features characteristic of spoken texts for which elements are defined elsewhere in these Guidelines:

- segmentation below the utterance level
- synchronization and overlap
- regularization of orthography

The elements discussed here are not provided by the module for spoken texts. Some of them are included in the core module and others are contained in the modules for linking and for analysis respectively. The selection of modules and their combination to define a TEI schema is discussed in section 1.2. *Defining a TEI Schema*.

### 8.4.1 Segmentation

For some analytic purposes it may be desirable to subdivide the divisions of a spoken text into units smaller than the individual utterance or turn. Segmentation may be performed for a number of different purposes and in terms of a variety of speech phenomena. Common examples include units defined both prosodically (by intonation, pausing, etc.) and syntactically (clauses, phrases, etc.) The term *macrosyntagm* has been used by a number of researchers to define units peculiar to speech transcripts.<sup>69</sup>

These Guidelines propose that such analyses be performed in terms of neutrally-named *segments*, represented by the <seg> element, which is discussed more fully in section 16.3. *Blocks, Segments, and Anchors*. This element may take a *type* attribute to specify the kind of segmentation applicable to a particular segment, if more than one is possible in a text. A full definition of the segmentation scheme or schemes used should be provided in the <segmentation> element of the <editorialDecl> element in the TEI header (see 2.3.3. *The Editorial Practices Declaration*).

In the first example below, an utterance has been segmented according to a notion of syntactic completeness not necessarily marked by the speech, although in this case a pause has been recorded between the two sentence-like units. In the second, the segments are defined prosodically (an acute accent has been used to mark the position immediately following the syllable bearing the primary accent or stress), and may be thought of as 'tone units'.

```
<u>
  <seg>we went to the pub yesterday</seg>
  <pause/>
  <seg>there was no one there</seg>
</u>
<u>
  <seg>although its an old ide´a</seg>
  <seg>it hasnt been on the mar´ket very long</seg>
</u>
```

In either case, the <segmentation> element in the header of the text should specify the principles adopted to define the segments marked in this way.

When utterances are segmented end-to-end in the same way as the s-units in written texts, the <s> element discussed in chapter 17. *Simple Analytic Mechanisms* may be used, either as an alternative or in addition to the more general purpose <seg> element. The <s> element is available without formality in all texts, but does not allow segments to nest within each other.

Where segments of different kinds are to be distinguished within the same stretch of speech, the *type* attribute may be used, as in the following example:

```
<u who="#T1">
  <seg type="C">I think </seg>
  <seg type="C">this chap was writing </seg>
  <seg type="C">and he <del type="repeated">said hello</del> said </seg>
  <seg type="M">hello </seg>
  <seg type="C">and he said </seg>
  <seg type="C">I'm going to a gate
    at twenty past seven </seg>
  <seg type="C">he said </seg>
  <seg type="M">ok </seg>
  <seg type="M">right away </seg>
  <seg type="C">and so <gap extent="1 syll"/> on they went </seg>
  <seg type="C">and they were <gap extent="3 sylls"/>
    writing there </seg>
</u>
```

<sup>69</sup>The term was apparently first proposed by Loman and Jørgensen (1971), where it is defined as follows: 'A text can be analysed as a sequence of segments which are internally connected by a network of syntactic relations and externally delimited by the absence of such relations with respect to neighbouring segments. Such a segment is a syntactic unit called a macrosyntagm' (trans. S. Johansson).

In this example, recoded from a corpus of language-impaired speech prepared by Fletcher and Garman, the speaker's utterance has been fully segmented into clausal (`type="C"`) or minor (`type="M"`) units.

For some features, it may be more appropriate or convenient to introduce a new element in a custom namespace:

```
<u who="#T1"
  xmlns:ext="http://www.example.org/ns/nonTEI">
<!-- ... -->
  <seg type="C">and he said </seg>
  <seg type="C">I'm going to a
  <ext:paraphasia>gate</ext:paraphasia>
    at twenty past seven </seg>
<!-- ... -->
</u>
```

Here, `<ext:paraphasia>` has been used to define a particular characteristic of this corpus for which no element exists in the TEI scheme. See further chapter 23.3. *Personalization and Customization* for a discussion of the way in which this kind of user-defined extension of the TEI scheme may be performed and chapter 1. *The TEI Infrastructure* for the mechanisms on which it depends.

This example also uses the core elements `<gap>` and `<del>` to mark editorial decisions concerning matter completely omitted from the transcript (because of inaudibility), and words which have been transcribed but which the transcriber wishes to exclude from the segment because they are repeated, respectively. See section 3.4. *Simple Editorial Changes* for a discussion of these and related elements.

It is often the case that the desired segmentation does not respect utterance boundaries; for example, syntactic units may cross utterance boundaries. For a detailed discussion of this problem, and the various methods proposed by these Guidelines for handling it, see chapter 20. *Non-hierarchical Structures*. Methods discussed there include these:

- 'milestone' tags may be used; the special-purpose `<shift>` tag discussed in section 8.3.6. *Shifts* is an extension of this method
- where several discontinuous segments are to be grouped together to form a syntactic unit (e.g. a phrasal verb with interposed complement), the `<join>` element may be used

### 8.4.2 Synchronization and Overlap

A major difference between spoken and written texts is the importance of the temporal dimension to the former. As a very simple example, consider the following, first as it might be represented in a playscript:

```
Jane: Have you read Vanity Fair?
Stig: Yes
Lou: (nods vigorously)
```

To encode this, we first define the participants:

```
<listPerson>
  <person xml:id="stig">
<!-- ... -->
  </person>
  <person xml:id="lou">
<!-- ... -->
  </person>
  <person xml:id="jane">
<!-- ... -->
  </person>
</listPerson>
```

Let us assume that Stig and Lou respond to Jane's question before she has finished asking it—a fairly normal situation in spontaneous speech. The simplest way of representing this *overlap* would be to use the *trans* attribute previously discussed:

```
<u who="#jane">have you read Vanity Fair</u>
<u trans="overlap" who="#stig">yes</u>
```

However, this does not allow us to indicate either the extent to which Stig's utterance is overlapped, nor does it show that there are in fact three things which are synchronous: the end of Jane's utterance, Stig's whole utterance, and Lou's kinesic. To overcome these problems, more sophisticated techniques, employing the mechanisms for pointing and alignment discussed in detail in section 16.5. *Synchronization*, are needed. If the module for linking has been enabled (as described in section 8.4.1. *Segmentation* above), one way to represent the simple example above would be as follows:

```
<u xml:id="utt1" who="#jane">have      you      read      Vanity      <anchor synch="#utt2
#k1"  xml:id="a1"/> Fair</u>
<u xml:id="utt2" who="#stig">yes</u>
<kinesic xml:id="k1" who="#lou"
  iterated="true">
  <desc>nods head vertically</desc>
</kinesic>
```

For a full discussion of this and related mechanisms, section 16.5.2. *Placing Synchronous Events in Time* should be consulted. The rest of the present section, which should be read in conjunction with that more detailed discussion, presents a number of ways in which these mechanisms may be applied to the specific problem of representing temporal alignment, synchrony, or overlap in transcribing spoken texts.

In the simple example above, the first utterance (that with identifier *utt1*) contains an *<anchor>* element, the function of which is simply to mark a point within it. The *synch* attribute associated with this anchor point specifies the identifiers of the other two elements which are to be synchronized with it: specifically, the second utterance (*utt2*) and the kinesic (*k1*). Note that one of these elements has content and the other is empty.

This example demonstrates only a way of indicating a point within one utterance at which it can be synchronized with another utterance and a kinesic. For more complex kinds of alignment, involving possibly multiple synchronization points, an additional element is provided, known as a *<timeline>*. This consists of a series of *<when>* elements, each representing a point in time, and bearing attributes which indicate its exact temporal position relative to other elements in the same timeline, in addition to the sequencing implied by its position within it.

For example:

```
<timeline unit="s" origin="#TS-P1">
  <when xml:id="TS-P1"
    absolute="12:20:01+01:00"/>
  <when xml:id="TS-P2" interval="4.5"
    since="#TS-P1"/>
  <when xml:id="TS-P6"/>
  <when xml:id="TS-P3" interval="1.5"
    since="#TS-P6"/>
</timeline>
```

This timeline represents four points in time, named TS-P1, TS-P2, TS-P6, and TS-P3 (as with all attributes named *xml:id* in the TEI scheme, the names must be unique within the document but have no other significance). TS-P1 is located absolutely, at 12:20:01:01 BST. TS-P2 is 4.5 seconds later than TS-P1 (i.e. at 12:20:05). TS-P6 is at some unspecified time later than TS-P2 and previous to TS-P3 (this is implied by its position within the timeline, as no attribute values have been specified for it). The fourth point, TS-P3, is 1.5 seconds later than TS-P6.

One or more such timelines may be specified within a spoken text, to suit the encoder's convenience. If more than one is supplied, the *origin* attribute may be used on each to specify which other <timeline> element it follows. The *unit* attribute indicates the units used for timings given on <when> elements contained by the alignment map. Alternatively, to avoid the need to specify times explicitly, the *interval* attribute may be used to indicate that all the <when> elements in a time line are a fixed distance apart.

Three methods are available for aligning points or elements within a spoken text with the points in time defined by the <timeline>:

- The elements to be synchronized may specify the identifier of a <when> element as the value of one of the *start*, *end*, or *synch* attributes
- The <when> element may specify the identifiers of all the elements to be synchronized with it using the *synch* attribute
- A free-standing <link> element may be used to associate the <when> element and the elements synchronized with it by specifying their identifiers as values for its *target* attribute.

For example, using the timeline given above:

```
<u xml:id="TS-U1" start="#TS-P2"
end="#TS-P3">This is my <anchor synch="#TS-P6" xml:id="TS-P6A"/> turn</u>
```

The start of utterance TS-U1 is aligned with TS-P2 and its end with TS-P3. The transition between the words *my* and *turn* occurs at point TS-P6A, which is synchronous with point TS-P6 on the timeline.

The synchronization represented by the preceding examples could equally well be represented as follows:

```
<timeline origin="#ts-p1" unit="s">
  <when xml:id="ts-p1"
    absolute="12:20:01+01:00"/>
  <when synch="#ts-u1" xml:id="ts-p2"
    interval="4.5" since="#ts-p1"/>
  <when synch="#ts-x1" xml:id="ts-p6"/>
  <when synch="#ts-u1" xml:id="ts-p3"
    interval="1.5" since="#ts-p6"/>
</timeline>
<u xml:id="ts-u1">This is my <anchor xml:id="ts-x1"/> turn</u>
```

Here, the whole of the object with identifier ts-u1 (the utterance) has been aligned with two different points, ts-p2 and ts-p3. This is interpreted to mean that the utterance spans at least those two points.

Finally, a <linkGrp> may be used as an alternative to the *synch* attribute:

```
<timeline origin="#TS-p1" unit="s">
  <when xml:id="TS-p1" absolute="12:20:01"/>
  <when xml:id="TS-p2" interval="4.5"
    since="#TS-p1"/>
  <when xml:id="TS-p6"/>
  <when xml:id="TS-p3" interval="1.5"
    since="#TS-p6"/>
</timeline>
<u xml:id="TS-u1">
  <anchor xml:id="TS-u1start"/>
  This is my <anchor xml:id="TS-x1"/> turn
  <anchor xml:id="TS-u1end"/>
</u>
<linkGrp type="synchronous">
  <link target="#TS-u1start #TS-p1"/>
```

```
<link target="#TS-u1end #TS-p2"/>
<link target="#TS-x1 #TS-p6"/>
</linkGrp>
```

As a further example of the three possibilities, consider the following dialogue, represented first as it might appear in a conventional playscript:

```
Tom: I used to smoke - -
Bob: (interrupting) You used to smoke?
Tom: (at the same time) a lot more than this. But I never
      inhaled the smoke
```

A commonly used convention might be to transcribe such a passage as follows:

```
(1) I used to smoke [ a lot more than this ]
(2)           [ you used to smoke ]
(1) but I never inhaled the smoke
```

Such conventions have the drawback that they are hard to generalize or to extend beyond the very simple case presented here. Their reliance on the accidentals of physical layout may also make them difficult to transport and to process computationally. These Guidelines recommend the following mechanisms to encode this.

Where the whole of one or another utterance is to be synchronized, the *start* and *end* attributes may be used:

```
<u who="#tom">I used to smoke <anchor xml:id="TS-p10"/> a lot more than this
<anchor xml:id="TS-p20"/>but I never inhaled the smoke</u>
<u start="#TS-p10" end="#TS-p20" who="#bob">You used to smoke</u>
```

Note that the second utterance above could equally well be encoded as follows with exactly the same effect:

```
<u who="#bob">
  <anchor synch="#TS-p10"/>You used to smoke<anchor synch="#TS-p20"/>
</u>
```

If synchronization with specific timing information is required, a `<timeline>` must be included:

```
<timeline origin="#TS-t01" unit="s">
  <when xml:id="TS-t01" absolute="15:33:01Z"/>
  <when xml:id="TS-t02" interval="2.5"
        since="#TS-t01"/>
</timeline>
<u who="#tom">I used to smoke
<anchor synch="#TS-t01"/>a lot more than this
<anchor synch="#TS-t02"/>but I never inhaled the smoke</u>
<u who="#bob">
  <anchor synch="#TS-t01"/>You used to smoke<anchor synch="#TS-t02"/>
</u>
```

(Note that if only the ordering or sequencing of utterances is needed, then specific timing information shown here in *unit*, *absolute* and *interval* does not need to be provided.)

As above, since the whole of Bob's utterance is to be aligned, the *start* and *end* attributes may be used as an alternative to the second pair of `<anchor>` elements:

```
<u start="#TS-t01" end="#TS-t02" who="#bob">You used to smoke</u>
```

An alternative approach is to mark the synchronization by pointing from the <timeline> to the text:

```
<timeline origin="#TS-T01">
  <when synch="#TS-nm1 #bob-u2"
    xml:id="TS-T01"/>
  <when synch="#TS-nm2 #bob-u2"
    xml:id="TS-T02"/>
</timeline>
<u who="#tom">I used to smoke
<anchor xml:id="TS-nm1"/>a lot more than this
<anchor xml:id="TS-nm2"/>but I never inhaled the smoke</u>
<u xml:id="bob-u2" who="#bob">You used to smoke</u>
```

To avoid deciding whether to point from the timeline to the text or vice versa, a <linkGrp> may be used:

```
<body>
  <timeline origin="#T001">
    <when xml:id="T001"/>
    <when xml:id="T002"/>
  </timeline>
  <u who="#tom">I used to smoke
  <anchor xml:id="NM01"/>a lot more than this
  <anchor xml:id="NM02"/>but I never inhaled the smoke</u>
  <u xml:id="bob-U2" who="#bob">You used to smoke</u>
  <linkGrp type="synchronize">
    <link target="#T001 #NM01 #bob-U2"/>
    <link target="#T002 #NM02 #bob-U2"/>
  </linkGrp>
</body>
```

Note that in each case, although Bob's utterance follows Tom's sequentially in the text, it is aligned temporally with its middle, without any need to disrupt the normal syntax of the text.

As a final example, consider the following exchange, first as it might be represented using a musical-score-like notation, in which points of synchronization are represented by vertical alignment of the text:

```
Stig: This is |my |turn
Jane:          |Balderdash
Lou :          |No, |it's mine
```

All three speakers are simultaneous at the words *my*, *Balderdash*, and *No*; speakers Stig and Lou are simultaneous at the words *turn* and *it's*. This could be encoded as follows, using pointers from the alignment map into the text:

```
<timeline origin="#TSp1">
  <when synch="#TSa1 #TSb1 #TSc1"
    xml:id="TSp1"/>
  <when synch="#TSa2 #TSc2" xml:id="TSp2"/>
</timeline>
<!-- ... -->
<u who="#stig">this is <anchor xml:id="TSa1"/> my <anchor xml:id="TSa2"/> turn</u>
<u who="#jane" xml:id="TSb1">balderdash</u>
<u who="#lou" xml:id="TSc1"> no <anchor xml:id="TSc2"/> it's mine</u>
```

### 8.4.3 Regularization of Word Forms

When speech is transcribed using ordinary orthographic notation, as is customary, some compromise must be made between the sounds produced and conventional orthography. Particularly when dealing with informal, dialectal, or other varieties of language, the transcriber will frequently have to decide whether a particular sound is to be treated as a distinct vocabulary item or not. For example, while in a given project *kinda* may not be worth distinguishing as a vocabulary item from *kind of*, *isn't* may clearly be worth distinguishing from *is not*; for some purposes, the regional variant *isnae* might also be worth distinguishing in the same way.

One rule of thumb might be to allow such variation only where a generally accepted orthographic form exists, for example, in published dictionaries of the language register being encoded; this has the disadvantage that such dictionaries may not exist. Another is to maintain a controlled (but extensible) set of normalized forms for all such words; this has the advantage of enforcing some degree of consistency among different transcribers. Occasionally, as for example when transcribing abbreviations or acronyms, it may be felt necessary to depart from conventional spelling to distinguish between cases where the abbreviation is spelled out letter by letter (e.g. *B B C* or *V A T*) and where it is pronounced as a single word (*VAT* or *RADA*). Similar considerations might apply to pronunciation of foreign words (e.g. *Monsewer* vs. *Monsieur*).

In general, use of punctuation, capitalization, etc., in spoken transcripts should be carefully controlled. It is important to distinguish the transcriber's intuition as to what the punctuation should be from the marking of prosodic features such as pausing, intonation, etc.

Whatever practice is adopted, it is essential that it be clearly and fully documented in the editorial declarations section of the header. It may also be found helpful to include normalized forms of non-conventional spellings within the text, using the elements for simple editorial changes described in section 3.4. *Simple Editorial Changes* (see further section 8.4.5. *Speech Management*).

### 8.4.4 Prosody

In the absence of conventional punctuation, the marking of prosodic features assumes paramount importance, since these structure and organize the spoken message. Indeed, such prosodic features as points of primary or secondary stress may be represented by specialized punctuation marks, or other characters such as those provided by the Unicode Spacing Modifier Letters block. Pauses have already been dealt with in section 8.3.2. *Pausing*; while tone units (or intonational phrases) can be indicated by the segmentation tag discussed in section 8.4.1. *Segmentation*. The <shift> element discussed in section 8.3.6. *Shifts* may also be used to encode some prosodic features, for example where all that is required is the ability to record shifts in voice quality.

In a more detailed phonological transcript, it is common practice to include a number of conventional signs to mark prosodic features of the surrounding or (more usually) preceding speech. Such signs may be used to record, for example, particular intonation patterns, truncation, vowel quality (long or short) etc. These signs may be preserved in a transcript either by using conventional punctuation or by marking their presence by <g> elements. Where a transcript includes many phonetic or phonemic aspects, it will generally be more convenient to use the appropriate Unicode characters (see further chapters *vi Languages and Character Sets* and 5. *Characters, Glyphs, and Writing Modes*). For representation of phonemic information, the use of the International Phonetic Alphabet, which can be represented in Unicode characters, is recommended.

In the following example, special characters have been defined as follows within the <encodingDesc> of the TEI header

```
<charDecl>
  <char xml:id="lf">
    <desc>low fall intonation</desc>
  </char>
  <char xml:id="lr">
    <desc>low rise intonation</desc>
  </char>
  <char xml:id="fr">
    <desc>fall rise intonation</desc>
  </char>
  <char xml:id="rf">
    <desc>rise fall intonation</desc>
```

```

</char>
<char xml:id="long">
  <desc>lengthened syllable</desc>
</char>
<char xml:id="short">
  <desc>shortened syllable</desc>
</char>
</charDecl>

```

These declarations might additionally provide information about how the characters concerned should be rendered, their equivalent IPA form, etc. In the transcript itself references to them can then be included as follows:

```

<div n="Lod E-03" type="exchange">
  <note>C is with a friend</note>
  <u who="#cwn">
    <unclear>Excuse me<g ref="#lf"/>
  </unclear>
    <pause/> You dont have some
    aesthetic<g ref="#short"/>
    <pause/>
    <unclear>specially on early</unclear>
    aesthetics terminology <g ref="#lr"/>
  </u>
  <u who="#aj"> No<g ref="#lf"/>
    <pause/>No<g ref="#lf"/>
    <gap extent="2 beats"/> I'm
    afraid<g ref="#lf"/>
  </u>
  <u trans="latching" who="#cwn"> No<g ref="#lr"/>
    <unclear>Well</unclear> thanks<g ref="#lr"/>
    <pause/> Oh<g ref="#short"/>
    <unclear>you couldnt<g ref="#short"/> can we</unclear> kind of<g ref="#long"/>
    <pause/>I mean ask you to order it for us<g ref="#long"/>
    <g ref="#fr"/>
  </u>
  <u trans="latching" who="#aj"> Yes<g ref="#fr"/> if you know the title<g ref="#lf"/>
  > Yeah<g ref="#lf"/>
  </u>
  <u who="#cwn">
    <gap extent="4 beats"/>
  </u>
  <u who="#aj"> Yes thats fine. <unclear>just as soon as it comes in we'll send
    you a postcard<g ref="#lf"/>
  </unclear>
  </u>
  <listPerson>
    <person xml:id="cwn">
      <p>Customer WN</p>
    </person>
    <person xml:id="aj">
      <p>Assistant K</p>
    </person>
  </listPerson>
</div>

```

This example, which is taken from a corpus of bookshop service encounters, also demonstrates the use of the <unclear> and <gap> elements discussed in section 3.4. *Simple Editorial Changes*. Where words are so unclear that

only their extent can be recorded, the empty `<gap>` element may be used; where the encoder can identify the words but wishes to record a degree of uncertainty about their accuracy, the `<unclear>` element may be used. More flexible and detailed methods of indicating uncertainty are discussed in chapter 21. *Certainty, Precision, and Responsibility*.

For more detailed work, involving a detailed phonological transcript including representation of stress and pitch patterns, it is probably best to maintain the prosodic description in parallel with the conventional written transcript, rather than attempt to embed detailed prosodic information within it. The two parallel streams may be aligned with each other and with other streams, for example an acoustic encoding, using the general alignment mechanisms discussed in section 8.3.6. *Shifts*.

### 8.4.5 Speech Management

Phenomena of *speech management* include disfluencies such as filled and unfilled pauses, interrupted or repeated words, corrections, and reformulations as well as interactional devices asking for or providing feedback. Depending on the importance attached to such features, transcribers may choose to adopt conventionalized representations for them (as discussed in section 8.4.3. *Regularization of Word Forms* above), or to transcribe them using IPA or some other transcription system. To simplify analysis of the lexical features of a speech transcript, it may be felt useful to ‘tidy away’ many of these disfluencies. Where this policy has been adopted, these Guidelines recommend the use of the tags for simple editorial intervention discussed in section 3.4. *Simple Editorial Changes*, to make explicit the extent of regularization or normalization performed by the transcriber.

For example, false starts, repetition, and truncated words might all be included within a transcript, but marked as editorially deleted, in the following way:

```
<u>
  <del type="truncation">s</del>see
<del type="repetition">you you</del> you know
<del type="falseStart">it's</del> he's crazy
</u>
```

As previously noted, the `<gap>` element may be used to mark points within a transcript where words have been omitted, for example because they are inaudible, as in the following example in which 5 seconds of speech is drowned out by an external event:

```
<gap reason="passing-truck" quantity="5"
  unit="s"/>
```

The `<unclear>` element may be used to mark words which have been included although the transcriber is unsure of their accuracy:

```
<u>...and then <unclear reason="passing-truck">marbled queen</unclear>
</u>
```

Where a transcriber is believed to have incorrectly identified a word, the elements `<corr>` or `<sic>` embedded within a `<choice>` element may be used to indicate both the original and a corrected form of it:

```
<choice>
  <corr>SCSI</corr>
  <sic>skuzzy</sic>
</choice>
```

These elements are further discussed in section 3.4.1. *Apparent Errors*.

Finally phenomena such as *code-switching*, where a speaker switches from one language to another, may easily be represented in a transcript by using the `<foreign>` element provided by the core tagset:

```
<u who="#P1">I proposed that <foreign xml:lang="de"> wir können  
<pause dur="PT1S"/> vielleicht </foreign> go to warsaw  
and <emph>vienna</emph>  
</u>
```

### 8.4.6 Analytic Coding

The recommendations made here only concern the establishment of a basic text. Where a more sophisticated analysis is needed, more sophisticated methods of markup will also be appropriate, for example, using stand-off markup to indicate multiple segmentation of the stream of discourse, or complex alignment of several segments within it. Where additional annotations (sometimes called ‘codes’ or ‘tags’) are used to represent such features as linguistic word class (noun, verb, etc.), type of speech act (imperative, concessive, etc.), or information status (theme/rheme, given/new, active/semi-active/new), etc., a selection from the general purpose analytic tools discussed in chapters 16. *Linking, Segmentation, and Alignment*, 17. *Simple Analytic Mechanisms*, and 18. *Feature Structures* may be used to advantage.

The general-purpose <annotationBlock> element may be used to group together a transcription and multiple layers of annotation. It also serves to divide a transcribed text up into meaningful analytic sections.

**<annotationBlock>** groups together various annotations, e.g. for parallel interpretations of a spoken segment.

## 8.5 Module for Transcribed Speech

The module described in this chapter makes available the following components:

### Module spoken: Transcribed Speech

- *Elements defined:* annotationBlock broadcast equipment incident kinesic pause recording recordingStmnt scriptStmnt shift transcriptionDesc u vocal writing
- *Classes defined:* att.duration model.divPart.spoken model.global.spoken model.recordingPart

The selection and combination of modules to form a TEI schema is described in 1.2. *Defining a TEI Schema*.

## 9 Dictionaries

This chapter defines a module for encoding lexical resources of all kinds, in particular human-oriented monolingual and multilingual dictionaries, glossaries, and similar documents. The elements described here may also be useful in the encoding of computational lexica and similar resources intended for use by language-processing software; they may also be used to provide a rich encoding for wordlists, lexica, glossaries, etc. included within other documents. Dictionaries are most familiar in their printed form; however, increasing numbers of dictionaries exist also in electronic forms which are independent of any particular printed form, but from which various displays can be produced.

Both typographically and structurally, print dictionaries are extremely complex. Such lexical resources are moreover of interest to many communities with different and sometimes conflicting goals. As a result, many general problems of text encoding are particularly pronounced here, and more compromises and alternatives within the encoding scheme may be required in the future.<sup>70</sup> Two problems are particularly prominent.

First, because the structure of dictionary entries varies widely both among and within dictionaries, the simplest way for an encoding scheme to accommodate the entire range of structures actually encountered is to allow virtually any element to appear virtually anywhere in a dictionary entry. It is clear, however, that strong and consistent structural principles do govern the vast majority of conventional dictionaries, as well as many or most entries even in more ‘exotic’ dictionaries; encoding guidelines should include these structural principles. We therefore define two distinct elements for dictionary entries, one (`<entry>`) which captures the regularities of many conventional dictionary entries, and a second (`<entryFree>`) which uses the same elements, but allows them to combine much more freely. It is however recommended that `<entry>` be used in preference to `<entryFree>` wherever possible. These elements and their contents are described in sections 9.2. *The Structure of Dictionary Entries*, 9.6. *Unstructured Entries*, and 9.4. *Headword and Pronunciation References*.

Second, since so much of the information in printed dictionaries is implicit or highly compressed, their encoding requires clear thought about whether it is to capture the precise typographic form of the source text or the underlying structure of the information it presents. Since both of these views of the dictionary may be of interest, it proves necessary to develop methods of recording both, and of recording the interrelationship between them as well. Users interested mainly in the printed format of the dictionary will require an encoding to be faithful to an original printed version. However, other users will be interested primarily in capturing the lexical information in a dictionary in a form suitable for further processing, which may demand the expansion or rearrangement of the information contained in the printed form. Further, some users wish to encode *both* of these views of the data, and retain the links between related elements of the two encodings. Problems of recording these two different views of dictionary data are discussed in section 9.5. *Typographic and Lexical Information in Dictionary Data*, together with mechanisms for retaining both views when this is desired.

To deal with this complexity, and in particular to account for the wide variety of linguistic contexts within which a dictionary may be designed, it can be necessary to customize or change the schema by providing more restriction or possibly alternate content models for the elements defined in this chapter. Section 9.3.2. *Grammatical Information* illustrates this with the provision of a closed set of values for grammatical descriptors.

This chapter contains a large number of examples taken from existing print dictionaries; in each case, the original source is identified. In presenting such examples, we have tried to retain the original typographic appearance of the example as well as presenting a suggested encoding for it. Where this has not been possible (for example in the display of pronunciation) we have adopted the transliteration found in the electronic edition of the *Oxford Advanced Learner's Dictionary*. Also, the middle dot in quoted entries is rendered with a full stop, while within the sample transcriptions hyphenation and syllabification points are indicated by a vertical bar |, regardless of their appearance in the source text.

### 9.1 Dictionary Body and Overall Structure

Overall, dictionaries have the same structure of front matter, body, and back matter familiar from other texts. In addition, this module defines `<entry>`, `<entryFree>`, and `<superEntry>` as component-level elements which can occur directly within a text division or the text body.

<sup>70</sup>We refer the reader to previous and current discussions of a common format for encoding lexical resources. For example, Amsler and Tompa (1988); Calzolari et al. (1990); Fought and Van Ess-Dykema; Ide and Veronis (1995); Ide et al. (1993); Ide et al. (1992); DANLEX Group (1987); and Tutin and Veronis (1998); Ide et al. (2000).

The following tags can therefore be used to mark the gross structure of a printed dictionary; the dictionary-specific tags are discussed further in the following section.

**<text>** contains a single text of any kind, whether unitary or composite, for example a poem or drama, a collection of essays, a novel, a dictionary, or a corpus sample.

**<front>** (front matter) contains any prefatory matter (headers, abstracts, title page, prefaces, dedications, etc.) found at the start of a document, before the main body.

**<body>** (text body) contains the whole body of a single unitary text, excluding any front or back matter.

**<back>** (back matter) contains any appendixes, etc. following the main part of a text.

**<div>** (text division) contains a subdivision of the front, body, or back of a text.

**<entry>** contains a single structured entry in any kind of lexical resource, such as a dictionary or lexicon.

**<entryFree>** (unstructured entry) contains a single unstructured entry in any kind of lexical resource, such as a dictionary or lexicon.

**<superEntry>** groups a sequence of entries within any kind of lexical resource, such as a dictionary or lexicon which function as a single unit, for example a set of homographs.

As members of the classes `att.entryLike` and `att.sortable`, `<entry>` and `<entryFree>` share the following attributes:

**att.entryLike** provides an attribute used to distinguish different styles of dictionary entries.

`@type` indicates type of entry, in dictionaries with multiple types.

**att.sortable** provides attributes for elements in lists or groups that are sortable, but whose sorting key cannot be derived mechanically from the element content.

`@sortKey` supplies the sort key for this element in an index, list or group which contains it.

The front and back matter of a dictionary may well contain specialized material such as lists of common and proper nouns, grammatical tables, gazetteers, a ‘guide to the use of the dictionary’, etc. These should be tagged using elements defined elsewhere in these Guidelines, chiefly in the core module (chapter 3. *Elements Available in All TEI Documents*) together with the specialized dictionary elements defined in this chapter.

The `<body>` element consists of a set of *entries*, optionally grouped into one or several `<div>` elements. These text divisions might, for example, correspond to sections for different letters of the alphabet, or to sections for different languages in a bilingual dictionary, as in the following example:

```
<body>
  <div>
    <head>English-French</head>
    <entry>
      <form>
        <orth>cat</orth>
      </form>
    <!-- ... -->
    </entry>
    <entry>
      <form>
        <orth>dog</orth>
      </form>
    <!-- ... -->
    </entry>
    <entry>
      <form>
        <orth>horse</orth>
      </form>
    <!-- ... -->
    </entry>
  </div>
  <div>
    <head>French-English</head>
```

```

<entry>
  <form>
    <orth>chat</orth>
  </form>
<!-- ... -->
</entry>
<entry>
  <form>
    <orth>chien</orth>
  </form>
<!-- ... -->
</entry>
<entry>
  <form>
    <orth>cheval</orth>
  </form>
<!-- ... -->
</entry>
</div>
</body>

```

In a print dictionary, the entries are typically typographically distinct entities, each headed by some morphological form of the lexical item described (the *headword*), and sorted in alphabetical order or (especially for non-alphabetic scripts) in some other conventional sequence. Dictionary entries should be encoded as distinct successive items, each marked as an `<entry>` or `<entryFree>` element. The *type* attribute may be used to distinguish different types of entries, for example main entries, related entries, run-on entries, or entries for cross-references, etc.

Some dictionaries provide distinct entries for homographs, on the basis of etymology, part-of-speech, or both, and typically provide a numeric superscript on the headword identifying the homograph number. In these cases each homograph should be encoded as a separate entry; the `<superEntry>` element may optionally be used to group such successive homograph entries. In addition to a series of `<entry>` elements, the `<superEntry>` may contain a preliminary `<form>` group (see section 9.3.1. *Information on Written and Spoken Forms*) when information about hyphenation, pronunciation, etc., is given only once for two or more homograph entries. If the homograph number is to be recorded, the global attribute *n* may be used for this purpose. In some dictionaries, homographs are treated in distinct parts of the same entry; in these cases, they may be separated by use of the `<hom>` element, for which see section 9.2.1. *Hierarchical Levels*.

A sort key, given in the *sortKey* attribute, is often required for superentries and entries, especially in cases where the order of entries does not follow the local character-set collating sequence (as, for example, when an entry for '3D' appears at the place where 'three-D' would appear).

A dictionary with no internal divisions might thus have a structure like the following; a `<superEntry>` is shown grouping two homograph entries.

```

<body>
  <entry>
    <form>
      <orth>manifestation</orth>
    <!-- demonstration -->
  </form>
</entry>
  <entry>
    <form>
      <orth>émeute</orth>
    <!-- riot -->
  </form>
</entry>

```

```

<superEntry>
  <entry type="hom" n="1">
    <form>
      <orth>grève</orth>
<!-- strike -->
    </form>
  </entry>
  <entry type="hom" n="2">
    <form>
      <orth>grève</orth>
<!-- shore -->
    </form>
  </entry>
</superEntry>
</body>

```

## 9.2 The Structure of Dictionary Entries

A simple dictionary entry may contain information about the form of the word treated, its grammatical characterization, its definition, synonyms, or translation equivalents, its etymology, cross-references to other entries, usage information, and examples. These we refer to as the *constituent parts* or *constituents* of the entry; some dictionary constituents possess no internal structure, while others are most naturally viewed as groups of smaller elements, which may be marked in their own right. In some styles of markup, tags will be applied only to the low-level items, leaving the constituent groups which contain them untagged. We distinguish the class of *top-level constituents* of dictionary entries, which can occur directly within the <entry> element, from the class of *phrase-level constituents*, which can normally occur only within top-level constituents. The top-level constituents of dictionary entries are described in section 9.2.2. *Groups and Constituents*, and documented more fully, together with their phrase-level sub-constituents, in section 9.3. *Top-level Constituents of Entries*.

In addition, however, dictionary entries often have a complex hierarchical structure. For example, an entry may consist of two or more sub-parts, each corresponding to information for a different part-of-speech homograph of the headword. The entry (or part-of-speech homographs, if the entry is split this way) may also consist of senses, each of which may in turn be composed of two or more sub-senses, etc. Each sub-part, homograph entry, sense, or sub-sense we call a *level*; at any level in an entry, any or all of the constituent parts of dictionary entries may appear. The hierarchical levels of dictionary entries are documented in section 9.2.1. *Hierarchical Levels*.

### 9.2.1 Hierarchical Levels

The outermost structural level of an entry is marked with the elements <entry> or <entryFree>. The <hom> element marks the subdivision of entries into homographs differing in their part-of-speech. The <sense> element marks the subdivision of entries and part-of-speech homographs into senses; this element nests recursively in order to provide for a hierarchy of sub-senses of any depth. It is recommended to use the <sense> element even for an entry that has only one sense to group together all parts of the definition relating to the word sense since this leads to more consistent encoding across entries. All of these levels may each contain any of the constituent parts of an entry. A special case of hierarchical structure is represented by the <re> (related entry) element, which is discussed in section 9.3.6. *Related Entries*. Finally, the element <dictScrap> may be used at any point in the hierarchy to delimit parts of the dictionary entry which are structurally anomalous, as further discussed in section 9.6. *Unstructured Entries*.

**<entry>** contains a single structured entry in any kind of lexical resource, such as a dictionary or lexicon.

**<entryFree>** (unstructured entry) contains a single unstructured entry in any kind of lexical resource, such as a dictionary or lexicon.

**<hom>** (homograph) groups information relating to one homograph within an entry.

**<sense>** groups together all information relating to one word sense in a dictionary entry, for example definitions, examples, and translation equivalents.

**@level** gives the nesting depth of this sense.

**<dictScrap>** (dictionary scrap) encloses a part of a dictionary entry in which other phrase-level dictionary elements are freely combined.

For example, an entry with two senses will have the following structure:

```
<entry>
  <sense n="1"/>
  <sense n="2"/>
</entry>
```

An entry with two homographs, the first with two senses and the second with three (one of which has two sub-senses), may have a structure like this:

```
<entry>
  <hom n="1">
    <sense n="1">
<!-- ... -->
    </sense>
    <sense n="2">
<!-- ... -->
    </sense>
  </hom>
  <hom n="2">
    <sense n="1">
      <sense n="a">
<!-- ... -->
      </sense>
    <sense n="b">
<!-- ... -->
    </sense>
  </sense>
    <sense n="2">
<!-- ... -->
    </sense>
    <sense n="3">
<!-- ... -->
    </sense>
  </hom>
</entry>
```

In some dictionaries, homographs have separate entries; in such a case, as noted in section 9.1. *Dictionary Body and Overall Structure*, the two homographs may be treated as entries, optionally grouped in a **<superEntry>**:

```
<superEntry>
  <entry n="1" type="hom">
    <sense n="1">
<!-- ... -->
    </sense>
    <sense n="2">
<!-- ... -->
    </sense>
  </entry>
  <entry n="2" type="hom">
    <sense n="1">
      <sense n="a">
```

```

<!-- ... -->
  </sense>
  <sense n="b">
<!-- ... -->
  </sense>
</sense>
  <sense n="2">
<!-- ... -->
  </sense>
  <sense n="3">
<!-- ... -->
  </sense>
</entry>
</superEntry>

```

The hierarchic structure of a dictionary entry is enforced by the structures defined in this module. The content model for `<entry>` specifies that entries do not nest, that homographs nest within entries, and that senses nest within entries, homographs, or senses, and may be nested to any depth to reflect the embedding of sub-senses. Any of the top-level constituents (`<def>`, `<usg>`, `<form>`, etc.) can appear at any level (i.e., within entries, homographs, or senses).

### 9.2.2 Groups and Constituents

As noted above, dictionary entries, and subordinate levels within dictionary entries, may comprise several constituent parts, each providing a different type of information about the word treated. The *top-level constituents* of dictionary entries are:

- information about the form of the word treated (orthography, pronunciation, hyphenation, etc.)
- grammatical information (part of speech, grammatical sub-categorization, etc.)
- definitions or translations into another language
- etymology
- examples
- usage information
- cross-references to other entries
- notes
- entries (often of reduced form) for related words, typically called *related entries*

Any of the hierarchical levels (`<entry>`, `<entryFree>`, `<hom>`, and `<sense>`) may contain any of these top-level constituents, since information about word form, particular grammatical information, special pronunciation, usage information, etc., may apply to an entire entry, or to only one homograph, or only to a particular sense. The examples below illustrate this point.

The following elements are used to encode these top-level constituents:

**<form>** (form information group) groups all the information on the written and spoken forms of one headword.

**<gramGrp>** (grammatical information group) groups morpho-syntactic information about a lexical item, e.g. `<pos>`, `<gen>`, `<number>`, `<case>`, or `<iType>` (inflectional class).

**<def>** (definition) contains definition text in a dictionary entry.

**<cit>** (cited quotation) contains a quotation from some other document, together with a bibliographic reference to its source. In a dictionary it may contain an example text with at least one occurrence of the word form, used in the sense being described, or a translation of the headword, or an example.

**<usg>** (usage) contains usage information in a dictionary entry.

**<xr>** (cross-reference phrase) contains a phrase, sentence, or icon referring the reader to some other location in this or another text.

**<etym>** (etymology) encloses the etymological information in a dictionary entry.

**<re>** (related entry) contains a dictionary entry for a lexical item related to the headword, such as a compound phrase or derived form, embedded inside a larger entry.

**<note>** contains a note or annotation.

In a simple entry with no internal hierarchy, all top-level constituents can appear as children of **<entry>**.

**com.peti.tor** /k@m"petit@(r)/ n person who competes. OALD

```
<entry>
  <form>
    <orth>competitor</orth>
    <hyph>com|peti|tor</hyph>
    <pron>k@m"petit@(r)</pron>
  </form>
  <gramGrp>
    <pos>n</pos>
  </gramGrp>
  <def>person who competes.</def>
</entry>
```

For the elements which appear within the **<form>** and **<gramGrp>** elements of this and other examples, see below, section 9.3.1. *Information on Written and Spoken Forms*, and section 9.3.2. *Grammatical Information*.

Any top-level constituent can appear at any level when the hierarchical structure of the entry is more complex. The most obvious examples are **<def>** and **<cit>**, which appear at the **<sense>** level when several senses or translations exist:

**disproof** (dIs"pru:f) n. 1. facts that disprove something. 2. the act of disproving. CED

```
<entry>
  <form>
    <orth>disproof</orth>
    <pron>dIs"pru:f</pron>
  </form>
  <gramGrp>
    <pos>n</pos>
  </gramGrp>
  <sense n="1">
    <def>facts that disprove something.</def>
  </sense>
  <sense n="2">
    <def>the act of disproving.</def>
  </sense>
</entry>
```

For ease of processing of such entries containing multiple senses along with those containing only a single sense, it is recommended to use **<sense>** in all entries to wrap those elements relating to a particular word sense.

In the following example, **<gramGrp>** is used to distinguish two homographs:

**bray** /breI/ n cry of an ass; sound of a trumpet. · vt [VP2A] make a cry or sound of this kind. OALD

```
<entry>
  <form>
    <orth>bray</orth>
```

```

    <pron>breI</pron>
  </form>
  <hom>
    <gramGrp>
      <pos>n</pos>
    </gramGrp>
    <sense>
      <def>cry of an ass; sound of a trumpet.</def>
    </sense>
  </hom>
  <hom>
    <gramGrp>
      <pos>vt</pos>
      <subc>VP2A</subc>
    </gramGrp>
    <sense>
      <def>make a cry or sound of this kind.</def>
    </sense>
  </hom>
</entry>

```

Information of the same kind can appear at different levels within the same entry; here, grammatical information occurs both at entry and homograph level.

ca.reen /k@"ri:n/ vt,vi 1 [VP6A] turn (a ship) on one side for cleaning, repairing, etc. 2 [VP6A, 2A] (cause to) tilt, lean over to one side. OALD

```

<entry>
  <form>
    <orth>careen</orth>
    <hyph>ca|reen</hyph>
    <pron>k@"ri:n</pron>
  </form>
  <gramGrp>
    <pos>vt</pos>
    <pos>vi</pos>
  </gramGrp>
  <sense n="1">
    <gramGrp>
      <subc>VP6A</subc>
    </gramGrp>
    <def>turn (a ship) on one side for cleaning, repairing, etc.</def>
  </sense>
  <sense n="2">
    <gramGrp>
      <subc>VP6A</subc>
      <subc>VP2A</subc>
    </gramGrp>
    <def>(cause to) tilt, lean over to one side.</def>
  </sense>
</entry>

```

Alone among the constituent groups, <form> can appear at the <superEntry> level as well as at the <entry>, <hom>, and <sense> levels:

a.ban.don 1/@"band@n/ v [T1] 1 to leave completely and for ever; desert: The sailors abandoned the burning ship. 2 ...abandon 2 n [U] the state when one's feelings and actions are uncontrolled; freedom from control...LDOCE

```

<superEntry>
  <form>
    <orth>abandon</orth>
    <hyph>a|ban|don</hyph>
    <pron>@"band@n/</pron>
  </form>
  <entry n="1">
    <gramGrp>
      <pos>v</pos>
      <subc>T1</subc>
    </gramGrp>
    <sense n="1">
      <def>to leave completely and for ever ... </def>
    </sense>
    <sense n="2"/>
  </entry>
  <entry n="2">
    <gramGrp>
      <pos>n</pos>
      <subc>U</subc>
    </gramGrp>
    <sense>
      <def>the state when one's feelings and actions are uncontrolled; freedom
        from control...</def>
    </sense>
  </entry>
</superEntry>

```

## 9.3 Top-level Constituents of Entries

This section describes the top-level constituents of dictionary entries, together with the phrase-level constituents peculiar to each.

- the <form> element, which groups orthographic information and pronunciations, is described in section 9.3.1. *Information on Written and Spoken Forms*
- the <gramGrp> element, which groups elements for the grammatical characterization of the headword, is described in section 9.3.2. *Grammatical Information*
- the <def> element, which describes the meaning of the headword, is described in section 9.3.3. *Sense Information*
- the <etym> element and its special phrase-level elements are documented in section 9.3.4. *Etymological Information*
- the <cit> element and its specific applications are described in section 9.3.3. *Sense Information* and section 9.3.5. *Other Information*
- the <usg>, <lbl>, <xr>, and <note> elements are described in section 9.3.5. *Other Information*
- the <re> element, which marks nested entries for related words, is described in section 9.3.6. *Related Entries*

### 9.3.1 Information on Written and Spoken Forms

Dictionary entries most often begin with information about the form of the word to which the entry applies. Typically, the orthographic form of the word, sometimes marked for syllabification or hyphenation, is the first item in an entry. Other information about the word, including variant or alternate forms, inflected forms, pronunciation, etc., is also often given.

The following elements should be used to encode this information: the <form> element groups one or more occurrences of any of them; it can also be recursively nested to reflect more complex sub-grouping of information about word form(s), as shown in the examples.

**<form>** (form information group) groups all the information on the written and spoken forms of one headword.

**@type** classifies form as simple, compound, etc.

**<orth>** (orthographic form) gives the orthographic form of a dictionary headword.

**@type** gives the type of spelling.

**@extent** gives the extent of the orthographic information provided.

**<pron>** (pronunciation) contains the pronunciation(s) of the word.

**@extent** indicates whether the pronunciation is for whole word or part.

**<hyph>** (hyphenation) contains a hyphenated form of a dictionary headword, or hyphenation information in some other form.

**<syll>** (syllabification) contains the syllabification of the headword.

**<stress>** contains the stress pattern for a dictionary headword, if given separately.

**<lbl>** (label) contains a label for a form, example, translation, or other piece of information, e.g. abbreviation for, contraction of, literally, approximately, synonyms:, etc.

In addition to those listed above, the following elements, which encode morphological details of the form, may also occur within <form> elements:

**<gram>** (grammatical information) within an entry in a dictionary or a terminological data file, contains grammatical information relating to a term, word, or form.

**@type** classifies the grammatical information given according to some convenient typology—in the case of terminological information, preferably the dictionary of data element types specified in ISO 12620.

**<gen>** (gender) identifies the morphological gender of a lexical item, as given in the dictionary.

**<number>** indicates grammatical number associated with a form, as given in a dictionary.

**<case>** contains grammatical case information given by a dictionary for a given form.

**<per>** (person) contains an indication of the grammatical person (1st, 2nd, 3rd, etc.) associated with a given inflected form in a dictionary.

**<tns>** (tense) indicates the grammatical tense associated with a given inflected form in a dictionary.

**<mood>** contains information about the grammatical mood of verbs (e.g. indicative, subjunctive, imperative).

**<iType>** (inflectional class) indicates the inflectional class associated with a lexical item.

**@type** indicates the type of indicator used to specify the inflection class, when it is necessary to distinguish between the usual abbreviated indications (e.g. *inv*) and other kinds of indicators, such as special codes referring to conjugation patterns, etc.

**<pos>** (part of speech) indicates the part of speech assigned to a dictionary headword such as noun, verb, or adjective.

**<subc>** (subcategorization) contains subcategorization information (transitive/intransitive, countable/non-countable, etc.)

**<colloc>** (collocate) contains any sequence of words that co-occur with the headword with significant frequency.

Of these, the <gram> element is most general, and all of the others are synonymous with a <gram> element with appropriate values (gen, number, case, etc.) for the *type* attribute.

The use of these elements as children of <form> is deprecated; instead, they should always be children of a <gramGrp> within <form> when describing that particular form of the word.

Different dictionaries use different means to mark hyphenation, syllabification, and stress, and they often use some unusual glyphs (e.g., the ‘middle dot’ for hyphenation). All of these glyphs are in the Unicode character set, as discussed in *v.6.1 Character References*. When transcribing representations of pronunciation the International Phonetic Alphabet should be used. It may be convenient (as has been done in the text of this chapter) to use a simple transliteration scheme for this; such a scheme should however be properly documented in the header.

In the simplest case, nothing is given but the orthography:

```
<form>
  <orth>doom-laden</orth>
</form>
```

Often, however, pronunciation is given.

soucoupe [sukup] ... DNT

```
<form>
  <orth>soucoupe</orth>
  <pron>sukup</pron>
</form>
```

For a variety of reasons including ease of processing, it may be desired to split into separate elements information which is collapsed into a single element in the source text; orthography and hyphenation may for example be transcribed as separate elements, although given together in the source text. For a discussion of the issues involved, and of methods for retaining both the presentation form and the interpreted form, see section 9.5. *Typographic and Lexical Information in Dictionary Data*.

This example splits orthography and hyphenation, and adds syllabification because it differs from hyphenation:

ar.ea ... W7

```
<form>
  <orth>area</orth>
  <hyph>ar|ea</hyph>
  <syll>ar|e|a</syll>
</form>
```

Multiple orthographic forms may be given, e.g. to illustrate a word's inflectional pattern:

brag ... vb. brags, bragging, bragged ... CED

```
<form>
  <orth>brag</orth>
</form>
<gramGrp>
  <pos>vb</pos>
</gramGrp>
<form type="inflected">
  <orth>brags</orth>
  <orth>bragging</orth>
  <orth>bragged</orth>
</form>
```

Or the inflectional pattern may be indicated by reference to a table of paradigms, as here:

horrifier [ORi fje] (7) vt ... [C/R]

```

<form>
  <orth>horrifier</orth>
  <pron>ORifje</pron>
  <gramGrp>
    <iType type="vtable">7</iType>
  <!-- ... -->
  </gramGrp>
</form>
<!-- ... -->

```

Explanatory labels may be attached to alternate forms:

MTBF *abbrev. for* mean time between failures. CED

```

<entry>
  <form type="abbrev">
    <orth>MTBF</orth>
  </form>
  <form type="full">
    <lbl>abbrev. for</lbl>
    <orth>mean time between failures</orth>
  </form>
</entry>

```

When multiple orthographic forms are given, a pronunciation may be associated with all of them, as here:

biryani or biriani (%bIrI"A:nI) ... CED

```

<form>
  <orth>biryani</orth>
  <orth>biriani</orth>
  <pron>%bIrI"A:nI</pron>
</form>

```

In other cases, different pronunciations are provided for different orthographic forms; here, the <form> element is repeated to associate the first orthographic form explicitly with the first pronunciation, and the second orthographic form with the second pronunciation:

mackle ("mak^@l) or macule ("makju:l) ... CED

```

<form>
  <orth>mackle</orth>
  <pron>"makə̀l</pron>
</form>
<form>
  <orth>macule</orth>
  <pron>"makju:l</pron>
</form>

```

Recursive nesting of the <form> element can preserve relations among elements that are implicit in the text. For example, in the CED entry for 'hospitaller', it is clear that 'U.S.' is associated only with 'hospitaler', but that the pronunciation applies to both forms. The following encoding preserves these relations:

hospitaller or U.S. hospitaler ("hQspIt@l@) ... CED

```
<form>
  <orth>hospitaller</orth>
  <form>
    <usg type="geo">U.S.</usg>
    <orth>hospitaler</orth>
  </form>
  <pron>"hQspIt@l@</pron>
</form>
```

### 9.3.2 Grammatical Information

The <gramGrp> element groups grammatical information, such as part of speech, subcategorization information (e.g., syntactic patterns for verbs, count/mass distinctions for nouns), etc. It can contain any of the morphological elements defined in section 9.3.1. *Information on Written and Spoken Forms* for <form> and can appear as a child of <entry>, <form>, <sense>, <cit>, or any other element containing content about which there is grammatical information. For example, in the entry ‘pinna (‘pIn@) n., pl. -nae (-ni:) or -nas’ CED, the word defined can be either singular or plural; the ‘pl.’ specification applies only to the inflected forms provided. Compare this with ‘pants (paents) pl. n.’, where ‘pl.’ applies to the headword itself.

As noted above in section 9.3.1. *Information on Written and Spoken Forms*, the elements for morphological information are simply shorthand for the general purpose <gram> element. Consider this entry for the French word *médire*:

médire v.t. ind. (de) ... PLC

This entry can be tagged using specialized grammatical elements:

```
<form>
  <orth>médire</orth>
</form>
<gramGrp>
  <pos>v</pos>
  <subc>t ind</subc>
  <colloc>de</colloc>
</gramGrp>
```

Or using the <gram> element:

```
<form>
  <orth>médire</orth>
</form>
<gramGrp>
  <gram type="pos">v</gram>
  <gram type="subc">t ind</gram>
  <gram type="collocPrep">de</gram>
</gramGrp>
```

Like <form>, <gramGrp> can be repeated, recursively nested, or used at the <sense> level to show relations among elements.

isotope adj. et n. m. ... DNT

```

<form>
  <orth>isotope</orth>
</form>
<gramGrp>
  <pos>adj</pos>
</gramGrp>
<gramGrp>
  <pos>n</pos>
  <gen>m</gen>
</gramGrp>

```

wits (wIts) pl. n. 1. (sometimes sing.) the ability to reason and act, esp. quickly ... CED

```

<entry>
  <form>
    <orth>wits</orth>
    <pron>wIts</pron>
  </form>
  <gramGrp>
    <number>pl</number>
    <pos>n</pos>
  </gramGrp>
  <sense n="1">
    <gramGrp>
      <number>sometimes sing.</number>
    </gramGrp>
    <def>the ability to reason and act, esp. quickly ...</def>
  </sense>
</entry>

```

### 9.3.3 Sense Information

Dictionaries may describe the meanings of words in a wide variety of different ways—by means of synonyms, paraphrases, translations into other languages, formal definitions in various highly stylized forms, etc. No attempt is made here to distinguish all the different forms which sense information may take; all of them may be tagged using the <def> element described in section 9.3.3.1. *Definitions*.

As a special case it is frequently desirable to distinguish the provision of translation equivalents in other languages from other forms of sense information; the use of <cit type="translation"> (which groups a translation equivalent with related information such as its grammatical description) for this purpose is described in section 9.3.3.2. *Translation Equivalents*.

#### 9.3.3.1 Definitions

Dictionary definitions are those pieces of prose in a dictionary entry that describe the meaning of some lexical item. Most often, definitions describe the headword of the entry; in some cases, they describe translated texts, examples, etc.; see <cit type="translation">, section 9.3.3.2. *Translation Equivalents*, and <cit type="example">, section 9.3.5.1. *Examples*. The <def> element directly contains the text of the definition; unlike <form> and <gramGrp>, it does not serve solely to group a set of smaller elements. The close analysis of definition text, such as the tagging of hypernyms, typical objects, etc., is not covered by these Guidelines.

Definitions may occur directly within an entry; when multiple definitions are given, they are typically identified as belonging to distinct senses, as here:

**demigod** (...) n. 1.a. a being who is part mortal, part god. b. a lesser deity. 2. a godlike person. CP

```

<entry>
  <form>
    <orth>demigod</orth>
    <pron> ... </pron>
  </form>
  <gramGrp>
    <pos>n</pos>
  </gramGrp>
  <sense n="1">
    <sense n="a">
      <def>a being who is part mortal, part god.</def>
    </sense>
    <sense n="b">
      <def>a lesser deity.</def>
    </sense>
  </sense>
  <sense n="2">
    <def>a godlike person.</def>
  </sense>
</entry>

```

In multilingual dictionaries, it is sometimes possible to distinguish translation equivalents from definitions proper; here a <def> element is distinguished from the translation information within which it appears.

rémoulade [Remuɫad] nf remoulade, rémoulade (*dressing containing mustard and herbs*). CR

```

<entry>
  <form>
    <orth>rémoulade</orth>
    <pron>Remuɫad</pron>
  </form>
  <gramGrp>
    <pos>n</pos>
    <gen>f</gen>
  </gramGrp>
  <cit type="translation" xml:lang="en">
    <quote>remoulade</quote>
    <quote>rémoulade</quote>
    <def>dressing containing mustard and herbs</def>
  </cit>
</entry>

```

### 9.3.3.2 Translation Equivalents

Multilingual dictionaries contain information about translations of a given word in some source language for one or more target languages. Minimally, the dictionary provides the corresponding translation in the target language; other material, such as morphological information (gender, case), various kinds of usage restrictions, etc., may also be given. If translation equivalents are to be distinguished from other kinds of sense information, they may be encoded using <cit type="translation">. The global *xml:lang* attribute should be used to specify the target language.

As in monolingual dictionaries, the <sense> element is used in multilingual dictionaries to group information (forms, grammatical information, usage, translation(s), etc.) about a given sense of a word where necessary. Information about the individual translation equivalents within a sense is grouped using <cit type="translation">. This information may include the translation text (tagged <q> or <quote>), morphological information (<gen>, <case>, etc.), usage notes (<usg>), translation labels (<lbl>), and definitions (<def>). When bibliographic data is provided, the <quote> element should be used.

**<cit>** (cited quotation) contains a quotation from some other document, together with a bibliographic reference to its source. In a dictionary it may contain an example text with at least one occurrence of the word form, used in the sense being described, or a translation of the headword, or an example.

**<lbl>** (label) contains a label for a form, example, translation, or other piece of information, e.g. abbreviation for, contraction of, literally, approximately, synonyms:, etc.

Note how in the following example, different translation equivalents are grouped into the same or different senses, following the punctuation of the source and the usage labels:

**dresser** ... (a) (Theat) habilleur m, -euse f; (Comm: window ~) étalagiste mf. she's a stylish ~elle s'habille avec chic; V hair. (b) (tool) (for wood) raboteuse f; (for stone) rabotin m. CR

```
<entry n="1">
  <form>
    <orth>dresser</orth>
  </form>
  <sense n="a">
    <sense>
      <usg type="dom">Theat</usg>
      <cit type="translation" xml:lang="fr">
        <quote>habilleur</quote>
        <gramGrp>
          <gen>m</gen>
        </gramGrp>
      </cit>
      <cit type="translation" xml:lang="fr">
        <quote>-euse</quote>
        <gramGrp>
          <gen>f</gen>
        </gramGrp>
      </cit>
    </sense>
    <sense>
      <usg type="dom">Comm</usg>
      <form type="compound">
        <orth>>window <oRef/>
      </orth>
      </form>
      <cit type="translation" xml:lang="fr">
        <quote>étalagiste</quote>
        <gramGrp>
          <gen>mf</gen>
        </gramGrp>
      </cit>
    </sense>
    <cit type="example">
      <quote>she's a stylish <oRef/>
    </quote>
    <cit type="translation" xml:lang="fr">
      <quote>elle s'habille avec chic</quote>
    </cit>
  </cit>
  <xr type="see">V. <ref target="#hair">hair</ref>
</xr>
</sense>
<sense n="b">
  <usg type="category">tool</usg>
</sense>
```

```

<usg type="hint">for wood</usg>
<cit type="translation" xml:lang="fr">
  <quote>raboteuse</quote>
  <gramGrp>
    <gen>f</gen>
  </gramGrp>
</cit>
</sense>
<sense>
  <usg type="hint">for stone</usg>
  <cit type="translation" xml:lang="fr">
    <quote>rabotin</quote>
    <gramGrp>
      <gen>m</gen>
    </gramGrp>
  </cit>
</sense>
</sense>
</entry>
<!-- ... -->
<entry xml:id="hair">
  <sense>
<!-- ... -->
  </sense>
</entry>

```

In the following example, a distinction is made between the translation equivalent ('OAS') and a descriptive phrase providing further information for the user of the dictionary.

O.A.S. ... nf (abrév de **Organisation de l'Armée secrète**) OAS (*illegal military organization supporting French rule of Algeria*). CR

```

<entry>
<!-- ... -->
  <cit type="translation" xml:lang="en">
    <quote>OAS</quote>
    <def>illegal military organization supporting French rule of
      Algeria</def>
  </cit>
</entry>

```

Note that <cit type="translation"> may also be used in monolingual dictionaries when a translation is given for a foreign word:

havdalah or havdoloh Hebrew. (Hebrew hAvdA"lA; Yiddish hAv"dOl@) n. Judaism. the ceremony marking the end of the sabbath or of a festival, including the blessings over wine, candles and spices. [literally: separation] CED

```

<entry type="foreign">
  <form>
    <orth>havdalah</orth>
    <orth>havdoloh</orth>
  <gramGrp>

```

```

    <gram type="pos">n.</gram>
  </gramGrp>
</form>
<sense>
  <usg type="dom">Judaism</usg>
  <def>the ceremony marking the end of the sabbath or of a festival,
    including the blessings over wine, candles and spices.</def>
</sense>
<cit type="translation" xml:lang="en">
  <usg type="style">literally</usg>
  <quote>separation</quote>
</cit>
</entry>

```

### 9.3.4 Etymological Information

The element `<etym>` marks a block of etymological information. Etymologies may contain highly structured lists of words in an order indicating their descent from each other, but often also include related words and forms outside the direct line of descent, for comparison. Not infrequently, etymologies include commentary of various sorts, and can grow into short (or long!) essays with prose-like structure. This variation in structure makes it impracticable to define tags which capture the entire intellectual structure of the etymology or record the precise interrelation of all the words mentioned. It is, however, feasible to mark some of the more obvious phrase-level elements frequently found in etymologies, using tags defined in the core module or elsewhere in this chapter. Of particular relevance for the markup of etymologies are:

**<etym>** (etymology) encloses the etymological information in a dictionary entry.

**<lang>** (language name) contains the name of a language mentioned in etymological or other linguistic discussion.

**<date>** contains a date in any format.

**<mentioned>** marks words or phrases mentioned, not used.

**<gloss>** identifies a phrase or word used to provide a gloss or definition for some other word or phrase.

**<pron>** (pronunciation) contains the pronunciation(s) of the word.

**<usg>** (usage) contains usage information in a dictionary entry.

**<lbl>** (label) contains a label for a form, example, translation, or other piece of information, e.g. abbreviation for, contraction of, literally, approximately, synonyms:, etc.

As in other prose, individual word forms mentioned in an etymological description are tagged with `<mentioned>` elements. Pronunciations, usage labels, and glosses can be tagged using the `<pron>`, `<usg>`, and `<gloss>` elements defined elsewhere in these Guidelines. In addition, the `<lang>` element may be used to identify a particular language name where it appears, in addition to using the `xml:lang` attribute of the `<mentioned>` element.

Examples:

abismo m. (del gr. a priv. y byssos, fondo). Sima, gran profundidad. ...

```

<entry>
  <form>
    <orth>abismo</orth>

### 9.3.5 Other Information

#### 9.3.5.1 Examples

Dictionaries typically include examples of word use, usually accompanying definitions or translations. In some cases, the examples are quotations from another source, and are occasionally followed by a citation to the author.

The `<cit type="example">` element contains usage examples and associated information; the example text itself should be enclosed in a `<q>` or `<quote>` element. The `<cit>` element associates a quotation with a bibliographic reference to its source.

**<q>** (quoted) contains material which is distinguished from the surrounding text using quotation marks or a similar method, for any one of a variety of reasons including, but not limited to: direct speech or thought, technical terms or jargon, authorial distance, quotations from elsewhere, and passages that are mentioned but not used.

**<quote>** (quotation) contains a phrase or passage attributed by the narrator or author to some agency external to the text.

**<cit>** (cited quotation) contains a quotation from some other document, together with a bibliographic reference to its source. In a dictionary it may contain an example text with at least one occurrence of the word form, used in the sense being described, or a translation of the headword, or an example.

Examples frequently abbreviate the headword, and so their transcription will frequently make use of the `<oRef>` or `<oVar>` elements described below in section 9.4. *Headword and Pronunciation References*.

Examples:

**multiplex** /.../ adj tech having many parts: the multiplex eye of the fly. LDOCE

```
<quote>the multiplex eye of the fly.</quote>
```

Or when one wants a more comprehensive representation of examples:

```
<cit type="example">
  <quote>the multiplex eye of the fly.</quote>
</cit>
```

As the following example shows, <cit> can also contain elements such as <pron>, <def>, etc.

some ... 4. (*S*~ and *any* are used with *more*): Give me ~more/s@'m0:(r)/ OALD

```
<sense n="4">
  <usg type="colloc">
    <oRef type="cap"/> and <mentioned>any</mentioned> are used with
  <mentioned>more</mentioned>
</usg>
  <cit type="example">
    <quote>Give me <oRef/> more</quote>
    <pron extent="part">s@m0:(r)</pron>
  </cit>
</sense>
```

In multilingual dictionaries, examples may also be accompanied by translations:

horrifier ... vt to horrify. elle était horrifiée par la dépense she was horrified at the expense. CR

```
<entry>
<!-- ... -->
  <cit type="translation" xml:lang="en">
    <quote>to horrify</quote>
  </cit>
  <cit type="example">
    <quote>elle était horrifiée par la dépense</quote>
    <cit type="translation" xml:lang="en">
      <quote>she was horrified at the expense.</quote>
    </cit>
  </cit>
</entry>
```

When a source is indicated, the example should be marked with a <bibl> element:

valeur ... n. f. ... 2. Vx. Vaillance, bravoure (spécial., au combat). 'La valeur n'attend pas le nombre des années' (Corneille). ... DNT

```
<sense n="2">
  <usg type="time">Vx.</usg>
  <def>Vaillance, bravoure (spécial., au combat)</def>
  <cit type="example">
    <quote>La valeur n'attend pas le nombre des années</quote>
    <bibl>
      <author>Corneille</author>
    </bibl>
  </cit>
</sense>
```

### 9.3.5.2 Usage Information and Other Labels

Most dictionaries provide restrictive labels and phrases indicating the usage of given words or particular senses. Other phrases, not necessarily related to usage, may also be attached to forms, translations, cross-references, and examples. The following elements are provided to mark up such labels:

**<usg>** (usage) contains usage information in a dictionary entry.

**<lbl>** (label) contains a label for a form, example, translation, or other piece of information, e.g. abbreviation for, contraction of, literally, approximately, synonyms:, etc.

As indicated in the following section (9.3.5.3. *Cross-References to Other Entries*), the **<lbl>** element may be used for any kind of significant phrase or label within the text. The **<usg>** element is a specialization of this to mark usage labels in particular. Usage labels typically indicate

- temporal use (archaic, obsolete, etc.)
- register (slang, formal, taboo, ironic, facetious, etc.)
- style (literal, figurative, etc.)
- connotative effect (e.g. derogatory, offensive)
- subject field (Astronomy, Philosophy, etc.)
- national or regional use (Australian, U.S., Midland dialect, etc.)

Many dictionaries provide an explanation and/or a list of such usage labels in a preface or appendix. The type of the usage information may be indicated in the *type* attribute on the **<usg>** element. Some typical values are:

**geo** geographic area

**time** temporal, historical era ('archaic', 'old', etc.)

**dom** domain

**reg** register

**style** style (figurative, literal, etc.)

**plev** preference level ('chiefly', 'usually', etc.)

**acc** acceptability

**lang** language for foreign words, spellings pronunciations, etc.

**gram** grammatical usage

In addition to this kind of information, multilingual dictionaries often provide 'semantic cues' to help the user determine the right sense of a word in the source language (and hence the correct translation). These include synonyms, concept subdivisions, typical subjects and objects, typical verb complements, etc. These labels may also be marked with the **<usg>** element; sample values for the *type* attribute in these cases include:

**syn** synonym given to show use

**hyper** hypernym given to show usage

**colloc** collocation given to show usage

**comp** typical complement

**obj** typical object

**subj** typical subject

**verb** typical verb

**hint** unclassifiable piece of information to guide sense choice

In this entry, one spelling is marked as geographically restricted:

**colour** or U.S. **color** ... CED

```

<form>
  <orth>colour</orth>
  <form>
    <usg type="geo">U.S.</usg>
    <orth>color</orth>
  </form>
</form>

```

In the next example, usage labels are used to indicate domains, register, and synonyms associated with different senses:

**palette** [paLEt] nf (a) (Peinture: lit, fig) palette. (b) (Boucherie) shoulder. (c) (aube de roue) paddle; (battoir à linge) beetle; (Manutention, Constr) pallet. CR

```

<sense n="a">
  <usg type="dom">Peinture</usg>
  <usg type="style">lit</usg>
  <usg type="style">fig</usg>
  <cit type="translation" xml:lang="en">
    <quote>palette</quote>
  </cit>
</sense>
<sense n="b">
  <usg type="dom">Boucherie</usg>
  <cit type="translation" xml:lang="en">
    <quote>shoulder</quote>
  </cit>
</sense>
<sense n="c">
  <sense>
    <usg type="syn">aube de roue</usg>
    <cit type="translation" xml:lang="en">
      <quote>paddle</quote>
    </cit>
  </sense>
  <sense>
    <usg type="syn">battoir à linge</usg>
    <cit type="translation" xml:lang="en">
      <quote>beetle</quote>
    </cit>
  </sense>
  <sense>
    <usg type="dom">Manutention</usg>
    <usg type="dom">Constr</usg>
    <cit type="translation" xml:lang="en">
      <quote>pallet</quote>
    </cit>
  </sense>
</sense>

```

When the usage label is hard to classify, it may be described as a 'hint':

**rempillage** [...] nm reseating, rebottoming (*with straw*). CR

```

<entry>
  <cit type="translation" xml:lang="en">
    <quote>reseating</quote>
    <quote>rebottoming</quote>
    <usg type="hint">with straw</usg>
  </cit>
</entry>

```

### 9.3.5.3 Cross-References to Other Entries

Dictionary entries frequently refer to information in other entries, often using extremely dense notations to convey the headword of the entry to be sought, the particular part of the entry being referred to, and the nature of the information to be sought there (synonyms, antonyms, usage notes, etymology, an illustration, etc.)

Cross-references may be tagged in dictionaries using the <ref> and <ptr> elements defined in the core module (section 3.6. *Simple Links and Cross-References*). In addition, the <xr> element may be used to group all the information relating to a cross-reference.

**<xr>** (cross-reference phrase) contains a phrase, sentence, or icon referring the reader to some other location in this or another text.

**<ref>** (reference) defines a reference to another location, possibly modified by additional text or comment.

**<ptr>** (pointer) defines a pointer to another location.

**<lbl>** (label) contains a label for a form, example, translation, or other piece of information, e.g. abbreviation for, contraction of, literally, approximately, synonyms:, etc.

As in other types of text, the actual pointing element (e.g. <ref> or <ptr>) is used to tag the cross-reference target proper (in dictionaries, usually the headword, possibly accompanied by a homograph number, a sense number, or other further restriction specifying what portion of the target entry is being referred to). The <xr> element is used to group the target with any accompanying phrases or symbols used to label the cross-reference; the cross-reference label itself may be tagged as a <lbl> or may remain untagged. Both of the following are thus legitimate:

glee ... Compare **madrigal** (sense 1) CED

```

<entry>
  <form>
    <orth>glee</orth>
  </form>
  <xr>Compare <ptr target="#madrigal.1"/>
</entry>
<entry xml:id="madrigal.1">
  <form>
<!-- ... -->
  </form>
</entry>

```

hostellerie Syn. de hôtellerie (sens 1). DNT

```

<xr type="syn">
  <lbl>Syn. de</lbl>
  <ref>hôtellerie (sens 1)</ref>.
</xr>

```

In addition to using, or not using, <lbl> to mark the cross-reference label, the two examples differ in another way. The former assumes that the first sense of *madrigal* has the identifier *madrigal.1*, and that the specific form of the

reference in the source volume can be reconstructed, if needed, from that information. The latter does not require the first sense of 'hôtellerie' to have an identifier, and retains the print form of the cross-reference; by omitting the *target* attribute of the <ref> element, however, the second example does assume implicitly either that some software could usefully parse the phrase tagged as a <ref> and find the location referred to, or else that such processing will not be necessary.

The *type* attribute on the pointing element or on the <xr> element may be used to indicate what kind of cross-reference is being made, using any convenient typology. Since different dictionaries may label the same kind of cross-reference in different ways, it may be useful to give normalized indications in the *type* attribute, enabling the encoder to distinguish irregular forms of cross-reference more reliably:

rose2 ... vb. the past tense of rise. CED

```
<entry n="2">
  <form>
    <orth>rose</orth>
  </form>
  <xr type="inflectedForm">
    <lbl>the past tense of</lbl>
    <ref target="#rise">rise</ref>
  </xr>
</entry>
<!-- ... -->
<entry xml:id="rise">
  <form>
    <orth>rise</orth>
  </form>
  <!-- main entry for "rise" as verb -->
</entry>
```

from cross-references for synonyms and the like:

antagonist ... syn see adverse W7

```
<xr type="synonym">
  <lbl>syn see</lbl>
  <ref target="#adverse">adverse</ref>
</xr>
<!-- ... -->
<entry xml:id="adverse">
  <form>
    <orth>adverse</orth>
  </form>
  <!-- list of synonyms for "adverse" -->
</entry>
```

Strictly speaking, the reference above is not to the entry for *adverse*, but to the list of synonyms found within that entry. In some cases, the cross-reference is to a particular subset of the meanings of the entry in question:

globe ...V. armillaire (sphère) PR

```
<xr>V. <ref target="#armillaire">armillaire</ref>
  <lbl type="sense-restriction">sphère</lbl>
</xr>
```

Cross-references occasionally occur in definition texts, example texts, etc., or may be free-standing within an entry. These may typically be encoded using <ref> or <ptr>, without an enclosing <xr>. For example:

**entacher** ... *Acte entaché de nullité*, contenant un vice de forme ou passé par un incapable\*. DNT

The asterisk signals a reference to the entry for *incapable*.

```
<def>contenant un vice de forme ou passé par un <ptr target="#incapable"/>.</def>
```

In some cases, the form in the definition is inflected, and thus <ref> must be used to indicate more exactly the intended target, as here:

**justifier** ...4. IMPRIM Donner a (une ligne) une longueur convenable au moyen de blancs (2, sens 1, 3). DNT

```
<sense n="4">
  <usg type="dom">imprim</usg>
  <def>Donner a (une ligne) une longueur convenable au moyen de
  <ref target="#blanc-2.1.3">blancs (2, sens 1, 3)</ref>
  </def>
</sense>
<entry xml:id="blanc" n="2">
  <!-- ... -->
  <sense n="1">
  <!-- ... -->
    <def xml:id="blanc-2.1.3">...</def>
  <!-- ... -->
  </sense>
  <!-- ... -->
</entry>
```

#### 9.3.5.4 Notes within Entries

Dictionaries may include extensive explanatory notes about usage, grammar, context, etc. within entries. Very often, such notes appear as a separate section at the end of an entry. The standard <note> element should be used for such material.

**<note>** contains a note or annotation.

For example:

**ain't** (eInt) *Not standard. contraction of am not, is not, are not, have not or has not: I ain't seen it. ....Usage. Although the interrogative form ain't I? would be a natural contraction of am I not?, it is generally avoided in spoken English and never used in formal English. CED*

```
<entry>
  <form type="contraction">
    <orth>ain't</orth>
    <pron>eInt</pron>
  </form>
  <usg type="reg">Not standard</usg>
  <form type="full">
    <lbl>contraction of</lbl>
    <orth>am not</orth>
    <orth>is not</orth>
    <orth>are not</orth>
    <orth>have not</orth>
    <orth>has not</orth>
```

```

</form>
<cit type="example">
  <quote>I ain't seen it.</quote>
</cit>
<note type="usage">Although the interrogative form <mentioned>ain't
  I?</mentioned> would be a natural contraction of <mentioned>am I
  not?</mentioned>, it is generally avoided in spoken English and
  never used in formal English.</note>
</entry>

```

The formal declaration for <note> is given in section 3.8. *Notes, Annotation, and Indexing*.

### 9.3.6 Related Entries

The <re> element encloses a degenerate entry which appears in the body of another entry for some purpose. Many dictionaries include related entries for direct derivatives or inflected forms of the entry word, or for compound words, phrases, collocations, and idioms containing the entry word.

Related entries can be complex, and may in fact include any of the information to be found in a regular entry. Therefore, the <re> element is defined to contain the same elements as an <entry> element, with the exception that it may not contain any nested <re> elements.

Examples:

- bevy ("bEvI) Dialect. ~n., pl. -vies. 1. a drink, esp. an alcoholic one: we had a few bevies last night.  
 2. a night of drinking. ~vb. - vies, -vying, -vied (intr.) 3. to drink alcohol [probably from Old French bevee, buvee, drinking] —'bevied adj. CED

```

<entry>
  <form>
    <orth>bevy</orth>
    <pron>"bEvI</pron>
  </form>
  <usg type="reg">Dialect</usg>
  <hom>
    <gramGrp>
      <pos>n</pos>
    </gramGrp>
    <sense n="1">

    </sense>
  </hom>
  <etym>probably from <lang>Old French</lang>
    <mentioned>bevee</mentioned>, <mentioned>buvee</mentioned>
    <gloss>drinking</gloss>
  </etym>
  <re type="derived">
    <form>
      <orth>bevied</orth>

```

```

</form>
<gramGrp>
  <pos>adj</pos>
</gramGrp>
</re>
</entry>

```

## 9.4 Headword and Pronunciation References

Examples, definitions, etymologies, and occasionally other elements such as cross-references, orthographic forms, etc., often contain a shortened or iconic reference to the headword, rather than repeating the headword itself. The references may be to the orthographic form or to the pronunciation, to the form given or to a variant of that form.

The following elements are used to encode such iconic references to a headword:

**<oRef>** (orthographic-form reference) in a dictionary example, indicates a reference to the orthographic form(s) of the headword.

**@type** indicates the kind of typographic modification made to the headword in the reference.

**<pRef>** (pronunciation reference) in a dictionary example, indicates a reference to the pronunciation(s) of the headword.

**<oVar>** (orthographic-variant reference) in a dictionary example, indicates a reference to variant orthographic form(s) of the headword.

**@type** indicates the kind of variant involved.

**<pVar>** (pronunciation-variant reference) in a dictionary example, indicates a reference to variant pronunciation(s) of the headword.

These elements all inherit the following attributes from the class **att.pointing** which may optionally be used to resolve any ambiguity about the headword form being referred to.

**att.pointing** provides a set of attributes used by all elements which point to other elements by means of one or more URI references.

**@target** specifies the destination of the reference by supplying one or more URI References

Headword references come in a variety of formats:

~ indicates a reference to the full form of the headword

pref~ gives a prefix to be affixed to the headword

~suf gives a suffix to be affixed to the headword

A~ gives the first letter in uppercase, indicating that the headword is capitalized

pref~suf gives a prefix and a suffix to be affixed to the headword

a. gives the initial of the word followed by a full stop, to indicate reference to the full form of the headword

A. refers to a capitalized form of the headword

The **<oRef>** element should be used for iconic or shortened references to the orthographic form(s) of the headword itself. It is an empty element and replaces, rather than enclosing, the reference. Note that the reference to a headword is not necessarily a simple string replacement. In the example ‘**colour**1, (US = color) ...~films; ~TV; Red, blue and yellow are ~s.’ OALD, the tilde stands for either headword form (*colour*, *color*).

Examples:

colonel ... army officer above a lieutenant~. OALD

```

<def>army officer above a lieutenant-<oRef/>
</def>

```

academy ... The Royal A~of Arts OALD

```
<q>The Royal <oRef type="cap"/> of Arts</q>
```

The following example demonstrates the use of the *target* attribute to refer to a specific form of the headword:

vag- or vago- comb form ... : vagus nerve < vagal > < vagotomy > W7

```
<entry>
  <form>
    <orth xml:id="di-o1">vag-</orth>
    <orth xml:id="di-o2">vago-</orth>
  </form>
  <def>vagus nerve</def>
  <cit type="example">
    <quote>
      <oRef target="#di-o1" type="nohyph"/>al</quote>
      <quote>
      <oRef target="#di-o2" type="nohyph"/>tomy</quote>
    </cit>
  </entry>
```

In many cases the reference is not to the orthographic form of the headword, but rather to another form of the headword—usually to an inflected form. In these cases, the element `<oVar>` should be used; this element takes as its content the string as it appears in the text.

take ... < Mr Burton **took** us for French > NPEG

```
<cit type="example">
  <quote>Mr Burton <oVar type="pt">took</oVar> us for French</quote>
</cit>
```

take ... < was quite ~n with him > NPEG

```
<cit type="example">
  <quote>was quite <oVar type="pp">
    <oRef/>n</oVar> with him</quote>
</cit>
```

The next example shows a discontinuous reference, using the attributes *next* and *prev*, which are defined in the additional module for linking, segmentation, and alignment (see chapter 16. *Linking, Segmentation, and Alignment*) and therefore require that that module be selected in addition to that for dictionaries.

mix up... < it's easy to **mix her up** with her sister > NPEG

```
<cit type="example">
  <quote>it's easy to <oVar next="#ov2" xml:id="ov1">mix</oVar>
    her <oVar prev="#ov1" xml:id="ov2">up</oVar> with her sister</quote>
</cit>
```

In addition, some dictionaries make reference to the pronunciation of the headword in the pronunciation of related entries, variants, or examples. The `<pRef>` and `<pVar>` elements should be used for such references.

hors d'oeuvre / ,aw' duhv (Fr O:r døvr)/ n, pl hors d'oeuvres also hors d'oeuvre / ' duhv (z) (Fr ~)/  
NPEG

```
<form>
  <orth>hors d'oeuvre</orth>
  <pron>%aU"dUv</pron>
  <form>
    <usg type="lang">Fr</usg>
    <pron xml:id="di-p2">OR d0vR</pron>
  </form>
</form>
<form type="inflected">
  <number>pl</number>
  <orth>hors d'oeuvres</orth>
  <orth>hors d'oeuvre</orth>
  <pron extent="part">"dUv(z)</pron>
  <form>
    <usg type="lang">Fr</usg>
    <pron>
      <pRef target="#di-p2"/>
    </pron>
  </form>
</form>
```

Because headword and pronunciation references can occur virtually anywhere in an entry, the <oRef>, <oVar>, <pRef>, and <pVar> elements can appear within any other element defined for dictionary entries.

Since existing printed dictionaries use different conventions for headword references (swung dash, first letter abbreviated form, capitalization, or italicization of the word, etc.) the exact method used should be documented in the header.

## 9.5 Typographic and Lexical Information in Dictionary Data

Among the many possible views of dictionaries, it is useful to distinguish at least the following three, which help to clarify some issues raised with particular urgency by dictionaries, on account of the complexity of both their typography and their information structure.

- (a) the *typographic view*—the two-dimensional printed page, including information about line and page breaks and other features of layout
- (b) the *editorial view*—the one-dimensional sequence of tokens which can be seen as the input to the typesetting process; the wording and punctuation of the text and the sequencing of items are visible in this view, but specifics of the typographic realization are not
- (c) the *lexical view*—this view includes the underlying information represented in a dictionary, without concern for its exact textual form

For example, a domain indication in a dictionary entry might be broken over a line and therefore hyphenated ('naut-' ical'); the typographic view of the dictionary preserves this information. In a purely editorial view, the particular form in which the domain name is given in the particular dictionary (as 'nautical', rather than 'naut.', 'Naut.', etc.) would be preserved, but the fact of the line break would not. Font shifts might plausibly be included in either a strictly typographic or an editorial view. In the lexical view, the only information preserved concerning domain would be some standard symbol or string representing the nautical domain (e.g. 'naut.') regardless of the form in which it appears in the printed dictionary.

In practice, publishers begin with the lexical view—i.e., lexical data as it might appear in a database—and generate first the editorial view, which reflects editorial choices for a particular dictionary (such as the use of the abbreviation 'Naut.' for 'nautical', the fonts in which different types of information are to be rendered, etc.), and then the typographic view, which is tied to a specific printed rendering. Computational linguists and philologists often begin with the typographic view and analyse it to obtain the editorial and/or lexical views. Some users may ultimately be

concerned with retaining only the lexical view, or they may wish to preserve the typographic or editorial views as a reference text, perhaps as a guard against the loss or misinterpretation of information in the translation process. Some researchers may wish to retain all three views, and study their interrelations, since research questions may well span all three views.

In general, an electronic encoding of a text will allow the recovery of at least one view of that text (the one which guided the encoding); if editorial and typographic practices are consistently applied in the production of a printed dictionary, or if exceptions to the rules are consistently recorded in the electronic encoding, then it is *in principle* possible to recover the editorial view from an encoding of the lexical view, and the typographic view from an encoding of the editorial view. In practice, of course, the severe compression of information in dictionaries, the variety of methods by which this compression is achieved, the complexity of formulating completely explicit rules for editorial and typographic practice, and the relative rarity of complete consistency in the application of such rules, all make the mechanical transformation of information from one view into another something of a vexed question.

This section describes some principles which may be useful in capturing one or the other of these views as consistently and completely as possible, and describes some methods of attempting to capture more than one view in a single encoding. Only the editorial and lexical views are explicitly treated here; for methods of recording the physical or typographic details of a text, see chapter 11. *Representation of Primary Sources*. Other approaches to these problems, such as the use of repetitive encoding and links to show their correspondences, or the use of feature structures to capture the information structure, and of the *ana* and *inst* attributes to link feature structures to a transcription of the editorial view of a dictionary, are not discussed here (for feature structures, see chapter 18. *Feature Structures*. For linkage of textual form and underlying information, see chapter 17. *Simple Analytic Mechanisms*).

### 9.5.1 Editorial View

Common practice in encoding texts of all sorts relies on principles such as the following, which can be used successfully to capture the editorial view when encoding a dictionary:

1. All characters of the source text should be retained, with the possible exception of *rendition text* (for which see further below).
2. Characters appearing in the source text should typically be given as character data content in the document, rather than as the value of an attribute; again, rendition text may optionally be excepted from this rule.
3. Apart from the characters or graphics in the source text, nothing else should appear as content in the document, although it may be given in attribute values.
4. The material in the source text should appear in the encoding in the same order. Complications of the character sequence by footnotes, marginal notes, etc., text wrapping around illustrations, etc., may be dealt with by the usual means (for notes, see section 3.8. *Notes, Annotation, and Indexing*).<sup>71</sup>

In a very conservative transcription of the editorial view of a text, *rendition characters* (e.g. the commas, parentheses, etc., used in dictionary entries to signal boundaries among parts of the entry) and *rendition text* (for example, conjunctions joining alternate headwords, etc.) are typically retained. Removing the tags from such a transcription will leave all and only the characters of the source text, in their original sequence.<sup>72</sup>

Consider, for example, the following entry:

**pinna** (pIn@) n., pl. -nae (-ni:) or -nas. 1. any leaflet of a pinnate compound leaf. 2. *Zoology*. a feather, wing, fin, or similarly shaped part. 3. another name for **auricle** (sense 2). [C18: via New Latin from Latin: wing, feather, fin] CED

A conservative encoding of the editorial view of this entry, which retains all rendition text, might resemble the following:

---

<sup>71</sup>Complications of sequence caused by marginal or interlinear insertions and deletions, which are frequent in manuscripts, or by unconventional page layouts, as in concrete poetry, magazines with imaginative graphic designers, and texts about the nature of typography as a medium, typically do not occur in dictionaries, and so are not discussed here.

<sup>72</sup>This is a slight oversimplification. Even in conservative transcriptions, it is common to omit page numbers, signatures of gatherings, running titles and the like. The simple description above also elides, for the sake of simplicity, the difficulties of assigning a meaning to the phrase 'original sequence' when it is applied to the printed characters of a source text; the 'original sequence' retained or recovered from a conservative transcription of the editorial view is, of course, the one established during the transcription by the encoder.

```

<entry>
  <form>

  </form>
</entry>

```

A somewhat simplified encoding of the editorial view of this entry might exploit the fact that rendition text is often systematically recoverable. For example, parentheses consistently appear around pronunciation in this dictionary, and thus are effectively implied by the start- and end-tags for `<pron>`.<sup>73</sup> In such an encoding, removing the tags should exactly reproduce the sequence of characters in the source, minus rendition text. The original character sequence can be recovered fully by replacing tags with any rendition text they imply.

Encoding in this way, the example given above might resemble the following. The `<tagUsage>` element in the header would be used to record the following patterns of rendition text:

- parentheses appear around `<pron>` elements
- commas appear before inflected forms
- the word ‘or’ appears before alternate forms
- brackets appear around the etymology
- full stops appear after `<pos>`, inflection information, and sense numbers
- senses are numbered in sequence unless otherwise specified using the global *n* attribute

```

<entry>
  <form>

```

<sup>73</sup>The omission of rendition text is particularly common in systems for document production; it is considered good practice there, since automatic generation of rendition text is more reliable and more consistent than attempting to maintain it manually in the electronic text.

```

    <orth>pinna</orth>
    <pron>"pIn@</pron>

    <ref>auricle (sense 2).</ref>
  </xr>
</sense>
<etym>
  <date>C18</date>: via <lang>New Latin</lang> from <lang>Latin</lang>:
  <gloss>wing</gloss>, <gloss>feather</gloss>, <gloss>fin</gloss>
</etym>
</entry>

```

When rendition text is omitted, it is recommended that the means to regenerate it be fully documented, using the <tagUsage> element of the TEI header.

If rendition text is used systematically in a dictionary, with only a few mistakes or exceptions, the global attribute *rend* may be used on any tag to flag exceptions to the normal treatment. The values of the *rend* attribute are not prescribed, but it can be used with values such as no-comma, no-left-paren, etc. Specific values can be documented using the <rendition> element in the TEI header.

In the following (imaginary) example, no left parenthesis precedes the pronunciation:

biryani or biriani %bIrI"A:nI) any of a variety of Indian dishes ... [from Urdu]

This irregularity can be recorded thus:

```

<entry>
  <form>
    <orth>biryani</orth>
    <orth>biriani</orth>
    <pron rend="noleftparen">%bIrI"A:nI</pron>
  </form>
  <def>any of a variety of Indian dishes ... </def>
  <etym>from <lang>Urdu</lang>
</etym>
</entry>

```

### 9.5.2 Lexical View

If the text to be interchanged retains only the lexical view of the text, there may be no concern for the recoverability of the editorial (not to speak of the typographic) view of the text. However, it is strongly recommended that the TEI header be used to document fully the nature of all alterations to the original data, such as normalization of domain names, expansion of inflected forms, etc.

In an encoding of the lexical view of a text, there are degrees of departure from the original data: normalizing inconsistent forms like ‘nautical’, ‘naut.’, ‘Naut.’, etc., to ‘nautical’ is a relatively slight alteration; expansion of ‘delay -ed -ing’ to ‘delay, delayed, delaying’ is a more substantial departure. Still more severe is the rearranging of the order of information in entries; for example:

- reorganizing the order of elements in an entry to show their relationship, as in

**clem** (klEm) or clam vb. clem, clemming, clemmed or clams, clamming, clammed CED

where in a strictly lexical view one might wish to group ‘clem’ and ‘clam’ with their respective inflected forms.

- splitting an entry into two separate entries, as in

**celi.bacy** /"sellb@sI/ n [U] state of living unmarried, esp as a religious obligation. **celi.bate** /"sellb@t/ n [C] unmarried person (esp a priest who has taken a vow not to marry). OALD

For some purposes, this entry might usefully be split into an entry for ‘celibacy’ and a separate entry for ‘celibate’.

An encoding which captures the lexical view of the example given in the previous section might look something like the following. In this encoding:

- abbreviated forms have been silently expanded
- some forms have been moved to allow related forms to be grouped together
- the part of speech information has been moved to allow all forms to be given together
- the cross-reference to ‘auricle’ has been simplified

```
<entry>

  </sense>
```

```

<etym>
  <date>C18</date>: via <lang>New Latin</lang> from <lang>Latin</lang>:
  <gloss>wing</gloss>, <gloss>feather</gloss>, <gloss>fin</gloss>
</etym>
</entry>

```

Whether the given dictionary encoding focusses on the lexical view and thus approaches the status of lexical databases, or uses the typographic/editorial view approach and needs to communicate the sometimes informally stated values for the particular descriptive features, the issue of ‘interoperability’ of the content and of the container objects becomes relevant, in view of the growing tendency to interlink pieces of information across Internet resources. In such cases, it becomes crucial to be able to encode the fact that whether the information on, for instance, the value of the grammatical category of Number is provided as "sg.", "sing.", "Singular", or equivalently "poj." in Polish, or "Ez." in German, etc., what is actually referred to is always the same grammatical value that can be rendered with a plethora of markers, depending on the publisher, language, or lexicographic tradition. In order to signal that this variety of surface markers in fact indicate the same underlying value, it is possible to align them with an external inventory of standardized values. The TEI provides means to align grammatical categories as well as their content with the ISOcat reference, which is a Web implementation of ISO 12620.

In the example below, a fragment of the entry for *isotope* cited in section 9.3.2. *Grammatical Information* is adorned by references to ISOcat definitions for "part of speech" (*dcr:datcat*) and "adjective" (*dcr:valueDatcat*). Depending on the status and extent of the dictionary, various strategies may be used to reduce the redundancy of the repeated ISOcat references.

```

```

### 9.5.3 Retaining Both Views

It is sometimes desirable to retain both the lexical and the editorial view, in which case a potential conflict exists between the two. When there is a conflict between the encodings for the lexical and editorial views, the principles described in the following sections may be applied.

#### 9.5.3.1 Using Attribute Values to Capture Alternate Views

If the order of the data is the same in both views, then both views may be captured by encoding one ‘dominant’ view in the character data content of the document, and encoding the other using attribute values on the appropriate elements. If all tags were to be removed, the remaining characters would be those of the dominant view of the text.

The attribute class `att.lexicographic` is used to provide attributes for use in encoding multiple views of the same dictionary entry. These attributes are available for use on all elements defined in this chapter when the base module for dictionaries is selected.

When the editorial view is dominant, the following attributes may be used to capture the lexical view:

**att.lexicographic** provides a set of attributes common to all elements in the dictionary module.

`@norm` (normalized) gives a normalized form of information given by the source text in a non-normalized form

`@split` gives the list of split values for a merged form

When the lexical view is dominant, the following attributes may be used to record the editorial view:

**att.lexicographic** provides a set of attributes common to all elements in the dictionary module.

*@Orig* (original) gives the original string or is the empty string when the element does not appear in the source text.

*@mergedIn* gives a reference to another element, where the original appears as a merged form.

One attribute is useful in either view:

**att.lexicographic** provides a set of attributes common to all elements in the dictionary module.

*@opt* (optional) indicates whether the element is optional or not

For example, if the source text had the domain label ‘naut.’, it might be encoded as follows. With the editorial view dominant:

```
<usg norm="nautical" type="dom">naut.</usg>
```

The lexical view of the same label would transcribe the normalized form as content of the <usg> element, the typographic form as an attribute value:

```
<usg orig="naut." type="dom">nautical</usg>
```

If the source text gives inflectional information for the verb *delay* as ‘delay, -ed, -ing’, it might usefully be expanded to ‘delayed, delayed, delaying’. An encoding of the editorial view might take this form:

```
<form>
  <orth>delay</orth>
  <form type="inflected">
    <orth norm="delayed" extent="part">-ed</orth>
    <tns norm="pst,pstp"/>
  </form>
  <form type="inflected">
    <orth norm="delaying" extent="part">-ing</orth>
    <tns norm="prsp"/>
  </form>
</form>
```

Note the use of the <tns> tag with null content, to enable the representation of implicit information even though it has no print realization.

The lexical view might be encoded thus:

```
<form>
  <orth>delay</orth>
  <form type="inflected">
    <orth orig="-ed">delayed</orth>
    <tns orig="">pst</tns>
    <tns orig="">pstp</tns>
  </form>
  <form type="inflected">
    <orth orig="-ing">delaying</orth>
    <tns orig="">prsp</tns>
  </form>
</form>
```

A particular problem may be posed by the common practice of presenting two alternate forms of a word in a single string, by marking some parts of the word as optional in some forms. The following entry is for a word which can be spelled either ‘thyrostimuline’ or ‘thyréostimuline’:

thyr(é)ostimuline [tiR(e)ostimylin] ...

With the editorial view dominant, this entry might begin thus:

```
<form>
  <orth split="thyrostimuline, thyréostimuline">thyr(é)ostimuline</orth>
  <pron split="tiRostimylin, tiReostimylin">tiR(e)ostimylin</pron>
</form>
```

With the lexical view dominant, however, two <orth> and two <pron> elements would be encoded, in order to disentangle the two forms; the *orig* attribute would be used to record the typographic presentation of the information in the source.

```
<form>
  <orth xml:id="dic-o1"
    orig="thyr(é)ostimuline">thyrostimuline</orth>
  <pron xml:id="dic-p1"
    orig="tiR(e)ostimylin">tiRostimylin</pron>
</form>
<form>
  <orth mergedIn="#dic-o1">thyréostimuline</orth>
  <pron mergedIn="#dic-p1">tiReostimylin</pron>
</form>
```

This example might also be encoded using the *opt* attribute combined with the attributes *next* and *prev* defined in chapter 16. *Linking, Segmentation, and Alignment*.

```
<form>
  <orth next="#dict-o2" xml:id="dict-o1">thyr</orth>
  <orth next="#dict-o3" prev="#dict-o1"
    xml:id="dict-o2" opt="true">é</orth>
  <orth prev="#dict-o2" xml:id="dict-o3">ostimuline</orth>
  <pron next="#dict-p2" xml:id="dict-p1">tiR</pron>
  <pron next="#dict-p3" prev="#dict-p1"
    xml:id="dict-p2" opt="true">e</pron>
  <pron prev="#dict-p2" xml:id="dict-p3">ostimylin</pron>
</form>
```

Note that this transcription preserves both the lexical and editorial views in a single encoding. However, it has the disadvantage that the strings corresponding to entire words do not appear in the encoding uninterrupted, and therefore complex processing is required to retrieve them from the encoded text. The use of the *opt* attribute is recommended, however, when long spans of text are involved, or when the optional part contains embedded tags.

For example, the following gives two definitions in one text: ‘picture drawn with coloured chalk made into crayons’, and ‘coloured chalk made into crayons’:

**pas.tel** /"pastl US: pa"stel/ n 1 (picture drawn with) coloured chalk made into crayons. 2... OALD

A simple encoding solution would be to leave the definition text unanalysed, but this might be felt inadequate since it does not show that there are two definitions. A possible alternative encoding would be:

```
<sense n="1">
  <def>coloured
    chalk made into crayons</def>
  <def>picture drawn with coloured chalk
    made into crayons</def>
</sense>
```

This transcribes some characters of the source text twice, however, which deviates from the usual practice. The following encoding records both the editorial and lexical views:

```
<sense n="1">
  <def next="#d2" xml:id="d1" opt="true">picture drawn
    with</def>
  <def prev="#d1" xml:id="d2">coloured chalk made into
    crayons</def>
</sense>
```

### 9.5.3.2 Recording Original Locations of Transposed Elements

The attributes described in the previous section are useful only when the order of material is the same in both the editorial and the lexical view. When the two views impose different orders on the data, the standard linking mechanisms may be used to show the original location of material transposed in an encoding of the lexical view.

If the original is only slightly modified, the `<anchor>` element may be used to mark the original location of the material, and the *location* attribute may be used on the lexical encoding of that material to indicate its original location(s). Like those in the preceding section, this attribute is defined for the attribute class `att.lexicographic`:

**att.lexicographic** provides a set of attributes common to all elements in the dictionary module.

*@opt* (optional) indicates whether the element is optional or not

For example:

pinna ("pIn@) n., pl. -nae (-ni) or -nas. CED

```
<form>
  <orth>pinna</orth>
  <pron>'pIn@</pron>
  <anchor xml:id="p01"/>
  <form type="inflected">
    <number>pl</number>
    <form>
      <orth extent="part">-nae</orth>
      <pron extent="part">-ni:</pron>
    </form>
    <orth extent="part">-nas</orth>
  </form>
</form>
<gramGrp>
  <pos location="#p01">n</pos>
</gramGrp>
```

## 9.6 Unstructured Entries

The content model for the `<entry>` element provides an entry structure suitable for many average dictionaries, as well as many regular entries in more exotic dictionaries. However, the structure of some dictionaries does not allow the restrictions imposed by the content model for `<entry>`. To handle these cases, the `<entryFree>` and `<dictScrap>` elements are provided to support much wider variation in entry structure. The `<dictScrap>` element offers less freedom, in that it can only contain phrase level elements, but it can itself appear at any point within a dictionary entry where any of the structural components of a dictionary entry are permitted. As such, it acts as a container for otherwise anomalous parts of an entry.

The `<entryFree>` element places no constraints at all upon the entry: any element defined in this chapter, as well as all the normal phrase-level and inter-level elements, can appear anywhere within it. With the `<entryFree>` element,

the encoder is free to use any element anywhere, as well as to use or omit grouping elements such as <form>, <gramGrp>, etc.

The <entryFree> element allows the encoding of entries which violate the structure specified for the <entry> element. For example, in the following entry from a dictionary already in electronic form, it is necessary to include a <pron> element within a <def>. This is not permitted in the content model for <entry>, but it poses no problem in the <entryFree> element.

```
<ent
h="demigod"> <hwd>demi|god</hwd> <pr> <ph>"demIgQd</ph> </pr> <hps
ps="n"> <hsn> <def>one who is partly divine and partly human</def>
<def>(in Gk myth, etc) the son of a god and a mortal woman,
eg<cf>Hercules</cf> <pr> <ph>"h3:kjUli:z</ph> </pr> </def> </hsn>
</hps> </ent>
```

(OALD)

```
<entryFree>
  <form>
    <orth>demigod</orth>
    <hyph>demi|god</hyph>
    <pron>"demIgQd</pron>
  </form>
  <gramGrp>
    <pos>n</pos>
  </gramGrp>
  <def>one who is partly divine and partly human</def>
  <def>(in Gk myth, etc) the son of a god and a mortal woman, eg
  <mentioned>Hercules</mentioned>
  </def>
  <pron>"h3:kjUli:z</pron>
</entryFree>
```

The <entryFree> element also makes it possible to transcribe a dictionary using only phrase-level ('atomic') elements—that is, using no grouping elements at all. This can be desirable if the encoder wants a completely 'flat' view, with no indication of or commitment to the association of one element with another. The following encoding uses no grouping elements, and keeps all rendition text:

biryani or biriani (%bIrI"A:nI) any of a variety of Indian dishes...[from Urdu] CED

```
<entryFree>
  <orth>biryani</orth> or <orth>biriani</orth>
  <pron>(%bIrI"A:nI)</pron>
  <def>any of a variety of Indian dishes ...</def>
  <etym>[from <lang>Urdu</lang>]</etym>
</entryFree>
```

Here is an alternative way of representing the same structure, this time using <dictScrap>:

```
<entry>
  <dictScrap>
    <orth>biryani</orth> or <orth>biriani</orth>
    <pron>(%bIrI"A:nI)</pron>
```

```

    <def>any of a variety of Indian dishes ...</def>
    <etym>[from <lang>Urdu</lang>]</etym>
  </dictScrap>
</entry>

```

## 9.7 The Dictionary Module

The module defined in this chapter makes available the following components:

**Module dictionaries:** Dictionaries

- *Elements defined:* case colloc def dictScrap entry entryFree etym form gen gram gramGrp hom hyph iType lang lbl mood number oRef oVar orth pRef pVar per pos pron re sense stress subc superEntry syll tns usg xr
- *Classes defined:* att.entryLike att.lexicographic model.entryLike model.formPart model.gramPart model.lexicalRefinement model.morphLike model.ptrLike.form

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

## 10 Manuscript Description

### 10.1 Overview

The `msdescription` module<sup>74</sup> defines a special purpose element which can be used to provide detailed descriptive information about handwritten primary sources. Although originally developed to meet the needs of cataloguers and scholars working with medieval manuscripts in the European tradition, the scheme presented here is general enough that it can also be extended to other traditions and materials, and is potentially useful for any kind of inscribed artefact.

The scheme described here is also intended to accommodate the needs of many different classes of encoders. On the one hand, encoders may be engaged in *retrospective conversion* of existing detailed descriptions and catalogues into machine tractable form; on the other, they may be engaged in cataloguing *ex nihilo*, that is, creating new detailed descriptions for materials never before catalogued. Some may be primarily concerned to represent accurately the description itself, as opposed to the ideas and interpretations the description represents; others may have entirely opposite priorities. At one extreme, a project may simply wish to capture an existing catalogue in a form that can be displayed on the Web, and which can be searched for literal strings, or for such features such as titles, authors and dates; at the other, a project may wish to create, in highly structured and encoded form, a detailed database of information about the physical characteristics, history, interpretation, etc. of the material, able to support practitioners of *quantitative codicology* as well as librarians.

To cater for this diversity, here as elsewhere, these Guidelines propose a flexible strategy, in which encoders must choose for themselves the approach appropriate to their needs, and are provided with a choice of encoding mechanisms to support those differing degrees.

### 10.2 The Manuscript Description Element

The `<msDesc>` element will normally appear within the `<sourceDesc>` element of the header of a TEI-conformant document, where the document being encoded is a digital representation of some manuscript original, whether as an encoded transcription, as a collection of digital images (as described in 11.1. *Digital Facsimiles*), or as some combination of the two. However, in cases where the document being encoded is essentially a collection of manuscript descriptions, the `<msDesc>` element may be used in the same way as the bibliographic elements (`<bibl>`, `<biblFull>`, and `<biblStruct>`) making up the TEI element class `model.biblLike`. These typically appear within the `<listBibl>` element.

**<msDesc>** (manuscript description) contains a description of a single identifiable manuscript or other text-bearing object.

The `<msDesc>` element has the following components, which provide more detailed information under a number of headings. Each of these component elements is further described in the remainder of this chapter.

**<msIdentifier>** (manuscript identifier) contains the information required to identify the manuscript being described.

**<head>** (heading) contains any type of heading, for example the title of a section, or the heading of a list, glossary, manuscript description, etc.

**<msContents>** (manuscript contents) describes the intellectual content of a manuscript or manuscript part, either as a series of paragraphs or as a series of structured manuscript items.

**<physDesc>** (physical description) contains a full physical description of a manuscript or manuscript part, optionally subdivided using more specialized elements from the `model.physDescPart` class.

**<history>** groups elements describing the full history of a manuscript or manuscript part.

**<additional>** groups additional information, combining bibliographic information about a manuscript, or surrogate copies of it with curatorial or administrative information.

**<msPart>** (manuscript part) contains information about an originally distinct manuscript or part of a manuscript, which is now part of a composite manuscript.

**<msFrag>** (manuscript fragment) contains information about a fragment of a scattered manuscript now held as a single unit or bound into a larger manuscript.

---

<sup>74</sup>This chapter is based on the work of the European MASTER (Manuscript Access through Standards for Electronic Records) project, funded by the European Union from January 1999 to June 2001, and led by Peter Robinson, then at the Centre for Technology and the Arts at De Montfort University, Leicester (UK). Significant input also came from a TEI Workgroup headed by Consuelo W. Dutschke of the Rare Book and Manuscript Library, Columbia University (USA) and Ambrogio Piazzoni of the Biblioteca Apostolica Vaticana (IT) during 1998-2000.

The first of these components, <msIdentifier>, is the only one which is mandatory; it is described in more detail in 10.4. *The Manuscript Identifier* below. It is followed optionally by one or more <head> elements, each holding a brief heading (see 10.5. *The Manuscript Heading*), and then either one or more paragraphs, marked up as a series of <p> elements, or one or more of the specialized elements <msContents> (10.6. *Intellectual Content*), <physDesc> (10.7. *Physical Description*), <history> (10.8. *History*), and <additional> (10.9. *Additional Information*). These elements are all optional, but if used they must appear in the order given here. Finally, in the case of a composite manuscript (a manuscript composed of several codicological units) or a fragmented manuscript (a manuscript whose parts are now dispersed and kept at different places), a full description may also contain one or more <msPart> (10.10. *Manuscript Parts*) elements and <msFrag> (10.11. *Manuscript Fragments*) elements, respectively.

To demonstrate the use of this module, consider the following sample manuscript description, chosen more or less at random from the Bodleian Library's *Summary catalogue* ([158])

**28843.** In Latin, on parchment: written in more than one hand of the 13th cent. in England:  $7\frac{1}{4} \times 5\frac{3}{8}$  in., i + 55 leaves, in double columns: with a few coloured capitals.

'Hic incipit Bruitus Anglie,' the De origine et gestis Regum Angliae of Geoffrey of Monmouth (Galfridus Monumetensis): beg. 'Cum mecum multa & de multis.'

On fol. 54<sup>v</sup> very faint is 'Iste liber est fratris guillelmi de buria de . . . Roberti ordinis fratrum Pred[icatorum],' 14th cent. (?): 'hanauilla' is written at the foot of the page (15th cent.). Bought from the rev. W. D. Macray on March 17, 1863, for £1 10s.

Now MS. Add. A. 61.

Figure 8: Entry for Bodleian MS. Add. A. 61 in Madan et al. 1895-1953

The simplest way of digitizing this catalogue entry would simply be to key in the text, tagging the relevant parts of it which make up the mandatory <msIdentifier> element, as follows:

```
<msDesc>
  <msIdentifier>
    <settlement>Oxford</settlement>
    <repository>Bodleian Library</repository>
    <idno>MS. Add. A. 61</idno>
    <altIdentifier type="SC">
      <idno>28843</idno>
    </altIdentifier>
  </msIdentifier>
  <p>In Latin, on parchment: written in more than one hand of the 13th
    cent. in England:  $7\frac{1}{4} \times 5\frac{3}{8}$  in., i + 55 leaves, in double columns: with
    a few coloured capitals.</p>
  <p>'Hic incipit Bruitus Anglie,' the De origine et gestis Regum
    Angliae of Geoffrey of Monmouth (Galfridus Monumetensis: beg. 'Cum
    mecum multa & de multis.'</p>
  <p>On fol. 54v very faint is 'Iste liber est fratris guillelmi de
    buria de . . . Roberti ordinis fratrum Pred[icatorum],' 14th cent. (?):
    'hanauilla' is written at the foot of the page (15th cent.). Bought
    from the rev. W. D. Macray on March 17, 1863, for £1 10s.</p>
</msDesc>
```

With a suitable stylesheet, this encoding would be as readable as the original; it would not, however, be very useful for search purposes since only shelfmarks and other identifiers are distinguished. To improve on this, one might

wrap the paragraphs in the appropriate special-purpose first-child-level elements of <msDesc> and add some of the additional phrase-level elements available when this module is in use:

```
<msDesc>
  <msIdentifier>
    <settlement>Oxford</settlement>
    <repository>Bodleian Library</repository>
    <idno>MS. Add. A. 61</idno>
    <altIdentifier type="SC">
      <idno>28843</idno>
    </altIdentifier>
  </msIdentifier>
  <msContents>
    <p>
      <quote>Hic incipit Bruitus Anglie,</quote> the
      <title>De origine et gestis Regum Angliae</title>
      of Geoffrey of Monmouth (Galfridus Monumetensis):
      beg. <quote>Cum mecum multa & de multis.</quote>
      In Latin.</p>
    </msContents>
    <physDesc>
      <p>
        <material>Parchment</material>: written in
        more than one hand: 7¼ x 5⅜ in., i + 55 leaves, in double
        columns: with a few coloured capitals.</p>
    </physDesc>
    <history>
      <p>Written in
      <origPlace>England</origPlace> in the
      <origDate>13th cent.</origDate> On fol. 54v very faint is
      <quote>Iste liber est fratris guillelmi de buria de ... Roberti
      ordinis fratrum Pred[icatorum],</quote> 14th cent. (?):
      <quote>hanauilla</quote> is written at the foot of the page
      (15th cent.). Bought from the rev. W. D. Macray on March 17, 1863, for
      £1 10s.</p>
    </history>
  </msDesc>
```

Note that in this version the text has been slightly reorganized, but no actual rewriting has been necessary. The encoding now allows the user to search for such features as title, material, and date and place of origin; it is also possible to distinguish quoted material from descriptive passages and to search within descriptions relating to a particular topic (for example, history as distinct from material).

This process could be continued further, restructuring the whole entry so as to take full advantage of many more of the encoding possibilities provided by the module described in this chapter:

```
<msDesc>
  <msIdentifier>
    <settlement>Oxford</settlement>
    <repository>Bodleian Library</repository>
    <idno>MS. Add. A. 61</idno>
    <altIdentifier type="SC">
      <idno>28843</idno>
    </altIdentifier>
  </msIdentifier>
  <msContents>
    <msItem>
```

```

</msDesc>

```

In the remainder of this chapter we discuss all of the encoding features demonstrated above, together with many other related matters.

## 10.3 Phrase-level Elements

When the `msdescription` module is in use, several extra elements are added to the phrase level class, and thus become available within paragraphs and elsewhere in the document. These elements are listed below in alphabetical order:

- <catchwords>** describes the system used to ensure correct ordering of the quires making up a codex or incunable, typically by means of annotations at the foot of the page.
- <dimensions>** contains a dimensional specification.
- <heraldry>** contains a heraldic formula or phrase, typically found as part of a blazon, coat of arms, etc.
- <locus>** defines a location within a manuscript or manuscript part, usually as a (possibly discontinuous) sequence of folio references.
- <locusGrp>** groups a number of locations which together form a distinct but discontinuous item within a manuscript or manuscript part, according to a specific foliation.
- <material>** contains a word or phrase describing the material of which the object being described is composed.
- <watermark>** contains a word or phrase describing a watermark or similar device.
- <objectType>** contains a word or phrase describing the type of object being referred to.
- <origDate>** (origin date) contains any form of date, used to identify the date of origin for a manuscript or manuscript part.
- <origPlace>** (origin place) contains any form of place name, used to identify the place of origin for a manuscript or manuscript part.
- <secFol>** (second folio) marks the word or words taken from a fixed point in a codex (typically the beginning of the second leaf) in order to provide a unique identifier for it.
- <signatures>** contains discussion of the leaf or quire signatures found within a codex.

Within a manuscript description, many other standard TEI phrase level elements are available, notably those described in the Core module (*3. Elements Available in All TEI Documents*). Additional elements of particular relevance to manuscript description, such as those for names and dates, may also be made available by including the relevant module in one's schema.

### 10.3.1 Origination

The following elements may be used to provide information about the origins of any aspect of a manuscript:

- <origDate>** (origin date) contains any form of date, used to identify the date of origin for a manuscript or manuscript part.
- <origPlace>** (origin place) contains any form of place name, used to identify the place of origin for a manuscript or manuscript part.

The `<origDate>` and `<origPlace>` elements are specialized forms of the existing `<date>` and `<name>` elements respectively, used to indicate specifically the date and place of origin of a manuscript or manuscript part. Such information would normally be encoded within the `<history>` element, discussed in section 10.8. *History*. `<origDate>` and `<origPlace>` can also be used to identify the place or date of origin of any aspect of the manuscript, such as its decoration or binding, when these are not of the same date or from the same location as rest of the manuscript. Both these elements are members of the `att.editLike` class, from which they inherit many attributes.

The `<origDate>` element is a member of the `att.dataable` class, and may thus also carry additional attributes giving normalized values for the associated dating.

### 10.3.2 Material and Object Type

The `<material>` element can be used to tag any specific term used for the physical material of which a manuscript (or binding, seal, etc.) is composed. The `<objectType>` element may be used to tag any term specifying the type of object or manuscript upon which the text is written.

- <material>** contains a word or phrase describing the material of which the object being described is composed.

**<objectType>** contains a word or phrase describing the type of object being referred to.

These elements may appear wherever a term regarded as significant by the encoder occurs, as in the following examples:

```
<binding>
  <p>Brown <material>calfskin</material>, previously with two clasps.</p>
</binding>
```

```
<support>
  <p>
    <material>Parchment</material>
    <objectType>codex</objectType> with half <material>goat-leather</material> bind-
    ing.</p>
</support>
```

### 10.3.3 Watermarks and Stamps

Two further elements are provided to mark up other decorative features characteristic of manuscript leaves and bindings:

**<watermark>** contains a word or phrase describing a watermark or similar device.

**<stamp>** contains a word or phrase describing a stamp or similar device.

These element may appear wherever a term regarded as significant by the encoder occurs. The **<watermark>** element is most likely to be of use within the **<support>** element discussed in 10.7.1.1. *Support* below. We give a simple example here:

```
<support>
  <material>Rag
    paper</material> with <watermark>anchor</watermark>
  watermark
</support>
```

The **<stamp>** element will typically appear when text from the source is being transcribed, for example within a rubric in the following case:

```
<rubric>
  <lb/>Apologyticu TTVLLIANI AC IGNORATIA IN XPO IHV<lb/>SI NON LICET<lb/>NOBIS RO<lb/
  >manii imperii <stamp>Bodleian stamp</stamp>
  <lb/>
</rubric>
```

It may also appear as part of the detailed description of a binding:

```
<binding>
  <p>Modern calf recasing with original armorial stamp
  <stamp>with legend <mentioned xml:lang="LA">Ex
    Bibliotheca J. Richard D.M.</mentioned>
  </stamp>
</p>
</binding>
```

If, as here, any text contained by a stamp is included in its description it should be clearly distinguished from that description. The element **<mentioned>** may be used for this purpose, as shown above.

### 10.3.4 Dimensions

The `<dimensions>` element can be used to specify the size of some aspect of the manuscript, and thus may be thought of as a specialized form of the existing TEI `<measure>` element.

**<dimensions>** contains a dimensional specification.

`@type` indicates which aspect of the object is being measured.

The `<dimensions>` element will normally occur within the element describing the particular feature or aspect of a manuscript whose dimensions are being given; thus the size of the leaves would be specified within the `<support>` or `<extent>` element (part of the `<physDesc>` element discussed in 10.7.1. *Object Description*), while the dimensions of other specific parts of a manuscript, such as accompanying materials, binding, etc., would be given in other parts of the description, as appropriate.

The following elements are available within the `<dimensions>` element:

**<height>** contains a measurement measured along the axis at right angles to the bottom of the written surface, i.e. parallel to the spine for a codex or book.

**<width>** contains a measurement measured along the axis parallel to the bottom of the written surface, i.e. perpendicular to the spine of a book or codex.

**<depth>** contains a measurement measured across the spine of a book or codex, or (for other text-bearing objects) perpendicular to the measurement given by the 'width' element.

**<dim>** contains any single measurement forming part of a dimensional specification of some sort.

These elements, as well as `<dimensions>` itself, are all members of the `att.dimensions` class, which also inherits attributes from the `att.ranging` class. They all thus carry the following attributes:

**att.dimensions** provides attributes for describing the size of physical objects.

`@scope` where the measurement summarizes more than one observation, specifies the applicability of this measurement.

`@extent` indicates the size of the object concerned using a project-specific vocabulary combining quantity and units in a single string of words.

`@unit` names the unit used for the measurement

`@quantity` specifies the length in the units specified

**att.ranging** provides attributes for describing numerical ranges.

`@atLeast` gives a minimum estimated value for the approximate measurement.

`@atMost` gives a maximum estimated value for the approximate measurement.

`@min` where the measurement summarizes more than one observation or a range, supplies the minimum value observed.

`@max` where the measurement summarizes more than one observation or a range, supplies the maximum value observed.

Attributes `scope`, `min`, and `max` are used only when the measurement applies to several items, for example the size of all leaves in a manuscript; attributes `atLeast` and `atMost` are used when the measurement applies to a single item, for example the size of a specific codex, but has had to be estimated. Attribute `quantity` is used when the measurement can be given exactly, and applies to a single item; this is the usual situation. In this case, the units in which dimensions are measured may be specified using the `unit` attribute, the value of which will normally be taken from a closed set of values appropriate to the project, using standard units of measurement wherever possible, such as cm, mm, in, line, char. If however the only data available for the measurement uses some other unit, or it is preferred to normalize it in some other way, then it may be supplied as a string value by means of the `extent` attribute.

In the simplest case, only the `extent` attribute may be supplied:

```
<width extent="6 cubit">six cubits</width>
```

More usually, the measurement will be normalized into a value and an appropriate SI unit:

```
<width quantity="270" unit="cm">six cubits</width>
```

Where the exact value is uncertain, the attributes *atLeast* and *atMost* may be used to indicate the upper and lower bounds of an estimated value:

```
<width atLeast="250" atMost="300" unit="cm">six cubits</width>
```

It is often convenient to supply a measurement which applies to a number of discrete observations: for example, the number of ruled lines on the pages of a manuscript (which may not all be the same), or the diameter of an object like a bell, which will differ depending where it is measured. In such cases, the *scope* attribute may be used to specify the observations for which this measurement is applicable:

```
<height unit="line" scope="most"
  atLeast="20"/>
```

This indicates that most pages have at least 20 lines. The attributes *min* and *max* can also be used to specify the possible range of values: for example, to show that all pages have between 12 and 30 lines:

```
<height unit="line" scope="all" min="12"
  max="30"/>
```

The `<dimensions>` element may be repeated as often as necessary, with appropriate attribute values to indicate the nature and scope of the measurement concerned. For example, in the following case the leaf size and ruled space of the leaves of the manuscript are specified:

```
<dimensions type="ruled" unit="mm">
  <height scope="most" quantity="90"
    unit="mm"/>
  <width scope="most" quantity="48" unit="mm"/>
</dimensions>
<dimensions type="leaves">
  <height min="157" max="160" unit="mm"/>
  <width quantity="105"/>
</dimensions>
```

This indicates that for most leaves of the manuscript being described the ruled space is 90 mm high and 48 mm wide, while the leaves throughout are between 157 and 160 mm in height and 105 mm in width.

The `<dim>` element is provided for cases where some measurement other than height, width, or depth is required. Its *type* attribute is used to indicate the type of measurement involved:

```
<dimensions unit="cm">
  <dim type="circumference" quantity="48"
    unit="mm"/>
  <height quantity="90" unit="mm"/>
</dimensions>
```

The order in which components of the `<dimensions>` element may be supplied is not constrained.

### 10.3.5 References to Locations within a Manuscript

The `<locus>` and its grouping element `<locusGrp>` element are specialized forms of the `<ref>` element, used to indicate a location, or sequence of locations, within a manuscript.

**<locus>** defines a location within a manuscript or manuscript part, usually as a (possibly discontinuous) sequence of folio references.

*@from* specifies the starting point of the location in a normalized form, typically a page number.

*@to* specifies the end-point of the location in a normalized form, typically as a page number.

*@scheme* identifies the foliation scheme in terms of which the location is being specified by pointing to some <foliation> element defining it, or to some other equivalent resource.

**<locusGrp>** groups a number of locations which together form a distinct but discontinuous item within a manuscript or manuscript part, according to a specific foliation.

*@scheme* identifies the foliation scheme in terms of which all the locations contained by the group are specified by pointing to some <foliation> element defining it, or to some other equivalent resource.

The <locus> element is used to reference a single location within a manuscript, typically to specify the location occupied by the element within which it appears. If, for example, it is used as the first component of a <msItem> or <msItemStruct> element, or of any of the more specific elements appearing within one (see further section 10.6. *Intellectual Content* below) then it is understood to specify the location (or locations) of that item within the manuscript being described.

### 10.3.5.1 Identifying a Location

A <locus> element can be used to identify any reference to one or more folios within a manuscript, wherever such a reference is appropriate. Locations are conventionally specified as a sequence of folio or page numbers, but may also be a discontinuous list, or a combination of the two. This specification should be given as the content of the <locus> element, using the conventions appropriate to the individual scholar or holding institution, as in the following example:

```
<msItem n="1">
  <locus>ff. 1-24r</locus>
  <title>Apocalypsis beati Ioannis Apostoli</title>
</msItem>
```

A normalized form of the location can also be supplied, using special purpose attributes on the <locus> element, as in the following revision of the above example:

```
<msItem n="1">
  <locus from="1r" to="24r">ff. 1-24r</locus>
  <title>Apocalypsis beati Ioannis Apostoli</title>
</msItem>
```

When the item concerned occupies a discontinuous sequence of pages, this may simply be indicated in the body of the <locus> element:

```
<msItem n="1">
  <locus>ff. 1-12v, 18-24r</locus>
  <title>Apocalypsis beati Ioannis Apostoli</title>
</msItem>
```

Alternatively, if it is desired to indicate normalized values for each part of the sequence, a sequence of <locus> elements can be supplied, grouped within the <locusGrp> element:

```
<msItem n="1">
  <locusGrp>
    <locus from="1r" to="12v">ff. 1-12v</locus>
    <locus from="18" to="24r">ff. 18-24r</locus>
  </locusGrp>
</msItem>
```

```

</locusGrp>
<title>Apocalypsis beati Ioannis Apostoli</title>
</msItem>

```

Finally, the content of the <locus> element may be omitted if a formatting application can construct it automatically from the values of the *from* and *to* attributes:

```

<msItem n="1">
  <locusGrp>
    <locus from="1r" to="12v"/>
    <locus from="18" to="24r"/>
  </locusGrp>
  <title>Apocalypsis beati Ioannis Apostoli</title>
</msItem>

```

### 10.3.5.2 Linking a Location to a Transcription or an Image

The <locus> attribute can also be used to associate a location within a manuscript with facsimile images of that location, using the *fac*s attribute, or with a transcription of the text occurring at that location. The former association is effected by means of the *fac*s attribute; the latter by means of the *target* attribute.

The *fac*s is available only when the **transcr** module described in chapter 11, *Representation of Primary Sources* is included in a schema. It associates a <locus> element with one or more digitized images, as in the following example:

```

<msItem>
  <locus facs="images/08v.jpg images/09r.jpg images/09v.jpg images/10r.jpg images/10v.jpg">fol. 8v-10v</locus>
  <title>Birds Praise of Love</title>
  <bibl>
    <title>IMEV</title>
    <biblScope>1506</biblScope>
  </bibl>
</msItem>

```

Here, the *fac*s attribute uses a URI reference to point directly to images of the relevant pages. This method may be found cumbersome when many images are to be associated with a single location. It is of most use when specific pages are referenced within a description, as in the following example:

```

<decoDesc>
  <p>Several of the miniatures in this section have been damaged and overpainted at a later date (e.g. the figure of Christ on <locus facs="http://www.example.com/images.fr#F33R">fol. 33r</locus>; the face of the Shepherdess on <locus facs="http://www.example.com/images.fr#F59V">fol. 59v</locus>, etc.).</p>
</decoDesc>

```

For further discussion of the *fac*s attribute, see section 11.1, *Digital Facsimiles*.

Where a transcription of the relevant pages is available, this may be associated with the <locus> element using its *target* attribute, as in the following example:

```

<msItem n="1">
  <locus target="#f1r #f1v #f2r">ff. 1r-2r</locus>
  <author>Ben Jonson</author>
  <title>Ode to himself</title>
  <rubric rend="italics">
    <lb/>
    An Ode<lb/> to him selfe.</rubric>
  <incipit>Com leaue the loathed stage</incipit>
  <explicit>And see his chariot triumph ore his wayne.</explicit>
  <bibl>
    <name>Beal</name>, <title>Index 1450-1625</title>, JnB 380</bibl>
</msItem>
<!-- within transcription ... -->
<pb xml:id="f1r"/>
<!-- ... -->
<pb xml:id="f1v"/>
<!-- ... -->
<pb xml:id="f2r"/>
<!-- ... -->

```

When (as in this example) a sequence of elements is to be supplied as target value, it may be given explicitly as above, or using the xPointer range() syntax defined at 16.2.4.6. range(). Note however that support for this pointer mechanism is not widespread in current XML processing systems.

The *target* attribute should only be used to point to elements that contain or indicate a transcription of the locus being described. To associate a <locus> element with a page image or other comparable representation, the global *fac*s attribute should be used instead.

### 10.3.5.3 Using Multiple Location Schemes

Where a manuscript contains more than one foliation, the *scheme* attribute may be used to distinguish them. For example, MS 65 Corpus Christi College, Cambridge contains two fly leaves bearing music. These leaves have modern foliation 135 and 136 respectively, but are also marked with an older foliation. This may be preserved in an encoding such as the following:

```

<locus scheme="#original">XCIII</locus>
<locus scheme="#modern">135</locus>

```

Here the *scheme* attribute points to a <foliation> element providing more details about the scheme used, as further discussed in 10.7.1.4. Foliation below.

Where discontinuous sequences are identified within two different foliations, the *scheme* attribute should be supplied on the <locusGrp> element in preference, as in the following:

```

<locusGrp scheme="#original">
  <locus>XCIII</locus>
  <locus>CC-CCII</locus>
</locusGrp>
<locusGrp scheme="#modern">
  <locus>135</locus>
  <locus>197-204</locus>
</locusGrp>

```

### 10.3.6 Names of Persons, Places, and Organizations

The standard TEI element <name> may be used to identify names of any kind occurring within a description: <name> (name, proper noun) contains a proper noun or noun phrase.

As further discussed in 3.5.1. *Referring Strings*, this element is a member of the class `att.canonical`, from which it inherits the following attributes:

**att.canonical** provides attributes which can be used to associate a representation such as a name or title with canonical information about the object being named or referenced.

**@key** provides an externally-defined means of identifying the entity (or entities) being named, using a coded value of some kind.

**@ref** (reference) provides an explicit means of locating a full definition or identity for the entity being named by means of one or more URIs.

Here are some examples of the use of the `<name>` element:

```
<name type="person">Thomas Hoccleve</name>
<name type="place">Villingaholt</name>
<name type="org">Vetus Latina Institut</name>
<name type="person" ref="#HOC001">Occeleve</name>
```

Note that the `<name>` element is defined as providing information about a *name*, not the person, place, or organization to which that name refers. In the last example above, the `ref` attribute is used to associate the name with a more detailed description of the person named. This is provided by means of the `<person>` element, which becomes available when the `namesdates` module described in chapter 13. *Names, Dates, People, and Places* is included in a schema. An element such as the following might then be used to provide detailed information about the person indicated by the name:

```
<person xml:id="HOC001">
  <persName>
    <surname>Hoccleve</surname>
    <forename>Thomas</forename>
  </persName>
  <birth notBefore="1368"/>
  <occupation>poet</occupation>
  <!-- other personal data -->
</person>
```

Note that an instance of the `<person>` element must be provided for each distinct `ref` value specified. For example, in the case above, the value `HOC001` must be found as the `xml:id` attribute of some `<person>` element; the same value will be used as the `ref` attribute of every reference to `Hoccleve` in the document (however spelled), but there will only be one `<person>` element with this identifier.

Alternatively, the `key` attribute may be used to supply a unique identifying code for the person referenced by the name independently of both the existence of a `<person>` element and the use of the standard URI reference mechanism. If, for example, a project maintains as its authority file some non-digital resource, or uses a database which cannot readily be integrated with other digital resources for this purpose, the unique codes used by such 'offline' resources may be used as values for the `key` attribute. Although such practices clearly reduce the interchangeability of the resulting encoded texts, they may be judged more convenient or practical in certain situations. As explained in 3.5.1. *Referring Strings*, interchange is improved by use of tag URIs in `ref` instead of `key`.

All the `<person>` elements referenced by a particular document set should be collected together within a `<listPerson>` element, located in the TEI header. This functions as a kind of prosopography for all the people referenced by the set of manuscripts being described, in much the same way as a `<listBibl>` element in the back matter may be used to hold bibliographic information for all the works referenced.

When the `namesdates` module described in chapter 13. *Names, Dates, People, and Places* is included in a schema, similar mechanisms are used to maintain and reference canonical lists of places or organizations, as further discussed in sections 13.2.3. *Place Names* and 13.2.2. *Organizational Names* respectively.

### 10.3.7 Catchwords, Signatures, Secundo Folio

The <catchwords> element is used to describe one method by which correct ordering of the quires of a codex is ensured. Typically, this takes the form of a word or phrase written in the lower margin of the last leaf verso of a gathering, which provides a preview of the first recto leaf of the successive gathering. This may be a simple phrase such as the following:

```
<catchwords>Quires signed on the last leaf verso in roman numerals.</catchwords>
```

Alternatively, it may contain more details:

```
<catchwords>Vertical catchwords in the hand of the scribe placed along the inner bounding line, reading from top to bottom.</catchwords>
```

The ‘Signatures’ element is used, in a similar way, to describe a similar system in which quires or leaves are marked progressively in order to facilitate arrangement during binding. For example:

```
<signatures>At the bottom of the first four leaves of quires 1-14 are the remains of a series of quire signatures a-o plus roman figures in a cursive hand of the fourteenth century.</signatures>
```

The <signatures> element can be used for either leaf signatures, or a combination of quire and leaf signatures, whether the marking is alphabetic, alphanumeric, or some ad hoc system, as in the following more complex example:

```
<signatures>Quire and leaf signatures in letters, [b]-v, and roman numerals; those in quires 10 (1) and 17 (s) in red ink and different from others; every third quire also signed with red crayon in arabic numerals in the centre lower margin of the first leaf recto: "2" for quire 4 (f. 19), "3" for quire 7 (f. 43); "4", barely visible, for quire 10 (f. 65), "5", in a later hand, for quire 13 (f. 89), "6", in a later hand, for quire 16 (f. 113).</signatures>
```

The <secFol> element (for ‘secundo folio’) is used to record an identifying phrase (also called *dictio probatoria*) taken from a specific known point in a codex (for example the first few words on the second leaf). Since these words will differ from one copy of a text to another, the practice originated in the middle ages of using them when cataloguing a manuscript in order to distinguish individual copies of a work in a way which its opening words could not.

```
<secFol>(ando-)ssene in una villa</secFol>
```

### 10.3.8 Heraldry

Descriptions of heraldic arms, supporters, devices, and mottos may appear at various points in the description of a manuscript, usually in the context of ownership information, binding descriptions, or detailed accounts of illustrations. A full description may also contain a detailed account of the heraldic components of a manuscript independently considered. Frequently, however, heraldic descriptions will be cited as short phrases within other parts of the record. The phrase level element <heraldry> is provided to allow such phrases to be marked for further analysis, as in the following examples:

```

<p>Ownership stamp (xvii cent.) on i recto with the arms <heraldry>A bull
  passant within a bordure bezanty, in chief a crescent for difference</heraldry>
[Cole], crest, and the legend <quote>Cole Deum</quote>.</p>
<!-- ... -->
<p>A c. 8r fregio su due lati, <heraldry>stemma e imprese medicee</heraldry>
racchiudono l'inizio dell'epistolario di Paolino.</p>

```

## 10.4 The Manuscript Identifier

The `<msIdentifier>` element is intended to provide an unambiguous means of uniquely identifying a particular manuscript. This may be done in a structured way, by providing information about the holding institution and the call number, shelfmark, or other identifier used to indicate its location within that institution. Alternatively, or in addition, a manuscript may be identified simply by a commonly used name.

**<msIdentifier>** (manuscript identifier) contains the information required to identify the manuscript being described.

A manuscript's actual physical location may occasionally be different from its place of ownership; at Cambridge University, for example, manuscripts owned by various colleges are kept in the central University Library. Normally, it is the ownership of the manuscript which should be specified in the manuscript identifier, while additional or more precise information on the physical location of the manuscript can be given within the `<adminInfo>` element, discussed in section 10.9.1. *Administrative Information* below.

The following elements are available within `<msIdentifier>` to identify the holding institution:

**<country>** contains the name of a geo-political unit, such as a nation, country, colony, or commonwealth, larger than or administratively superior to a region and smaller than a bloc.

**<region>** contains the name of an administrative unit such as a state, province, or county, larger than a settlement, but smaller than a country.

**<settlement>** contains the name of a settlement such as a city, town, or village identified as a single geo-political or administrative unit.

**<institution>** contains the name of an organization such as a university or library, with which a manuscript is identified, generally its holding institution.

**<repository>** contains the name of a repository within which manuscripts are stored, possibly forming part of an institution.

These elements are all structurally equivalent to the standard TEI `<name>` element with an appropriate value for its *type* attribute; however the use of this 'syntactic sugar' enables the model for `<msIdentifier>` to be constrained rather more tightly than would otherwise be possible. Specifically, only one of each of the elements listed above may appear within the `<msIdentifier>` and they must, if present, appear in the order given.

Like `<name>`, these elements are all also members of the attribute class `att.canonical`, and thus can use the attributes *key* or *ref* to reference a single standardized source of information about the entity named.

The following elements are used within `<msIdentifier>` to provide different ways of identifying the manuscript within its holding institution:

**<collection>** contains the name of a collection of manuscripts, not necessarily located within a single repository.

**<idno>** (identifier) supplies any form of identifier used to identify some object, such as a bibliographic item, a person, a title, an organization, etc. in a standardized way.

**<altIdentifier>** (alternative identifier) contains an alternative or former structured identifier used for a manuscript, such as a former catalogue number.

**<msName>** (alternative name) contains any form of unstructured alternative name used for a manuscript, such as an 'ocellus nominum', or nickname.

Major manuscript repositories will usually have a preferred form of citation for manuscript shelfmarks, including rules about punctuation, spacing, abbreviation, etc., which should be adhered to. Where such a format also contains information which might additionally be supplied as a distinct subcomponent of the `<msIdentifier>`, for example a collection name, a decision must be taken as to whether to use the more specific element, or to include such

information within the <idno> element. For example, the manuscript formally identified as 'El 26 C 9' forms a part of the Ellesmere ('El') collection. Either of the following encodings is therefore feasible:

```
<msIdentifier>
  <country>USA</country>
  <region>California</region>
  <settlement>San Marino</settlement>
  <repository>Huntington Library</repository>
  <collection>El</collection>
  <idno>26 C 9</idno>
  <msName>The Ellesmere Chaucer</msName>
</msIdentifier>
```

```
<msIdentifier>
  <country>USA</country>
  <region>California</region>
  <settlement>San Marino</settlement>
  <repository>Huntington Library</repository>
  <idno>El 26 C 9</idno>
  <msName>The Ellesmere Chaucer</msName>
</msIdentifier>
```

In the former example, the preferred form of the identifier can be retrieved by prefixing the content of the <idno> element with that of the <collection> element, while in the latter it is given explicitly. The advantage of the former is that it simplifies accurate retrieval of all manuscripts from a given collection; the disadvantage is that encoded abbreviations of this kind may not be as immediately comprehensible. Care should be taken to avoid redundancy: for example

```
<collection>El</collection>
<idno>El 26 C 9</idno>
```

would clearly be inappropriate. Equally clearly,

```
<collection>Ellesmere</collection>
<idno>El 26 C 9</idno>
```

might be considered helpful in some circumstances (if, for example, some of the items in the Ellesmere collection had shelfmarks which did not begin 'El').

In some cases the shelfmark may contain no information about the collection; in other cases, the item may be regarded as belonging to more than one collection. The <collection> element may be added, and repeated as often as necessary to cater for such situations:

```
<msIdentifier>
  <country>Hungary</country>
  <settlement>Budapest</settlement>
  <repository xml:lang="fr"> Bibliothèque de l'Académie des Sciences de Hongrie
</repository>
  <collection>Oriental Collection</collection>
  <collection>Sandor Kégl Bequest</collection>
  <idno>MS 1265</idno>
</msIdentifier>
```

```

<msIdentifier>
  <country>USA</country>
  <region>New Jersey</region>
  <settlement>Princeton</settlement>
  <repository>Princeton University Library</repository>
  <collection>Scheide Library</collection>
  <idno>MS 71</idno>
  <msName>Blickling Homiliary</msName>
</msIdentifier>

```

Note in the latter case the use of the <msName> element to provide a common name other than the shelfmark by which a manuscript is known. Where a manuscript has several such names, more than one of these elements may be used, as in the following example:

```

<msIdentifier>
  <country>Danmark</country>
  <settlement>København</settlement>
  <repository>Det Arnamagnæanske Institut</repository>
  <idno>AM 45 fol.</idno>
  <msName xml:lang="la">Codex Frisianus</msName>
  <msName xml:lang="is">Fríssbók</msName>
</msIdentifier>

```

Here the globally available *xml:lang* attribute has been used to specify the language of the alternative names.

In very rare cases a repository may have only one manuscript (or only one of any significance), which will have no shelfmark as such but will be known by a particular name or names. In such circumstances, the <idno> element may be omitted, and the manuscript identified by the name or names used for it, using one or more <msName> elements, as in the following example:

```

<msIdentifier>
  <settlement>Rossano</settlement>
  <repository xml:lang="it">Biblioteca arcivescovile</repository>
  <msName xml:lang="la">Codex Rossanensis</msName>
  <msName xml:lang="la">Codex purpureus</msName>
  <msName xml:lang="en">The Rossano Gospels</msName>
</msIdentifier>

```

Where manuscripts have moved from one institution to another, or even within the same institution, they may have identifiers additional to the ones currently used, such as former shelfmarks, which are sometimes retained even after they have been officially superseded. In such cases it may be useful to supply an alternative identifier, with a detailed structure similar to that of the <msIdentifier> itself. The following example shows a manuscript which had shelfmark II-M-5 in the collection of the Duque de Osuna, but which now has the shelfmark MS 10237 in the National Library in Madrid:

```

<msIdentifier>
  <settlement>Madrid</settlement>
  <repository>Biblioteca Nacional</repository>
  <idno>MS 10237</idno>
  <altIdentifier>
    <region>Andalucia</region>
    <settlement>Osuna</settlement>
    <repository>Duque de Osuna</repository>
  </altIdentifier>
</msIdentifier>

```

```
<idno>II-M-5</idno>
</altIdentifier>
</msIdentifier>
```

Normally, such information would be dealt with under <history>, except in cases where a manuscript is likely still to be referred to or known by its former identifier. For example, an institution may have changed its call number system but still wish to retain a record of the earlier number, perhaps because the manuscript concerned is frequently cited in print under its previous number:

```
<msIdentifier>
  <settlement>Berkeley</settlement>
  <institution>University of California</institution>
  <repository>Bancroft Library</repository>
  <idno>UCB 16</idno>
  <altIdentifier>
    <idno>2MS BS1145 I8</idno>
  </altIdentifier>
</msIdentifier>
```

Where (as in this example) no repository is specified for the <altIdentifier>, it is assumed to be the same as that of the parent <msIdentifier>. Where the holding institution has only one preferred form of citation but wishes to retain the other for internal administrative purposes, the secondary could be given within <altIdentifier> with an appropriate value on the *type* attribute:

```
<msIdentifier>
  <settlement>Oxford</settlement>
  <repository>Bodleian Library</repository>
  <idno>MS. Bodley 406</idno>
  <altIdentifier type="SC">
    <idno>2297</idno>
  </altIdentifier>
</msIdentifier>
```

It might, however, be preferable to include such information within the <adminInfo> element discussed in section 10.9.1. *Administrative Information* below.

Cases of such changed or alternative identifiers should be clearly distinguished from cases of ‘fragmented’ (10.11. *Manuscript Fragments*) manuscripts, that is to say manuscripts which although physically disjoint are nevertheless generally treated as single units.

As mentioned above, the smallest possible description is one that contains only the element <msIdentifier>; good practice in all but exceptional circumstances requires the presence within it of the three sub-elements <settlement>, <repository>, and <idno>, since they provide what is, by common consent, the minimum amount of information necessary to identify a manuscript.

## 10.5 The Manuscript Heading

Historically, the briefest possible meaningful description of a manuscript consists of no more than a title, e.g. *Polychronicon*. This will often have been enough to identify a manuscript in a small collection because the identity of the author is implicit. Where a title does not imply the author, and is thus insufficient to identify the main text of a manuscript, the author should be stated explicitly (e.g. *Augustinus, Sermones* or *Cicero, Letters*). Many inventories of manuscripts consist of no more than an author and title, with some form of copy-specific identifier, such as a shelfmark or ‘secundo folio’ reference (e.g. *Arch. B. 3. 2: Evangelium Matthei cum glossa, 126. Isidori Originum libri octo, Biblia Hieronimi, 2o fo. opus est*); information on date and place of writing will sometimes also be included. The standard TEI element <head> element can be used to provide a brief description of this kind.

**<head>** (heading) contains any type of heading, for example the title of a section, or the heading of a list, glossary, manuscript description, etc.

In this way the cataloguer or scholar can supply in one place a minimum of essential information, such as might be displayed or printed as the heading of a full description. For example:

```
<head>Marsilius de Inghen, Abbreviata phisicorum Aristotelis; Italy, 1463.</head>
```

Any phrase-level elements, such as `<title>`, `<name>`, `<date>`, or the specialized elements `<origPlace>` and `<origDate>`, can also be used within a `<head>` element, but it should be remembered that the `<head>` element is intended principally to contain a heading. More structured information concerning the contents, physical form, or history of the manuscript should be given within the specialized elements described below, `<msContents>`, `<physDesc>`, `<history>`, etc. However, in simple cases, the `<p>` element may also be used to supply an unstructured collection of such information, as in the example given above (10.2. *The Manuscript Description Element*).

## 10.6 Intellectual Content

The `<msContents>` element is used to describe the intellectual content of a manuscript or manuscript part. It comprises *either* a series of informal prose paragraphs *or* a series of `<msItem>` or `<msItemStruct>` elements, each of which provides a more detailed description of a single item contained within the manuscript. These may be prefaced, if desired, by a `<summary>` element, which is especially useful where one wishes to provide an overview of a manuscript's contents and describe only some of the items in detail.

**<msContents>** (manuscript contents) describes the intellectual content of a manuscript or manuscript part, either as a series of paragraphs or as a series of structured manuscript items.

**<msItem>** (manuscript item) describes an individual work or item within the intellectual content of a manuscript or manuscript part.

**<msItemStruct>** (structured manuscript item) contains a structured description for an individual work or item within the intellectual content of a manuscript or manuscript part.

**<summary>** contains an overview of the available information concerning some aspect of an item (for example, its intellectual content, history, layout, typography etc.) as a complement or alternative to the more detailed information carried by more specific elements.

In the simplest case, only a brief description may be provided, as in the following examples:

```
<msContents>
  <p>A collection of Lollard sermons</p>
</msContents>
<msContents>
  <p>Atlas of the world from Western Europe and Africa to Indochina,
    containing 27 maps and 26 tables</p>
</msContents>
<msContents>
  <p>Biblia sacra: Antiguo y Nuevo Testamento, con prefacios, prólogos
    y argumentos de san Jerónimo y de otros. Interpretaciones de los
    nombres hebreos.</p>
</msContents>
```

This description may of course be expanded to include any of the TEI elements generally available within a `<p>` element, such as `<title>`, `<bibl>`, or `<list>`. More usually, however, each individual work within a manuscript will be given its own description, using the `<msItem>` or `<msItemStruct>` element described in the next section, as in the following example:

```
<msContents>
  <msItem n="1">
```

```

<locus>fols. 5r -7v</locus>
<title>An ABC</title>
<bibl>
  <title>IMEV</title>
  <biblScope>239</biblScope>
</bibl>
</msItem>
<msItem n="2">
  <locus>fols. 7v -8v</locus>
  <title xml:lang="fr">Lenvoy de Chaucer a Scogan</title>
  <bibl>
    <title>IMEV</title>
    <biblScope>3747</biblScope>
  </bibl>
</msItem>
<msItem n="3">
  <locus>fol. 8v</locus>
  <title>Truth</title>
  <bibl>
    <title>IMEV</title>
    <biblScope>809</biblScope>
  </bibl>
</msItem>
<msItem n="4">
  <locus>fols. 8v-10v</locus>
  <title>Birds Praise of Love</title>
  <bibl>
    <title>IMEV</title>
    <biblScope>1506</biblScope>
  </bibl>
</msItem>
<msItem n="5">
  <locus>fols. 10v -11v</locus>
  <title xml:lang="la">De amico ad amicam</title>
  <title xml:lang="la">Responcio</title>
  <bibl>
    <title>IMEV</title>
    <biblScope>16 & 19</biblScope>
  </bibl>
</msItem>
<msItem n="6">
  <locus>fols. 14r-126v</locus>
  <title>Troilus and Criseyde</title>
  <note>Bk. 1:71-Bk. 5:1701, with additional losses due to
    mutilation throughout</note>
</msItem>
</msContents>

```

The <summary> element may be used in conjunction with one or more <msItem> elements if it is desired to provide both a general summary of the contents of a manuscript and more detail about some or all of the individual items within it. It may not however be used within an individual <msItem> element.

```

<msContents>
  <summary>A collection of Lollard sermons</summary>
  <msItem n="1">
    <locus>fol. 4r-8r</locus>

```

```

    <title>3rd Sunday Before Lent</title>
  </msItem>
  <msItem n="2">
    <locus>fol. 9r-16v</locus>
    <title>Sexagesima</title>
  </msItem>
</msContents>

```

### 10.6.1 The <msItem> and <msItemStruct> Elements

Each discrete item in a manuscript or manuscript part can be described within a distinct <msItem> or <msItemStruct> element, and may be classified using the *class* attribute.

These are the possible component elements of <msItem> and <msItemStruct>.

**<author>** in a bibliographic reference, contains the name(s) of an author, personal or corporate, of a work; for example in the same form as that provided by a recognized bibliographic name authority.

**<respStmt>** (statement of responsibility) supplies a statement of responsibility for the intellectual content of a text, edition, recording, or series, where the specialized elements for authors, editors, etc. do not suffice or do not apply. May also be used to encode information about individuals or organizations which have played a role in the production or distribution of a bibliographic work.

**<title>** contains a title for any kind of work.

*@type* classifies the title according to some convenient typology.

**<rubric>** contains the text of any *rubric* or heading attached to a particular manuscript item, that is, a string of words through which a manuscript signals the beginning of a text division, often with an assertion as to its author and title, which is in some way set off from the text itself, usually in red ink, or by use of different size or type of script, or some other such visual device.

**<incipit>** contains the *incipit* of a manuscript item, that is the opening words of the text proper, exclusive of any *rubric* which might precede it, of sufficient length to identify the work uniquely; such incipits were, in former times, frequently used a means of reference to a work, in place of a title.

**<quote>** (quotation) contains a phrase or passage attributed by the narrator or author to some agency external to the text.

**<explicit>** contains the *explicit* of a manuscript item, that is, the closing words of the text proper, exclusive of any rubric or colophon which might follow it.

**<finalRubric>** contains the string of words that denotes the end of a text division, often with an assertion as to its author and title, usually set off from the text itself by red ink, by a different size or type of script, or by some other such visual device.

**<colophon>** contains the *colophon* of a manuscript item: that is, a statement providing information regarding the date, place, agency, or reason for production of the manuscript.

**<decoNote>** (note on decoration) contains a note describing either a decorative component of a manuscript, or a fairly homogenous class of such components.

**<listBibl>** (citation list) contains a list of bibliographic citations of any kind.

**<bibl>** (bibliographic citation) contains a loosely-structured bibliographic citation of which the sub-components may or may not be explicitly tagged.

**<filiation>** contains information concerning the manuscript's *filiation*, i.e. its relationship to other surviving manuscripts of the same text, its *protographs*, *antigraphs* and *apographs*.

**<note>** contains a note or annotation.

**<textLang>** (text language) describes the languages and writing systems identified within the bibliographic work being described, rather than its description.

In addition, a <msItemStruct> may contain nested <msItemStruct> elements, just as an <msItem> may contain nested <msItem> elements.

The main difference between <msItem> and <msItemStruct> is that in the former, the order and number of child elements is not constrained; any element, in other words, may be given in any order, and repeated as often as is

judged necessary. In the latter, however, the sub-elements, if used, must be given in the order specified above and only some of them may be repeated; specifically, <rubric>, <finalRubric>. <incipit>, <textLang> and <explicit> can appear only once.

While neither <msItem> nor <msItemStruct> may contain untagged running text, both permit an unstructured description to be provided in the form of one or more paragraphs of text. They differ in this respect also: if paragraphs are supplied as the content of an <msItem>, then none of the other component elements listed above is permitted; in the <msItemStruct> case, however, paragraphs may appear anywhere as an alternative to any of the component elements listed above.

As noted above, both <msItem> and <msItemStruct> elements may also nest, where a number of separate items in a manuscript are grouped under a single title or rubric, as is the case, for example, with a work like *The Canterbury Tales*.

The elements <msContents>, <msItem>, <msItemStruct>, <incipit>, and <explicit> are all members of the class **att.msExcerpt** from which they inherit the *defective* attribute.

**att.msExcerpt** (manuscript excerpt) provides attributes used to describe excerpts from a manuscript placed in a description thereof.

@*defective* indicates whether the passage being quoted is defective, i.e. incomplete through loss or damage.

This attribute can be used for example with collections of fragments, where each fragment is given as a separate <msItem> and the first and last words of each fragment are transcribed as defective incipits and explicits, as in the following example, a manuscript containing four fragments of a single work:

```
<msContents>
  <msItem defective="true">
    <locus from="1r" to="9v">1r-9v</locus>
    <title>Knýtlinga saga</title>
    <msItem n="1.1">
      <locus from="1r:1" to="2v:30">1r:1-2v:30</locus>
      <incipit defective="true">dan<ex>n</ex>a a
        engl<ex>an</ex>di</incipit>
      <explicit defective="true">en meðan <expan>haraldr</expan>
        hein hafði k<ex>onung</ex>r v<am>
        <g ref="http://www.example.com/abbrevs.xml#er"/>
      </am>it
        yf<ex>ir</ex> danmork</explicit>
    </msItem>
  <!-- msItems 1.2 to 1.4 -->
</msItem>
</msContents>
```

The elements <ex>, <am>, and <expan> used in the above example are further discussed in section 11.3.1.2. *Abbreviation and Expansion*; they are available only when the **transcr** module defined by that chapter is selected. Similarly, the <g> element used in this example to represent the abbreviation mark is defined by the **gaiji** module documented in chapter 5. *Characters, Glyphs, and Writing Modes*.

## 10.6.2 Authors and Titles

When used within a manuscript description, the <title> element should be used to supply a regularized form of the item's title, as distinct from any rubric quoted from the manuscript. If the item concerned has a standardized distinctive title, e.g. *Roman de la Rose*, then this should be the form given as content of the <title> element, with the value of the *type* attribute given as **uniform**. If no uniform title exists for an item, or none has been yet identified, or if one wishes to provide a general designation of the contents, then a 'supplied' title can be given, e.g. *missal*, in which case the *type* attribute on the <title> should be given the value **supplied**.

Similarly, if used within a manuscript description, the <author> element should always contain the normalized form of an author's name, irrespective of how (or whether) this form of the name is cited in the manuscript. If it is desired to retain the form of the author's name as given in the manuscript, this may be tagged as a distinct <name> element, within the text at the point where it occurs.

Note that the *key* attribute can also be used, as on names in general, to specify the identifier of a <person> element carrying full details of the person concerned (see further 10.3.6. *Names of Persons, Places, and Organizations*).

The <respStmt> element can be used to supply the name and role of a person other than the author who is responsible for some aspect of the intellectual content of the manuscript:

```
<author>Diogenes Laertius</author>
<respStmt>
  <resp>in the translation of</resp>
  <name>Ambrogio Traversari</name>
</respStmt>
```

The <respStmt> element can also be used where there is a discrepancy between the author of an item as given in the manuscript and the accepted scholarly view, as in the following example:

```
<title type="supplied">Sermons on the Epistles and the Gospels</title>
<respStmt>
  <resp>here erroneously attributed to</resp>
  <name>St. Bonaventura</name>
</respStmt>
```

Note that such attributions of authorship, both correct and incorrect, are frequently found in the rubric or final rubric (and occasionally also elsewhere in the text), and can therefore be transcribed and included in the description, if desired, using the <rubric>, <finalRubric>, or <quote> elements, as appropriate.

### 10.6.3 Rubrics, Incipits, Explicits, and Other Quotations from the Text

It is customary in a manuscript description to record the opening and closing words of a text as well as any headings or colophons it might have, and the specialized elements <rubric>, <incipit>, <explicit>, <finalRubric>, and <colophon> are available within <msItem> for doing so, along with the more general <quote>, for recording other bits of the text not covered by these elements. Each of these elements has the same substructure, containing a mixture of phrase-level elements and plain text. A <locus> element can be included within each, in order to specify the location of the component, as in the following example:

```
<msContents>
  <msItem>
    <locus>f. 1-223</locus>
    <author>Radulphus Flaviacensis</author>
    <title>Expositio super Leviticum </title>
    <incipit>
      <locus>f. 1r</locus>
      Forte Hervei monachi</incipit>
    <explicit>
      <locus>f. 223v</locus>
      Benedictio salis et aquae</explicit>
    </msItem>
  </msContents>
```

In the following example, standard TEI elements for the transcription of primary sources have been used to mark the expansion of abbreviations and other features present in the original:

```

<msItem defective="true">
  <locus>ff. 1r-24v</locus>
  <title type="uniform">Ágrip af Noregs konunga sǫgum</title>
  <incipit defective="true">
    <lb/>regi oc h<ex>ann</ex> seti
    ho<gap reason="illegible" quantity="7"
    unit="mm"/>
    <lb/>sc heim se<ex>m</ex> þio</incipit>
  <explicit defective="true">h<ex>on</ex> hev<ex>er</ex>
  <ex>oc</ex> þa buit hesta .ij. <lb/>annan víp fé en
  h<ex>on</ex>o<ex>m</ex> annan til reiþ<ex>ar</ex>
</explicit>
</msItem>

```

Note here also the use of the *defective* attribute on <incipit> and <explicit> to indicate that the text begins and ends defectively.

The *xml:lang* attribute for <colophon>, <explicit>, <incipit>, <quote>, and <rubric> may always be used to identify the language of the text quoted, if this is different from the default language specified by the *mainLang* attribute on <textLang>.

#### 10.6.4 Filiation

The <filiation> element can be used to provide information on the relationship between the manuscript and other surviving manuscripts of the same text, either specifically or in a general way, as in the following example:

```

<msItem>
  <locus>118rb</locus>
  <incipit>Ecce morior cum nichil horum ... <ref>[Dn 13, 43]</ref>. Verba ista dixit
  Susanna de illis</incipit>
  <explicit>ut bonum comune conservatur.</explicit>
  <bibl>Schneyer 3, 436 (Johannes Contractus OFM)</bibl>
  <filiation>weitere Überl. Uppsala C 181, 35r.</filiation>
</msItem>

```

#### 10.6.5 Text Classification

One or more text classification or text-type codes may be specified, either for the whole of the <msContents> element, or for one or more of its constituent <msItem> elements, using the *class* attribute as specified above:

```

<msContents>
  <msItem n="1" defective="false"
  class="#law">
    <locus from="1v" to="71v">1v-71v</locus>
    <title type="uniform">Jónsbók</title>
    <incipit>Magnus m<ex>ed</ex> guds miskun Noregs
    k<ex>onungu</ex>r</incipit>
    <explicit>en<ex>n</ex> u<ex>ir</ex>da
    þo t<ex>il</ex> fullra aura</explicit>
  </msItem>
</msContents>

```

The value used for the *class* attribute in this example points to a <category> element with the identifier *law*, which defines the classification concerned. Such <category> elements will typically appear within a <taxonomy> element, within the <classDecl> element of the TEI header (2.3.7. *The Classification Declaration*) as in the following example:

```
<classDecl>
  <taxonomy>
<!-- -->
    <category xml:id="law">
      <catDesc>Legislation</catDesc>
    </category>
    <category xml:id="war">
      <catDesc>Military topics</catDesc>
    </category>
<!-- -->
  </taxonomy>
</classDecl>
```

More than one classification may apply to a single item. Another text, concerned with legislation about military topics might thus be specified as follows:

```
<msItem class="#law #war">
  <p>A treatise on Clausewitz</p>
<!-- details of the item here -->
</msItem>
```

### 10.6.6 Languages and Writing Systems

The `<textLang>` element should be used to provide information about the languages used within a manuscript item. It may take the form of a simple note, as in the following example:

```
<textLang>Old Church Slavonic, written in Cyrillic script.</textLang>
```

Where, for validation and indexing purposes, it is thought convenient to add keywords identifying the particular languages used, the *mainLang* attribute may be used. This attribute takes the same range of values as the global *xml:lang* attribute, on which see further *vi.1 Language Identification*. In the following example a manuscript written chiefly in Old Church Slavonic is described:

```
<textLang mainLang="chu">Old Church Slavonic</textLang>
```

A manuscript item will sometimes contain material in more than one language. The *mainLang* attribute should be used only for the chief language. Other languages used may be specified using the *otherLangs* attribute as in the following example:

```
<textLang mainLang="chu"
  otherLangs="RUS HEL">Mostly Old Church
Slavonic, with some Russian and Greek material</textLang>
```

Since Old Church Slavonic may be written in either Cyrillic or Glagolitic scripts, and even occasionally in both within the same manuscript, it might be preferable to use a more explicit identifier:

```
<textLang mainLang="chu-Cyrs">Old Church Slavonic in Cyrillic script</textLang>
```

The form and scope of language identifiers recommended by these Guidelines is based on the IANA standard described at *vi.1 Language Identification* and should be followed throughout. Where additional detail is needed

correctly to describe a language, or to discuss its deployment in a given text, this should be done using the `<langUsage>` element in the TEI header, within which individual `<language>` elements document the languages used: see 2.4.2. *Language Usage*.

Note that the `<language>` element defines a particular combination of human language and writing system. Only one `<language>` element may be supplied for each such combination. Standard TEI practice also allows this element to be referenced by any element using the global `xml:lang` attribute in order to specify the language applicable to the content of that element. For example, assuming that `<language>` elements have been defined with the identifiers `fr` (for French), `la` (for Latin), and `de` (for German), a manuscript description written in French which specifies that a particular manuscript contains predominantly German but also some Latin material, might have a `<textLang>` element like the following:

```
<textLang xml:lang="fr" mainLang="de"
  otherLangs="la">allemand et latin</textLang>
```

## 10.7 Physical Description

Under the general heading ‘physical description’ we subsume a large number of different aspects generally regarded as useful in the description of a given manuscript. These include:

- aspects of the form, support, extent, and quire structure of the manuscript object and of the way in which the text is laid out on the page (10.7.1. *Object Description*);
- the styles of writing, such as the way it is laid out on the page, the styles of writing, decorative features, any musical notation employed and any annotations or marginalia (10.7.2. *Writing, Decoration, and Other Notations*);
- and discussion of its binding, seals, and any accompanying material (10.7.3. *Bindings, Seals, and Additional Material*).

Most manuscript descriptions touch on several of these categories of information though few include them all, and not all distinguish them as clearly as we propose here. In particular, it is often the case that an existing description will include information for which we propose distinct elements within a single paragraph, or even sentence. The encoder must then decide whether to rewrite the description using the structure proposed here, or to retain the existing prose, marked up simply as a series of `<p>` elements, directly within the `<physDesc>` element.

The `<physDesc>` element may thus be used in either of two distinct ways. It may contain a series of paragraphs addressing topics listed above and similar ones. Alternatively, it may act as a container for any choice of the more specialized elements described in the remainder of this section, each of which itself contains a series of paragraphs, and may also have more specific attributes.

In general, it is not recommended to combine unstructured prose description with usage of the more specialized elements, as such an approach complicates processing, and may lead to inconsistency within a single manuscript description. A single `<physDesc>` element will normally contain either a series of `model.pLike` elements, or a sequence of specialized elements from the `model.physDescPart` class. There are however circumstances in which this is not feasible, for example:

- the description already exists in a prose form where some of the specialized topics are treated together in paragraphs of prose, but others are treated distinctly;
- although all parts of the description are clearly distinguished, some of them cannot be mapped to a pre-existing specialized element.

In such situations, both specialized and generic (`model.pLike`) elements may be combined in a single `<physDesc>`. Note however that all generic elements given must precede the first specialized element in the description. Thus the following is valid:

```
<physDesc>
  <p>Generic descriptive prose...</p>
  <!-- other generic elements here -->
  <objectDesc form="codex">
  <!-- ... -->
```

```

</objectDesc>
<!-- other specific elements here -->
</physDesc>

```

but neither of the following is valid:

```

<physDesc>
<objectDesc form="codex">
<!-- ... -->
</objectDesc>
<p>Generic descriptive prose...</p>
</physDesc>

```

```

<physDesc>
<objectDesc form="codex">
  <!-- ... -->
</objectDesc>
<p>Generic descriptive prose...</p>
<!-- other specific elements here -->
</physDesc>

```

The order in which specific elements may appear is also constrained by the content model; again this is for simplicity of processing. They may of course be processed or displayed in any desired order, but for ease of validation, they must be given in the order specified below.

### 10.7.1 Object Description

The `<objectDesc>` element is used to group together those parts of the physical description which relate specifically to the text-bearing object, its format, constitution, layout, etc. The *form* attribute is used to indicate the specific type of writing vehicle being described, for example, as a codex, roll, tablet, etc. If used it must appear first in the sequence of specialized elements. The `<objectDesc>` element has two parts: a description of the *support*, i.e. the physical carrier on which the text is inscribed; and a description of the *layout*, i.e. the way text is organized on the carrier.

Taking these in turn, the description of the support is tagged using the following elements, each of which is discussed in more detail below:

**<supportDesc>** (support description) groups elements describing the physical support for the written part of a manuscript.

**<support>** contains a description of the materials etc. which make up the physical support for the written part of a manuscript.

**<extent>** describes the approximate size of a text stored on some carrier medium or of some other object, digital or non-digital, specified in any convenient units.

**<collation>** contains a description of how the leaves or bifolia are physically arranged.

**<foliation>** describes the numbering system or systems used to count the leaves or pages in a codex.

**<condition>** contains a description of the physical condition of the manuscript.

Each of these elements contains paragraphs relating to the topic concerned. Within these paragraphs, phrase-level elements (in particular those discussed above at 10.3. *Phrase-level Elements*), may be used to tag specific terms of interest if so desired.

```

<objectDesc form="codex">
  <supportDesc>
    <p>Mostly <material>paper</material>, with watermarks
    <watermark>unicorn</watermark> (<ref>Briquet 9993</ref>) and
    <watermark>ox</watermark> (close to <ref>Briquet 2785</ref>).
    The first and last leaf of each quire, with the exception of
    quires xvi and xviii, are constituted by bifolia of parchment,
    and all seven miniatures have been painted on inserted
    singletons of parchment.</p>
  </supportDesc>
</objectDesc>

```

This example combines information which might alternatively be more precisely tagged using the more specific elements described in the following subsections.

#### 10.7.1.1 Support

The <support> element groups together information about the physical carrier. Typically, for western manuscripts, this will entail discussion of the material (parchment, paper, or a combination of the two) written on. For paper, a discussion of any watermarks present may also be useful. If this discussion makes reference to standard catalogues of such items, these may be tagged using the standard <ref> element as in the following example:

```

<support>
  <p>
    <material>Paper</material> with watermark: <watermark>anchor in a circle
    with star on top</watermark>, <watermark>countermark B-B with
    trefoil</watermark> similar to <ref>Moschin, Anchor N 1680</ref>
    <date>1570-1585</date>.</p>
</support>

```

#### 10.7.1.2 Extent

The <extent> element, defined in the TEI header, may also be used in a manuscript description to specify the number of leaves a manuscript contains, as in the following example:

```
<extent>ii + 97 + ii</extent>
```

Information regarding the size of the leaves may be specifically marked using the phrase level <dimensions> element, as in the following example, or left as plain prose.

```

<extent>ii + 321 leaves
<dimensions unit="cm">
  <height>35</height>
  <width>27</width>
</dimensions>
</extent>

```

Alternatively, the generic <measure> element might be used within <extent>, as in the following example:

```

<extent>
  <measure type="composition" unit="leaf"
  quantity="10">10 Bl.</measure>
  <measure type="height" quantity="37"

```

```

    unit="cm">37</measure> x
<measure type="width" quantity="29"
    unit="cm">29</measure> cm

</extent>

```

### 10.7.1.3 Collation

The <collation> element should be used to provide a description of a book's current and original structure, that is, the arrangement of its leaves and quires. This information may be conveyed using informal prose, or any appropriate notational convention. Although no specific notation is defined here, an appropriate element to enclose such an expression would be the <formula> element, which is provided when the **figures** module is included in a schema. Here are some examples of different ways of treating collation:

```

<collation>
  <p>
    <formula>1-3:8, 4:6, 5-13:8</formula>
  </p>
</collation>
<collation>
  <p>There are now four gatherings, the first, second and fourth originally consisting
of
  eight leaves, the third of seven. A fifth gathering thought to have followed has
left no trace.
  <list>
    <item>Gathering I consists of 7 leaves, a first leaf, originally conjoint with
<locus>fol. 7</locus>,
    having been cut away leaving only a narrow strip along the gutter; the others,
<locus>fols 1</locus>
    and <locus>6</locus>, <locus>2</locus> and <locus>5</locus>, and
<locus>3</locus> and <locus>4</locus>,
    are bifolia.</item>
    <item>Gathering II consists of 8 leaves, 4 bifolia.</item>
    <item>Gathering III consists of 7 leaves; <locus>fols 16</locus> and
<locus>22</locus> are conjoint,
    the others singletons.</item>
    <item>Gathering IV consists of 2 leaves, a bifolium.</item>
  </list>
  </p>
</collation>
<collation>
  <p>I (1, 2+9, 3+8, 4+7, 5+6, 10); II (11, 12+17, 13, 14, 15, 16, 18, 19).</p>
</collation>
<collation>
  <p>
    <formula>1-5.8 6.6 (catchword, f. 46, does not match following
    text) 7-8.8 9.10, 11.2 (through f. 82) 12-14.8 15.8(-7)</formula>
  </p>
</collation>

```

### 10.7.1.4 Foliation

The <foliation> element may be used to indicate the scheme, medium or location of folio, page, column, or line numbers written in the manuscript, frequently including a statement about when and, if known, by whom, the numbering was done.

```

<foliation>
  <p>Neuere Foliierung, die auch das Vorsatzblatt mitgezählt hat.</p>
</foliation>
<foliation>
  <p>Folio numbers were added in brown ink by Árni Magnússon
    ca. 1720-1730 in the upper right corner of all recto-pages.</p>
</foliation>

```

Where a manuscript contains traces of more than one foliation, each should be recorded as a distinct `<foliation>` element and optionally given a distinct value for its `xml:id` attribute. The `<locus>` element discussed in 10.3.5. *References to Locations within a Manuscript* can then indicate which foliation scheme is being cited by means of its `scheme` attribute, which points to this identifier:

```

<foliation xml:id="original">
  <p>Original foliation in red roman numerals in the middle of
    the outer margin of each recto</p>
</foliation>
<foliation xml:id="modern">
  <p>Foliated in pencil in the top right
    corner of each recto page.</p>
</foliation>
<!-- ... -->
<locus scheme="#modern">ff 1-20</locus>

```

#### 10.7.1.5 Condition

The `<condition>` element is used to summarize the overall physical state of a manuscript, in particular where such information is not recorded elsewhere in the description. It should not, however, be used to describe changes or repairs to a manuscript, as these are more appropriately described as a part of its custodial history (see 10.9.1.2. *Availability and Custodial History*). It should be supplied within the `<supportDesc>` element, if it discusses the condition of the physical support of the manuscript; within the `<bindingDesc>` or `<binding>` elements (10.7.3.1. *Binding Descriptions*) if it discusses only the condition of the binding or bindings concerned; or within the `<sealDesc>` element if it discusses the condition of any seal attached to the manuscript.

```

<supportDesc>
  <condition>
    <p>The manuscript shows signs of damage from water and mould on its outermost
    leaves.</p>
  </condition>
</supportDesc>

```

```

<condition>
  <p>Despite tears on many of the leaves the codex is reasonably well preserved.
    The top and the bottom of f. 1 is damaged, and only a thin slip is left of the
    original second
    leaf (now foliated as 1bis). The lower margin of f. 92 has been cut away. There is
    a lacuna of
    one leaf between ff. 193 and 194. The manuscript ends defectively (there are
    approximately six
    leaves missing).</p>
</condition>

```

### 10.7.1.6 Layout Description

The second part of the <objectDesc> element is the <layoutDesc> element, which is used to describe and document the *mise-en-page* of the manuscript, that is the way in which text and illumination are arranged on the page, specifying for example the number of written, ruled, or pricked lines and columns per page, size of margins, distinct blocks such as glosses, commentaries, etc. This may be given as a simple series of paragraphs. Alternatively, one or more different layouts may be identified within a single manuscript, each described by its own <layout> element.

**<layoutDesc>** (layout description) collects the set of layout descriptions applicable to a manuscript.

**<layout>** describes how text is laid out on the page, including information about any ruling, pricking, or other evidence of page-preparation techniques.

Where the <layout> element is used, the layout will often be sufficiently regular for the attributes on this element to convey all that is necessary; more usually however a more detailed treatment will be required. The attributes are provided as a convenient shorthand for commonly occurring cases, and should not be used except where the layout is regular. The value NA (not-applicable) should be used for cases where the layout is either very irregular, or where it cannot be characterized simply in terms of lines and columns, for example, where blocks of commentary and text are arranged in a regular but complex pattern on each page

The following examples indicate the range of possibilities:

```
<layout ruledLines="25 32">
  <p>Most pages have between 25 and 32 long lines ruled in lead.</p>
</layout>
<layout columns="1" writtenLines="24">
  <p>Written in one column throughout; 24 lines per page.</p>
</layout>
<layout>
  <p>Written in 3 columns, with 8 lines of text and interlinear glosses in
    the centre, and up to 26 lines of gloss in the outer two columns. Double
    vertical bounding lines ruled in hard point on hair side. Text lines ruled
    faintly in lead. Remains of prickings in upper, lower, and outer (for 8 lines
    of text only) margins.</p>
</layout>
```

Where multiple <layout> elements are supplied, the scope for each specification can be indicated by means of <locus> elements within the content of the element, as in the following example:

```
<layoutDesc>
  <layout ruledLines="25 32">
    <p>On <locus from="1r" to="202v">fols 1r-200v</locus> and
    <locus from="210r" to="212v">fols 210r-212v</locus> there are
    between 25 and 32 ruled lines.</p>
  </layout>
  <layout ruledLines="34 50">
    <p>On <locus from="203r" to="209v">fols 203r-209v</locus> there are between 34
    and 50 ruled lines.</p>
  </layout>
</layoutDesc>
```

### 10.7.2 Writing, Decoration, and Other Notations

The second group of elements within a structured physical description concerns aspects of the writing, illumination, or other notation (notably, music) found in a manuscript, including additions made in later hands—the ‘text’, as it were, as opposed to the carrier.

**<handDesc>** (description of hands) contains a description of all the different kinds of writing used in a manuscript.

**<handNote>** (note on hand) describes a particular style or hand distinguished within a manuscript.

- <scriptDesc>** contains a description of the scripts used in a manuscript or similar source.
- <scriptNote>** describes a particular script distinguished within the description of a manuscript or similar resource.
- <typeDesc>** contains a description of the typefaces or other aspects of the printing of an incunable or other printed source.
- <typeName>** describes a particular font or other significant typographic feature distinguished within the description of a printed resource.
- <decoDesc>** (decoration description) contains a description of the decoration of a manuscript, either as a sequence of paragraphs, or as a sequence of topically organized <decoNote> elements.
- <decoNote>** (note on decoration) contains a note describing either a decorative component of a manuscript, or a fairly homogenous class of such components.
- <musicNotation>** contains description of type of musical notation.
- <additions>** contains a description of any significant additions found within a manuscript, such as marginalia or other annotations.

#### 10.7.2.1 Writing

The <handDesc> element can contain a short description of the general characteristics of the writing observed in a manuscript, as in the following example:

```
<handDesc>
  <p>Written in a <term>late Caroline minuscule</term>; versals in a
  form of <term>rustic capitals</term>; although the marginal and
  interlinear gloss is written in varying shades of ink that are
  not those of the main text, text and gloss appear to have been
  copied during approximately the same time span.</p>
</handDesc>
```

Note the use of the <term> element to mark specific technical terms within the context of the <handDesc> element. Where several distinct hands have been identified, this fact can be registered by using the *hands* attribute, as in the following example:

```
<handDesc hands="2">
  <p>The manuscript is written in two contemporary hands, otherwise
  unknown, but clearly those of practised scribes. Hand I writes
  ff. 1r-22v and hand II ff. 23 and 24. Some scholars, notably
  Verner Dahlerup and Hreinn Benediktsson, have argued for a third hand
  on f. 24, but the evidence for this is insubstantial.</p>
</handDesc>
```

Alternatively, or in addition, where more specific information about one or more of the hands identified is to be recorded, the <handNote> element should be used, as in the following example:

```
<handDesc hands="3">
  <handNote xml:id="Eirsp-1" scope="minor">
    <p>The first part of the manuscript,
    <locus from="1v" to="72v:4">fols 1v-72v:4</locus>, is written in a practised
    Icelandic Gothic bookhand. This hand is not found elsewhere.</p>
  </handNote>
  <handNote xml:id="Eirsp-2" scope="major">
    <p>The second part of the manuscript, <locus from="72v:4" to="194v">fols
    72v:4-194</locus>, is written in a hand contemporary with the first; it can
    also be found in a fragment of <title>Knýtlinga saga</title>,</p>
  </handNote>
</handDesc>
```

```

    <ref>AM 20b II fol.</ref>.</p>
  </handNote>
  <handNote xml:id="Eirsp-3" scope="minor">
    <p>The third hand has written the majority of the chapter headings.
      This hand has been identified as the one also found in <ref>AM
        221 fol.</ref>.</p>
  </handNote>
</handDesc>

```

Note here the use of the <locus> element, discussed in section 10.3.5. *References to Locations within a Manuscript*, to specify exactly which parts of a manuscript are written by a given hand.

When a full or partial transcription of a manuscript is available in addition to the manuscript description, the <handShift> element described in 11.3.2.1. *Document Hands* can be used to link the relevant parts of the transcription to the appropriate <handNote> element in the description: for example, at the point in the transcript where the second hand listed above starts (i.e. at folio 72v:4), we might insert <handShift new="#Eirsp-2"/>.

The elements <typeDesc>, and <typeNote> are used to provide information about the printing of a source, in exactly the same way as the <handDesc> or <handNote> elements provide information about its writing. They are provided for the convenience of those using this module to provide information about early printed sources and incunables. The <typeDesc> element can simply provide a summary description:

```

<typeDesc>
  <p>Uses a mixture of Roman and Black Letter types.</p>
</typeDesc>

```

Where detailed information about individual typefaces is to be recorded, this may be done using the <typeNote> element:

```

<typeDesc>
  <summary>Uses a mixture of Roman and Black Letter types.</summary>
  <typeNote>Antiqua typeface, showing influence of Jenson's Venetian
    fonts.</typeNote>
  <typeNote>The black letter face is a variant of Schwabacher.</typeNote>
</typeDesc>

```

Where information is required about both typography and written script, for example where a printed book contains extensive handwritten annotation, both <handDesc> and <typeDesc> elements should be supplied. Similarly, in the following example, the source text is a typescript with extensive handwritten annotation:

```

<typeDesc>
  <typeNote xml:id="TSET">Authorial
    typescript, probably produced on Eliot's own Remington.
  </typeNote>
</typeDesc>
<handDesc>
  <handNote xml:id="EP" medium="red-ink">Ezra Pound's
    annotations.</handNote>
  <handNote xml:id="TSE" medium="black-ink">Commentary in
    Eliot's hand.</handNote>
</handDesc>

```

The elements <scriptNote> and <scriptDesc> may be used in exactly the same way to document a script used in this and other manuscripts, for example to record that this script was used mainly for the production of books or

for charters; or that it is characteristic of some geographical area or scriptorium or date. Such information as the letter forms characteristic of this script may also be recorded. By contrast, the <handNote> element would be used to document the way that a particular scribe uses a script, for example with long or short descenders, or using a pen which is cut in a different way, or an ink of a given colour, and so forth.

As with <typeNote>, the <scriptNote> element can be used in combination with <handNote>.

### 10.7.2.2 Decoration

It can be difficult to draw a clear distinction between aspects of a manuscript which are purely physical and those which form part of its intellectual content. This is particularly true of illuminations and other forms of decoration in a manuscript. We propose the following elements for the purpose of delimiting discussion of these aspects within a manuscript description, and for convenience locate them all within the physical description, despite the fact that the illustrative features of a manuscript will in many cases also be seen as constituting part of its intellectual content.

The <decoDesc> element may contain simply one or more paragraphs summarizing the overall nature of the decorative features of the manuscript, as in the following example:

```
<decoDesc>
  <p>The decoration comprises two full page miniatures, perhaps added
    by the original owner, or slightly later; the original major decoration
    consists of twenty-three large miniatures, illustrating the divisions of
    the Passion narrative and the start of the major texts, and the major
    divisions of the Hours; seventeen smaller miniatures, illustrating the
    suffrages to saints; and seven historiated initials, illustrating
    the pericopes and major prayers.</p>
</decoDesc>
```

Alternatively, it may contain a series of more specific typed <decoNote> elements, each summarizing a particular aspect or individual instance of the decoration present, for example the use of miniatures, initials (historiated or otherwise), borders, diagrams, etc., as in the following example:

```
<decoDesc>
  <decoNote type="miniature">
    <p>One full-page miniature, facing the beginning of the first
      Penitential Psalm.</p>
  </decoNote>
  <decoNote type="initial">
    <p>One seven-line historiated initial, commencing the first
      Penitential Psalm.</p>
  </decoNote>
  <decoNote type="initial">
    <p>Six four-line decorated initials, commencing the second through the
      seventh Penitential Psalm.</p>
  </decoNote>
  <decoNote type="initial">
    <p>Some three hundred two-line versal initials with pen-flourishes,
      commencing the psalm verses.</p>
  </decoNote>
  <decoNote type="border">
    <p>Four-sided border decoration surrounding the miniatures and three-sided
      border decoration accompanying the historiated and decorated initials.</p>
  </decoNote>
</decoDesc>
```

Where more exact indexing of the decorative content of a manuscript is required, the standard TEI elements <term> or <index> may be used within the prose description to supply or delimit appropriate iconographic terms, as in the following example:

```

<decoDesc>
  <decoNote type="miniatures">
    <p>Fourteen large miniatures with arched tops, above five lines of text:
    <list>
      <item>
        <locus>fol. 14r</locus>Pericopes. <term>St. John writing on
          Patmos</term>, with the Eagle holding his ink-pot and pen-case; some
          flaking of pigment, especially in the sky</item>
      <item>
        <locus>fol. 26r</locus>Hours of the Virgin, Matins.
        <term>Annunciation</term>; Gabriel and the Dove to the right</item>
      <item>
        <locus>fol. 60r</locus>Prime. <term>Nativity</term>; the
        <term>Virgin and Joseph adoring the Child</term>
      </item>
      <item>
        <locus>fol. 66r</locus>Terce. <term>Annunciation to the
          Shepherds</term>, one with <term>bagpipes</term>
      </item>
    </list>
  </decoNote>
</decoDesc>

```

### 10.7.2.3 Musical Notation

Where a manuscript contains music, the <musicNotation> element may be used to describe the form of notation employed, as in the following example:

```

<musicNotation>
  <p>Square notation on 4-line red staves.</p>
</musicNotation>
<musicNotation>
  <p>Neumes in campo aperto of the St. Gall type.</p>
</musicNotation>

```

### 10.7.2.4 Additions and Marginalia

The <additions> element can be used to list or describe any additions to the manuscript, such as marginalia, scribbles, doodles, etc., which are considered to be of interest or importance. Such topics may also be discussed or referenced elsewhere in a description, for example in the <history> element, in cases where the marginalia provide evidence of ownership. Some examples follow:

```

<additions>
  <p>Doodles on most leaves, possibly by children, and often quite amusing.</p>
</additions>
<additions>
  <p xml:lang="fr">Quelques annotations marginales des XVIe et XVIIe s.</p>
</additions>
<additions>
  <p>The text of this manuscript is not interpolated with sentences from
    Royal decrees promulgated in 1294, 1305 and 1314. In the margins, however,
    another somewhat later scribe has added the relevant paragraphs of these
    decrees, see pp. 8, 24, 44, 47 etc.</p>
</additions>

```

```

<p>As a humorous gesture the scribe in one opening of the manuscript, pp. 36
and 37, has prolonged the lower stems of one letter f and five letters þ
and has them drizzle down the margin.</p>
</additions>
<additions>
<p>Spaces for initials and chapter headings were left by the scribe but not filled in.
A later, probably fifteenth-century, hand has added initials and chapter headings
in
greenish-coloured ink on fols <locus>8r</locus>, <locus>8v</locus>,
<locus>9r</locus>,
<locus>10r</locus> and <locus>11r</locus>. Although a few of these chapter headings
are
now rather difficult to read, most can be made out, e.g. fol. <locus>8rb</locus>
<quote xml:lang="is">floti ast<ex>ri</ex>d<ex>ar</ex>
</quote>; fol. <locus>9rb</locus>
<quote xml:lang="is">v<ex>m</ex> olaf conung</quote>, and fol. <locus>10ra</locus>
<quote xml:lang="is">Gipti<ex>n</ex>g ol<ex>a</ex>fs k<ex>onun</ex>gs</quote>.</p>
<p>The manuscript contains the following marginalia:
<list>
<item>Fol. <locus>4v</locus>, left margin: <quote xml:lang="is">hialmadr
<ex>ok</ex>
<lb/>brynjadr</quote>,
in a fifteenth-century hand, imitating an addition made to the text by the
scribe at this point.</item>
<item>Fol. <locus>5r</locus>, lower margin: <quote xml:lang="is">þ<ex>e</ex>tta
þiki
m<ex>er</ex> v<ex>er</ex>a gott blek en<ex>n</ex>da kan<ex>n</ex> ek icki
betr sia</quote>, in a fifteenth-century hand, probably the same as that
on the previous page.</item>
<item>Fol. <locus>9v</locus>, bottom margin: <quote xml:lang="is">þessa bok uilda
eg <sic>gæt</sic>
lært med <lb/>an Gud gefe myer Gott ad <lb/>læra</quote>; seventeenth-
century hand.</item>
</list>
</p>
<p>There are in addition a number of illegible scribbles in a later hand (or hands)
on fols
<locus>2r</locus>, <locus>3r</locus>, <locus>5v</locus> and <locus>19r</locus>.</p>
</additions>

```

### 10.7.3 Bindings, Seals, and Additional Material

The third major component of the physical description relates to supporting but distinct physical components, such as bindings, seals and accompanying material. These may be described using the following specialist elements:

- <bindingDesc>** (binding description) describes the present and former bindings of a manuscript, either as a series of paragraphs or as a series of distinct **<binding>** elements, one for each binding of the manuscript.
- <binding>** contains a description of one binding, i.e. type of covering, boards, etc. applied to a manuscript.
- <sealDesc>** (seal description) describes the seals or other external items attached to a manuscript, either as a series of paragraphs or as a series of distinct **<seal>** elements, possibly with additional **<decoNote>**s.
- <seal>** contains a description of one seal or similar attachment applied to a manuscript.
- <accMat>** (accompanying material) contains details of any significant additional material which may be closely associated with the manuscript being described, such as non-contemporaneous documents or fragments bound in with the manuscript at some earlier historical period.

### 10.7.3.1 Binding Descriptions

The <bindingDesc> element contains a description of the state of the present and former bindings of a manuscript, including information about its material, any distinctive marks, and provenance information. This may be given as a series of paragraphs if only one binding is being described, or as a series of distinct <binding> elements, each describing a distinct binding where these are separately described. For example:

```
<bindingDesc>
  <p>Sewing not visible; tightly rebound over 19th-century pasteboards, reusing
    panels of 16th-century brown leather with gilt tooling à la fanfare, Paris
    c. 1580-90, the centre of each cover inlaid with a 17th-century oval medallion
    of red morocco tooled in gilt (perhaps replacing the identifying mark of a
    previous owner); the spine similarly tooled, without raised bands or title-piece;
    coloured endbands; the edges of the leaves and boards gilt. Boxed.</p>
</bindingDesc>
```

Within a binding description, the elements <decoNote> and <condition> are available, as alternatives to <p>, for paragraphs dealing exclusively with information about decorative features of a binding, or about its condition, respectively.

```
<binding>
  <p>Bound, s. XVIII (?), in <material>diced russia leather</material>
    retaining most of the original 15th century metal ornaments (but with
    some replacements) as well as the heavy wooden boards.</p>
  <decoNote>
    <p>On each cover: alternating circular stamps of the Holy Monogram,
      a sunburst, and a flower.</p>
  </decoNote>
  <decoNote>
    <p>On the cornerpieces, one of which is missing, a rectangular stamp
      of the Agnus Dei.</p>
  </decoNote>
  <condition>Front and back leather inlaid panels very badly worn.</condition>
  <p>Rebacked during the 19th century.</p>
</binding>
```

As noted above, (10.7.1.5. *Condition*) the element <condition> may also be used as an alternative to <p> for paragraphs concerned exclusively with the condition of a binding, where this has not been supplied as part of the physical description.

### 10.7.3.2 Seals

The <sealDesc> element supplies information about the seal(s) attached to documents to guarantee their integrity, or to show authentication of the issuer or consent of the participants. It may contain one or more paragraphs summarizing the overall nature of the seals, or may contain one or more <seal> elements.

```
<sealDesc>
  <seal n="1" type="pendant"
    subtype="cauda_duplex">
    <p>Round seal of <name>Anders Olufsen</name> in black wax:
  <bibl>
    <ref>DAS 930</ref>
  </bibl>. Parchment tag, on which is written:
  <quote>pertinere nos predictorum placiti nostri iusticarii precessorum
  dif</quote>.</p>
```

```

</seal>
<seal n="2" type="pendant"
  subtype="cauda_duplex">
  <p>The seal of <name>Jens Olufsen</name> in black wax:
  <bibl>
    <ref>DAS 1061</ref>
    </bibl>. Legend: <quote>S IOHANNES OLAVI</quote>.
    Parchment tag on which is written: <quote>Woldorp Iohanne G</quote>.</p>
  </seal>
</sealDesc>

```

### 10.7.3.3 Accompanying Material

The circumstance may arise where material not originally part of a manuscript is bound into or otherwise kept with a manuscript. In some cases this material would best be treated in a separate `<msPart>` element (see *10.10. Manuscript Parts* below). There are, however, cases where the additional matter is not self-evidently a distinct manuscript: it might, for example, be a set of notes by a later scholar, or a file of correspondence relating to the manuscript. The `<accMat>` element is provided as a holder for this kind of information.

**<accMat>** (accompanying material) contains details of any significant additional material which may be closely associated with the manuscript being described, such as non-contemporaneous documents or fragments bound in with the manuscript at some earlier historical period.

Here is an example of the use of this element, describing a note by the Icelandic manuscript collector Árne Magnússon which has been bound with the manuscript:

```

<accMat>
  <p>A slip in Árne Magnússon's hand has been stuck to the
  pastedown on the inside front cover; the text reads:
  <quote xml:lang="is">Þidreks Sögu þessa hefi eg
  feiged af Sekreterer Wielandt Anno 1715 i Kaupmanna høfn. Hun er,
  sem eg sie, Copia af Austfirda bókinni (Eidagás) en<ex>n</ex>
  ecki progenies Brædratungu bokarinnar. Og er þar fyrer eigi i
  allan<ex>n</ex> máta samhlioda þ<ex>eir</ex>re er
  Sr Jon Erlendz son hefer ritad fyrer Mag. Bryniolf. Þesse Þidreks
  Saga mun vera komin fra Sr Vigfuse á Helgafelle.</quote>
  </p>
</accMat>

```

## 10.8 History

The following elements are used to record information about the history of a manuscript:

**<history>** groups elements describing the full history of a manuscript or manuscript part.

**<origin>** contains any descriptive or other information concerning the origin of a manuscript or manuscript part.

**<provenance>** contains any descriptive or other information concerning a single identifiable episode during the history of a manuscript or manuscript part, after its creation but before its acquisition.

**<acquisition>** contains any descriptive or other information concerning the process by which a manuscript or manuscript part entered the holding institution.

The three components of the `<history>` element all have the same substructure, consisting of one or more paragraphs marked as `<p>` elements. Each of these three elements is also a member of the `att.dataable` attribute class, itself a member of the `att.dataable.w3c` class, and thus also carries the following optional attributes:

**att.dataable.w3c** provides attributes for normalization of elements that contain dataable events conforming to the *W3C XML Schema Part 2: Datatypes Second Edition*.

`@notBefore` specifies the earliest possible date for the event in standard form, e.g. yyyy-mm-dd.

`@notAfter` specifies the latest possible date for the event in standard form, e.g. yyyy-mm-dd.

Information about the origins of the manuscript, its place and date of writing, should be given as one or more paragraphs contained by a single `<origin>` element; following this, any available information on distinct stages in the history of the manuscript before its acquisition by its current holding institution should be included as paragraphs within one or more `<provenance>` elements. Finally, any information specific to the means by which the manuscript was acquired by its present owners should be given as paragraphs within the `<acquisition>` element.

Here is a fairly simple example of the use of this element:

```
<history>
  <origin>
    <p>Written in <origPlace>Durham</origPlace> during <origDate notBefore="1125"
      notAfter="1175">the
      mid-twelfth century</origDate>.</p>
  </origin>
  <provenance>
    <p>Recorded in two medieval catalogues of the books belonging
      to <name type="org">Durham Priory</name>, made in <date>1391</date> and
      <date>1405</date>.</p>
  </provenance>
  <provenance>
    <p>Given to <name type="person">W. Olleyf</name> by <name type="person">William
      Ebchester, Prior (1446-56)</name> and later belonged to
    <name type="person">Henry
      Dalton</name>, Prior of Holy Island (<name type="place">Lindisfarne</name>)
      according to inscriptions on ff. 4v and 5.</p>
  </provenance>
  <acquisition>
    <p>Presented to <name type="org">Trinity College</name> in
      <date>1738</date> by <name type="person">Thomas Gale</name> and
      his son <name type="person">Roger</name>.</p>
  </acquisition>
</history>
```

Here is a fuller example, demonstrating the use of multiple `<provenance>` elements where distinct periods of ownership for the manuscript have been identified:

```
<history>
  <origin notBefore="1225" notAfter="1275">Written in Spain or Portugal in the middle
  of the 13th century
  (the date 1042, given in a marginal note on f. 97v, cannot be correct.)</origin>
  <provenance>The Spanish scholar <name type="person">Benito Arias
  Montano</name> (1527-1598) has written his name on f. 97r, and may be
  presumed to have owned the manuscript. </provenance>
  <provenance>It came somehow into the
  possession of <foreign xml:lang="da">etatsråd</foreign>
  <name type="person">Holger Parsberg</name> (1636-1692), who has written his
  name twice, once on the front pastedown and once on f. 1r, the former dated
  <date>1680</date> and the latter <date>1682</date>.</provenance>
  <provenance>Following Parsberg's
  death the manuscript was bought by <foreign>etatsråd</foreign>
  <name type="person">Jens Rosenkrantz</name> (1640-1695) when Parsberg's
  library was auctioned off (23 October 1693).</provenance>
  <acquisition notBefore="1696"
  notAfter="1697">The manuscript was acquired by Árni
  Magnússon from the estate of Jens Rosenkrantz, presumably at
```

```

    auction (the auction lot number 468 is written in red chalk on the
    flyleaf), either in 1696 or 97.</acquisition>
</history>

```

## 10.9 Additional Information

Three categories of additional information are provided for by the scheme described here, grouped together within the <additional> element described in this section.

**<additional>** groups additional information, combining bibliographic information about a manuscript, or surrogate copies of it with curatorial or administrative information.

**<adminInfo>** (administrative information) contains information about the present custody and availability of the manuscript, and also about the record description itself.

**<surrogates>** contains information about any representations of the manuscript being described which may exist in the holding institution or elsewhere.

**<listBibl>** (citation list) contains a list of bibliographic citations of any kind.

None of the constituent elements of <additional> is required. If any is supplied, it may appear once only; furthermore, the order in which elements are supplied should be as specified above.

### 10.9.1 Administrative Information

The <adminInfo> element is used to hold information relating to the curation and management of a manuscript. This may be supplied as a note using the global <note> element. Alternatively, different aspects of this information may be presented grouped within one of the following specialized elements:

**<recordHist>** (recorded history) provides information about the source and revision status of the parent manuscript description itself.

**<availability>** supplies information about the availability of a text, for example any restrictions on its use or distribution, its copyright status, any licence applying to it, etc.

**<custodialHist>** (custodial history) contains a description of a manuscript's custodial history, either as running prose or as a series of dated custodial events.

#### 10.9.1.1 Record History

The <recordHist> element may contain simply a series of paragraphs. Alternatively it may contain a <source> element, followed by an optional series of <change> elements.

**<source>** describes the original source for the information contained with a manuscript description.

**<change>** documents a change or set of changes made during the production of a source document, or during the revision of an electronic file.

The <source> element is used to document the primary source of information for the record containing it, in a similar way to the standard TEI <sourceDesc> element within a TEI Header. If the record is a new one, made without reference to anything other than the manuscript itself, then it may simply contain a <p> element, as in the following example:

```

<source>
  <p>Directly catalogued from the original manuscript.</p>
</source>

```

Frequently, however, the record will be derived from some previously existing description, which may be specified using the standard TEI <bibl> element, as in the following example:

```

<recordHist>
  <source>
    <p>Information transcribed from <bibl>
      <title>The index of Middle English verse</title>

```

```

    <biblScope>123</biblScope>
  </bibl>.</p>
</source>
</recordHist>

```

If, as is likely, a full bibliographic description of the source from which cataloguing information was taken is included within the <listBibl> element contained by the current <additional> element, or elsewhere in the current document, then it need not be repeated here. Instead, it should be referenced using the standard TEI <ref> element, as in the following example:

```

<additional>
  <adminInfo>
    <recordHist>
      <source>
        <p>Information transcribed from
          <bibl>
            <ref target="#IMEV">IMEV</ref> 123</bibl>.</p>
          </source>
        </recordHist>
      </adminInfo>
    <listBibl>
      <bibl xml:id="IMEV">
        <author>Carleton Brown</author> and <author>Russell Hope Robbins</author>
        <title level="m">The index of Middle English verse</title>
        <pubPlace>New York</pubPlace>
        <date>1943</date>
      </bibl>
    <!-- other bibliographic records relating to this manuscript here -->
  </listBibl>
</additional>

```

The <change> element may also appear within the <revisionDesc> element of the standard TEI header; its use here is intended to signal the similarity of function between the two container elements. Where the TEI header should be used to document the revision history of the whole electronic file to which it is prefixed, the <recordHist> element may be used to document changes at a lower level, relating to the individual description, as in the following example:

```

<change when="2005-03-10">On 10 March 2005
<name>MJD</name> added provenance information</change>

```

### 10.9.1.2 Availability and Custodial History

The <availability> element is another element also available in the TEI header, which should be used here to supply any information concerning access to the current manuscript, such as its physical location (where this is not implicit in its identifier), any restrictions on access, information about copyright, etc.

```

<availability>
  <p>Viewed by appointment only, to be arranged with curator.</p>
</availability>
<availability>
  <p>In conservation, Jan. - Mar., 2002. On loan to the
    Bayerische Staatsbibliothek, April - July, 2002.</p>
</availability>

```

```
<availability>
  <p>The manuscript is in poor condition, due to many of the leaves being
    brittle and fragile and the poor quality of a number of earlier repairs;
    it should therefore not be used or lent out until it has been conserved.</p>
</availability>
```

The `<custodialHist>` record is used to describe the custodial history of a manuscript, recording any significant events noted during the period that it has been located within its holding institution. It may contain either a series of `<p>` elements, or a series of `<custEvent>` elements, each describing a distinct incident or event, further specified by a *type* attribute, and carrying dating information by virtue of its membership in the `att.dataable` class, as noted above.

**<custEvent>** (custodial event) describes a single event during the custodial history of a manuscript.

Here is an example of the use of this element:

```
<custodialHist>
  <custEvent type="conservation"
    notBefore="1961-03-01" notAfter="1963-02-28">
    <p>Conserved between March 1961 and February 1963 at Birgitte Dalls
      Konserveringsværksted.</p>
  </custEvent>
  <custEvent type="photography"
    notBefore="1988-05-01" notAfter="1988-05-30">
    <p>Photographed in May 1988 by AMI/FA.</p>
  </custEvent>
  <custEvent type="transfer"
    notBefore="1989-11-13" notAfter="1989-11-13">
    <p>Dispatched to Iceland 13 November 1989.</p>
  </custEvent>
</custodialHist>
```

## 10.9.2 Surrogates

The `<surrogates>` element is used to provide information about representations such as photographs or other representations of the manuscript which may exist within the holding institution or elsewhere.

**<surrogates>** contains information about any representations of the manuscript being described which may exist in the holding institution or elsewhere.

The `<surrogates>` element should not be used to repeat information about representations of the manuscript available within published works; this should normally be documented within the `<listBibl>` element within the `<additional>` element. However, it is often also convenient to record information such as negative numbers or digital identifiers for unpublished collections of manuscript images maintained within the holding institution, as well as to provide more detailed descriptive information about the surrogate itself. Such information may be provided as prose paragraphs, within which identifying information about particular surrogates may be presented using the standard TEI `<bibl>` element, as in the following example:

```
<surrogates>
  <bibl>
    <title type="gmd">microfilm (master)</title>
    <idno>G.neg. 160</idno> n.d.</bibl>
  <bibl>
    <title type="gmd">microfilm (archive)</title>
    <idno>G.pos. 186</idno> n.d.</bibl>
  <bibl>
    <title type="gmd">b/w prints</title>
```

```

<idno>AM 795 4to</idno>
<date when="1999-01-27">27 January 1999</date>
<note>copy of G.pos. 186</note>
</bibl>
<bibl>
  <title type="gmd">b/w prints</title>
  <idno>reg.nr. 75</idno>
  <date when="1999-01-25">25 January 1999</date>
  <note>photographs of the spine, outside covers, stitching etc.</note>
</bibl>
</surrogates>

```

Note the use of the specialized form of title (*general material designation*) to specify the kind of surrogate being documented.

At a later revision, the content of the <surrogates> element is likely to be expanded to include elements more specifically intended to provide detailed information such as technical details of the process by which a digital or photographic image was made. For information about the inclusion of digital facsimile images within a TEI document, refer also to 11.1. *Digital Facsimiles*.

## 10.10 Manuscript Parts

The <msPart> element may be used in cases where manuscripts or parts of manuscripts that were originally physically separate have been bound together and/or share the same call number.

**<msPart>** (manuscript part) contains information about an originally distinct manuscript or part of a manuscript, which is now part of a composite manuscript.

Since each component of such a composite manuscript will in all likelihood have its own content, physical description, history, and so on, the structure of <msPart> is in the main identical to that of <msDesc>, allowing one to retain the top level of identity (<msIdentifier>), but to branch out thereafter into as many parts, or even subparts, as necessary.

```

<msDesc xml:id="KBR_ms_10066-77"
  xml:lang="eng" type="composite">
  <msIdentifier>
    <settlement key="tgn_7007868">Brussels</settlement>
    <repository>Koninklijke Bibliotheek van België / Bibliothèque royale de Bel-
    gique</repository>
    <idno>ms. 10066-77</idno>
  </msIdentifier>
  <msContents>
    <summary xml:lang="lat">Miscellany of various texts; Prudentius, Psychomachia; Phys-
    iologus de natura animantium</summary>
    <textLang mainLang="lat">Latin</textLang>
  </msContents>
  <physDesc>
    <objectDesc form="composite_manuscript"/>
  </physDesc>
  <msPart>
    <msIdentifier>
      <idno>ms. 10066-77 ff. 140r-156v</idno>
    </msIdentifier>
    <msContents>
      <summary xml:lang="lat">Physiologus</summary>
      <textLang mainLang="lat">Latin</textLang>
    </msContents>
  </msPart>

```

```

<msPart>
  <msIdentifier>
    <idno>ms. 10066-77 ff. 112r-139r</idno>
  </msIdentifier>
  <msContents>
    <summary xml:lang="lat">Prudentius, Psychomachia</summary>
    <textLang mainLang="lat">Latin</textLang>
  </msContents>
</msPart>
</msDesc>

```

## 10.11 Manuscript Fragments

The `<msFrag>` element may be used inside `<msDesc>` when encoding one or more fragments of a scattered or fragmented manuscript. The fragment(s) described in a single `<msDesc>` element may be held either at several institutions or at a single institution, so different call numbers may be attached to the fragments. Inside the `<msFrag>` element, information about the single fragment or each dispersed part is provided: e.g. the current shelfmark or call number, the labels of the range of folios concerned if the fragment currently forms part of a larger manuscript, dimensions, extent, title, author, annotations, illuminations and so on.

**<msFrag>** (manuscript fragment) contains information about a fragment of a scattered manuscript now held as a single unit or bound into a larger manuscript.

One well-known example of fragmentation is the Old Church Slavonic manuscript known as *Codex Suprasliensis*, substantial parts of which are to be found in three separate repositories, in Ljubljana, Warsaw, and St. Petersburg. This manuscript should be represented using one single `<msDesc>` element in which `<msName>` is used to identify the fragmented manuscript, along with three distinct `<msFrag>` elements, each of which contains the current identifier of one of the fragments, a physical description, and other related information:

```

<msDesc>
  <msIdentifier>
    <msName xml:lang="la">Codex Suprasliensis</msName>
  </msIdentifier>
  <msFrag>
    <msIdentifier>
      <settlement>Ljubljana</settlement>
      <repository>Narodna in univerzitetna knjižnica</repository>
      <idno>MS Kopitar 2</idno>
    </msIdentifier>
    <msContents>
      <summary>Contains ff. 10 to 42 only</summary>
    </msContents>
  </msFrag>
  <msFrag>
    <msIdentifier>
      <settlement>Warszawa</settlement>
      <repository>Biblioteka Narodowa</repository>

## 10.12 Module for Manuscript Description

The module described in this chapter makes available the following components:

### Module msdescription: Manuscript Description

- *Elements defined:* accMat acquisition additional additions adminInfo altIdentifier binding bindingDesc catchwords collation collection colophon condition custEvent custodialHist decoDesc decoNote depth dim dimensions explicit filiation finalRubric foliation handDesc height heraldry history incipit institution layout layoutDesc locus locusGrp material msContents msDesc msFrag msIdentifier msItem msItemStruct msName msPart musicNotation objectDesc objectType origDate origPlace origin physDesc provenance recordHist repository rubric scriptDesc seal sealDesc secFol signatures source stamp summary support supportDesc surrogates typeDesc watermark width
- *Classes defined:* att.msExcerpt

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

## 11 Representation of Primary Sources

This chapter defines a module intended for use in the representation of primary sources, such as manuscripts or other written materials. Section 11.1. *Digital Facsimiles* provides elements for handling digitally-encoded images of such materials. This module may also be useful in the preparation of critical editions, but the module defined here is distinct from that defined in chapter 12. *Critical Apparatus*, and may be used independently of it. Detailed metadata relating to primary sources of any kind may be recorded using the elements defined by the manuscript description module discussed in chapter 10. *Manuscript Description*, but again the present module may be used independently if such data is not required.

Although this chapter discusses manuscript materials more frequently than other forms of written text, most of the recommendations presented are equally applicable *mutatis mutandis* to the encoding of printed matter or indeed any form of written source, including monumental inscriptions. Similarly, where in the following descriptions terms such as ‘scribe’, ‘author’, ‘editor’, ‘annotator’ or ‘corrector’ are used, these may be re-interpreted in terms more appropriate to the medium being transcribed. In printed material, for example, the ‘compositor’ plays a role analogous to the ‘scribe’, while in an authorial manuscript, the author and the scribe are the same person.

### 11.1 Digital Facsimiles

These Guidelines are mostly concerned with the preparation of digital texts in which pre-existing sources are transcribed or otherwise converted into character form, and marked up in XML. However, it is also very common practice to make a different form of ‘digital text’, which is instead composed of digital images of the original source, typically one per page, or other written surface. We call such a resource a *digital facsimile*. A digital facsimile may, in the simplest case, just consist of a collection of images, with some metadata to identify them and the source materials portrayed. It may sometimes contain a variety of images of the same source pages, perhaps of different resolutions, or of different kinds. Such a collection may form part of any kind of document, for example a commentary of a codicological or paleographic nature, where there is a need to align explanatory text with image data. It may also be complemented by a transcribed or encoded version of the original source, which may be linked to the page images. In this section we present elements designed to support these various possibilities and discuss the associated mechanisms provided by these Guidelines.

When this module is included in a schema, the class `att.global` is extended to include two new pointer attributes, *fac* and *change*:

**att.global.facs** provides an attribute used to express correspondence between an element containing transcribed text and all or part of an image representing that text.

`@facs` (facsimile) points to all or part of an image which corresponds with the content of the element.

**att.global.change** supplies the *change* attribute, allowing its member elements to specify one or more states or revision campaigns with which they are associated.

`@change` points to one or more `<change>` elements documenting a state or revision campaign to which the element bearing this attribute and its children have been assigned by the encoder.

The *change* attribute is discussed further below in section 11.7. *Identifying Changes and Revisions*. The *fac* attribute is used to associate any element in a transcription with an image of the corresponding part of the source, by means of the usual URI pointing mechanism.

In the simple case where a digital text is composed of page images, the *fac* attribute on the `<pb>` element may be used to associate each image with an appropriate point in the text:

```
<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
<!-- ... -->
  </teiHeader>
  <text>
    <pb facs="page1.png"/>
<!-- text contained on page 1 is encoded here -->
    <pb facs="page2.png"/>
<!-- text contained on page 2 is encoded here -->
  </text>
</TEI>
```

```
</text>
</TEI>
```

By convention, this encoding indicates that the image indicated by the *fac*s attribute represents the whole of the text following the <pb> (pagebreak) element, up to the next <pb> element. Any convenient milestone element (see further 3.10.3. *Milestone Elements*) could be used in the same way; for example if the images represent individual columns, the <cb> element might be used. Though simple, this method has some drawbacks. It does not scale well to more complex cases where, for example, the images do not correspond exactly with transcribed pages, or where the intention is to align specific marked up elements with detailed images, or parts of images. The management of information about the images may become more difficult if references to them are scattered through many files rather than being concentrated in a single identifiable location. Nevertheless, this solution may be adequate for many straightforward ‘digital library’ applications.

The recommended approach to encoding facsimiles is instead to use the *fac*s attribute in conjunction with the elements <facsimile> or <sourceDoc>, and the elements <surface>, <surfaceGrp>, and <zone>, which are also provided by this module. These elements make it possible to accommodate multiple images of each page, as well as to record the position and relative size of elements identified on any kind of written surface and to link such elements with digital facsimile images of them. Typical applications include the provision of full text search in ‘digital facsimile editions’, and ways of annotating graphics, for example so as to identify individuals appearing in group portraits and link them to data about the people represented.

The following elements are available to represent components of a digital facsimile:

**<facsimile>** contains a representation of some written source in the form of a set of images rather than as transcribed or encoded text.

**<sourceDoc>** contains a transcription or other representation of a single source document potentially forming part of a *dossier génétique* or collection of sources.

**<surface>** defines a written surface as a two-dimensional coordinate space, optionally grouping one or more graphic representations of that space, zones of interest within that space, and transcriptions of the writing within them.

**<surfaceGrp>** defines any kind of useful grouping of written surfaces, for example the recto and verso of a single leaf, which the encoder wishes to treat as a single unit.

**<zone>** defines any two-dimensional area within a <surface> element.

*@points [att.coordinated]* identifies a two dimensional area within the bounding box specified by the other attributes by means of a series of pairs of numbers, each of which gives the x,y coordinates of a point on a line enclosing the area.

Either of the <facsimile> or <sourceDoc> elements may be used to represent a digital facsimile. Either may appear within a TEI document along with, or instead of, the <text> element introduced in section 4. *Default Text Structure*. The <sourceDoc> element is used when a digital facsimile contains a documentary transcription; the <text> element when it contains a textual transcription. When the digital facsimile contains only images, however, only <facsimile> elements should be used. In this section, we first discuss the simpler case, returning to the use of the <sourceDoc> element in section 11.2. *Combining Transcription with Facsimile* below. When this module is selected therefore, a legal TEI document may thus comprise any of the following:

- a TEI header and a text element
- a TEI header and a facsimile element
- a TEI header and a sourceDoc element
- a TEI header, a facsimile element, and a text element
- a TEI header, one or more sourceDoc or facsimile elements, and a text element

Like the <text> element, a <facsimile> element may also contain an optional <front> or <back> element, used in the same way as described in sections 4.5. *Front Matter* and 4.7. *Back Matter*.

In the simplest case, a facsimile just contains a series of <graphic> elements, each of which identifies an image file:

```
<facsimile>
  <graphic url="page1.png"/>
  <graphic url="page2.png"/>
  <graphic url="page3.png"/>
  <graphic url="page4.png"/>
</facsimile>
```

If desired, the `<binaryObject>` element described in 3.9. *Graphics and Other Non-textual Components* (or any other element from the `model.graphicLike` class) can be used instead of a `<graphic>`.

In this simple case, the four page images are understood to represent the complete facsimile, and are to be read in the sequence given. Suppose, however, that the second page of this particular work is available both as an ordinary photograph and as an infra-red image, or in two different resolutions. The `<surface>` element may be used to group the two image files, since these correspond with the same area of the work:

```
<facsimile>
  <graphic url="page1.png"/>
  <surface>
    <graphic url="page2-highRes.png"/>
    <graphic url="page2-lowRes.png"/>
  </surface>
  <graphic url="page3.png"/>
  <graphic url="page4.png"/>
</facsimile>
```

The `<surface>` element provides a way of indicating that the two images of page2 represent the same surface within the source material. A *surface* might be one side of a piece of paper or parchment, an opening in a codex treated as a single surface by the writer, a face of a monument, a billboard, a membrane of a scroll, or indeed any two-dimensional surface, of any size.

The `<surfaceGrp>` element may be used to indicate that two (or more) surfaces are associated in some way, for example because they represent the recto and verso of the same leaf, as in this example:

```
<facsimile>
  <surfaceGrp n="leaf1">
    <surface>
      <graphic url="page1.png"/>
    </surface>
    <surface>
      <graphic url="page2-highRes.png"/>
      <graphic url="page2-lowRes.png"/>
    </surface>
  </surfaceGrp>
</facsimile>
```

The `<surfaceGrp>` element may also be useful as a means of identifying other groups of written surfaces, such as adjacent faces of a monument, or gatherings of leaves.

Simply grouping related graphics is not however the main purpose of the `<surface>` element: rather it is to help identify the location and size of the various two-dimensional spaces constituting the digital facsimile. Note that the actual dimensions of the object represented are not provided by the `<surface>` element; rather, the `<surface>` element defines an abstract coordinate space which may be used to address parts of the image. Four attributes supplied by the `att.coordinated` class are used to define this space.

**att.coordinated** provides attributes which can be used to position their parent element within a two dimensional coordinate system.

`@uLx` gives the x coordinate value for the upper left corner of a rectangular space.

@uly gives the y coordinate value for the upper left corner of a rectangular space.

@lrx gives the x coordinate value for the lower right corner of a rectangular space.

@lry gives the y coordinate value for the lower right corner of a rectangular space.

By default, the same coordinate space is used for a <surface> and for all of its child elements.<sup>75</sup> It may be most convenient to derive a coordinate space from a digital image of the surface in question such that each pixel in the image corresponds with a whole number of units (typically 1) in the coordinate space. In other cases it may be more convenient to use units such as millimetres. Neither practice implies any specific mapping between the coordinate system used and the actual dimensions of the physical object represented.

A <surface> element can contain one or more <zone> elements, each of which represents a region or *bounding box* defined in terms of the same coordinate space as that of its parent <surface> element. A zone may be rectangular or non-rectangular: a rectangular zone is defined by a sequence of four coordinates in the same way as a surface; a non-rectangular zone is defined using the attribute *points*, which provides a sequence of coordinates, each of which specifies a point on the perimeter of the zone.<sup>76</sup>

A zone may be used to define any region of interest, such as a detail or illustration, or some part of the surface which is to be aligned with a particular text element, or otherwise distinguished from the rest of the surface. A surface establishes a coordinate system which may be used to address parts or the whole of some digital representation of a written surface. A zone, by contrast, defines any arbitrary area of interest relative to that surface, using the same coordinate system. It might be bigger or smaller than its parent surface, or might overlap its boundaries. The only constraint is that it must be defined using the same coordinate system.

When an image of some kind is supplied within either a zone or a surface, the implication is that the image represents the whole of the zone or surface concerned. In the simple case therefore, we might imagine a surface defining a page, within which there is a graphic representing the whole of that page, and a number of zones defining parts of the page, each with its own graphic, each representing a part of the page. If however one of those graphics actually represents an area larger than the page (for example to include a binding or the surface of a desk on which the page rests), then it will be enclosed by a zone with coordinates larger than those of the parent surface.

For example, consider the following figure: This is an image of a two page spread from a manuscript in the Badische Landesbibliothek, Karlsruhe. We have no information as to the dimensions of the original object, but the low resolution image displayed here contains 500 pixels horizontally and 321 pixels vertically. For convenience, we might map each pixel to one cell of the coordinate space.<sup>77</sup>

We therefore define a <surface> element corresponding with the area of the image which represents the whole of the two page spread and embed the graphic within it:

```
<facsimile>
  <surface ulx="0" uly="0" lrx="500" lry="321">
    <graphic url="http://upload.wikimedia.org/wikipedia/commons/5/50/
Handschrift.karlsruhe.blb.jpg"/>
  </surface>
</facsimile>
```

If desired, the <binaryObject> element described in 3.9. *Graphics and Other Non-textual Components* (or any other element from the `model.graphicLike` class) may be used instead of a <graphic> element.

Since the image in this example is of a two page opening, we will probably wish to define at least two nested zones, one for each page:

<sup>75</sup>The coordinate space may be thought of as a grid superimposed on a rectangular space. Rectangular areas of the grid are defined as four numbers a b c d: the first two identify the grid point which is at the upper left corner of the rectangle; the second two give the grid point located at the lower right corner of the rectangle. The grid point a b is understood to be the point which is located a points from the origin along the x (horizontal) axis, and b points from the origin along the y (vertical) axis.

<sup>76</sup>The *points* attribute supplies a 'points specification' in the same form as that required by the <polyline> or <polygon> elements in the SVG standard. See <http://www.w3.org/TR/SVG/shapes.html#PointsBNF>

<sup>77</sup>The coordinate space used here is based on pixels, but the mapping between pixels and units in the coordinate space need not be one-to-one; it might be convenient to define a more delicate grid, to enable us to address much smaller parts of the image. This can be done simply by supplying appropriate values for the attributes which define the coordinate space; for example doubling them all would map each pixel to two grid points in the coordinate space.

Figure 9: Badische Landesbibliothek, Manuscript Durlach 1, Fols. 95v-96r

```

<facsimile>
  <surface ulx="50" uly="20" lrx="400"
    lry="280">
    <zone ulx="0" uly="0" lrx="500" lry="321">
      <graphic url="http://upload.wikimedia.org/wikipedia/commons/5/50/
Handschrift.karlsruhe.blb.jpg"/>
    </zone>
    <zone ulx="50" uly="20" lrx="210" lry="280">
<!-- left hand page -->
    </zone>
    <zone ulx="240" uly="25" lrx="400"
      lry="280">
<!-- right hand page -->
    </zone>
    <zone ulx="90" uly="40" lrx="200" lry="225">
<!-- written part of left hand page -->
    </zone>
  </surface>
</facsimile>

```

As this example shows, in addition to acting as a container for <graphic> elements, <zone> elements may be used to identify parts of a surface for analytical purposes.

The relationship between zone and surface can be quite complex: for example, it may be appropriate to treat the whole of a two page spread as a single written surface, perhaps because particular written zones span both pages. A zone may contain a nested surface, if for example a page has an additional scrap of paper attached to it. A zone may be of any shape, not simply rectangular. Discussion of these and other cases are provided in section 11.4. *Advanced Uses of surface and zone* below.

In the following extended example, we discuss a hypothetical digital edition of an early 16th century French work, Charles de Bovelles' *Géométrie Pratique*.<sup>78</sup> In this edition, each page has been digitized as a separate file: for example, recto page 49 is stored in a file called **Bovelles-49r.png**. In the <facsimile> element used to contain the whole set of pages, we define a <surface> element for this page, which we situate within a coordinate scale running from 0 to 200 in the x (horizontal) axis, and 0 to 300 in the y (vertical) axis. The <surface> element contains a <graphic> element which represents the whole of this surface:

```

<facsimile>
  <surface ulx="0" uly="0" lrx="200" lry="300">
    <graphic url="Bovelles-49r.png"/>
  </surface>
</facsimile>

```

We can now identify distinct zones within the page image using the coordinate scale defined for the surface. In the following figure 10 we show the upper part of the page, with boxes indicating four such zones. Each of these will be represented by a <zone> element, given within the <surface> element already defined, and specified in terms of the same coordinate system. Some zones of interest are indicated by red lines in the following image. The following encoding defines each of the four zones identified in the figure above.

```

<facsimile>
  <surface ulx="0" uly="0" lrx="200" lry="300">
    <graphic url="Bovelles-49r.png"/>
    <zone ulx="25" uly="25" lrx="180" lry="60">

```

<sup>78</sup>The image is taken from the collection at <http://ancilla.unice.fr/Illustr.html>, and was digitized from a copy in the Bibliothèque Municipale de Lyon, by whose kind permission it is included here.

**DU SON ET ACCORD DES CLOCHES ET des alleures des cheuaultx, chariotz & charges, des fontaines: & encyclie du monde, & de la dimension du corps humain.**

**Chapitre septiesme.**

1. **Le son & accord des cloches pendans en vng mesme axe, est faict en contraires parties.**

**L** Es cloches ont quasi figures de rondes pyramides imperfectes & irregulieres: & leur accord se fait par reigle geometrique. Comme si les deux cloches C & D sont pendans à vng mesme axe ou essieu A B: ie dis que leur accord se fera en cōtraires parties, cōme voyez icy figuré. Car quād lune sera en hault, laultre declinera embas. Aultrement si elles declinent toutes deux ensemble en vne mesme partie, elles feront discord. & sera leur sonnerie mal plaisante à oyr.

2. **Le vray accord de deux cloches par lattouchement des bataulx, est faict diametralement.**

**C** Hascune cloche a deux diuers costez, entre lesquels le batail touche par diuerses fois. Et à cause que laccord de deux cloches se fait par linclination delles en diuerses & contraires parties: Il fault que ledict accord se fasse diametralemēt  
G.j.

Figure 10: Detail of p 49r from Bovelles *Géometrie Pratique*

```

<!-- contains the title -->
  </zone>
  <zone ulx="28" uly="75" lrx="175" lry="178"/>
<!-- contains the paragraph in italics -->
  <zone ulx="105" uly="76" lrx="175"
    lry="160"/>
<!-- contains the figure -->
  <zone ulx="45" uly="125" lrx="60" lry="130"/>
<!-- contains the word "pendans" -->
  </surface>
</facsimile>

```

Note that the location of each zone is defined independently but using the same coordinate system.

A non rectangular-zone, for example that containing the word *cloche*. at bottom left of the page, could also be defined, using the *points* attribute:

```

<facsimile>
  <surface ulx="0" uly="0" lrx="200" lry="300">
    <graphic url="Bovelles-49r.png"/>
    <zone points="4.8,31.0 5.4,30.7 5.5,32.2 5.8,32.8 6.1,33.4 5.5,33.7 5.1,33.3
4.6,32.2"/>
  </surface>
</facsimile>

```

In this example a single `<graphic>` element has been associated directly with the surface of the page rather than nesting it within a zone. However, it is also possible to include multiple `<zone>` elements which contain a `<graphic>` element, if for example a detailed image is available. Since all `<zone>` elements use the same coordinate system (that defined by their parent `<surface>`), there is no need to demonstrate enclosure of one zone within another by means of nesting. To continue the current example, supposing that we have an additional image called `Bovelles49r-detail.png` containing an additional image of the figure in the third zone above, we might encode that zone as follows:

```

<zone ulx="105" uly="76" lrx="175" lry="160">
  <graphic url="Bovelles49r-detail.png"/>
</zone>

```

## 11.2 Combining Transcription with Facsimile

A digitized source document may contain nothing more than page images and a small amount of metadata. It may also contain an encoded transcription of the pages represented, which may either be 'embedded' within a `<sourceDoc>` element, or supplied in parallel with a `<facsimile>` as defined above.

If the transcription is regarded as a text in its own right, organized and structured independently of its physical realization in the document or documents represented by the facsimile, then the recommended practice is to use the `<text>` element to contain such a structured representation, and to present it in parallel. The `<text>` element is a sibling of the `<facsimile>` and `<sourceDoc>` elements. This approach is illustrated in section 11.2.1. *Parallel Transcription* below. Alternatively, if the transcription is intended not to prioritize representation of the final text so much as the process by which the document came to take its present form, or the physical disposition of its component parts, it may be preferable to present it as an embedding transcription, as further described in section 11.2.2. *Embedded Transcription* below.

### 11.2.1 Parallel Transcription

Suppose now that we wish to align a transcription of the page discussed in the preceding section with particular zones. We begin by giving each relevant part of the facsimile an identifier:

```

<facsimile>
  <surface ulx="0" uly="0" lrx="200" lry="300">
    <zone xml:id="B49r" ulx="0" uly="0"
      lrx="200" lry="300">
      <graphic url="Bovelles-49r.png"/>
    </zone>
    <zone ulx="105" uly="76" lrx="175"
      lry="160">
      <graphic url="Bovelles49r-detail.png"/>
    </zone>
    <zone xml:id="B49rHead" ulx="25" uly="25"
      lrx="180" lry="60"/>
  <!-- contains the title -->
  <zone xml:id="B49rPara2" ulx="28" uly="75"
    lrx="175" lry="178"/>
  <!-- contains the first paragraph in italics -->
  <zone xml:id="B49rFig1" ulx="105" uly="76"
    lrx="175" lry="160"/>
  <!-- contains the figure -->
  <zone xml:id="B49rW457" ulx="45" uly="125"
    lrx="60" lry="130"/>
  <!-- contains the word "pendans" -->
</surface>
</facsimile>

```

The alignment between transcription and image is made, as usual, by means of the *fac*s attribute:

```

<pb facs="#B49r"/>
<fw>De Geometrie 49</fw>
<head facs="#B49rHead"> DU SON ET ACCORD DES CLOCHES ET <lb/> des alleures des
chevaulx, chariotz & charges, des fontaines:& <lb/> encyclie du monde,
& de la dimension du corps humain.<lb/> Chapitre septiesme</head>
<div n="1">
  <p>Le son & accord des cloches pendans en ung mesme <lb/> axe, est faict en
  contraires parties.</p>
  <p rend="it" facs="#B49rPara2">LEs cloches ont quasi fi<lb/>gures de rondes
  pyra<lb/>mides imperfaictes & <lb/> irregulieres: & leur accord se
  <lb/> fait par reigle geometrique. Com<lb/>me si les deux cloches C & D
  <lb/> sont <w facs="#B49rW457">pendans</w> à ung mesme axe <lb/> ou essieu A B:
  je dis que leur ac<lb/>cord se fera en co<ex>n</ex>traires parties<lb/>
  co<ex>m</ex>me voyez icy figuré. Car qua<ex>n</ex>d <lb/> lune sera en
  hault, laultre declinera embas. Aultrement si elles decli<lb/>nent toutes deux
  ensembles en une mesme partie, elles seront discord, <lb/> & sera leur
  sonnerie mal plaisante à oyr.<figure facs="#B49rFig1">
  <graphic url="Bovelles49r-detail.png"/>
</figure>
</p>
</div>

```

It is also possible to point in the other direction, from a <surface> or <zone> to the corresponding text. This is the function of the *start* attribute, which supplies the identifier of the element containing at least the start of the transcribed text found within the surface or zone concerned. Thus, another way of linking this page with its transcription would be simply

```

<facsimile>
  <surface start="#PB49R">
    <graphic url="Bovelles-49r.png"/>
  </surface>
</facsimile>
<text>
  <body>
    <div>
<!-- ... -->
      <pb xml:id="PB49R"/>
      <fw>De Geometrie 49</fw>
<!-- ... -->
    </div>
  </body>
</text>

```

### 11.2.2 Embedded Transcription

An *embedded transcription* is one in which words and other written traces are encoded as subcomponents of elements representing the physical surfaces carrying them rather than independently of them.

The following elements are available for this purpose:

**<sourceDoc>** contains a transcription or other representation of a single source document potentially forming part of a *dossier génétique* or collection of sources.

**<surface>** defines a written surface as a two-dimensional coordinate space, optionally grouping one or more graphic representations of that space, zones of interest within that space, and transcriptions of the writing within them.

**<zone>** defines any two-dimensional area within a <surface> element.

**<line>** contains the transcription of a topographic line in the source document

**<seg>** (arbitrary segment) represents any segmentation of text below the ‘chunk’ level.

The elements <surface>, <surfaceGrp>, and <zone> were introduced above in section 11.1. *Digital Facsimiles*. When supplied within a <sourceDoc> element, these elements may contain transcriptions of the written content of a source in addition to or as an alternative to digital images of them. Such transcription may be placed directly within the <zone> element, or within one or more <line> elements, for cases where the writing is linear, in the sense that it is composed of discrete tokens organized physically into groups, typically organized in a sequence corresponding with the way they are intended to be read. Depending on the directionality of the writing system used, this might be any combination of top-down and left to right, or vice versa. The element <line> may be used to hold a complete group of such tokens. Where, however, the lineation is not considered significant, any group of tokens may be indicated using the <zone> element. The <seg> element described in section 16.3. *Blocks, Segments, and Anchors* may also be used to indicate smaller sequences of tokens within <zone>, or <line> as appropriate.

Returning to the preceding example, we might transcribe the content of the zone to which we gave the identifier B49rPara2 within a <sourceDoc> element as follows:

```

<sourceDoc>
  <surface ulx="0" uly="0" lrx="200" lry="300">
    <zone ulx="0" uly="0" lrx="200" lry="300">
      <graphic url="Bovelles-49r.png"/>
    </zone>
  <!-- ... -->
  <zone ulx="28" uly="75" lrx="175" lry="178">
    <line>LEs cloches ont quasi
      fi</line>
    <line>gures de rondes pyra</line>
    <line>mides imperfaites &
  </line>

```

```

<line> irregulieres: & leur accord se</line>
<line> fait par reigle geometrique. Com</line>
<line>me si les deux cloches C
    & D </line>
<line> sont <zone ulx="45" uly="125" lrx="60"
    lry="130">pendans</zone> à ung mesme axe</line>
<line> ou essieu A B: je dis que
    leur ac</line>
<line>cord se fera en cōtraires parties</line>
<line> cōme
    voyez icy figuré. Car quād </line>
<line> lune sera en hault, laultre
    declinera embas. Aultrement si elles declinent toutes deux ensembles en une
    mesme partie, elles seront discord,</line>
<line> & sera leur sonnerie
    mal plaisante à oyr.</line>
</zone>
<zone ulx="105" uly="76" lrx="175"
    lry="160">
<graphic url="Bovelles49r-detail.png"/>
</zone>
</surface>
</sourceDoc>

```

As mentioned above, some or all of the written surfaces being transcribed may be composed of physically distinct scraps. In the following example, taken from the Walt Whitman Archive, two pieces of newsprint have been glued to a piece of blue paper on which a poem is being drafted: The two pieces of newsprint might simply be regarded as special kinds of zone, but they are also new surfaces, since they might contain additional written zones themselves (such as the numbers in this case).

Using these elements, the Whitman draft above might be encoded as follows:

```

<surface>
  <zone>
    <line>Poem</line>
    <line>As in Visions of – at</line>
    <line>night –</line>
    <line>All sorts of fancies running through</line>
    <line>the head</line>
  </zone>
  <zone>
    <surface type="newsprint"
      attachment="glue" flipping="false">
      <zone>Spring has just set in here, and the weather[...] a steamer </zone>
      <metamark function="sequence">2</metamark>
    </surface>
  </zone>
  <zone>
    <surface type="newsprint"
      attachment="glue" flipping="false">
      <zone>"The shores on either side of the Sound are... The In- </zone>
      <metamark function="sequence">3</metamark>
    </surface>
  </zone>
</surface>

```

The <metamark> element used in this example is further discussed below (11.3.4.2. *Metamarks*)

Figure 11: Single leaf of notes possibly related to the poem eventually titled Sleepers. From the Walt Whitman Archive (Duke 258).

Note that in this example we have not included any <graphic> element corresponding with the <zone> or <surface> elements identified in the transcription. The encoder may choose to complement a transcription with graphic representations of its source at whatever level is considered effective, or not at all. Equally, the encoder may choose to provide only graphics without any transcription, to provide only a structured (non-embedded) transcription, or to provide any combination of the three.

This example also lacks any coordinate information to specify either the size of the two newspaper fragments or whereabouts on the parent <surface> element they are to be found, other than the reading order implicit in their sequence. Such information could be added if desired by specifying a coordinate system on the outermost <surface> element, and then indicating values within that system for each of the two fragments, as was discussed above. We discuss this in further detail in section 11.4. *Advanced Uses of surface and zone* below.

### 11.3 Scope of Transcriptions

When transcribing a primary source, scholars may wish to record information concerning individual readings of letters, words, or larger units, whether the object is simply a ‘neutral’ transcription or a critical edition. In either case they may also wish to include other editorial material, such as comments on the status or possible origin of particular readings, corrections, or text supplied to fill lacunae.

Such elements may also be used for digital transcriptions in which the object is not to represent a finished text, but rather to represent the creative process, as evidenced by different ‘layers’ or ‘traces’ of writing in one or more documents. Transcriptions of this kind are closely focussed on the physical appearance of specific documents, needing to distinguish the traces of different writing activities on them, such as additions and deletions but also other indications of how the writing is to be read, such as indications of transposition, re-affirmation of writing which has been deleted, and so on. Such distinctions are considered of particular importance when dealing with authorial manuscripts, but are also relevant in the case of historical sources such as charters or other legal documents.

In either case, it is customary in transcriptions to register certain features of the source, such as ornamentation, underlining, deletion, areas of damage and lacunae. This chapter provides ways of encoding such information:

- methods of recording editorial or other alterations to the text, such as expansion of abbreviations, corrections, conjectures, etc. (section 11.3.1. *Altered, Corrected, and Erroneous Texts*)
- methods of describing important extra-linguistic phenomena in the source: unusual spaces, lines, page and line breaks, changes of manuscript hand, etc. (section 11.3.2. *Hands and Responsibility*)
- methods of representing complex organizations of surfaces and zones (section 11.4. *Advanced Uses of surface and zone*)
- methods of representing aspects of layout such as spacing or lines 11.5. *Aspects of Layout*
- methods of representing material such as running heads, catch-words, and the like (section 11.6. *Headers, Footers, and Similar Matter*)

The remainder of this chapter describes a model for encoding such transcriptions, in which elements such as <mod>, <del>, etc. are used to mark writing traces and their functions within the document. Each such element can be assigned to one or more editorially-defined modification groups, termed a *change*, by means of a global *change* attribute, which references a definition for the modification group concerned, typically provided within the TEI header <creation> element; see further 11.7. *Identifying Changes and Revisions*. The transcription itself may be embedded within the elements <surface> and <zone> described in section 11.1. *Digital Facsimiles*, or provided in parallel within a <text> element. Within a <zone>, the transcription may be organized topographically in terms of lines of writing, using the <line> element, or in terms of further nested zones, or as a combination of the two; see further 11.2.2. *Embedded Transcription*.

These recommendations are not intended to meet every transcriptional circumstance likely to be faced by any scholar. Rather, they should be regarded as a base which can be elaborated if necessary by different scholars in different disciplines

As a rule, all elements which may be used in the course of a transcription of a single witness may also be used in a critical apparatus, i.e. within the elements proposed in chapter 12. *Critical Apparatus*. This can generally be achieved by nesting a particular reading containing tagged elements from a particular witness within the <rdg> element in an <app> structure.

Just as a critical apparatus may contain transcriptional elements within its record of variant readings in various

witnesses, one may record variant readings in an individual witness by use of the apparatus mechanisms `<app>` and `<rdg>`. This is discussed in section 12.3. *Using Apparatus Elements in Transcriptions*.

### 11.3.1 Altered, Corrected, and Erroneous Texts

In the detailed transcription of any source, it may prove necessary to record various types of actual or potential alteration of the text: expansion of abbreviations, correction of the text (either by author, scribe, or later hand, or by previous or current editors or scholars), addition, deletion, or substitution of material, and similar matters. The sections below describe how such phenomena may be encoded using either elements defined in the core module (defined in chapter 3. *Elements Available in All TEI Documents*) or specialized elements available only when the module described in this chapter is available.

#### 11.3.1.1 Core Elements for Transcriptional Work

In transcribing individual sources of any type, encoders may record corrections, normalizations, additions, and omissions using the elements described in section 3.4. *Simple Editorial Changes*. Representation of abbreviations and their expansions may also involve use of elements described in section 3.5. *Names, Numbers, Dates, Abbreviations, and Addresses*. Elements particularly relevant to this chapter include:

**<abbr>** (abbreviation) contains an abbreviation of any sort.

**<add>** (addition) contains letters, words, or phrases inserted in the source text by an author, scribe, or a previous annotator or corrector.

**<choice>** groups a number of alternative encodings for the same point in a text.

**<corr>** (correction) contains the correct form of a passage apparently erroneous in the copy text.

**<del>** (deletion) contains a letter, word, or passage deleted, marked as deleted, or otherwise indicated as superfluous or spurious in the copy text by an author, scribe, or a previous annotator or corrector.

**<expan>** (expansion) contains the expansion of an abbreviation.

**<gap>** indicates a point where material has been omitted in a transcription, whether for editorial reasons described in the TEI header, as part of sampling practice, or because the material is illegible, invisible, or inaudible.

**<sic>** (Latin for thus or so) contains text reproduced although apparently incorrect or inaccurate.

All of these elements bear additional attributes for specifying who is responsible for the interpretation represented by the markup, and the associated certainty. In addition, some of them bear an attribute allowing the markup to be categorized by type and source.

**att.editLike** provides attributes describing the nature of an encoded scholarly intervention or interpretation of any kind.

**@evidence** indicates the nature of the evidence supporting the reliability or accuracy of the intervention or interpretation.

**att.source** provides attributes for pointing to the source of a bibliographic reference.

**@source** provides a pointer to the bibliographical source from which a quotation or citation is drawn.

**att.global.responsibility** provides attributes indicating the agent responsible for some aspect of the text, the markup or something asserted by the markup, and the degree of certainty associated with it.

**@cert** (certainty) signifies the degree of certainty associated with the intervention or interpretation.

**@resp** (responsible party) indicates the agency responsible for the intervention or interpretation, for example an editor or transcriber.

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

**@type** characterizes the element in some sense, using any convenient classification scheme or typology.

**@subtype** provides a sub-categorization of the element, if needed

The specific aspect of the markup described by these attributes differs on different elements; for further discussion, see the relevant sections below, especially section 11.3.2.2. *Hand, Responsibility, and Certainty Attributes*.

The following sections describe how the core elements just named may be used in the transcription of primary source materials.

### 11.3.1.2 Abbreviation and Expansion

The writing of manuscripts by hand lends itself to the use of abbreviation to shorten scribal labour. Commonly occurring letters, groups of letters, words, or even whole phrases, may be represented by significant marks. This phenomenon of manuscript abbreviation is so widespread and so various that no taxonomy of it is here attempted. Instead, methods are shown which allow abbreviations to be encoded using the core elements mentioned above.

A manuscript abbreviation may be viewed in two ways. One may transcribe it as a particular sequence of letters or marks upon the page: thus, a ‘p with a bar through the descender’, a ‘superscript hook’, a ‘macron’. One may also interpret the abbreviation in terms of the letter or letters it is seen as standing for: thus, ‘per’, ‘re’, ‘n’. Both of these views are supported by these Guidelines.

In many cases the glyph found in the manuscript source also exists in the Unicode character set: for example the common Latin brevisgraph *ɿ*, standing for *et* and often known as the ‘Tironian et’ can be directly represented in any XML document as the Unicode character with code point U+204A (see further *v.6.1 Character References* and *vi.1 Language Identification*). In cases where it does not, these Guidelines recommend use of the `<g>` element provided by the `gaiji` module described in chapter 5. *Characters, Glyphs, and Writing Modes*. This module allows the encoder great flexibility both in processing and in documenting non-standard characters or glyphs, including the ability to provide detailed documentation and images for them.

These two methods of coding abbreviation may also be combined. An encoder may record, for any abbreviation, both the sequence of letters or marks which constitutes it, and its sense, that is, the letter or letters for which it is believed to stand. For example, in the following fragment the phrase *euery persone* is represented by a sequence of abbreviated characters: These lines may be transcribed directly, using the `<g>` element to indicate the two

Figure 12: Detail from fol. 126v of Bodleian MS Laud Misc 517

brevigraphs as follows:

```
eu<g ref="#b-er">er</g>y <g ref="#b-per">per</g>sone that loketh after heuen hath a
place in
this ladder
<!-- elsewhere -->
<charDecl>
  <char xml:id="b-er">
<!-- definition for the er brevisgraph -->
  </char>
  <char xml:id="b-per">
<!-- definition for the per brevisgraph -->
  </char>
</charDecl>
```

Note that in each case the `<g>` element may contain a suggested replacement for the referenced brevisgraph; this is purely advisory however, and may not be appropriate in all cases. The referenced character definitions may be located elsewhere in this or some other document, typically forming part of a `<charDecl>` element, as described in *5.2. Markup Constructs for Representation of Characters and Glyphs*.

The transcriber may also wish to indicate that, because of the presence of these particular characters, the two words are actually abbreviations, by using the `<abbr>` element:

```
<abbr>eu<g ref="#b-er">er</g>y</abbr>
<abbr>
  <g ref="#b-per">per</g>sone
</abbr> ...
```

Alternatively, the transcriber may choose silently to expand these abbreviations, using the <expan> element:

```
<expan>euery</expan>
<expan>persone</expan> ...
```

And, of course, the <choice> element can be used to show that one encoding is an alternative for the other:

```
<choice>
  <abbr>eu<g ref="#b-er">er</g>y</abbr>
  <expan>euery</expan>
</choice>
```

When abbreviated forms such as these are expanded, two processes are carried out: some characters not present in the abbreviation are added (always), and some characters or glyphs present in the abbreviation are omitted or replaced (often). For example, when the abbreviation *Dr.* is expanded to *Doctor*, the dot in the abbreviation is removed, and the letters *octo* are added. Where detailed markup of abbreviated words is required, these two aspects may be marked up explicitly, using the following elements:

**<ex>** (editorial expansion) contains a sequence of letters added by an editor or transcriber when expanding an abbreviation.

**<am>** (abbreviation marker) contains a sequence of letters or signs present in an abbreviation which are omitted or replaced in the expanded form of the abbreviation.

Using these elements, a transcriber may indicate the status of the individual letters or signs within both the abbreviation and the expansion. The <am> element surrounds characters or signs such as tildes or tildes, used to indicate the presence of an abbreviation, which are typically removed or replaced by other characters in the expanded form of the abbreviation:

```
<abbr>eu<am>
  <g ref="#b-er"/>
</am>y</abbr>
<abbr>
  <am>
  <g ref="#b-per"/>
  </am>sone
</abbr> ...
```

while the <ex> element may be used to indicate those characters within the expansion which are not present in the abbreviated form.

```
<expan>eu<ex>er</ex>y</expan>
<expan>
  <ex>per</ex>sone
</expan> ...
```

The content of the <abbr> element should usually include the whole of the abbreviated word, while the <expan> element should include the whole of its expansion. If this is not considered necessary, the <am> and <ex> elements may be used within a <choice> element, as in this example:

```

eu<choice>
  <am>
    <g ref="#b-er" />
  </am>
  <ex>er</ex>
</choice>y <choice>
  <am>
    <g ref="#b-per" />
  </am>
  <ex>per</ex>
</choice>sone ...

```

As implied in the preceding discussion, making decisions about which of these various methods of representing abbreviation to use will form an important part of an encoder's practice. As a rule, the <abbr> and <am> elements should be preferred where it is wished to signify that the content of the element is an abbreviation, without necessarily indicating what the abbreviation may stand for. The <ex> and <expan> elements should be used where it is wished to signify that the content of the element is not present in the source but has been supplied by the transcriber, without necessarily indicating the abbreviation used in the original. The decision as to which course of action is appropriate may vary from abbreviation to abbreviation; there is no requirement that the same system be used throughout a transcription, although doing so will generally simplify processing. The choice is likely to be a matter of editorial policy. If the highest priority is to transcribe the text *literatim* (letter by letter), while indicating the presence of abbreviations, the choice will be to use <abbr> or <am> throughout. If the highest priority is to present a reading transcription, while indicating that some letters or words are not actually present in the original, the choice will be to use <ex> or <expan> throughout.

Further information may be attached to instances of these elements by the <note> element, on which see section 3.8. *Notes, Annotation, and Indexing*, and by use of the *resp* and *cert* attributes. In this instance from the English *Brut*, a note is attached to an editorial expansion of the tail on the final d of *good* to *goode*:

```

For alle the while
that I had good<ex xml:id="exp01">e</ex> I was welbeloued

```

Then the note:

```

<note target="#exp01">The stroke added to
the final d could signify the plural ending (-es, -is, -ys) but the
singular <hi rend="it">goode</hi> was used with the meaning <q>property</q>,
<q>wealth</q>, at this time (v. examples quoted in OED, sb. Good, C. 7, b,
c, d and 8 spec.)</note>

```

The editor might declare a degree of certainty for this expansion, based on the OED examples, and state the responsibility for the expansion:

```

For alle the while that I
had good<ex resp="#mp" cert="high">e</ex> I was welbeloued

```

The value supplied for the *resp* attribute should point to the name of the editor responsible for this and possibly other interventions; an appropriate element therefore might be a <respStmt> element in the header like the following:

```

<respStmt xml:id="mp">
  <resp>Editorial emendations</resp>
  <name>Malcom Parkes</name>
</respStmt>

```

Observe that the *cert* and *resp* attributes are used with the `<ex>` element only to indicate confidence in the content of the element (i.e. the expansion), and responsibility for suggesting this expansion respectively.

The `<choice>` element may be used to indicate that the proposed expansion is one way of encoding what might equally well be represented as an abbreviation, represented by the hooked D, as follows:

```
For alle the while that I had
<choice>
  <sic>goo<abbr>d</abbr>
</sic>
  <expan resp="#mp" cert="high">good<ex>e</ex>
</expan>
</choice> I was
welbeloued
```

If it is desired to express aspects of certainty and responsibility for some other aspect of the use of these elements, then the mechanisms discussed in chapter 21. *Certainty, Precision, and Responsibility* should be used. See also 11.3.2.2. *Hand, Responsibility, and Certainty Attributes* for discussion of the issues of certainty and responsibility in the context of transcription.

If more than one expansion for the same abbreviation is to be recorded, multiple notes may be supplied. It may also be appropriate to use the markup for critical apparatus; an example is given in section 12.3. *Using Apparatus Elements in Transcriptions*.

### 11.3.1.3 Correction and Conjecture

The `<sic>`, `<corr>`, and `<choice>` elements, defined in the **core** module should be used to indicate passages deemed in need of correction, or actually corrected, during the transcription of a source. For example, in the manuscript of William James's *A Pluralistic Universe* as edited by Fredson Bowers (Cambridge: Harvard University Press, 1977), a sentence first written

One must have lived longer with this system, to appreciate its advantages.

has been modified by James to begin 'But One must ...', without the initial capital O having been reduced to lowercase. This non-standard orthography could be recorded thus:

```
But <sic>One</sic> must have lived
...
```

or corrected:

```
But
<corr>one</corr> must have lived ...
```

or the two possibilities might be represented as a choice:

```
But
<choice>
  <sic>One</sic>
  <corr>one</corr>
</choice> must have lived
...
```

Similarly, in this example from Albertus Magnus, both a manuscript error *angues* and its correction *augens* are registered within a `<choice>` element:

```
Nos autem iam
ostendimus quod nutrimentum et
<choice>
  <sic>angues</sic>
  <corr>augens</corr>
</choice>.
```

Note that the <corr> element is used to provide a corrected form which is *not* present in the source; in the case of a correction made in the source itself, whether scribal, authorial, or by some other hand, the <add>, <del>, and <subst> elements described in 11.3.1.4. *Additions and Deletions* should be used.

The <sic> element is used to mark passages considered by the transcriber to be erroneous; in such cases, the <corr> element indicates the transcriber's correction of them. Where the transcriber considers that one or more words have been erroneously omitted in the original source and corrects this omission, the <supplied> element discussed in 11.3.1.7. *Text Omitted from or Supplied in the Transcription* should be used in preference to <corr>. Thus, in the following example, from George Moore's draft of additional materials for *Memoirs of My Dead Life*, the transcriber supplies the word *we* omitted by the author:

```
You see that I avoid
the word create for we create nothing <supplied>we</supplied> developpe.
```

As with <expan> and <abbr>, the choice as to whether to record simply that there is an apparent error, or simply that a correction has been applied, or to record both possible readings within a <choice> element is left to the encoder. The decision is likely to be a matter of editorial policy, which might be applied consistently throughout or decided case by case. If the highest priority is to present an uncorrected transcription while noting perceived errors in the original, the choice will typically be to use only <sic> throughout. If the highest priority is to present a reading transcription, while indicating that perceived errors in the original have been corrected, the choice will be to use only <corr> throughout.

Further information may be attached to instances of these elements by the <note> element and *resp* and *cert* attributes. Instances of these elements may also be classified according to any convenient typology using the *type* attribute.

For example, consider the following encoding of an emendation in the Hengwrt manuscript proposed by E. Talbot Donaldson:

```
Telle me also, to what conclusioun Were
membres maad, of generacioun And of so parfit wis a <choice xml:id="corr117">
  <sic>wight</sic>
  <corr>wright</corr>
</choice> ywroght?
<!-- ... -->
<note target="#corr117">This emendation of the Hengwrt copy text, based on a Latin
source and on the reading of three late and usually unauthoritative
manuscripts, was proposed by E. Talbot Donaldson in
<bibl>
  <title>Speculum</title> 40 (1965) 626–33.</bibl>
</note>
```

The <note> element discussed in 3.8. *Notes, Annotation, and Indexing* may be used to give a more detailed discussion of the motivation for or scope of a correction. If linked by means of a pointer (as in this example) it may be located anywhere convenient within the transcription; typically all detailed notes will be collected together in a separate <div> element in the <back>. Alternatively, the pointer may be omitted, and the <note> placed immediately adjacent to the element being annotated. The advantage of the former solution is that it permits the same annotation to refer to several corrections, by supplying more than one pointer in the *target* attribute of the <note>, as shown in the example below.

The attribute *cert* may be used to indicate the degree of confidence ascribed by the encoder to the proposed emendation on a broad scale: high, medium, or low. The attribute *resp* is used to indicate who is responsible for the proposed emendation. Its value is a pointer, which will typically indicate a `<respStmt>` or `<name>` element in the header of the transcribed document, but can point anywhere, for example to some online authority file. Using these two attributes, the `<corr>` element presented above might usefully be enhanced as follows:

```
<!-- somewhere in the header ... --><name xml:id="ETD">E Talbot Donaldson</name>
<!-- ... --> And of so parfit wis a <choice>
  <sic>wight</sic>
  <corr resp="#ETD" cert="medium">wright</corr>
</choice> ywroght?
```

As remarked above, where the same annotation applies to several corrections, this may be represented by supplying multiple pointers on the note. Consider for example such corrections as the following, in Dudo of S. Quentin. Parkes cites two cases in this manuscript of the same phenomenon:

```
quamuis <choice xml:id="sic-1">
  <sic>mens</sic>
  <corr>iners</corr>
</choice> que nutu dei gesta
sunt ... unde esset uiriliter
<choice xml:id="sic-2">
  <corr>uegetata</corr>
  <sic>negata</sic>
</choice>
```

which may be described as follows:

```
<note target="#sic-1 #sic-2">Substitution of a more familiar word which resembles
graphically what the scribe should be copying but which does not make sense in
the context.</note>
```

The *target* attribute on the `<note>` element indicates the `<choice>` elements which exemplify this kind of scribal error. This necessitates the addition of an identifier to each `<choice>` element. However, if the number of corrections is large and the number of notes is small, it may well be both more practical and more appropriate to regard the collection of annotations as constituting a typology and then use the *type* attribute. Suppose that the note given above is one of half a dozen possible kinds of corrected phenomena identified in a given text; others might include, say, ‘repetition of a word from the preceding line’, etc. The *type* attribute on the `<corr>` element can be used to specify an arbitrary code for the particular kind of correction (or other editorial intervention) identified within it. This code can be chosen freely and is not treated as a pointer.

```
quamuis <choice>
  <sic>mens</sic>
  <corr type="graphSubs">iners</corr>
</choice> que nutu dei gesta sunt ... unde
esset uiriliter
<choice>
  <corr type="graphSubs">uegetata</corr>
  <sic>negata</sic>
</choice>
```

Note that this encoding might be extended to include a range of possible corrections:

```
quamuis <choice>
  <sic>mens</sic>
  <corr type="graphSubs">iners</corr>
  <corr type="reversal">inres</corr>
</choice> que
nutu dei gesta sunt ...
```

In addition, the conscientious encoder will provide documentation explaining the circumstances in which particular codes are judged appropriate. A suitable location for this might be within the <correction> element of the <encodingDesc> of the header, which might include a <list> such as the following:

```
<correction>
  <p>The following codes are used to categorize corrections identified in this
  transcription: <list type="gloss">
    <label>graphSubs</label>
    <item>Substitution of a more familiar word which resembles graphically
      what the scribe should be copying but which does not make sense in the
      context.</item>
  <!-- ... -->
  </list>
  </p>
</correction>
```

A *subtype* attribute may be used in conjunction with the *type* for subclassification purposes: the above examples might thus be represented as <choice type="substitution" subtype="graphicResemblance"> for example.

For a given project, it may well be desirable to limit the possible values for the *type* or *subtype* attributes automatically. This is easily done but requires customization of the TEI system using techniques described in 23.3. *Personalization and Customization*, in particular 23.3.1.4. *Modification of Attribute and Attribute Value Lists*, which should be consulted for further information on this topic.

When making a correction in a source which forms part of a textual tradition attested by many witnesses, a textual editor will sometimes use a reading from one witness to correct the reading of the source text. In the general case, such encoding is best achieved with the mechanisms provided by the module for textual criticism described in chapter 12. *Critical Apparatus*. However, for simple cases, the *source* attribute of the <corr> element may suffice. In the passage from Chaucer's *Wife of Bath's Tale* mentioned above, Parkes proposes to emend the problematic word *wight* to *wyf* which is the reading found in the Cambridge manuscript Gg.1. 27. This may be simply represented as follows:

```
And of so
parfit wis a <choice>
  <sic>wight</sic>
  <corr resp="#mp" source="#Gg">wyf</corr>
</choice> ywroght?
```

The value of the *source* attribute here is, like the value of the *resp* attribute, a pointer, in this case indicating the manuscript used as a witness. Elsewhere in the transcribed text, a list of witnesses used in this text will be given, one of which has an identifier Gg. Each witness will be represented either by a <witness> element (see 12.1. *The Apparatus Entry, Readings, and Witnesses*) or more fully by a <msDesc> element (see 10. *Manuscript Description*):

```
<msDesc xml:id="Gg">
  <msIdentifier>
    <settlement>Cambridge</settlement>
```

```

<repository>University Library</repository>
<idno>Gg.1. 27</idno>
</msIdentifier>
<!-- further description of the manuscript here -->
</msDesc>

```

The <app> element described in chapter 12. *Critical Apparatus* provides a more powerful way of representing all three possible readings in parallel:

```

And of so parfit wis a <app>
  <rdg wit="#Hg">wight</rdg>
  <rdg wit="#Ln #Ry2 #Ld">wright</rdg>
  <rdg wit="#Gg">wyf</rdg>
</app>

```

This encoding simply records the three readings found in the various traditions, and gives (by means of the *wit* attribute) an indication of the witnesses supporting each. If the *resp* attribute were supplied on the <rdg> element, it would indicate the person responsible for asserting that the manuscript indicated has this reading, who is not necessarily the same as the person responsible for asserting that this reading should be used to correct the others. Editorial intervention elements such as <corr> can however be nested within a <rdg> to provide this additional information:

```

And of so parfit wis a <app>
  <rdg wit="#Hg">wight</rdg>
  <rdg wit="#Ln #Ry2 #Ld">
    <corr resp="#ETD">wright</corr>
  </rdg>
  <rdg wit="#Gg">
    <corr resp="#mp">wyf</corr>
  </rdg>
</app>

```

This encoding asserts that the reading *wyf* found in *Gg* is regarded as a correction by Parkes.

Like the *resp* attribute, the *cert* attribute may be used with both <corr> and <rdg> elements. When used on the <rdg> element, these attributes indicate confidence in and responsibility for identifying the reading within the sources specified; when used on the <corr> element they indicate confidence in and responsibility for the use of the reading to correct the base text. If no other source is indicated (either by the *source* attribute, or by the *wit* attribute of a parent <rdg>), the reading supplied within a <corr> has been provided by the person indicated by the *resp* attribute.

If it is desired to express certainty of or responsibility for some other aspect of the use of these elements, then the mechanisms discussed in chapter 21. *Certainty, Precision, and Responsibility* may be found useful. See also 11.3.2.2. *Hand, Responsibility, and Certainty Attributes* for further discussion of the issues of certainty and responsibility in the context of transcription.

#### 11.3.1.4 Additions and Deletions

Additions and deletions observed in a source text may be described using the following elements:

- <add>** (addition) contains letters, words, or phrases inserted in the source text by an author, scribe, or a previous annotator or corrector.
- <addSpan>** (added span of text) marks the beginning of a longer sequence of text added by an author, scribe, annotator or corrector (see also <add>).
- <del>** (deletion) contains a letter, word, or passage deleted, marked as deleted, or otherwise indicated as superfluous or spurious in the copy text by an author, scribe, or a previous annotator or corrector.
- <delSpan>** (deleted span of text) marks the beginning of a longer sequence of text deleted, marked as deleted, or otherwise signaled as superfluous or spurious by an author, scribe, annotator, or corrector.

Of these, <add> and <del> are included in the core module, while <addSpan> and <delSpan> are available only when using the module defined in this chapter. These particular elements are members of the `att.spanning` class, from which they inherit the following attribute:

**att.spanning** provides attributes for elements which delimit a span of text by pointing mechanisms rather than by enclosing it.

`@spanTo` indicates the end of a span initiated by the element bearing this attribute.

Further characteristics of each addition and deletion, such as the hand used, its effect (complete or incomplete, for example), or its position in a sequence of such operations may conveniently be recorded as attributes of these elements, all of which are members of the `att.transcriptional` class:

**att.transcriptional** provides attributes specific to elements encoding authorial or scribal intervention in a text when transcribing manuscript or similar sources.

`@seq` (sequence) assigns a sequence number related to the order in which the encoded features carrying this attribute are believed to have occurred.

`@status` indicates the effect of the intervention, for example in the case of a deletion, strikeouts which include too much or too little text, or in the case of an addition, an insertion which duplicates some of the text already present.

`@hand [att.written]` points to a <handNote> element describing the hand considered responsible for the textual content of the element concerned.

As described in section 3.4. *Simple Editorial Changes*, the <add> element is used to record any manuscript addition observed in the text, whether it is considered to be authorial or scribal. In the autograph manuscript of Max Beerbohm's *The Golden Drugget*, the author's addition of *do ever* may be recorded as follows, with the *hand* attribute indicating that the addition was Beerbohm's by referencing a <handNote> element defined elsewhere in the document (see further 11.3.2.1. *Document Hands*):

```
Some things are best
at first sight. Others – and here is one of them – <add hand="#mb">do ever</add>
improve by recognition [...]
<handNote xml:id="mb">Max Beerbohm
holograph</handNote>
```

The <del> element is used to record manuscript deletions in a similar way. In the autograph manuscript of D. H. Lawrence's *Eloi, Eloi, lama sabachthani* the author's deletion of *my* may be recorded as follows. In this case, the *hand* attribute indicating that the deletion was Lawrence's is complemented by a *rend* attribute indicating that the deletion was by strike-through:

```
For I hate this <del rend="strikethrough" hand="#dhl">my</del> body, which is so dear
to me ...
<handNote xml:id="dhl">D H Lawrence holograph</handNote>
```

If deletions are classified systematically, the *type* attribute may be useful to indicate the classification; when they are classified by the manner in which they were effected, or by their appearance, however, this will lead to a certain arbitrariness in deciding whether to use the *type* or the *rend* attribute to hold the information. In general, it is recommended that the *rend* attribute be used for description of the appearance or method of deletion, and that the *type* attribute be reserved for higher level or more abstract classifications.

The *place* attribute is also available to indicate the location of an addition. For example, consider the following passage from a draft letter by Robert Graves: At the end of this extract, the writer inserts the word 'cant,' above the line, with a stroke to indicate insertion. Assuming that we have previously defined the identifier RG somewhere:

Figure 13: Draft letter from Robert Graves to Desmond Flower, 17 Dec 1938 (detail).

```
<listPerson>
  <person xml:id="RG">
<!-- information about Robert Graves here -->
  </person>
</listPerson>
```

, this extract might now be encoded as follows:

```
The O.E.D. is not a
dictionary so much as a corpus of precedents <del hand="#RG">in the</del>:
current, obsolete, <add hand="#RG" place="above">cant,</add> cataphretic and
nonce-words are all included.
```

A little earlier in the same extract, Graves writes ‘for an abridgement’ above the line, and then deletes it. This may be encoded similarly:

```
As for 'significant artist.' You quote the O.E.D. <del>
  <add hand="#RG" place="above">for an abridgement</add>
</del> in explanation...
```

Similarly, in the margin, the word ‘Norton’ has been added and then deleted:

```
You
quote the <del>
  <add hand="#RG" place="margin">Norton</add>
</del> O.E.D...
```

The word ‘O.E.D.’ in this first sentence has also clearly been the result of some redrafting: it may be that Graves started to write ‘Oxford’, and then changed it; it may be that he inserted other punctuation marks between the letters before replacing them with the centre dots used elsewhere to represent this acronym. We do not deal with these possibilities

here, and mention them only to indicate that any encoding of manuscript material of this complexity will need to make decisions about what is and is not worth mentioning.

An encoder may also wish to indicate that an addition replaces a specific deletion, that is to encode a substitution as a single intervention in the text. This may be achieved by grouping the addition and deletion together within a `<subst>` element. At the end of the passage illustrated above, Graves first writes ‘It is the expressed...’, then deletes ‘It is’, and substitutes an uppercase T at the start of ‘the’.

```
... are all included. <del hand="#RG">It is</del>
<subst>
  <add>T</add>
  <del>t</del>
</subst>he expressed
```

The use of this element and of the *seq* attribute to indicate the order in which interventions such as deletions are believed to have occurred are further discussed in section 11.3.1.5. *Substitutions* below.

The `<add>` and `<del>` elements defined in the core module suffice only for the description of additions and deletions which fit within the structure of the text being transcribed, that is, which each deletion or addition is completely contained by the structural element (paragraph, line, division) within which it occurs. Where this is not the case, for example because an individual addition or deletion involves several distinct structural subdivisions, such as poems or prose items, or otherwise crosses a structural boundary in the text being encoded, special treatment is needed. The `<addSpan>` and `<delSpan>` elements are provided by this module for that purpose. (For a general discussion of the issue see further 20. *Non-hierarchical Structures*).

In this example of the use of `<addSpan>`, the insertion by Helgi Ólafsson of a gathering containing four neo-Eddic poems into *Lbs 1562 4to* is recorded as follows. A `<handNote>` element is first declared, within the header of the document, to associate the identifier *heol* with Helgi. Each of the added poems is encoded as a distinct `<div>` element. In the body of the text, an `<addSpan>` element is placed to mark the beginning of the span of added text, and an `<anchor>` is used to mark its end. The *hand* attribute on the `<addSpan>` element ascribes responsibility for the addition to the manuscript to Helgi, and the *spanTo* attribute points to the end of the added text:

```
<handNote xml:id="heol"
  scribe="HelgiÓlafsson"/>
<!-- ... -->
<body>
  <div>
<!-- text here -->
  </div>
  <addSpan n="added gathering" hand="#heol"
    spanTo="#p025"/>
  <div>
<!-- text of first added poem here -->
  </div>
  <div>
<!-- text of second added poem here -->
  </div>
  <div>
<!-- text of third added poem here -->
  </div>
  <div>
<!-- text of fourth added poem here -->
  </div>
  <anchor xml:id="p025"/>
  <div>
<!-- more text here -->
  </div>
</body>
```

The `<delSpan>` element is used in the same way. An authorial manuscript will often contain several occasions where sequences of whole lines are marked for deletion, either by boxes or by being struck out. If the encoder is marking up individual verse lines with the `<l>` element, such deletions are problematic: deletion of two consecutive lines should be regarded as a single deletion, but the `<del>` element must be properly nested within a single `<l>` element. The `<delSpan>` element solves this problem:

```
<l>Flowed up the hill and down King William Street,</l>
<delSpan spanTo="#EPdelEnd" resp="#EP"
  rend="strikethrough"/>
<l>To where Saint Mary Woolnoth kept the time,</l>
<l>With a dead sound on the final stroke of nine.</l>
<anchor xml:id="EPdelEnd"/>
<l>There I saw one I knew, and stopped him, crying "Stetson!</l>...
```

It is also often the case that deletions and additions may themselves contain other deletions and additions. For example, in Thomas Moore's autograph of the second version of *Lalla Rookh* two lines are marked for omission by vertical strike-through. Within the first of the two lines, the word *upon* has also been struck out, and the word *over* has been added:

```
<l>
  <delSpan rend="verticalStrike"
    spanTo="#delend01"/> Tis moonlight
<del>upon</del>
  <add>over</add> Oman's sky
</l>
<l>Her isles of pearl look lovely<anchor xml:id="delend01"/>
</l>
```

In this case the `<anchor>` and `<delSpan>` have been placed within the structural elements (the `<l>`s) rather than between, as in the previous example. This is to indicate that placement of these empty elements is arbitrary.

The text deleted must be at least partially legible, in order for the encoder to be able to transcribe it. If all of part of it is not legible, the `<gap>` element should be used to indicate where text has not been transcribed, because it could not be. The `<unclear>` element described in section 11.3.3.1. *Damage, Illegibility, and Supplied Text* may be used to indicate areas of text which cannot be read with confidence. See further section 11.3.1.7. *Text Omitted from or Supplied in the Transcription* and section 11.3.3.1. *Damage, Illegibility, and Supplied Text*.

#### 11.3.1.5 Substitutions

Substitution of one word or phrase for another is perhaps the most common of all phenomena requiring special treatment in transcription of primary textual sources. It may be simply one word written over the top of another, or deletion of one word and its replacement by another written above it by the same hand on the same occasion; the deletion and replacement may be done by different hands at different times; there may be a long chain of substitutions on the same stretch of text, with uncertainty as to the order of substitution and as to which of many possible readings should be preferred.

As we have shown, the simplest method of recording a substitution is simply to record both the addition and the deletion. However, when the module defined by this chapter is in use, additional elements are available to indicate that the encoder believes the addition and the deletion to be part of the same intervention: a substitution.

**<subst>** (substitution) groups one or more deletions with one or more additions when the combination is to be regarded as a single intervention in the text.

**<substJoin>** (substitution join) identifies a series of possibly fragmented additions, deletions or other revisions on a manuscript that combine to make up a single intervention in the text

Using the `<subst>` element, the example at the end of the last section might be encoded as follows:

```

<l>
  <delSpan rend="verticalStrike"
    spanTo="#delend02"/> Tis moonlight
<subst>
  <del>upon</del>
  <add>over</add>
</subst> Oman's sky
</l>
<l>Her isles of pearl look lovely<anchor xml:id="delend02"/>
</l>

```

Since the purpose of this element is solely to group its child elements together, the order in which they are presented is not significant. When both deletion and addition are present, it may not always be clear which occurs first: using the *seq* attribute is a simple way of resolving any such ambiguities.

For example, returning to the example from William James, in a passage first written out by James as ‘One must have lived longer with this system, to appreciate its advantages’, the word *this* is first replaced by *such a* and this is then replaced by *a*.<sup>79</sup> This may be encoded as follows, representing the two changes as a sequence of additions and deletions:

```

One must have lived longer
with <subst>
  <del seq="1">this</del>
  <del seq="2">
    <add seq="1">such a</add>
  </del>
  <add seq="2">a</add>
</subst> system, to appreciate its advantages.

```

Note the nesting of an `<add>` element within a `<del>` to record text first added, then deleted in the source. The numbers assigned by the *seq* attribute may be used to identify the order in which the various additions and deletions are believed by the encoder to have been carried out, and thus provide a simple method of supporting the kind of ‘genetic’ textual criticism typified by (for example) Hans Walter Gabler's work on the reconstruction of the ‘overlay’ levels implicit in the manuscripts of James Joyce's *Ulysses*. A fuller and more complex way of supporting such an approach is discussed in 11.7. *Identifying Changes and Revisions*.

The case of a single substitution or scribal correction that involves non-contiguous addition and deletion can be handled by using the `<substJoin>` element to make an explicit connection between one or more `<add>` and `<del>` elements. In the following example from Thomas Moore's *Lalla Rookh*, the deletion and addition are not contiguous: they are separated by the word ‘thus’, which is not part of the scribal intervention being marked. Because of this intervening text, it would be inappropriate to use `<subst>` to group this `<add>` and `<del>`. `<substJoin>` allows the encoder to indicate that additions and deletions separated in this way are part of a single scribal intervention:

```

While <del xml:id="change1">pondering</del> thus <add xml:id="change2">she
mus'd</add>, her pinions
fann'd
<substJoin target="#change1 #change2"/>

```

Note that, unlike `<subst>`, the placement of the `<substJoin>` is arbitrary. It may occur before or after the relevant `<add>` and `<del>` elements.

As a more complex example, consider the following passage: This passage might be encoded as follows:

<sup>79</sup>The manuscript contains several other substitutions, ignored here for the sake of clarity.

Figure 14: Detail from *Dulce et decorum est* autograph manuscript in the English Faculty Library, Oxford University.

```
<l>And towards our distant rest began to trudge,</l>
<l>
  <subst>
    <del>Helping the worst amongst us</del>
    <add>Dragging the worst amongst
      us</add>
  </subst>, who'd no boots
</l>
<l>But limped on, blood-shod. All went lame; <subst>
  <del status="shortEnd">half-</del>
  <add>all</add>
</subst> blind;</l>
<l>Drunk with fatigue ; deaf even to the hoots</l>
<l>Of tired, outstripped <del>fif</del> five-nines that dropped
behind.</l>
```

In this representation,

- the authorial slip (*amongt* for *amongst*) is retained without comment.
- the other two authorial corrections are marked as substitutions, each combining a deletion and an addition.
- the false start *fif* in the last line is simply marked as a deletion;

The `<app>` element presented in chapter 12. *Critical Apparatus* provides similar facilities, by treating each state of the text as a distinct reading. The `<rdg>` element has a `varSeq` attribute which may be used in the same way as the `seq` attribute to indicate the preferred sequence. The James example above might thus be represented as follows:

```
One must have lived longer with <app>
  <rdg varSeq="1">
    <del>this</del>
  </rdg>
  <rdg varSeq="2">
    <del>
      <add>such a</add>
    </del>
  </rdg>
  <rdg varSeq="3">
    <add>a</add>
  </rdg>
</app> system, to appreciate its advantages.
```

### 11.3.1.6 Cancellation of Deletions and Other Markings

An author or scribe may mark a word or phrase in some way, and then on reflection decide to cancel the marking. For example, text may be marked for deletion and the deletion then cancelled, thus restoring the deleted text. Such cancellation may be indicated by the <restore> element:

**<restore>** indicates restoration of text to an earlier state by cancellation of an editorial or authorial marking or instruction.

This element bears the same attributes as the other transcriptional elements. These may be used to supply further information such as the hand in which the restoration is carried out, the type of restoration, and the person responsible for identifying the restoration as such, in the same way as elsewhere.

Presume that Lawrence decided to restore *my* to the phrase of *Eloi, Eloi, lama sabachthani* first written 'For I hate this my body', with the *my* first deleted then restored by writing 'stet' in the margin. This may be encoded:

```
For I hate this <restore hand="#dhl"
  type="marginalStetNote">
  <del>my</del>
</restore> body
```

Another feature commonly encountered in manuscripts is the use of circles, lines, or arrows to indicate transposition of material from one point in the text to another. No specific markup for this phenomenon is proposed at this time. Such cases are most simply encoded as additions at the point of insertion and deletions at the point of encirclement or other marking.

### 11.3.1.7 Text Omitted from or Supplied in the Transcription

Where text is not transcribed, whether because of damage to the original, or because it is illegible, or for some other reason such as editorial policy, the <gap> core element may be used to register the omission; where such text is transcribed, but the editor wishes to indicate that they consider it to be superfluous, for example because it is an inadvertent scribal repetition or an interpolation from another source, the <surplus> element may be used in preference. Where the editor believes text to be interpolated but genuine, the <secl> element may be used instead. Where text not present in the source is supplied (whether conjecturally or from other witnesses) to fill an apparent gap in the text, the <supplied> element may be used.

**<gap>** indicates a point where material has been omitted in a transcription, whether for editorial reasons described in the TEI header, as part of sampling practice, or because the material is illegible, invisible, or inaudible.

**@reason** gives the reason for omission. Sample values include sampling, inaudible, irrelevant, cancelled.

**@hand** in the case of text omitted from the transcription because of deliberate deletion by an identifiable hand, indicates the hand which made the deletion.

**@agent** in the case of text omitted because of damage, categorizes the cause of the damage, if it can be identified.

**<surplus>** marks text present in the source which the editor believes to be superfluous or redundant.

**@reason** one or more words indicating why this text is believed to be superfluous, e.g. *repeated*, *interpolated* etc.

**<secl>** (secluded text) Secluded. Marks text present in the source which the editor believes to be genuine but out of its original place (which is unknown).

**@reason** one or more words indicating why this text has been secluded, e.g. *interpolated* etc.

**<supplied>** signifies text supplied by the transcriber or editor for any reason; for example because the original cannot be read due to physical damage, or because of an obvious omission by the author or scribe.

**@reason** one or more words indicating why the text has had to be supplied, e.g. *overbinding*, *faded-ink*, *lost-folio*, *omitted-in-original*.

By its nature, the <gap> element has no content. It marks a point in the text where nothing at all can be read, whether because of authorial or scribal erasure, physical damage, or any other form of illegibility. Its attributes allow

the encoder to specify the amount of text which is illegible in this way at this point, using any convenient units, where this can be determined. For example, in the Beerbohm manuscript of *The Golden Drugget* cited above, the author has erased a passage amounting about 10 cm in length by inking over it completely:

```
Others <gap reason="cancelled" hand="#mb"
  quantity="10" unit="cm"/>—and here is one of
them...
```

In an autograph letter of Sydney Smith now in the Pierpont Morgan library three words in the signature are quite illegible:

```
I am dr Sr yr <gap reason="illegible" quantity="3"
  unit="word"/>Sydney Smith
```

The degree of precision attempted when measuring the size of a gap will vary with the purpose of the encoding and the nature of the material: no particular recommendation is made here.

As noted above, the <gap> element should only be used where text has not been transcribed. If partially legible text has been transcribed, one of the elements <damage> and <unclear> should be used instead (these elements are described in section 11.3.3.1. *Damage, Illegibility, and Supplied Text*); if the text is legible and has been transcribed, but the editor wishes to indicate that they regard it is superfluous or redundant, then the element <surplus> may be used in preference to the core element <sic> used to indicate text regarded as erroneous.

Amongst the many examples cited in Hans Krummrey & Silvio Panciera's classic text on the editing of epigraphic inscriptions is the following. In a late classical inscription, the form 'dedikararunt' is encountered. The editor may choose any of the following three possibilities:

- mark this as an erroneous form

```
<sic>dedikararunt</sic>
```

- additionally supply a corrected form

```
<choice>
  <sic>dedikararunt</sic>
  <corr>dedikarunt</corr>
</choice>
```

- indicate that the erroneous form contains surplus characters which the editor wishes to suppress

```
dedika<surplus>ra</surplus>runt
```

The <surplus> element may also be used to mark up interpolations, as in the following example taken from a 13th century Italian source:

```
<l n="4">a dar mi morte, poi m'avete preso <surplus reason="interpolated">a
  tradimento</surplus>
</l>
<l n="5">sì com' l'uccellator prende l'uccello</l>
<gap/>
<l n="43">e lettere dintorno che diriano <surplus reason="interpolated">in questa
  guisa</surplus>
</l>
<l n="44">Più v'amo, dëa, che non faccio Deo</l>
```

The words marked as <surplus> here are metrically inconsistent with the rest and have been marked by the editor as such.

In the case of an interpolation which the editor regards as genuine (i.e. written by the author in question), but out of its original place, the <secl> element should be used instead of <surplus>. For example:

```
<sp>
  <ab>
    <lb n="545"/>Great praise and thanks be to Perfidy as she
    <lb n="546"/>deserves, since by our swindles, tricks, and clever moves, relying
    <lb n="547"/>on the daring of our shoulder blades and the excellence of our
    <lb n="548"/>forearms who went against cattle-prods, hot iron-blades,
    <lb n="549-550"/>crosses and shackles, neck-irons, chains, prisons, collars, fetters,
    <lb n="551"/>and yokes, the fiercest painters fully acquainted with our backs
    <lb n="552"/><secl>who have often before put scars on our shoulder blades</secl>
    . . .
  </ab>
</sp>
```

The final line is bracketed in the Loeb edition, with a note: ‘versum secl. Bothe’, meaning Bothe regarded this line as Plautine, but probably interpolated. It is easy to see how the line might have crept in as a gloss on the metaphor in the previous line.

If some part of the source text is completely illegible or missing, an encoder may sometimes wish to supply new (conjectural) material to replace it. This conjectural reading is analogous to a correction in that it contains text provided by the encoder and not attested in the source. This is not however a correction, since no error is necessarily present in the original; for that reason a different element <supplied> should be used. If another (imaginary) copy of the letter above preserved the signature as reading ‘I am dear Sir your very humble Servt Sydney Smith’, the text illegible in the autograph might be supplied in the transcription:

```
I am dr Sr yr
<supplied reason="illegible" resp="#msm"
  source="#Ry2">very humble
Servt</supplied> Sydney Smith
```

Here the *source* and *resp* attributes are used, as elsewhere, to indicate respectively the sigil of a manuscript from which the supplied reading has been taken, and the identifier of the person responsible for deciding to supply the text. If the *source* attribute is not supplied, the implication is that the encoder (or whoever is indicated by the value of the *resp* attribute) has supplied the missing reading. Both <gap> and <supplied> may be used in combination with <unclear>, <damage>, and other elements; for discussion, see section 11.3.3.2. *Use of the gap, del, damage, unclear, and supplied Elements in Combination.*

## 11.3.2 Hands and Responsibility

This section discusses in more detail the representation of aspects of responsibility perceived or to be recorded for the writing of a primary source. These include points at which one scribe takes over from another, or at which ink, pen, or other characteristics of the writing change. A discussion of the usage of the *hand*, *resp*, and *cert* attributes is also included.

### 11.3.2.1 Document Hands

For many text-critical purposes it is important to signal the person responsible (the *hand*) for the writing of a whole document, a stretch of text within a document, or a particular feature within the document. A hand, as the name suggests, need not necessarily be identified with a particular known (or unknown) scribe or author; it may simply indicate a particular combination of writing features recognized within one or more documents. The examples given above of the use of the *hand* attribute with coding of additions and deletions illustrate this.

The <handNote> element is used to provide information about each hand distinguished within the encoded document.

**<handNote>** (note on hand) describes a particular style or hand distinguished within a manuscript.

A **<handNote>** element, with an identifier given by its *xml:id* attribute, may appear in either of two places in the TEI header, depending on which modules are included in a schema. When the **transcr** module defined by the present chapter is used, the element **<handNotes>** is available, within the **<profileDesc>** element of the TEI header, to hold one or more **<handNote>** elements. When the **msdescription** module defined in chapter 10, *Manuscript Description* is included, the **<handDesc>** element described in 10.7.2, *Writing, Decoration, and Other Notations* also becomes available as part of a structured manuscript description. The encoder may choose to place **<handNote>** elements identifying individual hands in either location without affecting their accessibility since the element is always addressed by means of its *xml:id* attribute. The **<handDesc>** element may be more appropriate when a full cataloguing of each manuscript is required; the **<handNotes>** element if only a brief characterization of each hand is needed. It is also possible to use the two elements together if, for example, the **<handDesc>** element contains a single summary describing all the hands discursively, while the **<handNotes>** element gives specific details of each. The choice will depend on individual encoders' priorities.

As shown above, the *hand* attribute is available on several elements to indicate the hand in which the content of the element (usually a deletion or addition) is carried out. The **<handShift>** element may also be used within the body of a transcription to indicate where a change of hand is detected for whatever reason.

**<handShift>** marks the beginning of a sequence of text written in a new hand, or the beginning of a scribal stint.

Both **<handShift>** and **<handNote>** are members of the **att.handFeatures** class, and thus share the following attributes:

**att.handFeatures** provides attributes describing aspects of the hand in which a manuscript is written.

**@scribe** gives a name or other identifier for the scribe believed to be responsible for this hand.

**@script** characterizes the particular script or writing style used by this hand, for example *secretary, copperplate, Chancery, Italian, etc.*

**@scribeRef** points to a full description of the scribe concerned, typically supplied by a **<person>** element elsewhere in the description.

**@scriptRef** points to a full description of the script or writing style used by this hand, typically supplied by a **<scriptNote>** element elsewhere in the description.

**@medium** describes the tint or type of ink, e.g. *brown*, or other writing medium, e.g. *pencil*

**@scope** specifies how widely this hand is used in the manuscript.

A single hand may employ different writing styles and inks within a document, or may change character. For example, the writing style might shift from 'anglicana' to 'secretary', or the ink from blue to brown, or the character of the hand may change. Simple changes of this kind may be indicated by assigning a new value to the appropriate attribute within the **<handShift>** element. It is for the encoder to decide whether a change in these properties of the writing style is so marked as to require treatment as a distinct hand.

Where such a change is to be identified, the *new* attribute indicates the hand applicable to the material following the **<handShift>**. The sequence of such **<handShift>** elements will often, but not necessarily, correspond with the order in which the material was originally written. Where this is not the case, the facilities described in section 11.7, *Identifying Changes and Revisions* may be found helpful.

As might be expected, a single hand may also vary renditions within the same writing style, for example medieval scribes often indicate a structural division by emboldening all the words within a line. Such changes should be indicated by use of the *rend* attribute, in the same manner as underlining, emboldening, font shifts, etc. are represented in transcription of a printed text, rather than by introducing a new **<handShift>** element.

In the following example there is a change of ink within a single hand. This is simply indicated by a new value for the *medium* attribute on the **<handShift>** element:

```
<L>When wolde the cat dwelle in his ynne</L>
<handShift medium="greenish-ink"/>
<L>And if the cattes skynne be slyk <handShift medium="black-ink"/> and
gaye</L>
```

In the following example, the encoder has identified two distinct hands within the document and given them identifiers h1 and h2, by means of the following declarations included in the document's TEI header:

```

<handNotes>
  <handNote xml:id="h1" script="copperplate"
    medium="brown-ink">Carefully written
    with regular descenders</handNote>
  <handNote xml:id="h2" script="print"
    medium="pencil">Unschooled
    scrawl</handNote>
</handNotes>

```

Then the change of hand is indicated in the text:

```

<handShift new="#h1" resp="#das"/>... and that good Order Decency and regular worship
may be once
more introduced and Established in this Parish according to the Rules and
Ceremonies of the Church of England and as under a good Consciencious and sober
Curate there would and ought to be <handShift new="#h2" resp="#das"/> and for that
purpose the parishioners pray

```

When a more precise or nuanced discussion of the writing in a manuscript is required, the `<handNote>` and `<scriptNote>` elements discussed in 10.7.2. *Writing, Decoration, and Other Notations* should be used. Either element may serve as the target for a `<handShift>`.

#### 11.3.2.2 Hand, Responsibility, and Certainty Attributes

The *hand* and *resp* attributes have similar, but not identical, meanings. Observe their distinctive uses in the following encoding of the William James passage mentioned above in section 11.3.1.3. *Correction and Conjecture*. In this example, the *But* inserted by James is tagged as an `<add>`, and the consequent editorial correction of *One* to *one* treated separately:

```

<add place="above" resp="#FB" hand="#WJ">But</add>
<choice>
  <sic>One</sic>
  <corr resp="#FB">one</corr>
</choice> must have lived ...
<!-- elsewhere -->
<respStmt xml:id="FB">
  <resp>editorial changes</resp>
  <name>Fredson Bowers</name>
</respStmt>
<respStmt xml:id="WJ">
  <resp>authorial changes</resp>
  <name>William James</name>
</respStmt>

```

As in this example, *hand* should be reserved for indicating the hand of any form of marking—here, addition but also deletion, correction, annotation, underlining, etc.—within the primary text being transcribed. The scribal or authorial responsibility for this marking may be inferred from the value of the *hand* attribute. The value of the *hand* attribute should be a pointer to a hand identifiers typically declared in the document header but potentially in another document or repository (see section 11.3.2.1. *Document Hands*).

The *resp* attribute, by contrast, indicates the person responsible for deciding to mark up this part of the text with this particular element. In the case of the `<add>` element, for example, the *resp* attribute will indicate the responsibility for identifying that the addition is indeed an addition, and also (if the *hand* attribute is supplied) to which hand it should be attributed. In this case, Bowers is credited with identifying the hand as that of William James. In the case of the `<corr>` element, the *resp* attribute indicates who is responsible for supplying the intellectual content of

the correction reported in the transcription: here, Bowers' correction of 'One' to 'one'. In the case of a deletion, the *resp* attribute will similarly indicate who bears responsibility for identifying or categorizing the deletion itself, while other attributes (*hand* most obviously) attribute responsibility for the deletion itself.

In cases where both the *resp* and *cert* attributes are defined for a particular element, the two attributes refer to the same aspect of the markup. The one indicates who is intellectually responsible for some item of information, the other indicates the degree of confidence in the information. Thus, for a correction, the *resp* attribute signifies the person responsible for supplying the correction, while the *cert* attribute signifies the degree of editorial confidence felt in that correction. For the expansion of an abbreviation, the *resp* attribute signifies the person responsible for supplying the expansion and the *cert* attribute signifies the degree of editorial confidence felt in the expansion.

This close definition of the use of the *resp* and *cert* attributes with each element is intended to provide for the most frequent circumstances in which encoders might wish to make unambiguous statements regarding the responsibility for and certainty of aspects of their encoding. The *resp* and *cert* attributes, as so defined, give a convenient mechanism for this. However, there will be cases where it is desirable to state responsibility for and certainty concerning other aspects of the encoding. For example, one may wish in the case of an apparent addition to state the responsibility for the use of the <add> element, rather than the responsibility for identifying the hand of the addition. It may also be that one editor may make an electronic transcription of another editor's printed transcription of a manuscript text—here, one will wish to assign layers of responsibility, so as to allow the reader to determine exactly what in the final transcription was the responsibility of each editor. In these complex cases of divided editorial responsibility for and certainty concerning the content, attributes, and application of a particular element, the more general mechanisms for representing certainty and responsibility described in chapter 21. *Certainty, Precision, and Responsibility* should be used.

It should be noted that the certainty and responsibility mechanisms described in chapter 21. *Certainty, Precision, and Responsibility* replicate all the functions of the *resp* and *cert* attributes on particular elements. For example, the encoding of Donaldson's conjectured emendation of *wight* to *wright* in line 117 of Chaucer's *Wife of Bath's Prologue* (see 11.3.1.3. *Correction and Conjecture*) may be encoded as follows using the *resp* and *cert* attributes on the <corr> element:

```
<choice>
  <sic>wight</sic>
  <corr resp="#ETD" cert="medium">wright</corr>
</choice>
```

Exactly the same information could be conveyed using the certainty and responsibility mechanisms, as follows:

```
<choice>
  <corr xml:id="c117">wright</corr>
  <sic>wight</sic>
</choice>
<certainty target="#c117" locus="value"
  degree="0.7"/>
<respons target="#c117" locus="value"
  resp="#ETD"/>
```

The choice of which mechanism to use is left to the encoder. In transcriptions where only such statements of responsibility and certainty are made as can be accommodated within the *resp* and *cert* attributes of particular elements, it will be economical to use the *resp* and *cert* attributes of those elements. Where many statements of responsibility and certainty are made which cannot be so accommodated, it may be economical to use the <respons> and <certainty> elements throughout.

The above discussion supposes that in each case an encoder is able to specify exactly what it is that one wishes to state responsibility for and certainty about. Situations may arise when an encoder wishes to make a statement concerning certainty or responsibility but is unable or unwilling to specify so precisely the domain of the certainty or responsibility. In these cases, the <note> element may be used with the *type* attribute set to 'cert' or 'resp' and the content of the note giving a prose description of the state of affairs.

### 11.3.3 Damage and Conjecture

The carrier medium of a primary source may often sustain physical damage which makes parts of it hard or impossible to read. In this section we discuss elements which may be used to represent such situations and give recommendations about how these should be used in conjunction with the other related elements introduced previously in this chapter.

#### 11.3.3.1 Damage, Illegibility, and Supplied Text

The `<gap>` and `<supplied>` elements described above (section 11.3.1.7. *Text Omitted from or Supplied in the Transcription*) should be used with appropriate attributes where the degree of damage or illegibility in a text is such that nothing can be read and the text must be either omitted or supplied conjecturally or from one or more other sources. In many cases, however, despite damage or illegibility, the text may yet be read with reasonable confidence. In these cases, the following elements should be used:

**<damage>** contains an area of damage to the text witness.

**<damageSpan>** (damaged span of text) marks the beginning of a longer sequence of text which is damaged in some way but still legible.

As members of the class `att.damaged`, these elements bear the following attributes:

**att.damaged** provides attributes describing the nature of any physical damage affecting a reading.

**@hand** [*att.written*] points to a `<handNote>` element describing the hand considered responsible for the textual content of the element concerned.

**@agent** categorizes the cause of the damage, if it can be identified.

**@degree** provides a coded representation of the degree of damage, either as a number between 0 (undamaged) and 1 (very extensively damaged), or as one of the codes *high*, *medium*, *low*, or *unknown*. The `<damage>` element with the *degree* attribute should only be used where the text may be read with some confidence; text supplied from other sources should be tagged as `<supplied>`.

**@group** assigns an arbitrary number to each stretch of damage regarded as forming part of the same physical phenomenon.

The class `att.damaged` is a subclass of the class `att.dimensions`, itself a subclass of the class `att.ranging`. Consequently these elements also therefore bear at least the following attributes:

**att.dimensions** provides attributes for describing the size of physical objects.

**@extent** indicates the size of the object concerned using a project-specific vocabulary combining quantity and units in a single string of words.

**@unit** names the unit used for the measurement

**@quantity** specifies the length in the units specified

**att.ranging** provides attributes for describing numerical ranges.

**@min** where the measurement summarizes more than one observation or a range, supplies the minimum value observed.

**@max** where the measurement summarizes more than one observation or a range, supplies the maximum value observed.

**@atLeast** gives a minimum estimated value for the approximate measurement.

**@atMost** gives a maximum estimated value for the approximate measurement.

From the `att.spanning` class, `<damageSpan>` inherits the following additional attribute:

**att.spanning** provides attributes for elements which delimit a span of text by pointing mechanisms rather than by enclosing it.

**@spanTo** indicates the end of a span initiated by the element bearing this attribute.

The following examples all refer to the recto of folio 5 of the unique manuscript of the Elder Edda. Here, the manuscript of *Völuspá* has been damaged through irregular rubbing so that letters in various places are obscured and in some cases cannot be read at all.

In the first line of this leaf, the transcriber may believe that the last three letters of *daga* can be read clearly despite the damage:

```
um aldr
d<damage>aga</damage> yndisniota
```

If, as is often the case, the damage crosses structural divisions, so that the `<damage>` element cannot be nested properly within the containing `<div>` elements, the `<damageSpan>` element may be used, in the same way as the `<delSpan>` and `<addSpan>` elements discussed in section 11.3.1.4. *Additions and Deletions*.

```
<p>
<!-- ... -->
  <pb n="5r"/>
  <damageSpan agent="rubbing"
    extent="whole leaf" spanTo="#damageEnd"/>
</p>
<p> [...] </p>
<p> [...] <pb n="5v" xml:id="damageEnd"/>
</p>
```

Note that in this example the `spanTo` element points to the next `<pb>` element rather than to an inserted `<anchor>` element, since it is the whole of the leaf (the text between the two `<pb>` elements) which has sustained damage. For other techniques of handling non-nesting information, see chapter 20. *Non-hierarchical Structures*.

If, as is also likely, the damage affects several disjoint parts of the text, each such part must be marked with a separate `<damage>` or `<damageSpan>` element. To indicate that each of these is to be regarded as forming part of the same damaged area, the `group` attribute may be used as in the following example. In this (imaginary) text of Fitzgerald's translation from Omar Khayam, water damage has affected an area covering parts of several lines:

```
<l> The Moving Finger wri<damage agent="water" group="1">es; and</damage> having
wit,</l>
<l>Moves <damage agent="water" group="1">on: nor all your</damage> Piety nor
Wit</l>
<l>
  <damageSpan agent="water" group="1"
    spanTo="#washOut"/>Shall lure it back to
cancel half a Line,
</l>
<l>Nor all your Tears wash <anchor xml:id="washOut"/> out a Word of it</l>
```

A more general solution to this problem is provided by the `<join>` element discussed in 16.7. *Aggregation* which may be used to link together arbitrary elements of any kind in the transcription. Here, several phenomena of illegibility and conjecture all result from a single cause: an area of damage to the text caused by rubbing at various points. The damage is not continuous, and affects the text at irregular points. In cases such as this, the `join` element may be used to indicate which tagged features are part of the same physical phenomenon.

If the damage has been so severe as to render parts of the text only imperfectly legible, the `<unclear>` element should be used to mark the fact. Returning to the Eddic example above, an encoder less confident in the *daga* reading might indicate this as follows:

```
um aldr d<unclear reason="damage">aga</unclear> yndisniota
```

If it is desired to supply more information about the kind of damage, it is also possible to nest an `<unclear>` element within the `<damage>` element:

```
um aldr d<damage agent="rubbing">
  <unclear>aga</unclear>
</damage> yndisniota
```

Alternatively, the transcriber may not feel able to read the last three letters of *daga* but may wish to supply them by conjecture. Note the use of the *resp* attribute to assign the conjecture to Finnur Jónsson:

```
um aldr d<supplied reason="rubbing" resp="#finjon">aga</supplied>
yndisniota
```

The <supplied> element may if desired be enclosed within a <damage> element:

```
um aldr d<damage agent="rubbing">
  <supplied source="#msm">aga</supplied>
</damage>
yndisniota
```

Contrast the use of <gap> in the next line, where the transcriber believes that four letters cannot be read at all because of the damage:

```
þar komr inn dimmi
dreki fliugandi nāþr frann neþan <gap reason="illegible" agent="rubbing"
  quantity="4" unit="letter"/>
```

As with <supplied>, this <gap> might be enclosed by a <damage> element.

Where elements are nested in this way, information about agency, etc. is by default inherited. In the following imaginary example, there is a smoke-damaged part within which two stretches can be read with some difficulty, and a third stretch which cannot be read at all:

```
<damage agent="smoke">
  <unclear>and the proof of this is</unclear>
  <gap/>
  <unclear>margin</unclear>
</damage>
```

The above examples record imperfect legibility due to damage. When imperfect legibility is due to some other reason (typically because the handwriting is ill-formed), the <unclear> element should be used without any enclosing <damage> element. In Robert Southey's autograph of *The Life of Cowper* the final six letters of *attention* are difficult to read because of the haste of the writing, though reasonably certain from the context.

```
and
from time to time invited in like manner his att<unclear>ention</unclear>
```

The *cert* attribute on the <unclear> element may be used to indicate the level of editorial confidence in the reading contained within it.

### 11.3.3.2 Use of the <gap>, <del>, <damage>, <unclear>, and <supplied> Elements in Combination

The <gap>, <damage>, <unclear>, <supplied>, and <del> elements may be closely allied in their use. For example, an area of damage in a primary source might be encoded with any one of the first four of these elements, depending on how far the damage has affected the readability of the text. Further, certain of the elements may nest within one another. The examples given in the last sections illustrate something of how these elements are to be distinguished in use. This may be formulated as follows:

- where the text has been rendered completely illegible by deletion or damage and no text is supplied by the editor in place of what is lost: place an empty <gap> element at the point of deletion or damage. Use the *reason* attribute to state the cause (damage, deletion, etc.) of the loss of text.
- where the text has been rendered completely illegible by deletion or damage and text is supplied by the editor in place of what is lost: surround the text supplied at the point of deletion or damage with the <supplied> element. Use the *reason* attribute to state the cause (damage, deletion, etc.) of the loss of text leading to the need to supply the text.
- where the text has been rendered partly illegible by deletion or damage so that the text can be read but without perfect confidence: transcribe the text and surround it with the <unclear> element. Use the *reason* attribute to state the cause (damage, deletion, etc.) of the uncertainty in transcription and the *cert* attribute to indicate the confidence in the transcription.
- where there is deletion or damage but at least some of the text can be read with perfect confidence: transcribe the text and surround it with the <del> element (for deletion) or the <damage> element (for damage). Use appropriate attribute values to indicate the cause and type of deletion or damage. Observe that the *degree* attribute on the <damage> element permits the encoding to show that a letter, word, or phrase is not perfectly preserved, though it may be read with confidence.
- where there is an area of deletion or damage and parts of the text within that area can be read with perfect confidence, other parts with less confidence, other parts not at all: in transcription, surround the whole area with the <del> element (for deletion; or the <delSpan> element where it crosses a structural boundary); or the <damage> element (for damage). Text within the damaged area which can be read with perfect confidence needs no further tagging. Text within the damaged area which cannot be read with perfect confidence may be surrounded with the <unclear> element. Places within the damaged area where the text has been rendered completely illegible and no text is supplied by the editor may be marked with the <gap> element. For each element, one may use appropriate attribute values to indicate the cause and type of deletion or damage and the certainty of the reading.

The rules for combinations of the <add> and <del> elements, and for the interpretation of such combinations, are similar:

- if one <add> element (with identifier ADD1) contains another (with identifier ADD2), then the addition ADD1 was first made to the text, and later a second addition (ADD2) was made within that added text:

```
This is the text <add xml:id="ADD1">with some added
<add xml:id="ADD2">(interlinear!)</add> material</add> as
written.
```

- if one <del> element contains another, and the *seq* attribute does not indicate otherwise, it should be assumed that the inner deletion was made before the enclosing one. In the following example, the word *redundant* was deleted before a second deletion removed the entire passage:

```
<del>This
sentence contains some <del>redundant</del> unnecessary
verbiage.</del>
```

- if a <del> element contains an <add> element, the normal interpretation will be that an addition was made within a passage which was later deleted in its entirety:

```
<del>This
sentence was deleted <add>originally</add> from the
text.</del>
```

- if an <add> element contains a <del> element, the normal interpretation will be that a deletion was made from a passage which had earlier been added:

```
<add>This sentence was
added <del>eventually</del> to the text.</add>
```

### 11.3.4 Marking up the Writing Process

Modifications of various kinds (correction, addition, deletion, etc.) are frequently found within a single document, and may also be inferred when different documents are compared, although it may be an open question as to whether inter-document discrepancies should be regarded in the same way as intra-document alterations. When two witnesses are collated, we may observe that a word present in one is missing from the other: this does not necessarily imply that the word was added to the first witness, nor that it was deleted from the other.

In this section we discuss a number of elements which may be useful when attempting to record traces of the writing process within a document.

#### 11.3.4.1 Generic Modification

Most, if not all, transcriptional elements imply a certain level of semantic interpretation. For instance, using the <add> element to encode a word or phrase that occupies interlinear space involves a decision that it has been deliberately inserted as an addition rather than an alternative, and indeed a judgment that it was written after, rather than before, the other lines. Where it is felt desirable to keep the recording of ‘what is on the page’ entirely separate from ‘what is the editor’s interpretation’, the generic <mod> element may be preferred.

**<mod>** represents any kind of modification identified within a single document.

This element simply indicates any kind of modification that has been identified in the document, without prejudice as to its function. Occurrences of the <mod> element may be categorized by means of their *type* attribute, and visual aspects of their appearance can be described by means of the *rend* attribute, but they provide no further interpretation of the function or intention of the passage so marked up. The *spanTo* attribute may be used to indicate the end of a modified passage if this extends across the boundaries of some other XML element, for example from the middle of one line tagged as a <line> to the middle of another <line> some distance further on in the document.

```
<line>words words words <mod rend="wavy-underlining"
  spanTo="#enduw"/>words with wavy
underline</line> <!-- more lines here -->
<line>wavy underlining finishes
here<anchor xml:id="enduw"/> more words</line>
```

The distinction between an example such as that above and the simple use of <hi> to mark the visual salience of the underlining (apart from the use of the *spanTo* attribute) is that <hi> does not imply that the visual effect being recorded is understood to represent some kind of modification.

#### 11.3.4.2 Metamarks

By *metamark* we mean marks such as numbers, arrows, crosses, or other symbols introduced by the writer into a document expressly for the purpose of indicating how the text is to be read. Such marks thus constitute a kind of markup of the document, rather than forming part of the text.

**<metamark>** contains or describes any kind of graphic or written signal within a document the function of which is to determine how it should be read rather than forming part of the actual content of the document.

*@function* describes the function (for example status, insertion, deletion, transposition) of the metamark.

*@target* identifies one or more elements to which the metamark applies.

Unlike marginal notes or other additions to the text, metamarks are used by the writer to indicate a deliberate alteration of the writing itself, such as ‘move this passage over there’. An addition or annotation by contrast would typically concern some property of the passage other than its intended location or status within the text flow. A metamark may contain text, or some other graphic which the encoder wishes to represent, or it may simply consist of arrows, dots, lines etc. which the encoder simply describes.

The <metamark> element carries a *function* attribute which specifies the function of the metamark, using values such as reorder, flag, delete, insert or used. The passage to which the metamark applies may be indicated in either of two ways: the *target* attribute may be used to point to the element or elements containing the passage concerned, or the *spanTo* element may be used to point to a position in the document at which the passage concerned finishes. In the latter case, the <metamark> itself must be supplied at the position in the document where the passage concerned begins; in the former case it may be supplied at any convenient point. Both attributes should not be supplied.

The following example is taken from an 15th century legal book from the city of Göttingen, containing regulations of everyday life issued by the city council

Figure 15: *Kundige bok 2, fol 1v.*

In the second paragraph, the word *lege* (“read”) was written in the left hand margin, next to the sentence beginning ‘Ock en schullen de bruwere...’. It is thought to function as a metamark, indicating that this sentence forms part of the regulations. A further sentence was then added, while at some later stage the text and also the metamark were deleted. We might encode this as follows:

```
<delSpan spanTo="#endDel" change="#L3"/>
<metamark function="flag" target="#zone-1"
  change="#L2">lege</metamark>
<zone xml:id="zone-1" change="#L1">Ock en schullen de bruwere des hilgen dages
nicht over setten noch uppe den stillen fridach bruwen.</zone>
<addSpan spanTo="#endDel" change="#L2"/>
<zone>Noch nymande over setten, se en sehin denne erst, dat uppe den bonen neyn
stro noch, huw noch flaß ligghe, by pine eyner halven roden, deme bruwere so
wol also dem bruwheren to murende.</zone>
<anchor xml:id="endDel"/>
```

The *change* attribute used here to indicate the sequencing of these various interventions is discussed below, in section 11.7. *Identifying Changes and Revisions*. The elements <addSpan> and <delSpan> are discussed in section 11.3.1.4. *Additions and Deletions*.

The <metamark> element may also be used to encode the symbols etc. often found in marked-up proofs such as the following, taken from the Walt Whitman archive:

In this example, the whole of what was originally the 14th section of the poem has been marked for deletion, both by horizontal and vertical lines, and by the proofreading mark resembling the ‘deleatur’ or ‘dele’ deletion symbol to left and right of the section. The deletion itself might be encoded by using the normal <del> or <delSpan> element, and the metamarks by the <metamark> element. This is quite a different case from that of the next example, in which the writer does not intend to suppress the content, but only to mark that it has been copied to another manuscript or reused.

Or animals feeding in the fields,  
Or birds—~~or~~ the wonderfulness of insects in the air,  
Or the wonderfulness of the sun-down—~~or~~ of stars  
shining so quiet and bright,  
Or the exquisite, delicate, thin curve of the new moon  
in spring ;  
~~Or whether I go among those I like best, and that like  
me best—mechanics, boatmen, farmers,  
Or among the savans—~~or~~ to the soiree—~~or~~ to the  
opera,  
Or stand a long while looking at the movements of  
machinery,  
Or behold children at their sports,  
Or the admirable sight of the perfect old man, or the  
perfect old woman,  
Or the sick in hospitals, or the dead carried to burial,  
Or my own eyes and figure in the glass ;~~  
These, with the rest, one and all, are to me miracles,  
The whole referring—yet each distinct, and in its  
place.

Figure 16: From a corrected proof of *Miracles* (Walt Whitman Archive)

I am that halfgrown <sup>angry</sup> boy, fallen asleep,  
The tears of bodiless passion yet undried  
upon my cheeks,  
years with all their events pass for me,  
Some are spent in travel—some in the ~~the~~  
usual hunt ~~for~~ after fortune.  
I pass through <sup>the</sup> travels and fortunes of ~~others~~  
years, and become old,  
Each in its due order comes and goes,  
And then a message for me comes,  
The  
Entered—yes

Figure 17: From "I am that halfgrown angry boy" (MS q 25), David M. Rubenstein Rare Book & Manuscript Library, Duke University.

This page contains internal deletions, additions, and retracings but these are semantically quite different from the apparent ‘deletion’ signalled by the larger of the two single vertical lines, which shows that the written material has been transferred or re-used, not deleted.

```
<surface>
  <metamark function="used" rend="line"
    target="#X2"/>
  <zone xml:id="X2">
    <line>I am that halfgrown <add>angry</add> boy, fallen asleep</line>
    <line>The tears of foolish passion yet undried</line>
    <line>upon my cheeks.</line>
  <!-- ... -->
    <line>I pass through <add>the</add> travels and <del>fortunes</del> of
    <retrace>thirty</retrace>
    </line>
    <line>years and become old,</line>
    <line>Each in its due order comes and goes,</line>
    <line>And thus a message for me comes.</line>
    <line>The</line>
  </zone>
  <metamark function="used" target="#X2">Entered - Yes</metamark>
</surface>
```

In this example, we class as metamarks both the long vertical line and the annotation ‘Entered - yes’. Both metamarks are assumed to indicate that the whole of the written zone with identifier X2 is marked as having been used.

#### 11.3.4.3 Fixation and Clarification

A writer may sometimes rewrite material a second time without significant change and in the same place. We consider this a distinct activity from addition as usually defined because no new textual material results; instead the status of existing material is reaffirmed. We may distinguish two variants of this: *fixation* where the first version was a tentative draft which is subsequently reaffirmed, for example by inking it over; and *clarification*, where the first version was badly written and has been rewritten for clarity. The element <retrace> is provided for both cases; its *cause* attribute may be used to distinguish these or other cases.

<retrace> contains a sequence of writing which has been retraced, for example by over-inking, to clarify or fix it.

In this simple example, taken from the papers of Henrik Ibsen, the writer wrote the word *skuldren* hastily, and then returned to it to make the letter *l* larger and clearer: We might transcribe this word as follows:

Figure 18: From autograph ms of *Peer Gynt*, Collin 2869, 4°, I.1.1, the Royal Library of Copenhagen

```
<line>... Sku<retrace cause="unclear">l</retrace>dren </line>
```

A single rewrite may not be sufficient, and it may be that the document becomes almost unreadable as a result of repeated clarification. In the following example, we can distinguish at least three attempts to write the letters *er* in the word *bægerklang*: We might encode this by nesting the `<retrace>` element as follows:

Figure 19: Detail from autograph ms *Brand* in The Royal Library, Denmark (KBK Collin 262)

```
<line>ved Bæg<retrace cause="unclear" change="#stage2">
  <retrace cause="unclear" change="#stage1">er</retrace>
</retrace> ...</line>
```

The *change* attribute used here is discussed further below (11.7. *Identifying Changes and Revisions*).

The `<retrace>` element is used only for cases where text has been written multiple times. When metamarks and other markup-like strokes have been rewritten multiple times, the `<redo>` element described in the next section should be used in preference.

#### 11.3.4.4 Confirmation, Cancellation, and Reinstatement of Modifications

A writer may indicate that an alteration is itself to be altered: for example, a struck-through passage may be restored via a dotted underlining, or the underlining of a passage may be deleted by a wavy line.

The following elements are provided to represent these situations:

**<redo>** indicates one or more cancelled interventions in a document which have subsequently been marked as reaffirmed or repeated.

**@target** points to one or more elements representing the interventions which are being reasserted.

**<undo>** indicates one or more marked-up interventions in a document which have subsequently been marked for cancellation.

**@target** points to one or more elements representing the interventions which are to be reverted or undone.

The element `<restore>` (11.3.1.6. *Cancellation of Deletions and Other Markings*) is provided for the comparatively simple case where a simple deletion is marked as having been subsequently cancelled. The `<undo>` element discussed here is more widely applicable and may be used for any kind of cancellation. It points to the element or elements which are being cancelled. These components need not be contiguous, provided that the cancellation is clearly a single act; each distinct act of cancellation requires a distinct `<undo>` element, however. Either of the attributes *target* or *spanTo* may be used to indicate the passages concerned.

Consider the following imaginary example: We hypothesize that the text has gone through three states or

Figure 20: Imaginary example demonstrating restoring and undoing

changes, as follows:

1. This is just some sample text, we need a real example.
2. This is not a real example.

3. This is just some text, not a real example.

This sequence of events might be encoded as follows:

```
<line>This is <del change="#s2" rend="overstrike">
  <undo spanTo="#Xa" rend="dotted"
    change="#s3"/>just some <anchor xml:id="Xa"/> sample <undo spanTo="#Xb" rend="dotted"
    change="#s3"/>text, <anchor xml:id="Xb"/> we need</del>
  <add change="#s2">not</add> a real example.</line>
```

using two `<undo>` elements, each with a *spanTo* attribute, to delimit the two parts of the deletion which were reverted at change s3. Note that in this case, since *target* is not supplied, it is the effect of the parent element (the `<del>`) which is assumed to be undone.

Alternatively, we might more economically use the generic `<seg>` element within the `<line>` to delimit the two sequences whose deletion is being reverted, and then use the *target* attribute on a single `<undo>` element:

```
<line>This is <del change="#s2" rend="overstrike">
  <seg xml:id="X-a">just some</seg> sample <seg xml:id="X-b">text</seg>, we
  need</del>
  <add change="#s2">not</add> a real example.</line>
<undo target="#X-a #X-b" rend="dotted"
  change="#s3"/>
```

#### 11.3.4.5 Transpositions

A *transposition* occurs when metamarks are found in a document indicating that passages should be moved to a different position. Typically this may be done using arrows, asterisks or numbers, or other means. By definition the result of a transposition is not present in the document, and should not therefore be encoded, if the intention is to represent the actual appearance of the document. Instead, the following elements may be used to indicate the intended reordering:

**<listTranspose>** supplies a list of transpositions, each of which is indicated at some point in a document typically by means of metamarks.

**<transpose>** describes a single textual transposition as an ordered list of at least two pointers specifying the order in which the elements indicated should be re-combined.

Consider for example, the following extract from an Ibsen manuscript The underlined numbers 1 and 2 here

Figure 21: Extract from autograph *Digte* (Poems) NBO Ms. 4° 1110a

indicate that, although the word *bör* precedes the word *hör* in the text, the order of the two words should be reversed. We may encode this as follows:

```

<line>
  <seg xml:id="ib01">bör</seg>
  <metamark rend="underline"
    function="transposition" target="#ib01" place="above">2.</metamark>          og
<seg xml:id="ib02">hör</seg>
  <metamark rend="underline"
    function="transposition" target="#ib02" place="above">1.</metamark>
</line>
<listTranspose>
  <transpose>
    <ptr target="#ib02"/>
    <ptr target="#ib01"/>
  </transpose>
</listTranspose>

```

Note the use of the generic <seg> element to identify the sections of text being transposed. When (as in the following example) the whole of a line is to be transposed, there is no need to delimit the sections concerned:

Figure 22: Detail from autograph ms of *Den episke Brand* (KBK Collin 2869)

```

<line xml:id="ib3">
  <metamark function="transposition"
    place="margin-left">2.)</metamark> thi da er du med Himmelen i Pagt; -
</line>
<line xml:id="ib4">
  <metamark function="transposition"
    place="margin-left">1.)</metamark> da kan du
Folkets Jøkelhjerter tine;
</line>
<listTranspose>
  <transpose>
    <ptr target="#ib4"/>
    <ptr target="#ib3"/>
  </transpose>
</listTranspose>

```

When transposition is made, the whole element indicated is understood to be moved, not just its contents. In the above example, the metamarks are thus understood to be moved along with the lines to which they apply.

One or more <listTranspose> elements may be supplied either embedded within the text or in the <profileDesc> of the header, depending on local preference. Each <listTranspose> can contain one or more <transpose> elements, each of which defines a single transposition.

#### 11.3.4.6 Alternative Readings

In this example two alternative readings are provided, but no preference is indicated. While the author apparently first composed the line 'Alone before his native river -', at some later point, he entertained the possibility of using

Figure 23: Detail from autograph manuscript of the second version of *Lalla Rookh*, Pierpont Morgan MA 310

the word *beside* instead of *before*. The manuscript supplies no indication of which word Moore favours at this point, although in fact, in the first printed edition of *Lalla Rookh* the word *beside* was chosen.

The element `<alt>` provided by the `linking` module gives a simple way of encoding the state of this manuscript, as follows:

```
<zone>
  <line>Alone <seg xml:id="alt1">before</seg>
    <add place="above" xml:id="alt2">beside</add> his native river </line>
  <alt target="#alt1 #alt2" mode="excl"
    weights="0 1"/>
</zone>
```

The *mode* attribute here indicates that the two possible readings indicated by the *target* attribute are mutually exclusive. The *weights* attribute indicates the relative importance or preference to be attached to the two readings on a scale running from zero (most improbable) to one (most probable). In this case, we have a very strong preference for the second reading because this is the one that appears in the published version of the poem. The `<alt>` element is further discussed in section 16.8. *Alternation*.

#### 11.3.4.7 Instant Corrections

The use of elements such as `<del>` and `<add>` necessarily implies that the modifications they indicate were made at some time after the original writing. An exception to this is where a false start or ‘instant’ correction has been identified: the author starts to write, and then immediately corrects what has been written.

The *instant* attribute defined by this module may be used on any element which is a member of the `att.editLike` class to modify this default assumption. When the value of *instant* is set to true, the addition or deletion is considered to belong to the same change as its parent element, while `false` means some change later than that of its parent.

An example of false start or instant correction can be seen in the following line: in which we can detect the

Figure 24: Detail from *[I am a curse]*, one of the drafts for Whitman's *Song of Myself*

following sequence of events:

1. The letter T is written and then immediately deleted
2. The word The is written, deleted, and replaced by the word His
3. The added word His is then deleted
4. The initial letter i of the words *iron necklace* is overwritten with a capital I

To indicate that the first of these acts must have taken place during the main act of writing, before the other deletion and additions, we might encode this revision campaign as follows:

```

<line>
  <del instant="true">T</del>
  <mod type="subst">
    <del>The</del>
    <add place="above">
      <del rend="overstrike">His</del>
    </add>
  </mod>
  <mod type="subst">
    <del rend="overwritten">i</del>
    <add place="superimposed">I</add>
  </mod>ron necklace
</line>

```

## 11.4 Advanced Uses of <surface> and <zone>

The function of the <surface> element is both to identify a specific area containing writing and to provide a two dimensional set of coordinates which can be used to position and provide dimensions for sub-parts of it. Furthermore, surfaces may nest within other surfaces, as in the case of ‘patches’ or other written materials attached to the main writing surface. In the general case, the position and dimensions of such nested surfaces will be defined using the same coordinate system as that supplied by the parent <surface> element. It is also possible, however, that a different coordinate system is required for such a nested surface, perhaps because it requires a more complex granularity. We consider both possibilities.

In the earlier examples showing nested examples we did not provide any coordinate information, for simplicity of presentation. Suppose however, that we wish to indicate the position and sizes of the newspaper scraps in 11 above, relative to the whole page. As previously noted, the four attributes *ulx*, *uly*, *lrx* and *lry* when given on the <surface> element define the coordinate scheme, rather than specifying the location of that surface. We must therefore introduce an additional <zone> element, as in the following revised encoding for this example

```

<surface ulx="0" uly="0" lrx="50" lry="50">
  <zone ulx="1" uly="1" lrx="10" lry="10">
    <line>Poem</line>
    <line>As in Visions of – at</line>
    <line>night –</line>
    <line>All sorts of fancies running through</line>
    <line>the head</line>
  </zone>
  <zone ulx="4" uly="4" lrx="20" lry="20">
    <surface type="newsprint"
      attachment="glue" flipping="false">
      <zone>Spring has just set in here, and the weather[...] a steamer </zone>
      <metamark function="sequence">2</metamark>
    </surface>
  </zone>
</surface>

```

In this version of the encoding, the inner surface, corresponding with the first piece of newsprint, inherits locational information from the <zone> element that contains it. This zone, and the preceding one, which contains a sequence of <line> elements, are both positioned in terms of the coordinates specified on the outermost <surface> element, which defines a scale running from 0 to 50 in either direction. On that scale, the <line> elements occupy a rectangle with coordinates (1,1,10,10), while the nested surface occupies a rectangle with coordinates (4,4,20,20).

Now suppose that we wish to define a finer scale grid for the newspaper patch, perhaps because we wish to localize zones within it with greater accuracy. To do this we will need to specify the position of the nested surface as in the previous example, but also to define the new coordinate system. We accomplish this as follows:

```

<surface ulx="0" uly="0" lrx="50" lry="50">
  <zone ulx="1" uly="1" lrx="10" lry="10">
    <line>Poem</line>
  <!-- ... -->
  <line>the head</line>
</zone>
<zone ulx="4" uly="4" lrx="20" lry="20">
  <surface ulx="0" uly="0" lrx="100"
    lry="100">
    <zone ulx="10" uly="10" lrx="90" lry="95"> Spring has just set in here, and the
      weather [...] a steamer </zone>
  </surface>
</zone>
</surface>

```

As before, the second zone defines the position and size of the newspaper patch itself in terms of a coordinate system running from 0 to 50 on both X and Y axes. The nested `<surface>` element however defines a new scale for all of its components, running from 0 to 100 on both X and Y axes. The position of the nested zone containing the text *Spring ... steamer* is now given in terms of this scale.

All of the examples so far given have involved rectangular zones, for clarity of exposition. As noted above, the *points* attribute may be used to define non-rectangular zones as a series of points. For example, in the last of the Whitman examples discussed in section 11.3.4.2. *Metamarks* above, we might wish to record the exact shape of the zone containing the metamark *Entered*. Since this is not a rectangular zone, we use the *points* attribute to indicate the points defining a polygon which contains it. The values used are expressed in terms of a coordinate space running from 0 to 229 in the X dimension, and 0 to 160 in the Y dimension.

```

<surface ulx="0" uly="0" lrx="229" lry="160">
  <graphic url="whitman-02.jpg"/>
  <zone xml:id="entered"
    points="142,122 155,113 178,122 208,144 198,154 178,139"/>
</surface>

```

In exactly the same way, we may wish to identify the curved zone in the following image containing the word *Northamptonshire*: This curved zone might be encoded in the following way:

```

<surface xml:id="badge" ulx="14.54"
  uly="16.14" lrx="0" lry="0">
  <graphic url="stone.jpg"/>
  <zone xml:id="county"
    points="4.6,6.3 5.25,5.85 6.2,6.6 8.2,7.4 9.9,6.6 10.9,6.1 11.4,6.7 8.2,8.3 6.2,7.6"/
  >
</surface>

```

Finally, it should be noted that a `<zone>` does not need to be entirely contained within the two-dimensional space defined by its parent surface. For example, we might wish to encode the example in 9 above not as a surface representing the whole of the two page spread, but as a surface representing only the written part of this opening. The written part appears 50 units from the left of the image and 20 units from the top, while the bottom right corner of the written part appears 400 units from the left of the image, and 280 units from the top. We therefore define the written surface within this image as follows:

Figure 25: Gravestone of Private Moulds

```
<facsimile>
  <surface ulx="50" uly="20" lrx="400"
    lry="280">
  <!-- ... -->
  </surface>
</facsimile>
```

To describe the whole image, we will now need to define a zone of interest which represents an area larger than this surface. Using the same coordinate system as that defined for the surface, its coordinates are 0,0,500,321. This zone of interest can be defined by a `<zone>` element, within which we can place the uncropped `<graphic>`:

```
<facsimile>
  <surface ulx="50" uly="20" lrx="400"
    lry="280">
    <zone ulx="0" uly="0" lrx="500" lry="321">
      <graphic url="http://upload.wikimedia.org/wikipedia/commons/5/50/
Handschrift.karlsruhe.blb.jpg"/>
    </zone>
  </surface>
</facsimile>
```

## 11.5 Aspects of Layout

The following methods are available to capture general aspects of the layout of material on a page where this is considered important. Within the `<sourceDoc>` element, as already indicated, the element `<surface>` and

<surfaceGrp> enable the encoder to represent directly the structure of a codex as gatherings or quires, leaves, and surfaces, as in the following example:

```
<sourceDoc>
  <surfaceGrp type="quire" n="1">
    <surfaceGrp type="leaf" n="1">
      <surface type="recto" n="1r">
<!-- ... -->
      </surface>
      <surface type="verso" n="1v">
<!-- ... -->
      </surface>
    </surfaceGrp>
    <surfaceGrp type="leaf" n="2">
      <surface type="recto" n="2r">
<!-- ... -->
      </surface>
      <surface type="verso" n="2v">
<!-- ... -->
      </surface>
    </surfaceGrp>
  <!-- other leaves in first quire -->
</surfaceGrp>
  <!-- other quires here -->
</sourceDoc>
```

In some cases, it may be preferable to define <surface>s corresponding with each two page opening, for example where it is clear that the writer regarded each such opening as a single writing surface, with written zones or other features crossing the page divide. An example is shown here:

Source gallica.bnf.fr / Bibliothèque nationale de France

Figure 26: Opening from autograph ms of Proust's *A la recherche du temps perdu* (f 42v-43r)

The coloured lines added to this image indicate a number of zones of writing, colour coded to indicate the order in which they were written (purple, then green, then red). For example, the zone marked in red on the left contains a note referring to the purple zone on the right.

This approach assumes that the transcription will primarily be organized in the same way as the physical layout of the source, using embedded transcription elements. Alternatively, where the a non-embedded transcription has been provided, using the <text> element, it is still possible to record gathering breaks, page breaks, column breaks, line breaks etc in the source, using the elements described in section 3.10. *Reference Systems*. Detailed metadata about the physical make-up of a source will usually be summarized by the <physDesc> component of a <msDesc> element discussed in 10.7. *Physical Description*.

### 11.5.1 Space

The author or scribe may have left space for a word, or for an initial capital, and for some reason the word or capital was never supplied and the space left empty. The presence of significant space in the text being transcribed may be indicated by the <space> element.

<space> indicates the location of a significant space in the text.

@resp (responsible party) (responsible party) indicates the individual responsible for identifying and measuring the space

Note that this element should not be used to mark normal inter-word space or the like.

In line 694 of Chaucer's *Wife of Bath's Prologue* in the Holkham manuscript the scribe has left a space for a word where other manuscripts read *preestes*:

```
By
god if wommen had writen storyes As <space quantity="7" unit="chars"/> han within her
oratoryes
```

The <supplied> element discussed in the previous section may be used to supply the text presumed missing:

```
By god if wommen had writen storyes As
<supplied reason="space" resp="#ETD"
source="#Hg">preestes</supplied> han within
her oratoryes
```

Here, the fact of the space within the manuscript is indicated by the value of the *reason* attribute. The source of the supplied text is shown by the value of the *source* attribute as the Hengwrt manuscript; the transcriber responsible for supplying the text is ES.

### 11.5.2 Lines

One of the more common forms of modification encountered in written documents of any kind is the presence of lines written under, beside, or through the text. Such lines may be of various types: they may be solid, dashed or dotted, doubled or tripled, wavy or straight, or a combination of these and other renderings. The line may be used for emphasis, or to mark a foreign or technical term, or to signal a quotation or a title, etc.: the elements <emph>, <foreign>, <term>, <mentioned>, or <title> may be used for these. Where the line has a clear paratextual function the <metamark> element may be considered more appropriate. Frequently, a scholar may judge that a line is used to delete text: the <del> element is available to indicate this. In all these cases, the *rend* attribute may be used to supply further details concerning the style of the line. Thus, Lawrence's deletion by strike-through of *my* in the autograph of *Eloi, Eloi, lama sabachthani* may be encoded:

```
For I hate this <del rend="strikethrough" hand="#dhl">my</del> body, which is so
dear to me
```

There will be instances, however, where a scholar wishes only to register the occurrence of lines in the text, without making any judgement as to what the lines signify. In these cases the <hi> element may be used, with the

*rend* attribute to mark the style of line. In the manuscript of a letter by Robert Browning to George Moulton-Barrett the underlining of the phrase *had obtained all the letters to Mr Boyd* may be marked-up as follows:

```
I have once – by
declaring I would prosecute by law – hindered a man's proceedings who
<hi rend="underline">had obtained all the letters to Mr Boyd</hi>
```

The above examples presume the common case where a single word or phrase is marked by a line, with no doubt as to where the marking begins or ends and with no overlapping of the area of text with other marked areas of text. Where there is doubt, the `<certainty>` element may be used to record the doubt. In the Browning example cited above the underlining actually begins half-way under *who*, and this uncertainty could be remarked as follows:

```
I have once – by declaring I would prosecute
by law – hindered a man's proceedings who <hi xml:id="cstart1" rend="underline">had
obtained all the letters to Mr Boyd</hi>
<!-- ... -->
<certainty target="#cstart1" locus="start"
  degree="0.70">
  <desc>may begin with previous word</desc>
</certainty>
```

Where the area of text marked overlaps other areas of text, for example crossing a structural division, one of the spanning mechanisms mentioned above must be used; for example where the line is thought to mark a deletion, the `<delSpan>` element may be used. Where it is desired simply to record the marking of a span of text in circumstances where it is not possible to surround the text with a `<hi>` element, the `<span>` element may be used with the *rend* or *type* attribute indicating the style of line-marking.

More work needs to be done on clarifying the treatment of other textual features marked by lines which might so overlap or nest. For example, in many Middle English manuscripts (e.g. the Jesus and Digby verse collections), marginal sidebars may indicate metrical structure: couplets may be linked in pairs, with the pairs themselves linked into stanzas. Or, marginal sidebars may indicate emphasis, or may point out a region of text on which there is some annotation: in many manuscripts of Chaucer's *Wife of Bath's Prologue* lines 655–8 are marked with nesting parentheses against which the scribe has written *nota*.

Such features could be captured by use of the `<note>` element, containing a prose description of the manuscript at this point, enhanced by a link to a visual representation (or facsimile) of the feature in question. For example, in the Chaucer example just cited, one may wish to record that the *nota* is written in the Hengwrt manuscript in the right margin against a single large left parenthesis bracketing the four lines, with two right parentheses in the right margin bracketing two overlapping pairs of lines: the first and third, the second and fourth. The `<note>` element allows us to record that the scribe wrote *nota*, but is not well-adapted to show that the *nota* points both at all four lines and at two pairs of lines within the four lines. The `<metamark>` element discussed in section 11.3.4.2. *Metamarks* above provides better facilities for this kind of complex annotation.

## 11.6 Headers, Footers, and Similar Matter

Such information as page numbers, signatures, or catchwords may be recorded in a specialized `<fw>` element provided for that purpose. Although the name derives from the term *forme work*, used in description of early printed documents (the 'forme' being the block used to hold movable type), the `<fw>` element may be used for such features of any document, written or printed. Note that the purpose of this element is to record page numbers etc. *actually present* in the document being encoded, not necessarily to provide a complete or accurate pagination of it.

Information about pagination etc. may also be provided using the *n* attribute of the `<pb>` or `<gb>` elements, or by other appropriate `<milestone>` elements, as further discussed in section 3.10. *Reference Systems*: since this information is usually provided by the encoder, it is not subject to the constraint that it should be present only if textually present in the source being encoded. In text-critical situations it may be useful to provide both a normalized version of the pagination and a representation of the catch-word or numbering, especially when the latter presents a variant reading, or is significant for compositor identification.

**<fw>** (forme work) contains a running head (e.g. a header, footer), catchword, or similar material appearing on the current page.

The **<fw>** element may be used to encode any of the unchanging portions of a page forme, such as:

- running heads (whether repeated or changing on every page, or alternating pages)
- running footers
- page numbers
- catch-words
- other material repeated from page to page, which falls outside the stream of the text

It should not be used for marginal glosses, annotations, or textual variants, which should be tagged using **<gloss>**, **<note>**, or the text-critical tags described in chapter 12. *Critical Apparatus*, respectively.

For example:

```
<fw type="head" place="top-centre">Poëms.</fw>
<fw type="pageNum" place="top-right">29</fw>
<fw type="sig" place="bot-centre">E3</fw>
<fw type="catch" place="bot-right">TEMPLE</fw>
```

## 11.7 Identifying Changes and Revisions

A major purpose of genetic editing is the identification of ‘revision campaigns’ or, more generally, *changes*. An editor may wish to regard a particular set of alterations (deletions, additions, substitutions, transpositions, etc.) or any other act of writing as a single object for which we use the general term *change*, to indicate both that one or more of such phenomena preceded or followed another and also to indicate that they are related in some way, for example that one is a consequence of the other. They might also wish to group together certain revisions, regardless of when they might have occurred, based on a variety of other shared characteristics (e.g., corrections of factual errors or revisions that incorporate suggestions made by a given reader). To document this we need:

- a system to assign phenomena to a particular ‘change’ as defined above
- a way to characterize each such change, in itself and in relation to others.

The element **<creation>** (within the TEI header profile description) contains all information relating to the genesis or production of a text. It may contain a **<listChange>** element which contains a number of **<change>** elements, one for each set of alterations identified:

**<listChange>** groups a number of change descriptions associated with either the creation of a source text or the revision of an encoded text.

**@ordered** indicates whether the ordering of its child **<change>** elements is to be considered significant or not

**<change>** documents a change or set of changes made during the production of a source document, or during the revision of an electronic file.

In the following example an editor has identified four distinct sets of alterations:

```
<profileDesc>
  <creation>
    <listChange ordered="true">
      <change xml:id="ST-1">First stage, written in ink </change>
      <change xml:id="ST-2">Second stage, with revisions written in the author's hand
        using pencil</change>
      <change xml:id="ST-3">Fixation of the pencilled revisions together with further
        revisions in the author's hand using ink</change>
      <change xml:id="ST-4">Additions in a different hand, probably at a later
        stage</change>
    </listChange>
  </creation>
</profileDesc>
```

```
</creation>
</profileDesc>
```

The `<listChange>` element carries an attribute *ordered*, which can take the values `true` or `false` (the default). The attribute specifies whether the order of child elements signifies a temporal order for the revision campaigns which they document. In the example above, the editor has asserted that the four sets distinguished are ordered chronologically according to the order of the `<change>` elements. If necessary, `<listChange>` elements can be nested hierarchically. This may be helpful in two cases. Firstly one can build up hypotheses about related revisions step-by-step, starting with `<change>` elements of smaller coverage, whose members are certainly related, and then in a subsequent pass grouping these in turn, thereby extending their reach.

```
<profileDesc>
  <creation>
    <listChange>
      <change xml:id="o">An unrelated change note</change>
      <listChange xml:id="m">
        <change xml:id="m1">Alterations on one manuscript page, certainly
          related</change>
        <change xml:id="m2">Alterations on another manuscript page, certainly
          related</change>
      </listChange>
      <change xml:id="p">Another unrelated change note</change>
    </listChange>
  </creation>
</profileDesc>
```

A nested `<listChange>` elements is also useful to indicate a *partial* ordering of `<change>` elements.

```
<listChange ordered="true">
  <change xml:id="ST1">The first stage</change>
  <listChange>
    <!-- We have no information about the order of these changes, except
    that they both followed ST1 and preceded STX -->
    <change xml:id="ST-rev1">A revision of the first stage</change>
    <change xml:id="ST-rev2">Another revision of the first stage</change>
  </listChange>
  <change xml:id="STX">The last stage</change>
</listChange>
```

In addition to the possibility of being ordered by their sequence within a `<listChange>` element, `<change>` elements may carry a number of attributes from the `att.dataable` class (*period*, *when*, *notBefore*, *notAfter*, *from*, and *to*) which allow each element to be dated as exactly or inexactly as necessary, in the same way as is currently possible for the TEI `<date>` element.

```
<profileDesc>

</listChange>
</creation>
</profileDesc>

```

Each `<change>` element, apart from declaring a distinct moment or phase in the creation of the document, may also contain references to other annotations contained within the `<teiHeader>` or in the document (as shown in the previous example). Such references, along with the textual content, are purely documentary. The association between a textual component and a `<change>` element is always made explicitly, either by using the *target* attribute on the `<change>` element to point to one or more textual elements, or by pointing from the element or elements concerned to the `<change>` element by means of their *change* attribute. If a `<change>` element is associated with some element, it is also associated with all of that element's children, unless otherwise indicated, for example by a new value for the *change* attribute.

In the following simple example, the text at one stage read 'This is a mouse', and at the next 'This is a house mouse':

```

<line change="#firstStage">This is a <add change="#secondStage">house</add>
mouse.</line>

```

In this example, however, the text originally read 'This is a house', and subsequently 'This is a mouse':

```

<line change="#firstStage">This is a <mod type="subst" change="#secondStage">
  <del>house</del>
  <add>mouse</add>
</mod>.</line>

```

Note that in this case both the deletion and the addition are associated with the second `<change>` element. The word 'house', because its deletion forms part of this second set of alterations, must have been present originally, whereas the word 'mouse' must have been added during the second set of alterations.

Elements such as `<add>` and `<del>` and the like carry an implied semantics concerning the order in which events in the writing of a document was carried out: something which is deleted must have been written before it was deleted; something which is added must have been added at a later stage of the writing. Even when a combination of such elements is used, the chronology can usually be inferred (see further *11.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination*). Explicit indication of the set of alterations to which some modification belongs is mostly useful in situations where all the alterations identified in a document are to be grouped, for example chronologically.

The interpretation of `<change>` elements with respect to a particular text passage is based on a number of implicit assumptions and constraints which have the effect of minimizing the amount of tagging necessary. The system is also flexible enough to support an explicit distinction between acts of writing and textual alterations, since either of

these can be associated with changes described in the encoding. The following example shows an encoding in which the same passage is transcribed twice, once from a documentary perspective, and once from a textual one:

```

```

The documentary transcription stresses the writing process, while the textual transcription emphasizes textual alterations. In either case, the change of writing activity associated with a particular feature in the transcript is explicitly indicated. From the documentary perspective, by assigning particular modifications to a specific <change> element, we describe the writing process, in that they specify which segment has been written when. From the textual perspective, the markup concentrates simply on the existence of textual alterations and makes no explicit claims about the order of writing.

## 11.8 Other Primary Source Features not Covered in these Guidelines

We repeat the advice given at the beginning of this chapter, that these recommendations are not intended to meet every transcriptional circumstance ever likely to be faced by any scholar. They are intended rather as a base to enable encoding of the most common phenomena found in the course of scholarly transcription of primary source materials. These guidelines particularly do not address the encoding of physical description of textual witnesses: the materials of the carrier, the medium of the inscribing implement, the organisation of the carrier materials themselves (as quiring, collation, etc.), authorial instructions or scribal markup, etc., except insofar as these are involved in the broader question of manuscript description, as addressed by the `msdescription` module described in chapter 10. *Manuscript Description*.

## 11.9 Module for Transcription of Primary Sources

The module described in this chapter makes available the following components:

**Module transcr:** Transcription of primary sources

- *Elements defined:* `addSpan` `am` `damage` `damageSpan` `delSpan` `ex` `facsimile` `fw` `handNotes` `handShift` `line` `listTranspose` `metamark` `mod` `redo` `restore` `retrace` `secl` `sourceDoc` `space` `subst` `substJoin` `supplied` `surface` `surfaceGrp` `surplus` `transpose` `undo` `zone`
- *Classes defined:* `att.coordinated` `att.global.change` `att.global.facs`

The selection and combination of modules to form a TEI schema is described in 1.2. *Defining a TEI Schema*.

## 12 Critical Apparatus

Scholarly editions of texts, especially texts of great antiquity or importance, often record some or all of the known variations among different *witnesses* to the text. Witnesses to a text may include authorial or other manuscripts, printed editions of the work, early translations, or quotations of a work in other texts. Information concerning variant readings of a text may be accumulated in highly structured form in a critical apparatus of variants. This chapter defines a module for use in encoding such an apparatus of variants, which may be used in conjunction with any of the modules defined in these Guidelines. It also defines an element class which provides extra attributes for some elements of the core tag set when this module is selected. In printed critical editions, the apparatus takes the form of highly-compressed notes at the bottom of each page. TEI's critical apparatus module allows variation to be encoded so that such notes may be generated, but it also models the variation so that, for example, interactive editions in which readers can choose which witness readings to display are possible.

Information about variant readings (whether or not represented by a critical apparatus in the source text) may be recorded in a series of *apparatus entries*, each entry documenting one *variation*, or set of readings, in the text. Elements for the apparatus entry and readings, and for the documentation of the witnesses whose readings are included in the apparatus, are described in section 12.1. *The Apparatus Entry, Readings, and Witnesses*. Special tags for fragmentary witnesses are described in section 12.1.5. *Fragmentary Witnesses*. The available methods for embedding the apparatus in the rest of the text, or for linking an external apparatus to the base text, are described in section 12.2. *Linking the Apparatus to the Text*. Finally, several extra attributes for some tags of the core tag set, made available when the additional tag set for text criticism is selected, are documented in section 11.3.1.1. *Core Elements for Transcriptional Work*.

Many examples given in this chapter refer to the following texts of the opening (usually just line 1) of Chaucer's *Wife of Bath's Prologue*, as it appears in each of the four different manuscripts

- Ellesmere, Huntingdon Library 26.C.9 (El)
- Hengwrt, National Library of Wales, Aberystwyth, Peniarth 392D (Hg)
- British Library Lansdowne 851 (La)
- Bodleian Library Rawlinson Poetic 149 (Ra2)

### 12.1 The Apparatus Entry, Readings, and Witnesses

This section introduces the fundamental markup methods used to encode textual variations:

- the <app> element for entries in the critical apparatus: see section 12.1.1. *The Apparatus Entry*.
- elements for identifying individual readings: see section 12.1.2. *Readings*.
- ways of grouping readings together: see section 12.1.3. *Indicating Subvariation in Apparatus Entries*.
- methods of identifying which witnesses support a particular reading, and for describing the witnesses included in the apparatus: see section 12.1.4. *Witness Information*.
- elements for indicating which portions of a text are covered by fragmentary witnesses: see section 12.1.5. *Fragmentary Witnesses*.

The <app> element is in one sense a more sophisticated and complex version of the <choice> element introduced in 3.4.1. *Apparent Errors* as a way of marking points where the encoding of a passage in a single source may be carried out in more than one way. Unlike <choice>, however, the <app> element allows for the representation of many different versions of the same passage taken from different sources.

#### 12.1.1 The Apparatus Entry

Individual textual variations are encoded using the <app> element, which groups together all the readings constituting the variation. The identification of discrete textual variations or apparatus entries is not a purely mechanical process; different editors may group readings differently. No rules are given here as to how to group readings into apparatus entries; the tags given here may be used to group readings in whatever way the editor finds most perspicuous or useful.

The individual apparatus entry is encoded with the <app> element:

**<app>** (apparatus entry) contains one entry in a critical apparatus, with an optional lemma and usually one or more readings or notes on the relevant passage.

**@type** classifies the variation contained in this element according to some convenient typology.

`@from` identifies the beginning of the lemma in the base text.

`@to` identifies the endpoint of the lemma in the base text.

`@loc` (location) indicates the location of the variation, when the location-referenced method of apparatus markup is used.

The attributes *loc*, *from*, and *to*, are used to link the apparatus entry to the base text, if present. In such cases, several methods may be used for such linkage, each involving a slightly different usage for these attributes. Linkage between text and apparatus is described below in section 12.2. *Linking the Apparatus to the Text*. For the use of the `<app>` element without a base text, see 12.2.3. *The Parallel Segmentation Method*.

Each `<app>` element usually comprises one or more readings, which in turn are encoded using the `<rdg>` or other elements, as described in the next section. A very simple partial apparatus for the first line of the *Wife of Bath's Prologue* might take a form something like this:

```
<app>
  <rdg wit="#E1">Experience though noon Auctoritee</rdg>
  <rdg wit="#La">Experiment thouh noon Auctoritee</rdg>
  <rdg wit="#Ra2">Eryment though none auctorite</rdg>
</app>
```

Of course, in practice the apparatus will be somewhat more complex. Specifically, it may be desired to record more obviously that manuscripts E1 and La agree on the words ‘noon Auctoritee’, to indicate a preference for one reading, etc. The following sections on readings, subvariation, and witness information describe some of the more important complications which can arise.

### 12.1.2 Readings

Individual readings are the crucial elements in any critical apparatus of variants. The following elements should be used to tag individual readings within an apparatus entry:

**<lem>** (lemma) contains the lemma, or base text, of a textual variation.

**<rdg>** (reading) contains a single reading within a textual variation.

N.B. the term *lemma* is used here in the text-critical sense of ‘the reading accepted as that of the original or of the base text’. This sense differs from that in which the word is used elsewhere in the Guidelines, for example as in the attribute *lemma* where the intended sense is ‘the root form of an inflected word’, or ‘the heading of an entry in a reference book, especially a dictionary’.

In recording readings within an apparatus entry, the `<rdg>` element should always be used; each `<app>` usually contains at least one `<rdg>`, though it may contain only `<note>`s.

The `<lem>` element may also be used to record the base text of the source edition, to mark the readings of a base witness, to indicate the preference of an editor or encoder for a particular reading, or (e.g. in the case of an external apparatus) to indicate precisely to which portion of the main text the variation applies. Those who prefer to work without the notion of a base text or who are not using the parallel segmentation method may prefer not to use it at all. How it is used depends in part on the method chosen for linking the apparatus to the text; for more information, see section 12.2. *Linking the Apparatus to the Text*.

Readings may be encoded individually, or grouped for perspicuity using the `<rdgGrp>` element described in section 12.1.3. *Indicating Subvariation in Apparatus Entries*.

As members of the attribute classes `att.witnessed` and `att.textCritical`, both of these elements inherit the following attributes.

**att.witnessed** supplies the attribute used to identify the witnesses supporting a particular reading in a critical apparatus.

`@wit` (witness or witnesses) contains a space-delimited list of one or more pointers indicating the witnesses which attest to a given reading.

**att.textCritical** defines a set of attributes common to all elements representing variant readings in text critical work.

`@type` classifies the reading according to some useful typology.

`@cause` classifies the cause for the variant reading, according to any appropriate typology of possible origins.

`@varSeq` (variant sequence) provides a number indicating the position of this reading in a sequence, when there is reason to presume a sequence to the variants.

`@hand [att.written]` points to a `<handNote>` element describing the hand considered responsible for the textual content of the element concerned.

These elements also inherit the following attributes from the `att.global.responsibility` class: **`att.global.responsibility`** provides attributes indicating the agent responsible for some aspect of the text, the markup or something asserted by the markup, and the degree of certainty associated with it.

`@resp` (responsible party) indicates the agency responsible for the intervention or interpretation, for example an editor or transcriber.

`@cert` (certainty) signifies the degree of certainty associated with the intervention or interpretation.

As elsewhere, these attributes may be used to indicate the person responsible for the editorial decision being recorded, and also the degree of certainty associated with that decision by the person carrying out the encoding.

The `wit` attribute identifies the witnesses which have the reading in question. It is required if the apparatus gathers together readings from different witnesses, but may be omitted in an apparatus recording the readings of only one witness, e.g. substitutions, divergent opinions on what is in the witness or on how to expand abbreviations, etc. Even in such a one-witness apparatus, however, the `wit` attribute may still be useful when it is desired to record the occurrence of a particular reading in some other witness. For other methods of identifying the witnesses to a reading, see section 12.1.4. *Witness Information*.

The `type` attribute allows the encoder to classify readings in any convenient way, for example as substantive variants of the lemma:

```
<app>
  <lem wit="#E1 #Hg">Experience</lem>
  <rdg wit="#La" type="substantive">Experiment</rdg>
  <rdg wit="#Ra2" type="substantive">Eryment</rdg>
</app>
```

or as orthographic variants:

```
<app>
  <lem wit="#E1 #Ra2">though</lem>
  <rdg wit="#La" type="orthographic">thouh</rdg>
</app>
```

The `varSeq` and `cause` attributes may be used to convey information on the sequence and cause of variation. In the following apparatus fragment, the reading *Eryment* is tagged as sequential to (derived from) the reading *Experiment*, and the cause is given as loss of the abbreviation for *per*.

```
<app>
  <rdg wit="#La" varSeq="1">Experiment</rdg>
  <rdg wit="#Ra2" cause="abbreviation_loss"
    varSeq="2">Eryment</rdg>
</app>
```

If a manuscript is written in several hands, and it is desired to report which hand wrote a particular reading, the `hand` attribute should be used. For example, in the Munich manuscript containing the *Carmina Burana*, the word *alle* has been changed to *allen*:

```

<l>Swaz hi gât umbe</l>
<l>daz sint alle megede,</l>
<l>die wellent ân man</l>
<l>
  <app>
    <rdg wit="#Mu" varSeq="1" hand="#m1">alle</rdg>
    <rdg wit="#Mu" cause="nachgetragen"
      varSeq="2" hand="#m2">allen</rdg>
  </app>
  disen sumer gân.
</l>

```

Similarly, if a witness is hard to decipher, it may be desired to indicate responsibility for the claim that a particular reading is supported by a particular witness. In line 2212a of *Beowulf*, for example, the manuscript is read in different ways by different scholars; the editor Klaeber prints one text, using parentheses to indicate his expansion, and records in the apparatus two different accounts of the manuscript reading, by Zupitza and Chambers:<sup>80</sup>

```

<l>se ðe on
<app>
  <rdg wit="#Kl">hea(um) h(æp)e</rdg>
  <rdg wit="#ms" resp="#Z">heaðo hlæwe</rdg>
  <rdg wit="#ms" resp="#Cha">heaum hope</rdg>
</app>
</l>
<l>hord beweotode,</l>

```

The *hand* and *resp* attributes are intelligible only on an element recording a reading from a single witness, and should not be used if more than one witness is given on the same <rdg> or <lem> element. If more than one witness is given for the reading, they are undefined. To convey this information when the witness is one among several, the <witDetail> element should be used; see section 12.1.4. *Witness Information*.

Where there is a greater weight of editorial discussion and interpretation than can conveniently be expressed through the attributes provided on these elements (for example where there are multiple witnesses for a single reading or multiple editorial responsibility for an emendation) this information can be attached to the apparatus in a note, or recorded in the feature structure notation defined in chapter 18. *Feature Structures*. In particular, such recurring text-critical situations as palaeographic confusion of particular letters, or homœoarchy or homœoteleuton involving specific character groups, may lend themselves to feature structure treatment. Information concerning these recurrent situations may be encoded into database-like fragments within the text which would then be available to sophisticated computer-assisted analysis. Further work remains to be done on such mechanisms, however, and so no examples are given here of the use of feature structures in text-critical apparatus.

The <note> element may also be used to record the specific wording of notes in the apparatus of the source edition, as here in a transcription of Friedrich Klaeber's note on *Beowulf* 2207a:

```

<l n="2207a">syððan Beowulfe
<note resp="#Kl" place="app">Fol. 179a <mentioned>beowulfe</mentioned>.
  Folio 179, with the last page (Fol. 198b), is the worst part of the
  entire MS. It has been freshened up by a later hand, but not always
  correctly. Information on doubtful readings is in the notes of
  Zupitza and Chambers.</note>
</l>
<l n="2207b">brade rice</l>

```

<sup>80</sup>For the sake of legibility in the example, long marks over vowels are omitted.

Notes providing details of the reading of one particular witness should be encoded using the specialized `<witDetail>` element described in section 12.1.4. *Witness Information*.

Encoders should be aware of the distinct fields of use of the attribute values *wit*, *hand*, and *resp*. Broadly, *wit* identifies the physical entity in which the reading is found (manuscript, clay tablet, papyrus, printed edition); *hand* refers to the agent responsible for inscribing that reading in that physical entity (scribe, author, inscriber, hand 1, hand 2); *resp* indicates the scholar responsible for asserting the existence of that reading in that physical entity. In some cases, the categories may blur: a scholar may produce an edition introducing readings for which he or she is responsible; that edition may itself become a witness in a later critical apparatus. Thus, readings introduced as corrections in the earlier edition will be seen in the later apparatus as witnessed by the earlier edition. As observed in the discussion concerning the discrimination of *hand* and *resp* in transcription of primary sources in section 11.3.2.2. *Hand, Responsibility, and Certainty Attributes*, the division of layers of responsibility through various scholars for particular aspects of a particular reading may require the more complex mechanisms for assigning responsibility described in chapter 21. *Certainty, Precision, and Responsibility*.

### 12.1.3 Indicating Subvariation in Apparatus Entries

The `<rdgGrp>` element may be used to group readings, either because they have identical values on one or more attributes, or because they are seen as forming a self-contained variant sequence, or for some other reason. This grouping of readings is entirely optional: no such grouping of readings is required.

**<rdgGrp>** (reading group) within a textual variation, groups two or more readings perceived to have a genetic relationship or other affinity.

The `<rdgGrp>` element is a member of class `att.textCritical` and therefore can carry the *wit*, *type*, *cause*, *varSeq*, *hand*, and *resp* attributes described in the preceding section. When values for any of these attributes are given on a `<rdgGrp>` element, the values given are inherited by the `<rdg>` or `<lem>` elements nested within the reading group, unless overridden by a new specification on the individual reading element.

To indicate that both Hg and La vary only orthographically from the lemma, one might tag both readings `<rdg type='orthographic'>`, as shown in the preceding section. This fact can be expressed more perspicuously, however, by grouping their readings into a `<rdgGrp>`, thus:

```
<app>
  <lem wit="#El #Ra2">though</lem>
  <rdgGrp type="orthographic">
    <rdg wit="#La">thogh</rdg>
    <rdg wit="#Hg">thouh</rdg>
  </rdgGrp>
</app>
```

Similarly, `<rdgGrp>` may be used to organize the substantive variants of an apparatus entry. Editors may need to indicate that each of a group of witnesses may be taken as all supporting a particular reading, even though there may be variation concerning the exact form of that reading in, or the degree of support offered by, those witnesses. For example: one may identify three substantive variants on the first word of Chaucer's *Wife of Bath's Prologue* in the manuscripts: these might be expressed in regularized spelling as *Experience*, *Experiment*, and *Eriment*. In fact, the manuscripts display many different spellings of these words, and a scholar may wish both to show that the manuscripts have all these variant spellings and that these variant spellings actually support only the three regularized spelling forms. One may term these variant spellings as 'subvariants' of the regularized spelling forms.

This subvariation can be expressed within an `<app>` element by gathering the readings into three groups according to the normalized form of their reading. All the readings within each group may be accounted subvariants of the main reading for the group, which may be indicated by tagging it as a `<lem>` element or as `<rdg type='groupBase'>`.

In this example, the different subvariants on *Experience*, *Experiment*, and *Eriment* are held within three `<rdgGrp>` elements nested within the enclosing `<app>` element:

```
<app type="substantive">
  <rdgGrp type="subvariants">
    <lem wit="#El #Hg">Experience</lem>
```

```

    <rdg wit="#Ha4">Experiens</rdg>
  </rdgGrp>
  <rdgGrp type="subvariants">
    <lem wit="#Cp #Ld1">Experiment</lem>
    <rdg wit="#La">Ex<g ref="#per"/>iment</rdg>
  </rdgGrp>
  <rdgGrp type="subvariants">
    <lem resp="#ed2013">Eriment</lem>
    <rdg wit="#Ra2">Eryment</rdg>
  </rdgGrp>
</app>

```

From this, one may deduce that the regularized reading *Experience* is supported by all three manuscripts El Hg Ha4, although the spelling differs in Ha4, and that the regularized reading *Eriment* is supported by Ra2, even though the form differs in that manuscript. Accordingly, an application which recognizes that these apparatus entries show subvariation may then assign all the witnesses instanced as attesting the sub-variants on that lemma as actually supporting the reading of the lemma itself at a higher level of classification. Thus, Ha4 here supports the reading *Experience* found in El and Hg, even though it is spelled slightly differently in Ha4.

Reading groups may nest recursively, so that variants can be classified to any desired depth. Because apparatus entries may also nest, the <app> element might also be used to group readings in the same way. The example above is substantially identical to the following, which uses <app> instead of <rdgGrp>:

```

<app n="a1" type="substantive">
  <rdg wit="#El #Hg #Ha4">
    <app n="a2" type="orthographic">
      <lem wit="#El #Hg">Experience</lem>
      <rdg wit="#Ha4">Experiens</rdg>
    </app>
  </rdg>
  <rdg wit="#Cp #Ld1 #La">
    <app n="a3" type="orthographic">
      <lem wit="#Cp #Ld1">Experiment</lem>
      <rdg wit="#La">Ex<g ref="#per"/>iment</rdg>
    </app>
  </rdg>
  <rdg wit="#Ra2">
    <app n="a4" type="orthographic">
      <lem resp="#ed2013">Eriment</lem>
      <rdg wit="#Ra2">Eryment</rdg>
    </app>
  </rdg>
</app>

```

This expresses even more clearly than the previous encoding of this material that at the highest level of classification (apparatus entry A1), this variation has three normalized readings, and that the first of these is supported by manuscripts El, Hg, and Ha4; the second by Cp, Ld1, and La; and the third by Ra2. Some encoders may find the use of nested apparatus entries less intuitive than the use of reading groups, however, so both methods of classifying the readings of a variation are allowed.

Reading groups may also be used to bring together variants which form an apparent developmental sequence, and to make clear that other readings are not part of that sequence, as in the following example, which makes clear that the variant sequence *experiment* to *eriment* says nothing about the relative priority of *experiment* and *experience*:

```

<app type="substantive">
  <rdgGrp type="subvariants">
    <lem wit="#El #Hg">Experience</lem>
    <rdg wit="#Ha4">Experiens</rdg>
  </rdgGrp>
  <rdgGrp type="sequence">
    <rdgGrp varSeq="1" type="subvariants">
      <lem wit="#Cp #Ld1">Experiment</lem>
      <rdg wit="#La">Ex<g ref="#per"/>iment</rdg>
    </rdgGrp>
    <rdgGrp varSeq="2"
      cause="abbreviation_loss">
      <lem resp="#ed2013">Eriment</lem>
      <rdg wit="#Ra2">Eryment</rdg>
    </rdgGrp>
  </rdgGrp>
</app>

```

#### 12.1.4 Witness Information

A given reading is associated with the set of witnesses attesting it by listing the witnesses in the *wit* attribute on the <rdg>, <lem>, or <rdgGrp> element. Special mechanisms, described in the following sections, are needed to associate annotation on a reading with one specific witness among several (section 12.1.4.1. *Witness Detail Information*), to transcribe witness information verbatim from a source edition (section 12.1.4.2. *Witness Information in the Source*), and to identify the formal lists of witnesses typically provided in the front matter of critical editions (section 12.1.4.3. *The Witness List*).

##### 12.1.4.1 Witness Detail Information

When it is desired to give additional information about a particular witness or witnesses for the reading, the information may be given in a <witDetail> element. This is a specialized form of note, which can be linked to both a reading and to one or more of the witnesses for that reading. The former linkage is effected by the *target* attribute which <witDetail> inherits from the attribute class **att.pointing**, and the latter by the *wit* attribute.

**att.pointing** provides a set of attributes used by all elements which point to other elements by means of one or more URI references.

@*target* specifies the destination of the reference by supplying one or more URI References

<witDetail> (witness detail) gives further information about a particular witness, or witnesses, to a particular reading.

@*wit* (witnesses) indicates the sigil or sigla identifying the witness or witnesses to which the detail refers.

Unlike <note>, <witDetail> cannot be included in the text at the point of attachment; it must point to the reading(s) being annotated by means of its *target* attribute. To indicate, on the authority of editor PR, that the Ellesmere manuscript has an ornamental capital in the word *Experience*, for example, one might write:

```

<app type="substantive">
  <rdgGrp type="subvariants">
    <lem xml:id="W026" wit="#El #Hg">Experience</lem>
    <rdg wit="#Ha4">Experiens</rdg>
  </rdgGrp>
</app>
<witDetail target="#W026" wit="#El"
  resp="#PR">Ornamental capital.</witDetail>

```

This encoding makes clear that the ornamental capital mentioned is in the Ellesmere manuscript, and not in Hengwrt or Ha4. The *resp* attribute assigns responsibility to PR.

Like `<note>`, `<witDetail>` may be used to record the specific wording of information in the source text, even when the information itself is captured in some more formal way elsewhere. The example from the *Carmina Burana* above (section 12.1.2. *Readings*), for example, might be extended thus, to record the wording of the note explaining the variant:

```
<l>Swaz hi gât umbe</l>
<l>daz sint alle megede,</l>
<l>die wellent ân man</l>
<l>
  <app>
    <rdg wit="#Mu" hand="#m1">alle</rdg>
    <rdg xml:id="anon.6.4" wit="#Mu"
      hand="#m2">allen</rdg>
  </app>
  disen sumer gân.
</l>
<witDetail target="#anon.6.4" wit="#Mu">
  <ref>allen</ref>
  <mentioned>n</mentioned> nachgetragen.
</witDetail>
```

Observe that a single witness detail element may be linked to several different readings (noting, for example, a recurrent phenomenon in a particular manuscript) by having the *target* attribute point at all the readings in question. Similarly, feature structures containing information about the text in a witness (whether retroversion, regularization, or other) can also be linked to specific `<lem>` and `<rdg>` instances. See chapter 18. *Feature Structures*.

#### 12.1.4.2 Witness Information in the Source

In the transcription of printed critical editions, it may be desirable to retain for future reference the exact form in which the source edition records the witnesses to a particular reading; this is particularly important in cases of ambiguity in the information, or uncertainty as to the correct interpretation. The `<wit>` element may be used to transcribe such lists of witnesses to a particular reading.

**<wit>** contains a list of one or more sigla of witnesses attesting a given reading, in a textual variation.

The `<wit>` list may appear following a `<rdg>`, `<rdgGrp>`, or `<lem>` element in any apparatus entry, and should be used only to transcribe the witness information in the form found in the source. The advantage of holding witness information in the *wit* attribute of `<lem>` or `<rdg>` is that an application can check that every sigil<sup>81</sup> for the identifier has been declared elsewhere in the document. Because the *wit* attribute has declared datatype of one or more `data.pointer` values, a check can be made that readings are assigned only to witness sigla which have been identified (using the *xml:id* attribute) within a `<listWit>` element (see section 12.1.4.3. *The Witness List*). Such checking is more difficult for witness sigla held as the content of a `<wit>` element. For this reason, it is recommended that encoders always hold witness information in the *wit* attribute of `<lem>` and `<rdg>`, where possible. Thus, as in the examples below, even when a reference to a witness is exactly reproduced in the `<wit>` element, the corresponding sigil for that witness can be written into the *wit* attribute of the matching `<rdg>` or `<lem>`. However, in cases where it is uncertain how the witness reference contained in the `<wit>` element should be interpreted, or where no witness exists, the *wit* attribute on the matching `<rdg>` or `<lem>` may be left empty.

```
<lg type="stanza">
  <l xml:id="Diet1.1">Slăfest du, vriedel ziere?</l>
  <l xml:id="Diet1.2">wan wecket uns leider schiere;</l>
  <l xml:id="Diet1.3">ein vogellin sô wol getän</l>
  <l xml:id="Diet1.4">daz ist der linden an daz zwī gegän.</l>
</lg>
```

<sup>81</sup>We use the term sigil as the English equivalent of the Latin term *siglum* (sign) traditionally used for the brief identifier associated with a particular document.

```

<app type="secondary" loc="Diet.1.1">
  <rdg wit="#Kb">släfst</rdg>
  <wit>K(Ba)</wit>
</app>
<app type="secondary" loc="Diet.1.2">
  <rdg wit="#Kv">Man</rdg>
  <wit>K(V)</wit>
  <rdg wit="#K">weckt</rdg>
  <wit>K (Wackernagel 401)</wit>
  <rdg wit="#Ju">Ich waen ez taget uns schiere</rdg>
  <wit>Jungbluth, Festschr. Pretzel 1963, 122.</wit>
</app>

```

Of course, the sigil used for a particular witness in the source, as recorded in the <wit> element, may well differ from that used to indicate the same witness in the *wit* attribute, as shown particularly in the apparatus for the second line of the poem (Diet.1.2).

#### 12.1.4.3 The Witness List

A list of all identified witnesses should normally be supplied in the front matter of the edition, or in the <sourceDesc> element of its header. This may be given either as a simple bibliographic list, using the <listBibl> element described in 3.11. *Bibliographic Citations and References*, or as a <listWit> element, which contains a series of <witness> elements. Each <witness> element may contain a brief characterization of the witness, given as one or more prose paragraphs. If more detailed information about a manuscript witness is available, it should be represented using the <msDesc> element provided by the *msdescription* module; a <msDesc> may appear within a <listBibl>.

Whether information about a particular witness is supplied by means of a <bibl>, <msDesc>, or <witness> element, a unique sigil for this source should always be supplied, using the global *xml:id* attribute. This identifier can then be used elsewhere to refer to this particular witness.

**<listWit>** (witness list) lists definitions for all the witnesses referred to by a critical apparatus, optionally grouped hierarchically.

**<witness>** contains either a description of a single witness referred to within the critical apparatus, or a list of witnesses which is to be referred to by a single sigil.

**<msDesc>** (manuscript description) contains a description of a single identifiable manuscript or other text-bearing object.

**<bibl>** (bibliographic citation) contains a loosely-structured bibliographic citation of which the sub-components may or may not be explicitly tagged.

**<listBibl>** (citation list) contains a list of bibliographic citations of any kind.

The minimal information provided by a witness list is thus the set of sigla for all the witnesses named in the apparatus. For example, the witnesses referenced by the examples of this chapter might simply be listed thus:

```

<listWit>
  <witness xml:id="Chi3"/>
  <witness xml:id="Ha4"/>
  <witness xml:id="Ju"/>
  <witness xml:id="K"/>
  <witness xml:id="Kb"/>
  <witness xml:id="Kl"/>
  <witness xml:id="Kv"/>
  <witness xml:id="Ld"/>
  <witness xml:id="Ld1"/>
  <witness xml:id="Ln"/>
  <witness xml:id="Mu"/>
  <witness xml:id="Ry2"/>
  <witness xml:id="Wa"/>

```

```
<witness xml:id="X"/>
</listWit>
```

It is more helpful, however, for witness lists to be somewhat more informative: each <witness> element should contain at least a brief prose description of the witness, perhaps including a bibliographic citation, as in the following examples:

```
<listWit>
  <witness xml:id="El">Ellesmere, Huntingdon Library 26.C.9</witness>
  <witness xml:id="Hg">Hengwrt, National Library of Wales,
    Aberystwyth, Peniarth 392D</witness>
  <witness xml:id="Ra2">Bodleian Library Rawlinson Poetic 149
    (see further <ptr target="http://example.com/msDescs#MSRP149"/>)</witness>
</listWit>
```

As the last example shows, the witness description here may be complemented by a reference to a full description of the manuscript supplied elsewhere, typically as the content of a <msDesc> or <bibl> element. Alternatively, it may contain a whole paragraph of commentary for each witness:

```
<listWit>
  <witness xml:id="A">die sog. <soCalled>Kleine (oder alte)
    Heidelberger Liederhandschrift</soCalled>.
  <bibl>Universitätsbibliothek Heidelberg col. pal.
    germ. 357. Pergament, 45 Fll. 18,5 × 13,5 cm.</bibl>
    Wahrscheinlich die älteste der drei großen Hss. Sie
  <quote>datiert aus dem 13. Jahrhundert, etwa um 1275. Ihre Sprache
    weist ins Elsaß, evtl. nach Straßburg. Man geht wohl nicht
    fehl, in ihr eine Sammlung aus dem Stadtpatriziat zu sehen</quote>
  (<bibl>
    <author>Blank</author>, [vgl. <ref>Lit. z. Hss. Bd. 2,
      S. 39</ref>] S. 14</bibl>). Sie enthält 34 namentlich
    genannte Dichter. <quote>Zu den Vorzügen von A gehört, daß
    sie kaum je bewußt geändert hat, so daß sie für
    manche Dichter ... oft den besten Text liefert</quote> (so wohl mit
    Recht <bibl>
    <author>v. Kraus</author>
  </bibl>).</witness>
  <witness xml:id="a">Bezeichnung <bibl>
    <author>Lachmann</author>
  </bibl>s für die von einer 2. Hand auf bl. 40–43
    geschriebenen Strophen der Hs. A.</witness>
  <witness xml:id="B">die <soCalled>Weingartner (Stuttgarter)
    Liederhandschrift</soCalled>. <bibl>Württembergische
    Landesbibliothek Stuttgart, HB XIII poetae germanici 1.
    Pergament, 156 Bll. 15 × 11,5 cm; 25 teils ganzseitig,
    teils halbseitige Miniaturen.</bibl> Kaum vor 1306 in Konstanz
    geschrieben. Sie enthält Lieder von 25 namentlich genannten
    Dichtern. (Dazu kommen Gedichte von einigen ungenannten
    bzw. unbekanntem Dichtern, ein Marienlobpreis und eine
    Minnelehre.)</witness>
</listWit>
```

It would however generally be preferable to represent such detailed information using an appropriately structured <msDesc> element, as discussed in chapter 10. *Manuscript Description*. Note also that if the witnesses being recorded

are not manuscripts but printed works, it may be preferable to document them using the standard `<bibl>` or `<biblStruct>` elements described in 3.11. *Bibliographic Citations and References*, as in this example:

```
<listBibl>
  <bibl xml:id="bcn_1482">T. Kempis, De la imitació de Jesuchrist e del
    menyspreu del món (trad. Miquel Peres); Barcelona, 1482, Pere
    Posa. Editio princeps.</bibl>
  <bibl xml:id="val_1491">T. Kempis, Del menyspreu del món (trad. Miquel
    Peres); València, 1491.</bibl>
  <bibl xml:id="bcn_1518">T. Kempis, Libre del menysprey del món e de la
    imitació de nostre senyor Déu Jesucrist, (trad. Miquel Peres);
    Barcelona, 1518, Carles Amorós. </bibl>
</listBibl>
```

In text-critical work it is customary to refer to frequently occurring groups of witnesses by means of a single common sigil. Such sigla may be documented as pseudo-witnesses in their own right by including a nested witness list within the witness list, which uses the sigil for the group as its identifier, and supplies a fuller name for the group in its optional child `<head>` element, before listing the other witnesses contained by the group. For example, the Constant Group C of manuscripts comprising witnesses Cp, La, and S12, might be represented as follows:

```
<listWit>
  <witness xml:id="Ellesmere">Ellesmere, Huntingdon Library 26.C.9</witness>
  <!-- ... -->
  <listWit xml:id="Con">
    <head>Constant Group C</head>
    <witness xml:id="Cp">Corpus Christi Oxford MS 198</witness>
    <witness xml:id="La">British Library Lansdowne 851</witness>
    <witness xml:id="S12">British Library Sloane MS 1686</witness>
  </listWit>
</listWit>
```

That the reading *Experiment* occurs in all three manuscripts can now be indicated simply as follows:

```
<rdg wit="#Con">Experiment</rdg>
```

Note that a single witness cannot appear more than once in a witness list, and therefore cannot be assigned to more than one group of witnesses.

Situations commonly arise where there are many more or less fragmentary witnesses, such that there may be quite distinct groups of witnesses for different parts of a text or collection of texts. One may treat this with distinct `<listWit>` elements for each different part. Alternatively, one may have a single `<listWit>` element at the beginning of the file or in its header listing all the witnesses, partial and complete, for the text, with the attestation of fragmentary witnesses indicated within the apparatus by use of the `<witStart>` and `<witEnd>` elements described in section 12.1.5. *Fragmentary Witnesses*.

If a witness list is provided, it may be unnecessary to give, in each apparatus entry, an exhaustive list of the witnesses which agree with the base text. An application program can—in principle—compare the witnesses given for each variant found with those given in the full list of witnesses, subtracting from this list all the witnesses not active at this point (perhaps because of lacuna, or because they contain a variation on a different, overlapping lemma) and thence calculate all the manuscripts agreeing with the base text. In practice, encoders may find it less error-prone to list all witnesses explicitly in each apparatus entry.

### 12.1.5 Fragmentary Witnesses

If a witness is incomplete (whether a single fragment, a series of fragments, or a relatively complete text with one or more lacunae), it is usually desirable to record explicitly where its preserved portions begin and end. The

following empty tags, which may occur within any <lem> or <rdg> element, indicate the beginning or end of a fragmentary witness or of a lacuna within a witness:

**<witStart>** (fragmented witness start) indicates the beginning, or resumption, of the text of a fragmentary witness.

**<witEnd>** (fragmented witness end) indicates the end, or suspension, of the text of a fragmentary witness.

**<lacunaStart>** indicates the beginning of a lacuna in the text of a mostly complete textual witness.

**<lacunaEnd>** indicates the end of a lacuna in a mostly complete textual witness.

These elements constitute the class `model.rdgPart`, members of which are permitted within the elements <lem> and <rdg> when the module defined by this chapter is included in a schema.

Suppose a fragment of a manuscript X of the *Wife of Bath's Prologue* has a physical lacuna, and the text of the manuscript begins with *auctorite*. In an apparatus this might appear thus, distinguished from the reading of other manuscripts by the presence of the <lacunaEnd> element:

```
<app>
  <lem wit="#E1 #Hg">Auctoritee</lem>
  <rdg wit="#La #Ra2">auctorite</rdg>
  <rdg wit="#X">
    <lacunaEnd/>auctorite</rdg>
</app>
```

Alternatively, it may be clearer to record this as

```
<app>
  <lem wit="#E1 #Hg">Auctoritee</lem>
  <rdg wit="#La #Ra2 #X">
    <lacunaEnd wit="#X"/>auctorite</rdg>
</app>
```

since this shows more clearly that the lacuna and the reading of 'auctorite' both appear in witness X. In some cases, the apparatus in the source may commence recording the readings for a particular witness without its being clear whether the previous absence of readings for this witness is due to a lacuna, or to some other reason. The <witStart> element may be used in this circumstance:

```
<app>
  <lem wit="#E1 #Hg">Auctoritee</lem>
  <rdg wit="#La #Ra2">auctorite</rdg>
  <rdg wit="#X">
    <witStart/>auctorite</rdg>
</app>
```

## 12.2 Linking the Apparatus to the Text

Three different methods may be used to link a critical apparatus to the text:

1. the location-referenced method,
2. the double-end-point-attached method, and
3. the parallel segmentation method.

Both the location-referenced and the double end-point methods may be used with either *in-line* or *external* apparatus, the former dispersed within the base text, the latter held in some separate location, within or outside the document with the base text. The parallel segmentation method does not use the concept of a base text and may only be used for in-line apparatus.

Where an *external* apparatus is used, the <listApp> element provides a useful means of grouping together a series of <app> elements of a specific type, or from a particular source:

**<listApp>** (list of apparatus entries) contains a list of apparatus entries.

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

**@type** characterizes the element in some sense, using any convenient classification scheme or typology.

**@subtype** provides a sub-categorization of the element, if needed

**<listApp>** elements would normally appear in the **<back>** of a document, but they may also be placed in any other convenient location.

Any document containing **<app>** elements requires a **<variantEncoding>** declaration in the **<encodingDesc>** element of its TEI header, thus:

**<variantEncoding>** declares the method used to encode text-critical variants.

**@method** indicates which method is used to encode the apparatus of variants.

**@location** indicates whether the apparatus appears within the running text or external to it.

### 12.2.1 The Location-referenced Method

The location-referenced method of encoding apparatus provides a convenient method for encoding printed apparatus; in this method as in most printed editions, the apparatus is linked to the base text by indicating explicitly only the block of text on which there is a variant (noted usually by a canonical reference scheme, or by line number in the edition, such as *A 137* or *Page 15 line 1*).

If the location-referenced method is used for an apparatus stored externally to the base text, the TEI header must have the declaration:

```
<variantEncoding method="location-referenced"
  location="external"/>
```

In the **<body>** of the document, the base text (here *El*) will appear:

```
<text>
  <body>
    <div n="WBP" type="prologue">
      <head>The Prologe of the Wyves Tale of Bathe</head>
      <l n="1">Experience though noon Auctoritee</l>
      <l>Were in this world ...</l>
    </div>
  </body>
</text>
```

Elsewhere in the document, or in a separate file, the apparatus will appear. On each **<app>** element, the *loc* attribute should be specified to indicate where the variant occurs in the base text.

```
<app loc="WBP 1">
  <rdg wit="#La">Experiment</rdg>
  <rdg wit="#Ra2">Eryment</rdg>
</app>
```

If the same text is encoded using in-line storage, the apparatus is dispersed through the base text block to which it refers. In this case, the location of the variant can be read from the line in which it occurs.

```
<variantEncoding method="location-referenced"
  location="internal"/>
<!-- ... -->
```

```
<l n="1">Experience
<app>
  <rdg wit="#La">Experiment</rdg>
  <rdg wit="#Ra2">Eryment</rdg>
</app>
though noon Auctoritee</l>
<l>Were in this world ...</l>
```

Since the location is not required to be exact, the apparatus for a line might also appear at the end of the line:

```
<l n="1">Experience though noon Auctoritee
<app>
  <rdg wit="#La"> Experiment</rdg>
  <rdg wit="#Ra2"> Eryment</rdg>
</app>
</l>
<l>Were in this world ...</l>
```

When the apparatus is linked to the text by means of location references, as shown here, it is not possible to find automatically the precise portion of text varied by the readings. In order to show explicitly what portion of the base text is replaced by the variant readings, the `<lem>` element may be used:

```
<l n="1">Experience though noon Auctoritee
<app>
  <lem wit="#E1">Experience</lem>
  <rdg wit="#La">Experiment</rdg>
  <rdg wit="#Ra2">Eryment</rdg>
</app>
</l>
<l>Were in this world ...</l>
```

Often the lemma will have no attributes, being simply the ‘base text reading’ and requiring no qualification, but it may optionally carry the normal attributes, as shown here. Some text critics prefer to abbreviate or elide the lemma, in order to save space or trouble; such practice is not forbidden by these Guidelines, but no recommendations are made for conventions of abbreviating the lemma, whether abbreviation of each word, or suppression of all but the first and last word, etc.

Where it is intended that the apparatus be complete enough to allow the reconstruction of the witnesses (or at least of their non-orthographic variations), simple location-reference methods are unlikely to be as successful as the other two methods, which allow the unambiguous reconstruction of the lemma from the encoding.

### 12.2.2 The Double End-Point Attachment Method

In the double end-point attachment method, the beginning and end of the lemma in the base text are both explicitly indicated. It thus differs from the location-referenced method, in which only the larger span of text containing the lemma is indicated. Double end-point attachment permits unambiguous matching of each variant reading against its lemma. It or the parallel-segmentation method should be used in all cases where this is desired, for example where the apparatus is intended to enable full reconstruction of the text, or of the substantives, of every witness.

When the double end-point attachment method is used, the *from* and *to* attributes of the `<app>` element are used to indicate the beginning and ending points of the reading in the base text: their values are identifiers which occur at the locations in question. If no other markup is present there, the beginning and ending points should be marked using the `<anchor>` element defined in chapter 16. *Linking, Segmentation, and Alignment*. In cases where it is not possible to insert anchors within the base text (e.g. where the text is on a read-only medium) the beginning and end of the lemma may be indicated by using the ‘indirect pointing’ mechanisms discussed in chapter 16. *Linking, Segmentation, and Alignment*. Explicit anchors are more likely to be reliable, and are therefore to be preferred.

The double end-point attachment method may be used with in-line or external apparatus. In the latter case, the base text (here El) will appear with <anchor> elements inserted at every place where a variant begins or ends (unless some element with an identifier already begins or ends at that point):

```
<variantEncoding method="double-end-point"
  location="external"/>
<!-- ... -->
<div n="WBP" type="prologue">
  <head>The Prologe ... </head>
  <l n="1" xml:id="WBP.1">Experience<anchor xml:id="WBP-A2"/> though noon Auctori-
tee</l>
  <l>Were in this world ...</l>
</div>
```

The apparatus will be separately encoded:

```
<app from="#WBP.1" to="#WBP-A2">
  <rdg wit="#La">Experiment</rdg>
  <rdg wit="#Ra2">Eryment</rdg>
</app>
```

No <anchor> element is needed at the beginning of the line, since the *from* attribute can use the identifier for the line as a whole; the lemma is assumed to run from the beginning of the element indicated by the *from* attribute, to the end of that indicated by the *to* attribute. If no value is given for *to*, the lemma runs from the beginning to the end of the element indicated by the *from* attribute.

When the apparatus is encoded in-line, it is dispersed through the base text. Only the beginning of the lemma need be marked with an <anchor>, since the <app> is inserted at the end of the lemma, and itself therefore marks the end of the lemma.

```
<variantEncoding method="double-end-point"
  location="internal"/>
<!-- ... -->
<l n="1" xml:id="wbp.1">Experience
<app from="#wbp.1">
  <rdg wit="#La">Experiment</rdg>
  <rdg wit="#Ra2">Eryment</rdg>
</app>
though noon Auctoritee</l>
<l>Were in this world ...</l>
```

The lemma need not be repeated within the <app> element in this method, as it may be extracted reliably from the base text. If an exhaustive list of witnesses is available, it will also not be necessary to specify just which manuscripts agree with the base text to enable reconstruction of witnesses. An application will be able to determine the manuscripts that witness the base reading, by noting which witnesses are attested as having a variant reading, and inferring the base text reading for all others after adjusting for fragmentary witnesses and for witnesses carrying overlapping variant readings.

Alternatively, if it is desired to make an explicit record of the attestation of the base text, the <lem> element may be embedded within <app>, carrying the witnesses to the base. Thus

```
<app from="#WBP.1" to="#WBP-A2">
  <lem wit="#El #Hg">Experience</lem>
  <rdg wit="#La">Experiment</rdg>
```

```
<rdg wit="#Ra2">Eryment</rdg>
</app>
```

This method is designed to cope with ‘overlapping lemmata’. For example, at line 117 of the Wife of Bath's Prologue, the manuscripts Hg (Hengwrt), El (Ellesmere), and Ha4 (British Library Harleian 7334) read:

Hg And of so parfit wys a wight ywroght

El And for what profit was a wight ywroght

Ha4 And in what wise was a wight ywroght

In this case, one might wish to record *in what wise was* in Ha4 as a single variant for *of so parfit wys* in Hg, and *was a wight* in El and Ha4 as a variant on *wys a wight* in Hg. This method can readily cope with such difficult situations, typically found in large and complex traditions:

```
<l xml:id="WBP.117" n="117"> And
<anchor xml:id="WBP-A117.1"/> of so parfit
<anchor xml:id="WBP-A117.2"/> wys
<anchor xml:id="WBP-A117.3"/> a wight
<anchor xml:id="WBP-A117.4"/> ywroght
<app from="#WBP-A117.1" to="#WBP-A117.3">
  <lem wit="#Hg">of so parfit wys</lem>
  <rdg wit="#Ha4">in what wise was</rdg>
</app>
<app from="#WBP-A117.2" to="#WBP-A117.4">
  <lem wit="#Hg">wys a wight</lem>
  <rdg wit="#El #Ha4">was a wight</rdg>
</app>
</l>
```

The parallel segmentation method, to be discussed next, cannot handle overlaps among variants, and would require the individual variants to be split into pieces.

Because creation and interpretation of double end-point attachment apparatus will be lengthy and difficult it is likely that they will usually be created and examined by scholars only with mechanical assistance.

### 12.2.3 The Parallel Segmentation Method

This method differs from the double end-point attachment method in that all variants at any point of the text are expressed as variants on one another. In this method, no two variations can overlap, although they may nest. The texts compared are divided into matching segments all synchronized with one another. This permits direct comparison of any span of text in any witness with that in any other witness. It is also very easy with this method for an application to extract the full text of any one witness from the apparatus.

This method will (by definition) always be satisfactory when there are just two texts for comparison (assuming they are in the same language and script). It will however be less convenient for very complex traditions, where establishing a base text with variations from it is not a satisfactory goal for the edition, or in some cases where every detail of variation needs to be modeled.

In the parallel segmentation method, each segment of text on which there is variation is marked by an <app> element. If there is a preferred (or base) reading it is tagged with <lem>; each reading is given in a <rdg> element:

```
<variantEncoding method="parallel-segmentation"
  location="internal"/>
<!-- ... -->
<l n="1">
  <app>
```

```

    <lem wit="#El #Hg">Experience</lem>
    <rdg wit="#La">Experiment</rdg>
    <rdg wit="#Ra2">Eryment</rdg>
  </app>
  though noon Auctoritee
</l>
<l>Were in this world ...</l>

```

This method cannot be used with external apparatus: it must be used in-line. Note that apparatus encoded with this method may be translated into the double end-point attachment method and back without loss of information. Where double-end-point-attachment encodings have no overlapping lemmata, translation of these to the parallel segmentation encoding and back will also be possible without loss of information.

For economy, the witnesses to the reading most widely attested need not be stated. Since all manuscripts must be represented in all apparatus entries, it will be possible for an application to read a <listWit> declaring all the witnesses to the text and then calculate which witnesses have not been named. In the example below, only La and Ra2 are identified explicitly with a reading; an application might successfully infer from this that *Experience*, whose witnesses are not given, must be attested by El and Hg. To avoid confusion, however, witnesses may be omitted only for a single reading.

```

<l n="1">
  <app>
    <lem>Experience</lem>
    <rdg wit="#La">Experiment</rdg>
    <rdg wit="#Ra2">Eryment</rdg>
  </app>
  though noon Auctoritee
</l>
<l>Were in this world ...</l>

```

Alternatively, the witnesses for every reading may be stated, as in the first example.

As noted, apparatus entries may nest in this method: if an imaginary fifth manuscript of the text read *Auctoritee*, *though none experience*, the variation on the individual words of the line would nest within that for the line as a whole:

```

<l n="1">
  <app>
    <rdg wit="#Chi3">Auctoritee, though none experience</rdg>
    <rdg>
      <app>
        <rdg wit="#El #Hg">Experience</rdg>
        <rdg wit="#La">Experiment</rdg>
        <rdg wit="#Ra2">Eryment</rdg>
      </app>
      <app>
        <rdg wit="#El #Ra2">though</rdg>
        <rdg wit="#Hg">thogh</rdg>
        <rdg wit="#La">thouh</rdg>
      </app>
      <app>
        <rdg wit="#El #Hg">noon Auctoritee</rdg>
        <rdg wit="#La #Ra2">none auctoritee</rdg>
      </app>
    </rdg>
  </app>

```

```
</app>
</l>
```

Parallel segmentation cannot, however, deal very gracefully with variants which overlap without nesting: such variants must be broken up into pieces in order to keep all witnesses synchronized.

### 12.2.4 Other Linking Methods

When an apparatus is provided it does not need to be given at the location in the transcription where the variation, emendation, attribution, or other apparatus observation occurs. Instead it may be stored in a separate place in the same file, or indeed in another file, and point to the location at which it is meant to be used. Storing apparatus entries separately can be beneficial when encoding multiple competing, potentially overlapping, interpretations of the same point in the source texts.

The location-referenced method can be used to point a position in a text using the *loc* attribute and a canonical reference that is understood and documented in the context of the file where it is used. Where possible it is recommended that other methods use the *from* attribute to point to an *xml:id* attribute on an `<anchor>` or other element at the location where the apparatus observation takes place. The contents of an element pointed to are understood to be equivalent to a `<lem>` if none exists in the `<app>`, and if a `<lem>` does exist this should replace any content.

The *from* attribute is a `data.pointer` datatype and thus contains a URI as a value. This means that it can point directly to an *xml:id*, an *xml:id* in another local file, or indeed a file identified by any URL or URN.

```
<l n="1">
  <seg xml:id="WBP-so.1.1">Experience</seg> though noon Auctoritee
</l>
<!-- In another file -->
<app from="example.xml#WBP-so.1.1">
  <rdg wit="#La">Experiment</rdg>
  <rdg wit="#Ra2">Eryment</rdg>
</app>
```

This could also be encoded as:

```
<l n="1">
  <anchor xml:id="WBP-so.1.1a"/> though noon Auctoritee
</l>
<!-- In another file -->
<app from="http://www.example.com/example.xml#WBP-so.1.1a">
  <lem>Experience</lem>
  <rdg wit="#La">Experiment</rdg>
  <rdg wit="#Ra2">Eryment</rdg>
</app>
```

However, this should be considered more fragile since a full reading of the `<lem>` is not provided in the source file.

In addition, URLs can contain XPointer schemes including `xpath()`, `range()`, and `string-range()` which can be used in providing the location of an `<app>` that is stored separately from the text to which it applies. Both *from* and *to* can be used, as in the double end-point attachment method, to identify the starting and ending location for an apparatus using XPointer schemes described in 16.2.4. *TEI XPointer Schemes* section to more precisely identify this location where beneficial.

```
<l n="1" xml:id="WP.1a">Experience though noon Auctoritee</l>
<!-- In another file -->
```

```
<app from="example.xml#string-range(WP.1a, 0, 10)">
  <lem>Experience</lem>
  <rdg wit="#La">Experiment</rdg>
  <rdg wit="#Ra2">Eryment</rdg>
</app>
```

If only the *from* attribute is provided then it should be understood that this supplies the location of the textual variance that the apparatus documents. If the *from* attribute contains an XPointer scheme that identifies a range of text (or elements) then this is understood to record the starting and ending of the range as in the double end-point attachment method. In such a case a @to attribute is unnecessary.

## 12.3 Using Apparatus Elements in Transcriptions

It is often desirable to record different transcriptions of one stretch of text. These variant transcriptions may be grouped within a single <app> element. An application may then construct different ‘views’ of the transcription by extraction of the appropriate variant readings from the apparatus elements embedded in the transcription.

For example, alternative expansions can be recorded in several different <expan> elements, all grouped within an <app> element. Consider, for example, the three different transcriptions given below of line 105 of the Hengwrt manuscript of Chaucer’s *The Wife of Bath’s Prologue*. The last word of the line *Virginite is grete perfection* is written *perfectio* followed by two minims over which a bar has been drawn, which has been read in different ways by different scholars. The first transcription, by Elizabeth Solopova, represents the two minims with bar above as a special composite character using the <g> element. This transcription notes this as a mark of abbreviation but gives no expansion for it. A second transcriber, F. J. Furnivall, regards the bar as an abbreviation of *u*, and therefore reads the two minims as an *n*. A third transcriber, P. G. Ruggiers, regards the bar as an abbreviation of *n*, reading the minims as *u*. This information may be held within an <app> structure, as follows:

```
Virginite is grete
<app>
  <rdg source="#ES">perfectio<am>
    <g ref="#ii"/>
  </am>
</rdg>
  <rdg source="#FJF">perfectio<ex>u</ex>n</rdg>
  <rdg source="#PGR">perfectiou<ex>n</ex>
</rdg>
</app>
```

This example uses special purpose elements <am> and <ex> used to represent abbreviation marks and editorial expansion respectively; these elements are provided by the `transcr` module documented in chapter 11. *Representation of Primary Sources*, which should be consulted for further discussion of methods of representing multiple readings of a source.

Editorial notes may also be attached to <app> structures within transcriptions. Here, editorial preference for Ruggiers’ expansion and an explanation of that preference is given:

```
Virginite is grete
<app>
  <rdg source="#ES">perfecti<am>
    <g ref="#ii"/>
  </am>
</rdg>
  <rdg xml:id="f105" source="#FJF">perfectio<ex>u</ex>n</rdg>
  <rdg xml:id="r105" source="#PGR">perfectiou<ex>n</ex>
</rdg>
```

```

</app>
<!-- ... <note> appearing elsewhere in the document ... -->
<note target="#r105 #f105">Furnivall's expansion implies that the bar
is an abbreviation for 'u'. There are no certain instances of
this mark as an abbreviation for 'u' in these manuscripts and it is
widely used as an abbreviation for 'n'. Ruggiers' expansion is to
be accepted.</note>

```

In most cases, elements used to indicate features of a primary textual source may be represented within an `<app>` structure simply by nesting them within its readings, just as the `<am>` and `<ex>` elements are nested within the `<rdg>` elements in the example just given. However, in cases where the tagged feature extends across a span of text which might itself contain variant readings which it is desired to represent by `<app>` structures, some adaptation of the tagging may be necessary. For example, a span of text may be marked in the transcription of the primary source as a single deletion but it may be desirable to represent just a few words from this source as individual deletions within the context of a critical apparatus drawing together readings from this and several other witnesses. In this case, the tagging of the span of words as one deletion may need to be decomposed into a series of one-word deletions for encoding within the apparatus. If it is important to record the fact that all were deleted by the same act, the markup may use the `<join>` element or the *next* and *prev* attributes defined by chapter 16. *Linking, Segmentation, and Alignment*.

## 12.4 Strategies for Encoding Variation

Textual variation may manifest itself in many ways. Variation most frequently occurs at the phrase level, but is also common at higher structural levels, such as the verse line, paragraph, or chapter. When these structures are involved, some care must be taken in their encoding to ensure that TEI's Abstract Model is not being broken. It would be an error, for example, to have a `<div>` in the `<lem>`, but a `<p>` in a `<rdg>` inside the same apparatus entry, because these structures cannot occur at the same level. Similarly, it is an error if the contents of an apparatus entry place a `<p>` inside another `<p>` or an `<l>` inside an `<l>`.

Phenomena such as omissions and transpositions in witnesses will require some encoding strategies that differ from those in the examples above. An omission in one witness may be encoded using an empty `<rdg>`, thus:

```

<app xml:id="d1e372">
  <lem xml:id="d1e373" source="#Heyworth">
    <l n="18">Hypsipyle uacuo constitit in thalamo:</l>
  </lem>
  <rdg xml:id="d1e376" wit="#J"
    cause="homeoarchon"/>
</app>

```

Notice that in this example, the variation occurs at the unit of the verse line. The scribe of MS J has skipped line 18 (probably by mistake) because, like line 19, it begins with the name "Hypsipyle."

Transpositions are harder to encode, because they involve variation that occurs in different locations. A single `<app>` will therefore not be sufficient, and the variants must be linked. For example, in his edition of Propertius 1.16, Housman printed lines 25-6 after line 32, Heyworth prints them in place. We might encode Heyworth's edition, which records Housman's conjecture despite disagreeing with it, as follows:

```

<app xml:id="app-lem-l25-l26"
  exclude="#app-rdg-Housman-l25-26">
  <lem xml:id="d1e462" source="#Heyworth">
    <l n="25" xml:id="l25">desine iam reuocare tuis periuria verbis,</l>
    <l n="26" xml:id="l26">Cynthia, et oblitos parce movere deos;</l>
  </lem>
</app>

```

and then, after line 32:

```
<app xml:id="app-rdg-Housman-l25-26"
  exclude="#app-lem-l25-l26">
  <rdg xml:id="d1e603" source="#Housman">
    <l copyOf="#l25"/>
    <l copyOf="#l26"/>
  </rdg>
  <note target="#d1e603">Housman put these lines after 32.</note>
</app>
```

Note that both `<app>`s are linked via the *exclude* attribute, because they are mutually exclusive: if one reading is chosen for display in a reading interface, for example, the other must disappear and vice versa. To avoid repetition, the second pair of lines can make use of the *copyOf* attribute. If they were both transposed and somewhat different, then both sets would be written in full.

Apparatus entries may nest when there is variation at both higher and lower structural levels, e.g.:

```
<app xml:id="d1e275">
  <lem xml:id="d1e277" source="#Heyworth">
    <l n="8">
      <app xml:id="d1e280">
        <lem xml:id="d1e281" wit="#N #A">ut</lem>
        <rdg xml:id="d1e283" wit="#A">et</rdg>
        <rdg xml:id="d1e285" source="#Nodell">ac</rdg>
        <note target="#d1e287">perhaps</note>
        <rdg xml:id="d1e287" source="#Heyworth"
          cert="low">quam</rdg>
      </app> formosa nouo quae parat ire uiro.</l>
    <l n="9">
      <app xml:id="d1e294">
        <lem xml:id="d1e295">at</lem>
        <rdg xml:id="d1e297" wit="#A">et</rdg>
      </app> non sic, Ithaci digressu <app xml:id="d1e300">
        <lem xml:id="d1e301">mota</lem>
        <rdg xml:id="d1e303" source="#Graevius">immota</rdg>
      </app>, Calypso</l>
    <l n="10">desertis olim fleuerat aequoribus:</l>
    <l n="11">multos illa dies incomptis maesta capillis</l>
  </lem>
  <rdg xml:id="d1e314" wit="#C"
    cause="homoeoteleuton"/>
  <note target="#d1e314">omits lines 8-11 because of homoeoteleuton.</note>
</app>
```

Here, MS C omits lines 8-11, but there are variations the editor wishes to record in the other witnesses which do have these lines. Therefore, an outer `<app>` gives the lines in the `<lem>` and the omission in a `<rdg>`. Further variation is encoded for lines 8 and 9 using nested `<app>`s.

## 12.5 Module for Critical Apparatus

The module described in this chapter makes available the following components:

Module textcrit: Critical Apparatus

- *Elements defined:* app lacunaEnd lacunaStart lem listApp listWit rdg rdgGrp variantEncoding wit witDetail witEnd witStart witness

- *Classes defined:* att.rdgPart att.textCritical att.witnessed model.rdgLike model.rdgPart

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

## 13 Names, Dates, People, and Places

This chapter describes a module which may be used for the encoding of names and other phrases descriptive of persons, places, or organizations, in a manner more detailed than that possible using the elements already provided for these purposes in the Core module. In section 3.5. *Names, Numbers, Dates, Abbreviations, and Addresses* it was noted that the elements provided in the core module allow an encoder to specify that a given text segment is a proper noun, or a *referring string*, and to specify the kind of object named or referred to only by supplying a value for the *type* attribute. The elements provided by the present module allow the encoder to supply a detailed sub-structure for such referring strings, and to distinguish explicitly between names of persons, places, and organizations.

This module also provides elements for the representation of information about the person, place, or organization to which a given name is understood to refer and to represent the name itself, independently of its application. In simple terms, where the core module allows one simply to represent that a given piece of text is a *name*, this module allows one further to represent a *personal name*, to represent the *person* being named, and to represent the *canonical name* being used. A similar range is provided for names of places and organizations. The main intended applications for this module are in biographical, historical, or geographical data systems such as gazetteers and biographical databases, where these are to be integrated with encoded texts.

The chapter begins by discussing attributes common to many of the elements discussed in the remaining parts of the chapter (13.1. *Attribute Classes Defined by This Module*) before discussing specifically the elements provided for the encoding of component parts of personal names (section 13.2.1. *Personal Names*), place names (section 13.2.3. *Place Names*) and organizational names (section 13.2.2. *Organizational Names*). Elements for encoding personal and organizational data are discussed in section 13.3. *Biographical and Prosopographical Data*. Elements for the encoding of geographical data are discussed in section 13.3.4. *Places*. Finally, elements for encoding onomastic data are discussed in 13.3.5. *Names and Nyms*, and the detailed encoding of dates and times is described in section 13.3.6. *Dates and Times*.

### 13.1 Attribute Classes Defined by This Module

Most of the elements made available by this chapter share some important characteristics which are expressed by their membership in specific attribute classes. Members of the class `att.naming` have specialized attributes which support linkage of a naming element with the entity (person, place, organization) being named; members of the class `att.dateable` have specialized attributes which support a number of ways of normalizing the date or time of the data encoded by the element concerned.

#### 13.1.1 Linking Names and Their Referents

The class `att.naming` is a subclass of the class `att.canonical`, from which it inherits the following attributes:

**`att.canonical`** provides attributes which can be used to associate a representation such as a name or title with canonical information about the object being named or referenced.

**`@key`** provides an externally-defined means of identifying the entity (or entities) being named, using a coded value of some kind.

**`@ref`** (reference) provides an explicit means of locating a full definition or identity for the entity being named by means of one or more URIs.

As discussed elsewhere, these attributes provide two different ways of associating any sort of name with its referent. For cases where all that is required is to provide some minimal information about the person name, for example their occupation or status, the `att.naming` class also provides a simple *role* attribute. It also provides an additional attribute, which allows the name itself to be associated with a base or canonical form:

**`att.naming`** provides attributes common to elements which refer to named persons, places, organizations etc.

**`@role`** may be used to specify further information about the entity referenced by this name in the form of a set of whitespace-separated values, for example the occupation of a person, or the status of a place.

**`@nymRef`** (reference to the canonical name) provides a means of locating the canonical form (*nym*) of the names associated with the object named by the element bearing it.

The encoder may use these attributes in combination as appropriate. For example:

That silly man  
`<name role="politician" type="person">David Paul Brown</name>` has suffered ...

The *ref* attribute should be used wherever it is possible to supply a direct link such as a URI to indicate the location of canonical information about the referent.

That silly man  
`<name ref="#DPB1" type="person">David Paul Brown</name>` has suffered ...

This encoding requires that there exist somewhere a `<person>` element with the identifier `DPB1`, which will contain canonical information about this particular person, marked up using the elements discussed in 13.3. *Biographical and Prosopographical Data* below. The same element might alternatively be provided by some other document, of course, which the same attribute could refer to by means of a URI, as explained in 16.2. *Pointing Mechanisms*:

That silly man  
`<name ref="http://www.example.com/personography.xml#DPB1" type="person">David Paul Brown</name>` has suffered ...

More than one URI may be supplied if the name refers to more than one person. For example, assuming the existence of another `<person>` element for Mrs Brown, with identifier `EBB1`, a reference to 'the Browns' might be encoded

That wretched pair  
`<name ref="#DPB1 #EBB1" type="person">the Browns</name>` came to dine ...

The *key* attribute is provided for cases where no such direct link is required: for example because resolution of the reference is carried out by some local convention, or because the encoder judges that no such resolution is necessary. As an example of the first case, a project might maintain its own local database system containing canonical information about persons and places, each entry in which is accessed by means of some system-specific identifier constructed in a project-specific way from the value supplied for the *key* attribute.<sup>82</sup> As an example of the second case, consider the use of well-established codifications such as country or airport codes, which it is probably unnecessary for an encoder to expand further:

I never fly from `<name key="LHR" type="place">Heathrow Airport</name>`  
to  
`<name key="FR" type="place">France</name>`

However, as explained in 3.5.1. *Referring Strings*, interchange is improved by use of tag URIs in *ref* instead of *key*.

The *nymRef* attribute has a more specialized use, where it is the name itself which is of interest rather than the person, place, or organization being named. See section 13.3.5. *Names and Nyms* for further discussion.

All members of the `att.naming` class inherit the following attributes from the `att.global.responsibility` class:

**att.global.responsibility** provides attributes indicating the agent responsible for some aspect of the text, the markup or something asserted by the markup, and the degree of certainty associated with it.

**@resp** (responsible party) indicates the agency responsible for the intervention or interpretation, for example an editor or transcriber.

**@cert** (certainty) signifies the degree of certainty associated with the intervention or interpretation.

This enables an encoder to record the agency responsible for a given assertion (for example, the name) and the confidence placed in that assertion by the encoder. Examples are given below.

<sup>82</sup>In the module described by chapter 22. *Documentation Elements* a similar method is used to link element descriptions to the modules or classes to which they belong, for example.

### 13.1.2 Dating Attributes

Members of the `att.dataable` class share the following attributes:

**att.dataable** provides attributes for normalization of elements that contain dates, times, or datable events.

`@period` supplies a pointer to some location defining a named period of time within which the datable item is understood to have occurred.

**att.dataable.w3c** provides attributes for normalization of elements that contain datable events conforming to the *W3C XML Schema Part 2: Datatypes Second Edition*.

`@when` supplies the value of the date or time in a standard form, e.g. yyyy-mm-dd.

`@notBefore` specifies the earliest possible date for the event in standard form, e.g. yyyy-mm-dd.

`@notAfter` specifies the latest possible date for the event in standard form, e.g. yyyy-mm-dd.

`@from` indicates the starting point of the period in standard form, e.g. yyyy-mm-dd.

`@to` indicates the ending point of the period in standard form, e.g. yyyy-mm-dd.

The `when` attribute is used to specify a normalized form for any temporal expression, independently of how it is represented in the text, as in the following example:

```
<date when="1807-06-09">June 9th</date> The
period is approaching which will terminate my present
copartnership. On the <date when="1808-01-01">1st Jany.</date> next,
it expires by its own limitation.
```

The `period` attribute provides a convenient way of associating an event or date with a named period. Its value is a pointer which should indicate some other element where the period concerned is more precisely defined. A convenient location for such definitions is the `<taxonomy>` element in the `<classDecl>` (classification declaration) in the `<encodingDesc>` of a TEI Header. A `<taxonomy>` may contain simply a bibliographic reference to an external definition for it. More usefully, it may also contain a series of `<category>` elements, each with an identifier and a description. The identifier can then be used as the target for a `period` attribute. For example, a taxonomy of named periods might be defined as follows:

```
<taxonomy xml:id="greekperiods">
  <category xml:id="tyranny">
    <catDesc>Before 510 BC</catDesc>
  </category>
  <category xml:id="classical">
    <catDesc>Between 510 and 323 BC</catDesc>
  </category>
  <category xml:id="hellenistic">
    <catDesc>
      <ref target="http://www.wikipedia.com/wiki/Hellenistic">Hellenistic</ref>.  Com-
      monly treated as
      <date notBefore="-0323" notAfter="-0031">from
        the death of Alexander to the Roman conquest.</date>
    </catDesc>
  </category>
  <category xml:id="roman">
    <catDesc>
      <ref target="http://www.wikipedia.com/wiki/Roman_Empire">Roman</ref>
    </catDesc>
  </category>
  <category xml:id="christian">
    <catDesc> The Christian period technically starts at the
      birth of Jesus, but in
      practice is considered to date from the conversion of Constantine
```

```

    in <date when="0312">312 AD</date>. </catDesc>
  </category>
</taxonomy>

```

With these definitions in place, any datable element may be associated with a specific period:

```
<placeName period="#christian">Stauropolis</placeName>
```

The other dating attributes provided by this class support a wide range of methods of specifying temporal information in a normalized form. The *from* and *to* attributes may be used to express the beginning and ending of a period of time, for example:

```

<event xml:id="eMBB" from="1955-12-01"
  to="1956-12-20">
  <label>Montgomery Bus Boycott</label>
  <desc>A political and social protest campaign against the policy of
    racial segregation on the public transit system of the city of
    <placeName ref="#MONT">Montgomery</placeName>.</desc>
</event>

```

The *notBefore* and *notAfter* attributes may be used to express a range of possibilities for a particular date (or time). For example the following element, extracted from an imaginary prosopographic entry for Anne Calthorpe, indicates that although the exact date of her death is not known, it can be narrowed down to a particular range: from 22 August 1579 to 28 March 1582, inclusive. Ostensibly the encoder has evidence that Anne Calthorpe was alive on the 22nd of August 1579 and evidence that she was already dead on the 28th of March 1582.

```

<death notBefore="1579-08-22"
  notAfter="1582-03-28"/>

```

Since *when* is used for a particular date or time, *from* and *to* for a duration, and *notBefore* and *notAfter* for a date or time within a range, it makes no sense to use *when* in combination with one or more of the others. Thus these Guidelines at present recommend against the use of *when* in combination with any of *from*, *to*, *notBefore*, or *notAfter*.

The *from* or *to* attributes imply that the temporal expression to which they are attached signifies a duration, so the use of either with *notBefore* or *notAfter* means a duration is indicated.

|                 | <i>notBefore</i>   | <i>from</i>  |
|-----------------|--|--|
| <i>notAfter</i> | range of possibilities, inclusive                                      | duration from <i>from</i> to sometime before <i>notAfter</i> , inclusive |
| <i>to</i>       | duration from sometime after <i>notBefore</i> to <i>to</i> , inclusive | duration from <i>from</i> to <i>to</i> , inclusive                       |

Some further self-explanatory examples follow:

```
<birth when="1857-03-15">15 March 1857.</birth>
```

```

<birth notBefore="1857-03-01"
  notAfter="1857-04-30">Some time in
  March or April of 1857.</birth>

```

```
<residence from="1857-03-01"
  to="1857-04-30">Lived in Amsterdam
during March and April of 1857.</residence>
```

```
<date from="1857-03-01"
  notAfter="1857-04-30">From the 1st of March to
some time later in March or April of 1857.</date>
```

```
<residence notBefore="1857-03-01"
  to="1857-04-30">From the 1st of
March or sometime later to the end of April, 1857.</residence>
```

```
<residence from="1856-03" to="1858-04">From sometime in March of
1856 to sometime in April of 1858.</residence>
```

Normalization of date and time values permits the efficient processing of data (for example, to determine whether one event precedes or follows another). These examples all use the W3C standard format for representation of dates and times. Further examples, and discussion of some alternative approaches to normalization are given in section 13.3.6.3. *More Expressive Normalizations* below.

## 13.2 Names

### 13.2.1 Personal Names

The core `<rs>` and `<name>` elements can distinguish names in a text but are insufficiently powerful to mark their internal components or structure. To conduct nominal record linkage or even to create an alphabetically sorted list of personal names, it is important to distinguish between a family name, a forename and an honorary title. Similarly, when confronted with a string such as ‘John, by the grace of God, king of England, lord of Ireland, duke of Normandy and Aquitaine, and count of Anjou’, the analyst will often wish to distinguish amongst the various constituent elements present, since they provide additional information about the status, occupation, or residence of the person to whom the name belongs. The following elements are provided for these and related purposes:

- <persName>** (personal name) contains a proper noun or proper-noun phrase referring to a person, possibly including one or more of the person's forenames, surnames, honorifics, added names, etc.
- <surname>** contains a family (inherited) name, as opposed to a given, baptismal, or nick name.
- <forename>** contains a forename, given or baptismal name.
- <roleName>** contains a name component which indicates that the referent has a particular role or position in society, such as an official title or rank.
- <addName>** (additional name) contains an additional name component, such as a nickname, epithet, or alias, or any other descriptive phrase used within a personal name.
- <nameLink>** (name link) contains a connecting phrase or link used within a name but not regarded as part of it, such as *van der* or *of*.
- <genName>** (generational name component) contains a name component used to distinguish otherwise similar names on the basis of the relative ages or generations of the persons named.

In addition to the `att.naming` attributes mentioned above, all of the above elements are members of the class `att.personal`, and thus share the following attributes:

- att.personal** (attributes for components of names usually, but not necessarily, personal names) common attributes for those elements which form part of a name usually, but not necessarily, a personal name.

*@full* indicates whether the name component is given in full, as an abbreviation or simply as an initial.

*@sort* specifies the sort order of the name component in relation to others within the name.

The `<persName>` element may be used in preference to the general `<name>` element irrespective of whether or not the components of the personal name are also to be marked. The element `<persName>` is synonymous with the element `<name type="person">`, except that its *type* attribute allows for further subcategorization of the personal name itself, for example as a married, birth, pen, pseudo, or religious name. Consequently the following examples are equivalent:

```
That silly man
<rs ref="tag:projectname.org,2012:DPB1"
  type="person">David Paul Brown</rs> has suffered the
furniture of his office to be seized
the third time for rent.
```

```
That silly man
<rs ref="tag:projectname.org,2012:DPB1"
  type="person">
  <name>David Paul Brown</name>
</rs> has suffered ...
```

```
That silly man
<name ref="tag:projectname.org,2012:DPB1"
  type="person">David Paul Brown</name> has suffered ...
```

```
That silly man
<persName ref="tag:projectname.org,2012:DPB1">David Paul Brown</persName> has suffered
...
```

The `<persName>` element is more powerful than the `<rs>` and `<name>` elements because distinctive name components occurring within it can be marked as such.

Many cultures distinguish between a family or inherited *surname* and additional personal names, often known as *given names*. These should be tagged using the `<surname>` and `<forename>` elements respectively and may occur in any order:

```
<persName>
  <surname>Roosevelt</surname>,
<forename>Franklin</forename>
  <forename>Delano</forename>
</persName>
<persName>
  <forename>Franklin</forename>
  <forename>Delano</forename>
  <surname>Roosevelt</surname>
</persName>
```

The *type* attribute may be used with both `<forename>` and `<surname>` elements to provide further culture- or project-specific detail about the name component, for example:

```

<persName>
  <forename type="first">Franklin</forename>
  <forename type="middle">Delano</forename>
  <surname>Roosevelt</surname>
</persName>
<persName>
  <forename type="given">Margaret</forename>
  <forename type="unused">Hilda</forename>
  <surname type="birth">Roberts</surname>
  <surname type="married">Thatcher</surname>
</persName>
<persName type="religious">Muhammad Ali</persName>
<persName>
  <forename>Norman</forename>
  <surname type="complex">St John Stevas</surname>
</persName>

```

Values for the *type* attribute are not constrained, and may be chosen as appropriate to the encoding needs of the project. They may be used to distinguish different kinds of forename or surname, as well as to indicate the function a name component fills within the whole. In this example, we indicate that a surname is toponymic, and also point to the specific place name from which it is derived:

```

<persName>
  <forename>Johan</forename>
  <surname type="toponymic" ref="#dystvold">Dystvold</surname>
</persName>
<!-- ... -->
<placeName xml:id="dystvold">Dystvold</placeName>

```

The value *complex* was suggested above for the not uncommon case where the whole of a surname is composed of several other surname elements. These nested surnames may be individually tagged as well, together with appropriate type values:

```

<persName>
  <forename>Kara</forename>
  <surname type="complex">
    <surname type="paternal">Hattersley</surname>-
    <surname type="maternal">Smith</surname>
  </surname>
</persName>

```

The *full* attribute may be used to indicate whether a name is an abbreviation, initials, or given in full:

```

<persName>
  <forename full="abb">Maggie</forename>
  <surname>Thatcher</surname>
</persName>

```

These elements may be applied as the encoder considers appropriate, including cases where phrases or expressions are used to stand for surnames or forenames, as in the following:

```

<s>
  <persName>
    <forename>Peter</forename>
    <surname>son of Herbert</surname>
  </persName> gives the king 40 m. for
  having custody of the land and heir of <persName>
    <forename>John</forename>
    <surname>son of Hugh</surname>
  </persName>...
</s>

```

Similarly, patronymics may be treated as forenames, thus:

```

... but it remained for
<persName>
  <forename>Snorri</forename>
  <forename>Sturluson</forename>
</persName>
to combine the two traditions in cyclic form.

```

When a patronymic is used as a surname, however (e.g. by an individual who otherwise would have no surname, but lives in a culture which requires surnames), it may be tagged as such:

```

Even <persName>
  <forename>Finnur</forename>
  <surname>Jonsson</surname>
</persName>
acknowledged the artificiality of the procedure...

```

Alternatively, it may be felt more appropriate to mark a patronymic as a distinct kind of name, neither a forename nor a surname, using the <addName> element:

```

<persName>
  <forename>Egill</forename>
  <addName type="patronym">Skallagrmsson</addName>
</persName>

```

In the following example, the *type* attribute is used to distinguish a patronymic from other forenames:

```

<persName ref="tag:projectname.org,2012:pn9">
  <forename sort="2">Sergei</forename>
  <forename sort="3" type="patronym">Mikhailovic</forename>
  <surname sort="1">Uspensky</surname>
</persName>

```

This example also demonstrates the use of the *sort* attribute common to all members of the `model.persNamePart` class; its effect is to state the sequence in which <forename> and <surname> elements should be combined when constructing a sort key for the name.

Some names include generational or dynastic information, such as a number, or phrases such as ‘Junior’, or ‘the Elder’; these qualifications may also be used to distinguish similarly named but unrelated people. In either case, the <genName> element may be used to distinguish such labels from other parts of the name, as in the following examples:

```
<persName ref="tag:projectname.org,2012:HEMA1">
  <surname>Marques</surname>
  <genName>Junior</genName>,
  <forename>Henrique</forename>
</persName>
```

```
<persName>
  <forename>Charles</forename>
  <genName>II</genName>
</persName>
```

```
<persName>
  <forename>Rudolf</forename>
  <genName>II</genName>
  <surname type="dynasty">Hapsburg</surname>
</persName>
```

```
<persName>
  <surname>Smith</surname>
  <genName>Minor</genName>
</persName>
```

It is also often convenient to distinguish phrases (historically similar to the generational labels mentioned above) used to link parts of a name together, such as ‘von’, ‘of’, ‘de’ etc. It is often a matter of arbitrary choice whether such components are regarded as part of the surname or not; the `<nameLink>` element is provided as a means of making clear what the correct usage should be in a given case, as in the following examples:

```
<persName ref="tag:projectname.org,2012:DUD01">
  <roleName type="honorific" full="abb">Mme</roleName>
  <nameLink>de la</nameLink>
  <surname>Rochefoucault</surname>
</persName>
```

```
<persName>
  <forename>Walter</forename>
  <surname>de la Mare</surname>
</persName>
```

Finally, the `<addName>` and `<roleName>` elements are used to mark all name components other than those already listed. The distinction between them is that a `<roleName>` encloses an associated name component such as an aristocratic or official title which exists in some sense independently of its bearer. The distinction is not always a clear one. As elsewhere, the *type* attribute may be used with either element to supply culture- or application-specific distinctions. Some typical values for this attribute for names in the Western European tradition follow:

**nobility** An inherited or life-time title of nobility such as *Lord*, *Viscount*, *Baron*, etc.

**honorific** An academic or other honorific prefixed to a name e.g. *Doctor, Professor, Mrs.*, etc.

**office** Membership of some elected or appointed organization such as *President, Governor*, etc.

**military** Military rank such as *Colonel*.

**epithet** A traditional descriptive phrase or nick-name such as *The Hammer, The Great*, etc.

Note, however, that the *role* a person has in a given context (such as *witness, defendant*, etc. in a legal document) should not be encoded using the <roleName> element, since this is intended to mark roles which function as part of a person's name, not the role of the person bearing the name in general. Information about roles, occupations, etc. of a person are encoded within the <person> element discussed below in 13.3. *Biographical and Prosopographical Data*.

Here are some further examples of the usage of these elements:

```
<persName ref="tag:projectname.org,2012:PGK1">
  <roleName type="nobility">Princess</roleName>
  <forename>Grace</forename>
</persName>
```

```
<persName ref="tag:projectname.org,2012:GRM01"
  type="pseudo">
  <addName type="honorific">Grandma</addName>
  <surname>Moses</surname>
</persName>
```

```
<persName ref="tag:projectname.org,2012:SLWICL1">
  <roleName type="office">President</roleName>
  <forename>Bill</forename>
  <surname>Clinton</surname>
</persName>
```

```
<persName ref="tag:projectname.org,2012:MOGA1">
  <roleName type="military">Colonel</roleName>
  <surname>Gaddafi</surname>
</persName>
```

```
<persName ref="tag:projectname.org,2012:FRTG1">
  <forename>Frederick</forename>
  <addName type="epithet">the Great</addName>
</persName>
```

A name may have any combination of the above elements:

```
<persName ref="tag:projectname.org,2012:EGBR1">
  <roleName type="office">Governor</roleName>
  <forename sort="2">Edmund</forename>
  <forename full="init" sort="3">G.</forename>
```

```

<addName type="nick">Jerry</addName>
<addName type="epithet">Moonbeam</addName>
<surname sort="1">Brown</surname>
<genName full="abb">Jr</genName>.

</persName>

```

Although highly flexible, these mechanisms for marking personal name components will not cater for every personal name, nor for every processing need. Where the internal structure of personal names is highly complex or where name components are particularly ambiguous, feature structures are recommended as the most appropriate mechanism to mark and analyze them, as further discussed in chapter 18. *Feature Structures*.

White space is allowed and therefore significant between elements within `<name>`, `<persName>`, `<orgName>`, and `<placeName>`. Therefore

```

<persName> <forename>Mary</forename> <forename>Ann</forename> <nameLink>De</
nameLink><surname>Mint</surname> </persName>

```

encodes ‘Mary Ann DeMint’ and

```

<persName> <forename>Mary</forename><forename>Ann</forename> <nameLink>De</nameLink>
<surname>Mint</surname> </persName>

```

encodes ‘MaryAnn De Mint’. See 1.3.1.1.5. *XML Whitespace* for more information on whitespace in XML.

### 13.2.2 Organizational Names

In these Guidelines, we use the term ‘organization’ for any named collection of people regarded as a single unit. Typical examples include institutions such as ‘Harvard College’ or ‘the BBC’ and businesses such as ‘Apple’ or ‘Google’ but also racial or ethnic groupings or political factions where these are regarded as forming a single agency such as ‘the Scythians’ or ‘the Militant Tendency’. Giving a loosely-defined group of individuals a name often serves a particular political or social agenda and an analysis of the way such phrases are constructed and used may therefore be of considerable importance to the social historian, even where the objective existence of an ‘organization’ in this sense is harder to demonstrate than that of (say) a named person. In the case of businesses or other formally constituted institutions, the component parts of an organizational name may help to characterize the organization in terms of its perceived geographical location, ownership, likely number of employees, management structure, etc.

Like names of persons or places, organizational names can be marked up as referring strings or as proper names with the `<rs>` or `<name>` elements respectively. The element `<orgName>` is provided for use where it is desired to distinguish organizational names more explicitly.

**<orgName>** (organization name) contains an organizational name.

This element is a member of the same attribute classes as `<persName>`, as discussed above in 13.1.1. *Linking Names and Their Referents*.

The `<orgName>` element may be used to mark up any form of organizational name:

```

About a year back, a question of considerable
interest was agitated in the
<orgName type="voluntary"
ref="tag:projectname.org,2012:PA51">Pennsyla. Abolition Society</orgName>

```

This encoding is equivalent to, but more specific than, either of the following representations:

```
About a year back, a question of considerable
interest was agitated in the <rs ref="tag:projectname.org,2012:PAS1"
  type="org">
  <name>Pennsyla. Abolition Society</name>
</rs>.
```

```
About a year back, a question of considerable
interest was agitated in the
<name ref="tag:projectname.org,2012:PAS1"
  type="org">Pennsyla. Abolition
Society</name>.
```

As shown above, like the `<rs>` and `<name>` elements, the `<orgName>` element has a *key* attribute with which an external identifier such as a database key can be assigned to the organization name, and also a *ref* attribute which can be used to point directly to an `<org>` element containing information about the organization itself (see further 13.3.3. *Organizational Data*). Its *type* attribute should be used to characterize the name (rather than the organization), for example as an acronym:

```
Mr Frost will be able to earn an extra fee from
<orgName type="acronym">BSkyB</orgName>
rather than the
<orgName type="acronym">BBC</orgName>
```

as a phrase:

```
The feeling in <country>Canada</country> is one of
strong aversion to the <orgName type="phrase">United
States Government</orgName>, and of
predilection for self-government under
the
<orgName type="phrase">English Crown</orgName>
```

```
<orgName>The Justified Ancients of Mu Mu</orgName>
```

or as a composite of other kinds of name:

```
<orgName type="partnerNames">
  <surname>Ernst</surname> & <surname>Young</surname>
</orgName>
```

The components of an organization's name may include place names as well as personal names:

```
A spokesman from
<orgName type="regional">
  <orgName>IBM</orgName>
  <country>UK</country>
</orgName> said ...
```

or role names:

```
THE TICKET which you will receive herewith has been formed by
the <orgName>Democratic Whig <name type="role">party</name>
</orgName> after the most careful deliberation,
with a reference to all the great objects of NATIONAL, STATE,
COUNTY and CITY concern, and with a single eye to the <hi>Welfare and Best Interests of
the Community</hi>.
```

As indicated above, organizational names may also be specified hierarchically particularly where the named organization is itself a department or a branch of a larger organizational entity. ‘The Department of Modern History, Glasgow University’ is an example:

```
<orgName>
  <orgName>Department of Modern History</orgName>
  <orgName>
    <name type="city">Glasgow</name>
    <name type="role">University</name>
  </orgName>
</orgName>
```

### 13.2.3 Place Names

Like other proper nouns or noun phrases used as names, place names can simply be marked up with the <rs> element, or with the <name> element. For cartographers and historical geographers, however, the component parts of a place name provide important information about the relation between the name and some spot in space and time. They also provide important evidence in historical linguistics.

These Guidelines distinguish three ways of referring to places. A place name (represented using the <placeName> element) may consist of one or more names for hierarchically-organized geo-political or administrative units (see section 13.2.3.1. *Geo-political Place Names*). A place named simply in terms of geographical features such as mountains or rivers is represented using the <geogName> element (see section 13.2.3.2. *Geographic Names*). Finally, an expression consisting of phrases expressing spatial or other kinds of relationship between other kinds of named place may itself be regarded as a way of referring to a place, and hence as a kind of named place (see section 13.2.3.3. *Relative Place Names*).

**<placeName>** contains an absolute or relative place name.

**<geogName>** (geographical name) identifies a name associated with some geographical feature such as Windrush Valley or Mount Sinai.

As members of the `att.naming` class, all of these elements bear the attributes *key*, *ref*, and *nymRef* mentioned above. These attributes are primarily useful as a means of linking a place name with information about a specific place. Recommendations for the encoding of information about a place, as distinct from its name, are provided in 13.3.4. *Places* below.

Like the <persName> element discussed in section 13.2.1. *Personal Names*, the <placeName> element may be regarded simply as an abbreviation for the elements <name type="place"> or <rs type="place">. The following encodings are thus equivalent:<sup>83</sup>

```
After
spending some time in our <rs ref="tag:projectname.org,2012:NY1"
  type="place">modern <name ref="tag:projectname.org,2012:BA1"
  type="place">Babylon</name>
```

<sup>83</sup>Strictly, a suitable value such as *figurative* should be added to the two place names which are presented periphrastically in the second version of this example. This would preserve the distinction indicated by the choice of <rs> rather than <name> to encode them in the first version of this example.

```
</rs>, <name ref="tag:projectname.org,2012:NY1"
  type="place">New York</name>, I have proceeded to
the <rs ref="tag:projectname.org,2012:PH1"
  type="place">City of Brotherly Love</rs>.
```

```
After spending some
time in our <placeName ref="tag:projectname.org,2012:NY1">modern
<placeName ref="tag:projectname.org,2012:BA1">Babylon</placeName>
</placeName>,
<placeName ref="tag:projectname.org,2012:NY1">New
York</placeName>, I have proceeded to the <placeName ref="tag:projectname.org,
2012:PH1">City of
Brotherly Love</placeName>.
```

### 13.2.3.1 Geo-political Place Names

A place name may contain text with no indication of its internal structure:

```
<placeName>Rochester,
NY</placeName>
```

More usually however, a place name of this kind will be further analysed in terms of its constitutive geo-political or administrative units. These may be arranged in ascending sequence according to their size or administrative importance, for example: ‘Rochester, New York’, or as a single such unit, for example ‘Belgium’. These Guidelines provide a hierarchy of generic element names, each of which may be more exactly specified by means of a *type* attribute:

- <district>** contains the name of any kind of subdivision of a settlement, such as a parish, ward, or other administrative or geographic unit.
  - <settlement>** contains the name of a settlement such as a city, town, or village identified as a single geo-political or administrative unit.
  - <region>** contains the name of an administrative unit such as a state, province, or county, larger than a settlement, but smaller than a country.
  - <country>** contains the name of a geo-political unit, such as a nation, country, colony, or commonwealth, larger than or administratively superior to a region and smaller than a bloc.
  - <bloc>** contains the name of a geo-political unit consisting of two or more nation states or countries.
- These elements are all members of the `model.placeNamePart` class, members of which may be used anywhere that text is permitted, including within each other as in the following examples:

```
<placeName>
  <settlement type="city">Rochester</settlement>,
  <region type="state">New York</region>
</placeName>
```

```
<placeName ref="tag:projectname.org,2012:LSEA1">
  <country type="nation">Laos</country>,
  <bloc type="sub-continent">Southeast Asia</bloc>
</placeName>
```

```
<placeName>
  <district type="arrondissement">6ème</district>
  <settlement type="city">Paris, </settlement>
  <country>France</country>
</placeName>
```

### 13.2.3.2 Geographic Names

Places may also be named in terms of geographic features such as mountains, lakes, or rivers, independently of geopolitical units. The `<geogName>` is provided to mark up such names, as an alternative to the `<placeName>` element discussed above. For example:

```
<geogName ref="tag:projectname.org,2012:MIRI1"
  type="river">Mississippi River</geogName>
```

In addition to the usual phrase level elements, the `<geogName>` element may contain the following specialized element:

**<geogFeat>** (geographical feature name) contains a common noun identifying some geographical feature contained within a geographic name, such as valley, mount, etc.

Where the `<geogFeat>` element is used to characterize the kind of geographic feature being named, the `<name>` element will generally also be used to mark the associated proper noun or noun phrase:

```
<geogName ref="tag:projectname.org,2012:MIRI1"
  type="river">
  <name>Mississippi</name>
  <geogFeat>River</geogFeat>
</geogName>
```

A more complex example, showing a variety of practices, follows:

```
The isolated ridge
separates two great corridors which run from <name ref="tag:projectname.org,2012:GLC01"
  type="place">Glencoe</name> into
<geogName ref="tag:projectname.org,2012:GLET1"
  type="glen">
  <geogFeat>Glen</geogFeat>
  <name>Etive</name>
</geogName>, the
<geogName ref="tag:projectname.org,2012:LAGA1"
  type="hill">
  <geogFeat xml:lang="gd">Lairig</geogFeat>
  <name>Gartain</name>
</geogName> and the

<geogName ref="tag:projectname.org,2012:LAEI1"
  type="hill">
  <geogFeat xml:lang="gd">Lairig</geogFeat>
  <name>Eilde</name>
</geogName>
```

The Gaelic word *lairig* may be glossed as *sloping hill face*. The most efficient way of including this information in the above encoding would be to create a separate `<nym>` element for this component of the name and then point to it using the `nymRef` attribute, as further discussed in 13.3.5. *Names and Nyms*.

### 13.2.3.3 Relative Place Names

All the place name specifications so far discussed are *absolute*, in the sense that they define only one place. A place may however be specified in terms of its relationship to another place, for example ‘10 miles northeast of Paris’ or ‘near the top of Mount Sinai’. These *relative place names* will contain a place name which acts as a referent (e.g. ‘Paris’ and ‘Mount Sinai’). They will also contain a word or phrase indicating the position of the place being named in relation to the referent (e.g. ‘the top of’, ‘north of’). A distance, possibly only vaguely specified, between the referent place and the place being indicated may also be present (e.g. ‘10 miles’, ‘near’).

Relative place names may be encoded using the following elements in combination with either a `<placeName>` or a `<geogName>` element.

**<offset>** marks that part of a relative temporal or spatial expression which indicates the direction of the offset between the two place names, dates, or times involved in the expression.

**<measure>** contains a word or phrase referring to some quantity of an object or commodity, usually comprising a number, a unit, and a commodity name.

Some examples of relative place names are:

```
<placeName ref="tag:projectname.org,2012:NRPA1">
  <offset>near the top of</offset>
  <geogName>
    <geogFeat>Mount</geogFeat>
    <name>Sinai</name>
  </geogName>
</placeName>
```

```
<placeName>
  <measure>20 km</measure>
  <offset>north of</offset>
  <settlement type="city">Paris</settlement>
</placeName>
```

If desired, the distance specified may be normalized using the *unit* and *quantity* attributes of `<measure>`:

```
<placeName ref="tag:projectname.org,2012:Duncan">
  <measure unit="km" quantity="17.7">11 miles</measure>
  <offset>Northwest of</offset>
  <settlement type="city">Providence</settlement>, <region type="state">RI</region>
</placeName>
```

The internal structure of place names is like that of personal names—complex and subject to an enormous amount of variation across time and different cultures. The recommendations in this section should however be adequate for a majority of users and applications; they may be extended using the mechanisms described in chapter 23.3. *Personalization and Customization* to add new elements to the existing classes. When the focus of interest is on the name components themselves, as in place name studies for example, the elements discussed in 13.3.5. *Names and Nyms* may also be of use. Alternatively, the meaning structure itself may be represented using feature structures (18. *Feature Structures*).

## 13.3 Biographical and Prosopographical Data

This module defines a number of special purpose elements which can be used to markup biographical, historical, and prosopographical data. We envisage a number of users and uses for these elements. For example, an encoder may be interested in creating or converting a set of biographical records, for example of the type found in a Dictionary of National Biography. Another use is the creation or conversion of a database-like collection of information about a group of people, such as the people referenced in a marked-up collection of documents, or persons who have served

as informants in the creation of spoken corpora. It is also appropriate to use these elements to register information relating to those who have taken part in the creation of a TEI document.

To cater for this diversity, these Guidelines propose a flexible strategy, in which encoders may choose for themselves the approach appropriate to their needs. If one were interested, for example, in converting existing DNB-type records, and wanted to preserve the text as is, the <person> element (see 13.3.2. *The Person Element*) could simply contain the text of an article, placed within <p> elements, possibly using elements such as <name> or <date> to mark up features of that text. For a more structured entry, however, one would extract the data and place information contained in the text, and encode it directly using the more specific elements described in this section.

### 13.3.1 Basic Principles

Information about people, places, and organizations, of whatever type, essentially comprises a series of statements or assertions relating to:

- characteristics or *traits* which do not, by and large, change over time
- characteristics or *states* which hold true only at a specific time
- *events* or incidents which may lead to a change of state or, less frequently, trait.

‘Characteristics’ or ‘traits’ are typically independent of an individual’s volition or action and can be either physical, such as sex or hair and eye colour, or cultural, such as ethnicity, caste, or faith. The distinction is not entirely straightforward, however: while sex is fairly obviously a physical trait, gender should rather be regarded as culturally determined, and the division of mankind into different ‘races’, proposed by early (white European) anthropologists on the basis of physical characteristics such as skin colour, hair type and skull measurements, is now considered to be more a social or mental construct. Furthermore, while some characteristics will obviously change over time, hair colour for example, none, in principle—not even sex—is immutable.

‘States’ include, for example, marital status, place of residence and position or occupation. Such states have a definite duration, that is, they have a beginning and an end and are typically a consequence of the individual’s own action or that of others.

By ‘changes in state’ are meant the events in a person’s life such as birth, marriage, or appointment to office; such events will normally be associated with a specific date or a fairly narrow date-range. Changes in states can also cause or be caused by changes in characteristics. Any statement or assertion on any of these aspects of a person’s life will be based on some source, possibly multiple sources, possibly contradictory. Taking all this into account it follows that each such statement or assertion needs to be able to be documented, put into a time frame and be relatable to other statements or assertions of the same or any of the other types.

The elements defined by the module described in this chapter may, for the most part, all be regarded as specializations of one or other of the above three classes. Generic elements for state, trait, and event are also defined:

**<state>** contains a description of some status or quality attributed to a person, place, or organization often at some specific time or for a specific date range.

**<trait>** contains a description of some status or quality attributed to a person, place, or organization typically, but not necessarily, independent of the volition or action of the holder and usually not at some specific time or for a specific date range.

**<event>** contains data relating to any kind of significant event associated with a person, place, or organization.

*@where* indicates the location of an event by pointing to a <place> element

**<listEvent>** (list of events) contains a list of descriptions, each of which provides information about an identifiable event.

### 13.3.2 The Person Element

Information about a person, as distinct from references to a person, for example by name, is grouped together within a <person> element. Information about a group of people regarded as a single entity (for example ‘the audience’ of a performance) may be encoded using the <personGrp> element. Note however that information about a group of people with a distinct identity (for example a named theatrical troupe) should be recorded using the <org> element described in section 13.3.3. *Organizational Data* below.

These elements may appear only within a `<listPerson>` element, which groups such descriptions together, and optionally also describes relationships amongst the people listed.

**<listPerson>** (list of persons) contains a list of descriptions, each of which provides information about an identifiable person or a group of people, for example the participants in a language interaction, or the people referred to in a historical source.

**<listRelation>** provides information about relationships identified amongst people, places, and organizations, either informally as prose or as formally expressed relation links.

One or more `<listPerson>` elements may be supplied within the `<particDesc>` (participant description) element in the `<profileDesc>` element of a TEI header (see 2.4. *The Profile Description*). Like other forms of list, however, the `<listPerson>` can also appear within the body of a text when the module defined by this chapter is included in a schema.

The *type* attribute may be used to distinguish lists of people of different kinds where this is considered convenient:

```
<profileDesc>
  <particDesc>
    <listPerson type="historical">
      <person xml:id="ART1">
        <persName>Arthur</persName>
      </person>
      <person xml:id="BERT1">
        <persName>Bertrand</persName>
      </person>
    <!-- ... -->
  </listPerson>
  <listPerson type="mythological">
    <person xml:id="ART2">
      <persName>Arthur</persName>
    </person>
    <person xml:id="BERT2">
      <persName>Bertrand</persName>
    </person>
  <!-- ... -->
</listPerson>
</particDesc>
</profileDesc>
```

The `<person>` element carries several attributes. As a member of the classes `att.global.responsibility`, and `att.editLike`, which is a subclass of the `att.source` class, it carries the usual attributes for providing details about the information recorded for that person, such as its reliability or source:

**att.global.responsibility** provides attributes indicating the agent responsible for some aspect of the text, the markup or something asserted by the markup, and the degree of certainty associated with it.

`@cert` (certainty) signifies the degree of certainty associated with the intervention or interpretation.

`@resp` (responsible party) indicates the agency responsible for the intervention or interpretation, for example an editor or transcriber.

**att.editLike** provides attributes describing the nature of an encoded scholarly intervention or interpretation of any kind.

`@evidence` indicates the nature of the evidence supporting the reliability or accuracy of the intervention or interpretation.

**att.source** provides attributes for pointing to the source of a bibliographic reference.

`@SOURCE` provides a pointer to the bibliographical source from which a quotation or citation is drawn.

In addition, a small number of very commonly used personal properties may be recorded using attributes specific to `<person>` and `<personGrp>`:

**<person>** provides information about an identifiable individual, for example a participant in a language interaction, or a person referred to in a historical source.

**@role** specifies a primary role or classification for the person.

**@sex** specifies the sex of the person.

**@age** specifies an age group for the person.

**<personGrp>** (personal group) describes a group of individuals treated as a single person for analytic purposes.

These attributes are intended for use where only a small amount of data is to be encoded in a more or less normalized form, possibly for many person elements, for example when encoding basic facts about respondents to a questionnaire. When however a more detailed encoding is required for all kinds of information about a person, for example in a historical gazetteer, then it will be more appropriate to use the elements **<age>**, **<sex>** and others described elsewhere in this chapter.

Note that the *age* attribute is not intended to record the person's age expressed in years, months, or other temporal unit. Rather it is intended to record into which age bracket, for the purposes of some analysis, the person falls. A simple (perhaps too simple to be useful) binary classification of age brackets would be child and adult. The actual age brackets useful to various projects are likely to be varied and idiosyncratic, and thus these Guidelines make no particular recommendation as to possible values. Instead, individual projects are recommended to define the values they use in their own customization file, using a declaration like the following:

```
<elementSpec ident="person"
  module="namesdates" mode="change">
  <attList>
    <attDef mode="replace" ident="age">
      <datatype>
        <rng:ref name="data.enumerated"/>
      </datatype>
      <valList type="closed">
        <valItem ident="child">
          <desc>less than 18 years of age</desc>
        </valItem>
        <valItem ident="adult">
          <desc>18 to 65 years of age</desc>
        </valItem>
        <valItem ident="retired">
          <desc>over 65 years of age</desc>
        </valItem>
      </valList>
    </attDef>
  </attList>
</elementSpec>
```

The above declaration, were it properly placed in a customization file, establishes that the *age* attribute of **<person>** has only three possible values, child, adult, and retired. For more information on customization see *23.3. Personalization and Customization*.

The **<person>** element may contain many sub-elements, each specifying a different property of the person being described. The remainder of this section describes these more specific elements. For convenience, these elements are grouped into three classes, corresponding with the tripartite division outlined above: one for traits, one for states and one for events. Each class may contain specific elements for common types of biographical information, and contains a generic element for other, user-defined, types of information.

All the elements in these three classes belong to the attribute class **att.datable**, which provides the following attributes:

**att.datable.w3c** provides attributes for normalization of elements that contain datable events conforming to the *W3C XML Schema Part 2: Datatypes Second Edition*.

**@when** supplies the value of the date or time in a standard form, e.g. yyyy-mm-dd.

*@notBefore* specifies the earliest possible date for the event in standard form, e.g. yyyy-mm-dd.

*@notAfter* specifies the latest possible date for the event in standard form, e.g. yyyy-mm-dd.

*@from* indicates the starting point of the period in standard form, e.g. yyyy-mm-dd.

*@to* indicates the ending point of the period in standard form, e.g. yyyy-mm-dd.

as discussed in 13.1. *Attribute Classes Defined by This Module* above.

### 13.3.2.1 Personal Characteristics

The `model.persStateLike` class contains elements describing physical or socially-constructed characteristics, traits, or states of a person. Members of the class comprise the following specific elements:

**<faith>** specifies the faith, religion, or belief set of a person.

**<langKnowledge>** (language knowledge) summarizes the state of a person's linguistic knowledge, either as prose or by a list of `<langKnown>` elements.

**<nationality>** contains an informal description of a person's present or past nationality or citizenship.

**<sex>** specifies the sex of a person.

**<age>** specifies the age of a person.

**<socecStatus>** (socio-economic status) contains an informal description of a person's perceived social or economic status.

**<persName>** (personal name) contains a proper noun or proper-noun phrase referring to a person, possibly including one or more of the person's forenames, surnames, honorifics, added names, etc.

**<occupation>** contains an informal description of a person's trade, profession or occupation.

**<residence>** describes a person's present or past places of residence.

**<affiliation>** contains an informal description of a person's present or past affiliation with some organization, for example an employer or sponsor.

**<education>** contains a description of the educational experience of a person.

**<floruit>** contains information about a person's period of activity.

**<state>** contains a description of some status or quality attributed to a person, place, or organization often at some specific time or for a specific date range.

**<trait>** contains a description of some status or quality attributed to a person, place, or organization typically, but not necessarily, independent of the volition or action of the holder and usually not at some specific time or for a specific date range.

All, apart from `<langKnowledge>`, allow content of ordinary prose containing phrase-level elements.

```
<socecStatus ref="tag:projectname.org,2012:AB1">Status AB1 in the RG Classification scheme</socecStatus>
```

The meanings of concepts such as sex, nationality, or age are highly culturally-dependent, and the encoder should take particular care to be explicit about any assumptions underlying their usage of them. For example, when recording personal age in different cultures, there may be different assumptions about the point from which age is reckoned. A statement of the practice adopted in a given encoding may usefully be provided in the `<editorialDecl>` element discussed in 2.3.3. *The Editorial Practices Declaration*.

The `<langKnowledge>` element contains either paragraphs or a number of `<langKnown>` elements; it may take a *tags* attribute, which provides one or more standard codes or 'tag's for the languages. The `<langKnown>` element must have a *tag* attribute, which indicates the language with the same kind of 'language tag'. These 'language tags' are discussed in detail in *vi.1 Language Identification*.

Furthermore, the `<langKnown>` element also has a *level* attribute to indicate the level of the person's competence in the language. It is thus possible either to say:

```
<langKnowledge tags="ff fr wo en">
  <p>Speaks fluent Fulani, Wolof, and French. Some knowledge of English.</p>
</langKnowledge>
```

or

```
<langKnowledge>
  <langKnown level="fluent" tag="ff">Fulani</langKnown>
  <langKnown level="fluent" tag="wo">Wolof</langKnown>
  <langKnown level="fluent" tag="fr">French</langKnown>
  <langKnown level="basic" tag="en">English</langKnown>
</langKnowledge>
```

The `<sex>` element carries a *value* attribute to give values from a project-internal taxonomy, or an external standard, such as vCard's sex property <http://microformats.org/wiki/gender-formats> (in which M indicates male, F indicates female, O indicates other, N indicates none or not applicable, U indicates unknown) or the often used ISO 5218:2004 *Representation of Human Sexes* [http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266\\_ISO\\_IEC\\_5218\\_2004\(E\\_F\).zip](http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266_ISO_IEC_5218_2004(E_F).zip) (in which 0 indicates unknown; 1 indicates male; 2 indicates female; and 9 indicates not applicable, although the ISO standard is widely considered inadequate).

```
<sex value="F">female</sex>
```

As elsewhere, these coded values may be used as an alternative to or normalization of the actual descriptive text contained in the element. The previous example might equally well be given as

```
<sex value="F"/>
```

The generic `<trait>` and `<state>` elements are also a member of this class,

**<trait>** contains a description of some status or quality attributed to a person, place, or organization typically, but not necessarily, independent of the volition or action of the holder and usually not at some specific time or for a specific date range.

**<state>** contains a description of some status or quality attributed to a person, place, or organization often at some specific time or for a specific date range.

These elements can be used to extend the range of information supplied about an individual's personal characteristics. Either may contain an optional `<label>` element, used to provide a human-readable specification for the characteristic concerned and a description of the feature itself supplied within a `<desc>` element. These may be followed by one or more `<p>` elements supplying more detailed information about the trait. In either case, these may be followed by one or more notes or bibliographical references. The *type*, *ref*, and *key* attributes may be used to indicate a fuller definition of the combination of feature and value.

```
<trait type="ethnicity" key="alb">
  <label>Ethnicity</label>
  <desc>Ethnic Albanian.</desc>
</trait>
```

These elements are provided as a simple means of extending the set of descriptive features available in a standardized way. For example, there are no predefined elements for such features as eye or hair colour. If these are to be recorded, they may simply be added as new types of trait:

```
<trait type="physical">
  <label>eye colour</label>
  <desc>blue</desc>
```

```

</trait>
<trait type="physical">
  <label>hair colour</label>
  <desc>brown</desc>
</trait>

```

If none of the more specialized elements listed above is appropriate, then a choice must be made between the two generic elements <trait> and <state>. If you wish to distinguish between characteristics that are generally perceived to be transient and those which are generally considered unchanging, use <state> for the former, and <trait> for the latter. It may also be helpful to note that traits are typically, but not necessarily, independent of the volition or action of the holder. If the distinction between state and trait is not considered relevant or useful, use <state>.

The <persName> element is repeatable and can, like all TEI elements, take the attribute *xml:lang* to indicate the language of the content of the element, as well as a *type* attribute to indicate the type of name, whether a nickname, maiden or birth name, alternative form, etc. This is useful in cases where, for example, a person is known by a Latin name and also by any number of vernacular names, many or all of which may have claims to ‘authenticity’. In order to ensure uniformity, the method generally employed in the library world has been to accept the form found in some authority file, for example that of the American Library of Congress, as the ‘base’ or ‘neutral’ form. Feelings can run high on this matter, however, and people are often reluctant to accept as ‘neutral’ an overtly foreign form of the name of their local saint or hero. Within the <person> element any number of variant forms of a name can be given, with no prioritization, and hence less likelihood of offence. The Icelandic scholar and manuscript collector Árni Magnússon, to give his name in standard modern Icelandic spelling, is known in Danish as Arne Magnusson, the form which he himself, as a long term resident of Denmark, generally used; there is also a Latinized form, Arnas Magnæus, which he used in his scholarly writings. All three forms can be given, and in any order:

```

<person xml:id="ArnMag">
  <persName xml:lang="is">Árni Magnússon</persName>
  <persName xml:lang="da">Arne Magnusson</persName>
  <persName xml:lang="la">Arnas Magnæus</persName>
</person>

```

At the other extreme, a person may be named periphrastically as in the following example:

```

<person xml:id="simon_son_of_richard2">
  <persName>Simon, son of Richard</persName>
  <residence>
    <placeName>
      <region>Essex</region>
    </placeName>
  </residence>
  <floruit notBefore="1219" notAfter="1223">1219-1223</floruit>
</person>

```

Alternatively, the generic <name> element may be used for all of the naming components in a description. For example, a description of the first living held by the Icelandic clergyman and poet Jón Oddsson Hjaltalín might be tagged as follows:

```

<state type="office" from="1777-04-07"
  to="1780-07-12">
  <p>Jón's first living – which he apparently accepted rather reluctantly – was at
  <name type="place">Háls í Hamarsfirði</name>, <name type="place">Múlasýsla</name>,
  to which

```

he was presented on 7 April 1777. He was ordained the following month and spent three years at Háls, but was never happy there, due largely to the general penury in which he was forced to live – a recurrent theme throughout the early part of his life. In June of 1780 the bishop recommended that Jón should `<q xml:lang="da">promoveres til andet bedre kald, end det hand hidindtil har havt</q>`, and on 12 July it was agreed that he should exchange livings with

```
<name type="person"
  ref="tag:projectname.org,2012:ThorJon">sr. Þórður Jónsson</name> at
<name type="place">Kálfafell á Síðu</name>,
<name type="place">Skaftafellssýsla</name>.</p>
<bibl>ÞÍ, Stms I.15, p. 733.</bibl>
<bibl>ÞÍ, Stms I.17, p. 102.</bibl>
</state>
```

Similarly, the generic `<state>` or `<trait>` element may be used in preference to the more specific elements listed above:

```
<state type="nationality"
  notBefore="2002-01-15">
  <label>Nationality</label>
  <desc>American citizen from 15 January 2002.</desc>
</state>
```

is the same as:

```
<nationality notBefore="2002-01-15">American      citizen      from      15      January
2002.</nationality>
```

or even:

```
<nationality notBefore="2002-01-15"
  key="US"/>
```

### 13.3.2.2 Personal Events

Events in a person's history are not characteristics of an individual, but often cause an individual to gain such characteristics, or to enter a new state. Most such events, for example marriage, appointment, promotion, or a journey may be recorded using the generic element `<event>`, which may be grouped with `<listEvent>`, and has a content model similar to that of `<state>` and `<trait>`. The chief difference is that `<event>` can include a `<placeName>` element to identify the name of the place where the event occurred.

Two particular events in a persons life, namely birth and death, are both ubiquitous and usually considered particularly important, and thus may be represented by specialized elements for the purpose:

**<birth>** contains information about a person's birth, such as its date and place.

**<death>** contains information about a person's death, such as its date and place.

In the following example, we give a brief summary of the wedding of Jane Burden to the English writer, designer, and socialist William Morris, encoded as an `<event>` element embedded within the `<person>` element used to record data about Morris, though we could equally well have embedded the `<event>` element within the `<person>` element for Burden, or have encoded it independently of either `<person>` element:

```

<person xml:id="WM">
<!-- ... -->
  <event type="marriage" when="1859-04-26">
    <label>Marriage</label>
    <desc>
      <name type="person" ref="#WM">William Morris</name> and <name type="person"
      ref="http://en.wikipedia.org/wiki/Jane_Burden">Jane Burden</name> were
      married at <name type="place">St Michael's Church, Ship Street, Oxford</name>
on
    <date when="1859-04-26">26 April 1859</date>. The wedding was
      conducted by Morris's friend <name type="person" ref="#RWD">R. W.
      Dixon</name> with <name type="person" ref="#CBF">Charles
      Faulkner</name> as
      the best man. The bride was given away by her father,
      <name type="person" ref="#RB">Robert Burden</name>.
      According to the account that <name type="person"
      ref="http://en.wikipedia.org/wiki/Edward_Burne-Jones">Burne-Jones</name>
      gave <name type="person" ref="#JWM">Mackail</name>
    <quote>M. said to Dixon beforehand <said>Mind
      you don't call her Mary</said> but he did</quote>. The entry in the
      Register reads: <quote>William Morris, 25, Bachelor Gentleman, 13
      George Street, son of William Morris decd. Gentleman. Jane Burden,
      minor, spinster, 65 Holywell Street, d. of Robert Burden,
      Groom.</quote> The witnesses were Jane's parents and Faulkner. None of
      Morris's family attended the ceremony. Morris presented Jane with a
      plain gold ring bearing the London hallmark for 1858. She gave her
      husband a double-handled antique silver cup.</desc>
    <bibl>J. W. Mackail, <title>The Life of William Morris</title>, 1899.</bibl>
  </event>
</person>
<person xml:id="RB">
  <persName>Robert Burden</persName>
</person>
<person xml:id="RWD">
  <persName>R.W. Dixon</persName>
</person>
<person xml:id="CBF">
  <persName>Charles Faulkner</persName>
</person>
<person xml:id="EBJ">
  <persName>
    <forename>Edward</forename>
    <surname>Burne-Jones</surname>
  </persName>
</person>
<person xml:id="JWM">
  <persName>J.W. Mackail</persName>
</person>

```

In this example the *ref* attributes on the various `<name>` elements point either to an external source or to a `<person>` element within which other information about the person named may be found. As further discussed below (13.3.2.3. *Personal Relationships*), a `<relation>` element may then be used to link them in a more meaningful way:

```

<relation name="spouse" mutual="#WM #JBM"/>
<relation name="friend" mutual="#WM #RWD"/>

```

```
<relation name="parent" active="#RB"
  passive="#JBM"/>
```

As mentioned above, all these elements, both the specific and the generic, are members of the `att.dataable` attribute class, which means they can be limited in terms of time. The following encoding, for example, demonstrates that the person named David Jones changed his name in 1966 to David Bowie:

```
<person xml:id="DB">
  <persName notAfter="1966">David Jones</persName>
  <persName notBefore="1966">David Bowie</persName>
</person>
```

All the generic elements are also members of the `att.global.responsibility` and `att.editLike` classes. These classes make available the attributes *cert*, to indicate the degree of certainty, *resp*, the agency responsible, *evidence*, the nature of the evidence used, and *source*, a pointer to a resource from which the information derives. In this way it is possible, in the case of multiple and conflicting sources, to provide more than one view of what happened, as in the following example:

```
<event type="birth" resp="#XYZ" cert="high">
  <p>Born in <name type="place">Brixton</name> on 8 January 1947.</p>
</event>
<event type="birth" resp="#ABC" cert="low">
  <p>Born in <name type="place">Berkhamsted</name> on 9 January 1947.</p>
</event>
```

### 13.3.2.3 Personal Relationships

When the module defined by this chapter is included in a schema, the following two elements may be used to document relationships amongst the persons, places, or organizations identified:

**<listRelation>** provides information about relationships identified amongst people, places, and organizations, either informally as prose or as formally expressed relation links.

**<relation>** (relationship) describes any kind of relationship or linkage amongst a specified group of places, events, persons, objects or other items.

*@name* supplies a name for the kind of relationship of which this is an instance.

*@active* identifies the ‘active’ participants in a non-mutual relationship, or all the participants in a mutual one.

*@mutual* supplies a list of participants amongst all of whom the relationship holds equally.

*@passive* identifies the ‘passive’ participants in a non-mutual relationship.

These elements are both members of the `att.typed` class, from which they inherit the *type* and *subtype* attributes in the usual way. The value specified for either attribute on a `<listRelation>` element is implicitly applicable to all of its child `<relation>` elements, unless overridden.

A *relationship*, as defined here, may be any kind of describable link between specified participants. A participant (in this sense) might be a person, a place, or an organization. In the case of persons, therefore, a relationship might be a social relationship (such as employer/employee), a personal relationship (such as sibling, spouse, etc.) or something less precise such as ‘possessing shared knowledge’. A relationship may be *mutual*, in that all the participants engage in it on an equal footing (for example the ‘sibling’ relationship); or it may not be if participants are not identical with respect to their role in the relationship (for example, the ‘employer’ relationship). For non-mutual relationships, only two kinds of role are currently supported; they are named *active* and *passive*. These names are chosen to reflect the fact that non-mutual relations are *directed*, in the sense that they are most readily described by a transitive verb, or a verb phrase of the form *is X of* or *is X to*. The subject of the verb is classed as *active*; the direct object of the verb, or the object of the concluding preposition, as *passive*. Thus parents are ‘active’ and children ‘passive’ in the

relationship ‘parent’ (interpreted as *is parent of*); the employer is ‘active’, the employee ‘passive’, in the relationship *employs*. These relationships can be inverted: parents are ‘passive’ and children ‘active’ in the relationship *is child of*; similarly ‘works for’ inverts the active and passive roles of ‘employs’.

For example:

```
<listRelation>
  <relation name="parent" active="#P1 #P2"
    passive="#P3 #P4"/>
  <relation name="spouse" mutual="#P1 #P2"/>
  <relation type="social" name="employer"
    active="#P1" passive="#P3 #P4"/>
</listRelation>
```

This example defines the relationships amongst a number of people not further described here; we assume however that each person has been allocated an identifier such as P1, P2, etc. which can be linked to using references such as #P1, #P2, etc. Then the above set of <relation> elements describe the following three relationships amongst the people referenced:

- P1 and P2 are parents of P3 and P4.
- P1 and P2 are linked in a mutual relationship called ‘spouse’—that is, P2 is the spouse of P1, and P1 is the spouse of P2.
- P1 has the social relationship ‘employer’ with respect to P3 and P4.

Relationships within places and organizations are further discussed in the relevant sections below. Relationships between for example organizations and places, or places and persons, may be handled in exactly the same way.

### 13.3.3 Organizational Data

The <org> and <listOrg> elements are used to store data about an organization such as its preferred name, its locations, or key persons within it.

**<org>** (organization) provides information about an identifiable organization such as a business, a tribe, or any other grouping of people.

**<listOrg>** (list of organizations) contains a list of elements, each of which provides information about an identifiable organization.

These elements are intended to be used in a way analogous to the <place> and <person> elements discussed elsewhere in this chapter, that is to provide a unique wrapper element for information about an entity, distinct from references to that entity which are typically encoded using a naming element such as <name type="org"> or <orgName>. The content of a naming element will represent the way an organization is named in a given context; the content of an <org> represents the information known to the encoder about that organization, gathered together in a single place, and independent of its textual realization.

An organization is not the same thing as a list or group of people because it has an identity of its own. That identity may be expressed solely in the existence of a name (for example ‘The Scythians’), but is likely to consist in the combination of that name with a number of events, traits, or states which are considered to apply to the organization itself, rather than any of its members. For example, a sports team might be described in terms of its membership (a <listPerson>), its fixtures (a <listPlace>), its geographical affiliation (a <placeName>), or any combination of these. It will also have properties which may be used to categorize it in some way such as the kind of sport played, whether the team is amateur or professional, and so on: these are probably best dealt with by means of the *type* attribute. However, it is the name of the sports team alone which identifies it.

The content model for <org> permits any mixture of generic <state>, <trait>, or <event> elements: the presence of the <orgName> element described in 13.2.2. *Organizational Names* is however strongly recommended.

In other respects, the <org> element is used in much the same way as <place> or <person>. An organization may have different names at different times:

```
<org xml:id="fab4">
  <orgName notAfter="1960">The Silver Beetles</orgName>
```

```
<orgName from="1960-08">The Beatles</orgName>
</org>
```

The names of the people making up an organization can also change over time, (if they are known at all). For example:

```
<org xml:id="FAB4">
  <orgName notAfter="1960">The Silver Beatles</orgName>
  <orgName notBefore="1960">The Beatles</orgName>
  <state type="membership" from="1960-08"
    to="1962-05">
    <desc>
      <persName>John Lennon</persName>
      <persName>Paul McCartney</persName>
      <persName>George Harrison</persName>
      <persName>Stuart Sutcliffe</persName>
      <persName>Pete Best</persName>
    </desc>
  </state>
  <state type="membership" notBefore="1963">
    <desc>
      <persName>John Lennon</persName>
      <persName>Paul McCartney</persName>
      <persName>George Harrison</persName>
      <persName>Ringo Starr</persName>
    </desc>
  </state>
</org>
```

An <org> may contain subordinate <org>s:

```
<org xml:id="OUCS">
  <orgName>Oxford University Computing Services</orgName>
  <org xml:id="OUCSig">
    <orgName>Information and Support Group</orgName>
  </org>
  <org xml:id="OUCSig">
    <orgName>Infrastructure Group</orgName>
    <org xml:id="OUCSig.nt">
      <orgName>Networking Team</orgName>
    </org>
    <org xml:id="OUCSig.sdt">
      <orgName>System Development Team</orgName>
    </org>
  </org>
  <org xml:id="OUCSltg">
    <orgName>Learning Technologies Group</orgName>
  </org>
</org>
```

The following example demonstrates the use of the <listOrg> element to group together a number of <org> elements, each of which is defined solely by means of an informal description, itself containing other names.

```

<p>The TEI institutional hosts are: <listOrg>
  <org xml:id="bu">
    <orgName>Brown University</orgName>
    <desc>The host contribution is made jointly by the <name type="project">Brown
University Women Writers Project</name> and the
    <orgName>Brown University Library's Center for Digital
      Initiatives</orgName>.</desc>
  </org>
  <org xml:id="na">
    <orgName>Nancy</orgName>
    <desc>Hosting is provided by a group of institutions located in
      Nancy, France, coordinated by <orgName>Loria</orgName> and also
      including <orgName>ATILF</orgName> and <orgName>INIST</orgName>.</desc>
  </org>
  <org xml:id="ou">
    <orgName>Oxford University</orgName>
    <desc>Hosting is provided by the <orgName>Research Technologies
      Service</orgName> at <orgName>Oxford University Computing
      Services</orgName>.</desc>
  </org>
  <org xml:id="uv">
    <orgName>University of Virginia</orgName>
    <desc>Virginia's host support comes jointly from the
    <orgName>Institute for Advanced Technology in the
      Humanities</orgName> and the <orgName>University of Virginia
      Library</orgName>.</desc>
  </org>
</listOrg>
</p>

```

In a more elaborated version of this example, the organizational names tagged using `<orgName>` might be linked using the *key* or *ref* attribute to a unique `<org>` element elsewhere.

### 13.3.4 Places

In 13.2.3. *Place Names* we discuss various ways of naming places such as towns, countries, etc. In much the same way as these Guidelines distinguish between the encoding of names for people and the encoding of other data about people, so they also distinguish between the encoding of names for places and the encoding of other data about places. In this section we present elements which may be used to record in a structured way data about places of any kind which might be named or referenced within a text. Such data may be useful as a way of normalizing or standardizing references to particular places, as the raw material for a gazetteer or similar reference document associated with a particular text or set of texts, or in conjunction with any form of geographical information system.

The following elements are provided for this purpose:

**<listPlace>** (list of places) contains a list of places, optionally followed by a list of relationships (other than containment) defined amongst them.

**<place>** contains data about a geographic location

The `model.placeStateLike` class contains elements describing characteristics of a place which have a definite duration, such as its name. Any member of the `model.placeNamePart` may be used for this purpose, since a `<place>` element will usually contain at least one, and possibly several, `<placeName>`-like elements indicating the names associated with it, by different people, in different languages, or at different times.

For example, the modern city of Lyon in France was in Roman times known as Lugdunum. Although the modern and the Roman city are not physically co-extensive, they have significant areas which overlap, and we may therefore wish to regard them as the same place, while supplying both names with an indication of the time period during which each was current.

A place is defined, however, by its physical location, which does not typically change over time. Locations may be specified in a number of ways: as a set of coordinates defining a point or an area on the surface of the earth, or by

providing a description of how the place may be found, usually in terms of other place names. For example, we can identify the location of the Canadian city of London, either by specifying its latitude and longitude, or by specifying that we mean the city called London located in the province called Ontario within the country called Canada.

In addition we may wish to supply a brief characterization of the place identified, for example to state that it is a city, an administrative area such as a country, or a landmark of some kind such as a monument or a battlefield. If our typology of places is simple, the open ended *type* attribute is the easiest way to represent it: so we might say `<place type="city">`, `<place type="battlefield">` etc.

Within the `<place>` element, the following elements may be used to provide more information about specific aspects of the place in a structured form:

**<placeName>** contains an absolute or relative place name.

**<location>** defines the location of a place as a set of geographical coordinates, in terms of other named geo-political entities, or as an address.

#### 13.3.4.1 Varieties of Location

A location may be specified in one or more of the following ways:

1. by supplying a string representing its coordinates in some standardized way within a `<geo>` element, as shown below
2. by supplying one or more place name component elements (e.g. `<country>`, `<settlement>` etc.) to place it within a geo-political context
3. by supplying a postal address, e.g. using the `<address>` element
4. by supplying a brief textual description, e.g. using the `<desc>` element
5. by using a non-TEI XML vocabulary such as the Geography Markup Language

We give examples of all of these methods in the remainder of this section.

The simplest method of specifying a location is by means of its geographic coordinates, supplied within the `<geo>` element. This may be used to supply any kind of positional information, using one of the many different geodetic systems available. Such systems vary in their format, in their scope or coverage, and more fundamentally in the reference frame (the ‘datum’) used for the coordinate system itself. The default recommended by these Guidelines is to supply a string containing two real numbers separated by whitespace, of which the first indicates latitude and the second longitude according to the 1984 World Geodetic System (WGS84); this is the system currently used by most GPS applications which TEI users are likely to encounter.<sup>84</sup>We might therefore record the information about the place known as ‘Lyon’ as follows:

```
<place xml:id="LYON1" type="city">
  <placeName notBefore="1400">Lyon</placeName>
  <placeName notAfter="0056">Lugdunum</placeName>
  <location>
    <geo>45.769559 4.834843</geo>
  </location>
</place>
```

Identifying Lyon by its geo-political status as a settlement within a country forming part of a larger political entity, we might represent the same ‘place’ as follows:

```
<place xml:id="LYON2">
  <placeName notBefore="1400">Lyon</placeName>
  <placeName notAfter="0056">Lugdunum</placeName>
  <location>
    <bloc>EU</bloc>
```

<sup>84</sup>See <http://earth-info.nga.mil/GandG/wgs84/index.html>. The most recent revision of this standard is known as the Earth Gravity Model 1996.

```
<country>France</country>
</location>
</place>
```

Elements such as <bloc> are specialized forms of <placeName>, as discussed in 13.2.3.1. *Geo-political Place Names*.

We may use the same procedure to represent the location of smaller places, such as a street or even an individual building:

```
<place xml:id="BGbldg" type="building">
  <placeName>Brasserie Georges</placeName>
  <location>
    <country key="FR"/>
    <settlement type="city">Lyon</settlement>
    <district type="arrondissement">IIème</district>
    <district type="quartier">Perrache</district>
    <placeName type="street">
      <num>30</num>, Cours de Verdun</placeName>
    </location>
  </place>
```

Note the use of the *type* attribute to categorize more precisely both the kind of place concerned (a building) and the kind of name used to locate it, for example by characterizing the generic <district> as an 'arrondissement', or a 'quartier'.

We may also treat imaginary places in the same way:

```
<place xml:id="Atl" type="imaginary">
  <placeName>Atlantis</placeName>
  <location>
    <offset>beyond</offset>
    <placeName>The Pillars of <persName>Hercules</persName>
    </placeName>
  </location>
</place>
```

A <location> sometimes resembles a set of instructions for finding a place, rather than a name:

```
<place xml:id="MYF">
  <placeName notAfter="1969">Yasgur's Farm</placeName>
  <placeName notBefore="1969">Woodstock Festival Site</placeName>
  <location>
    <measure>one mile</measure>
    <offset>north west of</offset>
    <settlement>Bethel</settlement>
    <region>New York</region>
  </location>
</place>
```

The element <address> may also be used to identify a location in terms of its postal or other address:

```

<place xml:id="locCA" type="cemetery">
  <placeName>Protestant Cemetery</placeName>
  <placeName type="official" xml:lang="it">Cimitero Acattolico</placeName>
  <location type="geopolitical">
    <country>Italy</country>
    <settlement>Rome</settlement>
    <district>Testaccio</district>
  </location>
  <location type="address">
    <address>
      <addrLine>Via Caio Cestio, 6</addrLine>
      <addrLine>00153 Roma</addrLine>
    </address>
  </location>
</place>

```

When, as here, the same place is given multiple locations, the *type* attribute should be used to characterize the kind of location, as a means of indicating that these are alternative ways of identifying the same place, rather than that the place is spread across several locations.

The `<location>` element may thus identify a place to a greater or lesser degree of precision, using a variety of means: a name, a set of names, or a set of coordinates. The `<geo>` element introduced earlier is by default understood to supply a value expressed in a specific (and widely used) notation. If a `<location>` contains more than one `<geo>`, this is interpreted as being really the same place in the universe, but with different systems used to refer to it. If there is a lack of consensus about the location (of, for example, Camelot), more than one `<location>` should be used, each with its own `<geo>`.

By default, the content of `<geo>` is interpreted as following the standard known as the World Geodetic System (WGS). This may be modified, however, in two ways.

Firstly, the content of the `<geo>` element can be expressed some other way, that is, according to some different geodetic system. The *decls* attribute is used point to a `<geoDecl>` element defined in the document header, which describes a different datum.

Secondly, the element `<geo>` may be redefined to contain markup from a different XML vocabulary which is specifically designed to represent this kind of information. This technique is used throughout these Guidelines where specialized markup is required, for example to embed mathematical expressions or vector graphics, and is further described and exemplified in 23.3.4. *Examples of Modification*. For geographic information, suitable non-TEI vocabularies include:

- the OpenGIS Geography Markup Language (GML) being defined by the OGC<sup>85</sup>
- the Keyhole Markup Language (KML) used by Google Maps<sup>86</sup>

In the following example, we have defined the location of the place ‘Lyon’ using GML and indicated the two names associated with it at different times:

```

<place xml:id="locLyon" type="city"
  xmlns:gml="http://www.opengis.net/gml">
  <placeName notBefore="1400">Lyon</placeName>
  <placeName notAfter="0056">Lugdunum</placeName>
  <location>
    <geo>
      <gml:Polygon>
        <gml:exterior>
          <gml:LinearRing> 45.256 -110.45 46.46 -109.48 43.84 -109.86 45.8 -109.2

```

<sup>85</sup>The OGC is an international voluntary consensus standards organization whose members maintain the Geography Markup Language standard. The OGC coordinates with the ISO TC 211 standards organization to maintain consistency between OGC and ISO standards work. GML is also an ISO standard (ISO 19136:2007).

<sup>86</sup>See <https://developers.google.com/kml/documentation/>

```

                45.256 -110.45 </gml:LinearRing>
            </gml:exterior>
        </gml:Polygon>
    </geo>
</location>
</place>

```

A <bibl> element may be used within <location> to indicate the source of the location information.

```

<location>
  <geo>53.226658 -0.541254</geo>
  <bibl>
    <title>Roman Inscriptions of Britain</title>, <idno>262</idno>
  </bibl>
</location>

```

### 13.3.4.2 Multiple Places

A place may contain other places. This containment relation can be directly modelled in XML: thus we can say that the towns of Vilnius and Kaunas are both in a place called Lithuania (or Lietuva) as follows:

```

<place xml:id="locLith">
  <country>Lithuania</country>
  <country xml:lang="lt">Lietuva</country>
  <place>
    <settlement>Vilnius</settlement>
  </place>
  <place>
    <settlement>Kaunas</settlement>
  </place>
</place>

```

This does not, of course, imply that Vilnius and Kaunas are the only places constituting Lithuania; only that they are within it. A separate <place> element may indicate that it is a part of Lithuania by supplying a <relation> element, as discussed below (13.3.4.4. *Relations Between Places*).

As a further example, the islands of Mauritius, Réunion, and Rodrigues are collectively known as the Mascarene Islands. Grouped together with Mauritius there are also several smaller offshore islands, with rather picturesque French names. These offshore islands do not however constitute an identifiable place as a whole. One way of representing this is as follows:

```

<place xml:id="locMascarenes"
  type="islandGroup">
  <placeName>Mascarene Islands</placeName>
  <placeName>Mascarenhas Archipelago</placeName>
  <place type="island">
    <placeName>Mauritius</placeName>
    <listPlace type="offshoreIslands">
      <place>
        <placeName>La roche qui pleure</placeName>
      </place>
      <place>
        <placeName>Île aux cerfs</placeName>
      </place>
    </listPlace>
  </place>
</place>

```

```

    </listPlace>
  </place>
  <place type="island">
    <placeName>Rodrigues</placeName>
  </place>
  <place type="island">
    <placeName>Réunion</placeName>
  </place>
</place>

```

Here is a more complex example, showing the variety of names associated at different times and in different languages with a set of hierarchically grouped places—the settlement of Carmarthen Castle, within the town of Carmarthen, within the administrative county of Carmarthenshire, Wales.

```

<place xml:id="wales" type="country">
  <placeName xml:lang="cy">Cymru</placeName>
  <placeName xml:lang="en">Wales</placeName>
  <placeName xml:lang="la">Wallie</placeName>
  <placeName xml:lang="la">Wallia</placeName>
  <placeName xml:lang="fro">Le Waleis</placeName>
  <place xml:id="carmarthenshire"
    type="region">
    <region type="county" xml:lang="en"
      notBefore="1284">Carmarthenshire</region>
    <place xml:id="carmarthen"
      type="settlement">
      <placeName xml:lang="en">Carmarthen</placeName>
      <placeName xml:lang="la"
        notBefore="1090" notAfter="1300">Kaermerdin</placeName>
      <placeName xml:lang="cy">Caerfyrddin</placeName>
      <place xml:id="carmarthen_castle"
        type="castle">
        <settlement>castle of Carmarthen</settlement>
      </place>
    </place>
  </place>
</place>

```

As noted previously, <country>, <region>, and <settlement> are all specializations of the generic <placeName> element; they are not specializations of the <place> element. If it is desired to distinguish amongst kinds of *place* this can only be done by means of the *type* attribute as in the above example.

This use of multiple <place> elements should be distinguished from the (possibly simpler) case where a number of places with some property in common are being grouped together for convenience, for example, in a gazetteer. The <listPlace> element is provided as a means of grouping places together where there is no implication that the grouped elements constitute a distinct place. For example:

```

<place xml:id="pl-c-H" type="county">
  <placeName>Herefordshire</placeName>
  <listPlace type="villages">
    <place xml:id="pl-v-AD">
      <placeName>Abbey Dore</placeName>
      <location>
        <geo>51.969604 -2.893146</geo>
      </location>
    </place>
  </listPlace>
</place>

```

```

    </place>
    <place xml:id="pl-v-AB">
      <placeName>Acton Beauchamp</placeName>
    </place>
  <!-- ... -->
</listPlace>
<listPlace type="towns">
  <place xml:id="pl-t-H">
    <placeName>Hereford</placeName>
  </place>
  <place xml:id="pl-t-L">
    <placeName>Leominster</placeName>
  </place>
<!-- ... -->
</listPlace>
</place>

```

### 13.3.4.3 States, Traits, and Events

There are many different kinds of information which it might be considered useful to record for a place in addition to its name and location, and the categories selected are likely to be very project-specific. As with persons therefore these Guidelines make no claim to comprehensiveness in this context. Instead, the generic `<state>`, `<trait>`, and `<event>` elements defined by this module should be used. Each of these may be customized for particular needs by means of their *type* attribute. These are complemented by a small number of predefined elements of general utility:

**<population>** contains information about the population of a place.

**<climate>** contains information about the physical climate of a place.

**<terrain>** contains information about the physical terrain of a place.

These are all specializations of the generic `<trait>` element. This element may be used for almost any kind of event in the life of a place; no specialized version of this element is proposed, nor do we attempt to enumerate the possible values which might be appropriate for the *type* attribute on any of these generic elements.

Here is an example, showing how the specific and generic elements may be combined:

```

<place xml:id="IS">
  <placeName xml:lang="en">Iceland</placeName>
  <placeName xml:lang="is">Ísland</placeName>
  <location>
    <geo>65.00 -18.00</geo>
  </location>
  <terrain>
    <desc>Area: 103,000 sq km</desc>
  </terrain>
  <state type="governance" notBefore="1944">
    <p>Constitutional republic</p>
  </state>
  <state type="governance" notAfter="1944">
    <p>Part of the kingdom of <placeName key="DK">Denmark</placeName>
    </p>
  </state>
  <event type="governance" when="1944-06-17">
    <desc>Iceland became independent on 17 June 1944.</desc>
  </event>
  <state type="governance" from="1944-06-17">
    <p>An independent republic since June 1944</p>
  </state>

```

```

</state>
</place>

```

In the following example, the <climate> example is used to provide a detailed discussion of this particular aspect of the information available about a particular place:

```

<place xml:id="greece">
  <placeName>Greece</placeName>
  <climate>
    <desc>Greece's climate is divided into three well defined
      classes:</desc>
    <climate>
      <label>Mediterranean</label>
      <desc>It features mild, wet winters and hot, dry
        summers. Temperatures rarely reach extremes, although snowfalls do
        occur occasionally even in <placeName>Athens</placeName>,
        <placeName>Cyclades</placeName> or <placeName>Crete</placeName>
        during the winter.</desc>
    </climate>
    <climate>
      <label>Alpine</label>
      <desc>It is found primarily in <placeName>
        <offset>Western</offset>
        Greece</placeName> (<placeName>Epirus</placeName>,
        <placeName>
          <offset>Central</offset> Greece</placeName>,
        <placeName>Thessaly</placeName>,
        <placeName>
          <offset>Western</offset> Macedonia</placeName> as well
          as central parts of <placeName>Peloponnesus</placeName> like
          <placeName>Achaea</placeName>, <placeName>Arcadia</placeName> and
          parts of <placeName>Laconia</placeName> where the Alpine range pass
          by)</desc>
    </climate>
    <climate>
      <label>Temperate</label>
      <desc>It is found in <placeName>
        <offset>Central</offset> and
        <offset>Eastern</offset> Macedonia</placeName> as well as in
        <placeName>Thrace</placeName> at places like
        <placeName>Komotini</placeName>, <placeName>Xanthi</placeName> and
        <placeName>
          <offset>northern</offset> Evros</placeName>. It features
          cold, damp winters and hot, dry summers.</desc>
    </climate>
  </climate>
</place>

```

As the above example shows, <state> and <trait> elements, and others of the same class, can be nested hierarchically within each other. When this is done, values for the *type* attribute are to be understood as cumulatively inherited, as elsewhere in the TEI scheme (for example on <category> or <linkGrp>). In the following example, the outermost <population> element concerns the squirrel population between the dates given. This is then broken down into red and gray squirrel populations, and within that into male and female:

```

<population type="squirrel"
  notBefore="1901" notAfter="1902-01-11" resp="#strabo">
  <population type="red" when="1901-01-10">
    <population type="female">
      <desc>12</desc>
    </population>
    <population type="male">
      <desc>15</desc>
    </population>
  </population>
  <population type="gray" when="1902-01-10"
    cert="high">
    <population type="female">
      <desc>23</desc>
    </population>
    <population type="male" cert="low"
      resp="#biber">
      <desc>45</desc>
    </population>
  </population>
</population>

```

The dating and responsibility attributes here behave slightly differently from the *type* attribute: responsibility is not an additive property, and therefore an element either states it explicitly, or inherits it from its nearest ancestor. Dating is slightly different again, in that a child element may specify a date more precisely than its parent, as in the example above

Events may also be subdivided into other events. For example, a two part meeting might be represented as follows:

```

<event type="meeting" when="2007-05-29">
  <desc>All day meeting to resolve content models</desc>
  <event type="preamble" notAfter="13:00:00">
    <desc>first part</desc>
  </event>
  <event type="conclusions"
    notBefore="13:00:00">
    <desc>second part</desc>
  </event>
</event>

```

An `<event>` element is usually used to record information about a place, or a person; for this reason the element usually appears as content of a `<place>` or `<person>`. However, it is also possible to describe events independently of either a person or a place. This may be useful in such applications as chronologies, lists of significant events such as battles, legislation, etc.

The `<listEvent>` element is a member of the `model.listLike` class, and may therefore appear wherever lists are permitted, in the same way as the `<listPerson>`, `<listPlace>` etc. elements described elsewhere in this chapter.

```

<listEvent>
  <event when="1713"
    ref="http://eco.canadiana.ca/view/oocihm.9_01832">
    <label>Treaty of Utrecht</label>
    <desc>France ceded to Great Britain its claims to the <orgName>Hudson's Bay
      Company</orgName> territories in <placeName>Rupert's Land</placeName>,
    <placeName>Newfoundland</placeName>, and

```

```

    <placeName>Acadia</placeName> and recognized British suzerainty over
<orgName type="tribe">the Iroquois</orgName> but retained its other pre-war
    North American possessions, including
    <placeName key="PEI">Île-Saint-Jean</placeName> (now <placeName key="PEI">Prince
Edward
    Island</placeName>)...</desc>
</event>
<event when="1774" key="14-GeoIII-c83">
    <label>Quebec Act</label>
    <desc>This act of the British Parliament guaranteed free practice of
    the Catholic faith and restored use of the French Civil Code for
    private matters throughout the Province of Quebec, which had been
    expanded in territory following the <ref>Treaty of Paris</ref>.</desc>
</event>
<event when="1778"
    ref="http://avalon.law.yale.edu/18th_century/del1778.asp">
    <label>Treaty of Fort Pitt</label>
    <desc>Also known as the <name type="event">Treaty with the
    Delawares</name>, this was the first written treaty between the newly
    formed <orgName>United States</orgName> and any Native American people, in this
    case, the <orgName type="tribe">Lenape</orgName> or Delawares.</desc>
</event>
</listEvent>

```

#### 13.3.4.4 Relations Between Places

The <relation> element may also be used to express relationships of various kinds between places, or between places and persons, in much the same way as it is used to express relationships between persons alone. Returning to the Mascarene Islands example cited above, we might define the island group and its constituents separately, but indicate the relationship by means of a <relation> element:

```

<listPlace>
    <place xml:id="MASC">
        <placeName>Mascarene islands</placeName>
        <placeName>Mascarenhas Archipelago</placeName>
    </place>
    <place xml:id="MRU">
        <placeName>Mauritius</placeName>
    <!-- ... -->
    </place>
    <place xml:id="ROD">
        <placeName>Rodrigues</placeName>
    </place>
    <place xml:id="REN">
        <placeName>Réunion</placeName>
    </place>
    <relation name="contains" active="#MASC"
        passive="#ROD #MRU #REN"/>
</listPlace>

```

This ‘stand-off’ style of representation has the advantage that we can now also represent the fact that a place may be a ‘part of’ more than one other place; for example, Réunion is part of France, as well as part of the Mascarenes. If we add a declaration for France to the list above:

```
<place type="country" xml:id="FRA">
  <placeName>France</placeName>
</place>
```

we can now model this dual allegiance by means of a <relation> element:

```
<relation name="partOf" active="#REN"
  passive="#FRA #MASC"/>
```

### 13.3.5 Names and Nyms

So far we have discussed ways in which a name or referring string encountered in running text may be resolved by considering the object that the name refers to: in the case of a personal name, the name refers to a person; in the case of a place name, to a place, for example. The resolution of this reference is effected by means of the *key* or *ref* attributes available to all elements which are members of the `att.naming` class, such as <persName> or <placeName> and their more specialized variants such as <forename> or <country>. However, *names* can also be regarded as objects in their own right, irrespective of the objects to which they are attached, notably in onomastic studies. From this point of view, the names *John* in English, *Jean* in French, and *Ivan* in Russian might all be regarded as existing independently of any person to which they are attached, and also independently of any variant forms that might be attested in different sources (such as Jon or Johnny in English, or Jehan or Jojo in French). We use the term *nym* to refer to the canonical or normalized form of a name regarded in such a way, and provide the following elements to encode it:

**<listNym>** (list of canonical names) contains a list of nyms, that is, standardized names for any thing.

**<nym>** (canonical name) contains the definition for a canonical name or name component of any kind.

Any element which is a member of the `att.naming` class may use the attribute *nymRef* to indicate the nym with which it corresponds. Thus, given the following <nym> for the name *Antony*:

```
<listNym>
  <nym xml:id="N123">
    <form>Antony</form>
  </nym>
<!-- other nym definitions here -->
</listNym>
```

an occurrence of this name in running text might be encoded as follows:

```
<forename nymRef="#N123">Tony</forename> Blair
```

Note that this association (between "Tony" and "Antony") has nothing to do with any individual who might use the name.

The person identified by this particular Tony may however be indicated independently using the *ref* attribute, either on the forename or on the whole name component:

```
<forename nymRef="#N123" ref="#BLT">Tony</forename>
<!-- ... -->
<person xml:id="BLT">
  <persName>Tony Blair</persName>
  <occupation>politician</occupation>
</person>
```

The `<nym>` element may be thought of as providing a specialized kind of dictionary entry. Like a dictionary entry, it may contain any element from the `model.entryPart` class, such as `<form>`, `<etym>`, etc. For example, we may show that the canonical form for a given `nym` has two orthographic variants in this way:

```
<nym xml:id="J451">
  <form>
    <orth xml:lang="en-US">Ian</orth>
    <orth xml:lang="en-x-Scots">Iain</orth>
  </form>
</nym>
```

Because a schema intending to make use of the `<nym>` or `<listNym>` element must include the `dictionaries` module as well as the `namesdates` module, many other elements are available in addition to `<form>`. For example, to provide a more complex etymological decomposition of a name, we might use the existing `<etym>` element, as follows:

```
<nym xml:id="XYZ">
  <form>Bogomil</form>
  <etym>Means <gloss>favoured by God</gloss> from the
  <lang>Slavic</lang> elements <mentioned xml:lang="ru">bog</mentioned>
  <gloss>God</gloss> and <mentioned xml:lang="ru">mil</mentioned>
  <gloss>favour</gloss>
</etym>
</nym>
```

Where it is necessary to mark the substructure of `nym`s, this may be done by `<seg>` elements within the `<form>`:

```
<nym xml:id="ABC">
  <form>
    <choice>
      <seg type="morph">
        <seg>Bog</seg>
        <seg>o</seg>
        <seg>mil</seg>
      </seg>
      <seg type="morph">
        <seg>Bogo</seg>
        <seg>mil</seg>
      </seg>
    </choice>
  </form>
</nym>
```

The `<seg>` element used here is provided by the TEI `linking` module, which would therefore also need to be included in a schema built to validate such markup. Other possibilities for more detailed linguistic analysis are provided by elements included in that and the `analysis` (see 17. *Simple Analytic Mechanisms*) or `iso-fs` modules (see 18. *Feature Structures*).

Alternatively, each of the constituents of *Bogomil* might be regarded as a `nym` in its own right:

```
<nym xml:id="B1" type="part">
  <form>bog</form>
</nym>
```

```
<nym xml:id="M1" type="part">
  <form>mil</form>
</nym>
```

Within running text, a name can specify all the nyms associated with it:

```
...<name nymRef="#B1 #M1">Bogomil</name>...
```

Similarly, within a nym, the attribute *parts* is used to indicate its constituent parts, where these have been identified as distinct nyms:

```
<nym xml:id="BM1" parts="#B1 #M1">
  <form>Bogomil</form>
</nym>
```

The `<nym>` element may also combine a number of other `<nym>` elements together, where it is intended to show that they are all regarded as variations on the same root. Thus the different forms of the name John, all being derived from the same root, may be represented as a hierarchic structure like this:

```
<nym xml:id="J45">
  <form xml:lang="la">Iohannes</form>
  <nym xml:id="J450">
    <form xml:lang="en">John</form>
    <nym xml:id="J4501">
      <form>Johnny</form>
    </nym>
    <nym xml:id="J4502">
      <form>Jon</form>
    </nym>
  </nym>
  <nym xml:id="J455">
    <form xml:lang="ru">Ivan</form>
  </nym>
  <nym xml:id="J453">
    <form xml:lang="fr">Jean</form>
  </nym>
</nym>
```

The `<nym>` element may be used for components of geographical or organizational names as well. For example:

```
<geogName ref="tag:projectname.org,2012:LAEI1"
  type="hill">
  <geogFeat xml:lang="gd" nymRef="#LAIRG">Lairig</geogFeat>
  <name>Eilde</name>
</geogName>
...

<nym xml:id="LAIRG">
  <form xml:lang="gd">lairig</form>
  <def>sloping hill face</def>
```

```
</nym>
...
```

As noted above, use of these elements implies that both the `dictionaries` and the `namesdates` modules are included in a schema.

### 13.3.6 Dates and Times

The following elements for the encoding of dates and times were introduced in section 3.5.4. *Dates and Times*:

**<date>** contains a date in any format.

**<time>** contains a phrase defining a time of day in any format.

The current module `namesdates` provides a mechanism for more detailed encoding of relative dates and times. A *relative temporal expression* describes a date or time with reference to some other (absolute) temporal expression, and thus may contain an `<offset>` element in addition to one or more `<date>` or `<time>` elements:

**<offset>** marks that part of a relative temporal or spatial expression which indicates the direction of the offset between the two place names, dates, or times involved in the expression.

As members of the `att.datable` and `att.duration` classes, which in turn are members of `att.datable.w3c` and `att.duration.w3c` respectively, the `<date>` and `<time>` elements share the following attributes:

**att.datable.w3c** provides attributes for normalization of elements that contain datable events conforming to the *W3C XML Schema Part 2: Datatypes Second Edition*.

`@when` supplies the value of the date or time in a standard form, e.g. yyyy-mm-dd.

**att.duration.w3c** provides attributes for recording normalized temporal durations.

`@dur` (duration) indicates the length of this element in time.

#### 13.3.6.1 Relative Dates and Times

As noted above, relative dates and times such as ‘in the Two Hundredth and First Year of the Republic’, ‘twenty minutes before noon’, and, more ambiguously, ‘after the lamented death of the Doctor’ or ‘an hour after the game’ have two distinct components. As well as the absolute temporal expression or event to which reference is made (e.g. ‘noon’, ‘the game’, ‘the death of the Doctor’, ‘[the foundation of] the Republic’), they also contain a description of the ‘distance’ between the time or date which is indicated and the referent expression (e.g. ‘the Two Hundredth and First Year’, ‘twenty minutes’, ‘an hour’); and (optionally) an ‘offset’ describing the direction of the distance between the time or date indicated and the referent expression (e.g. ‘of’ implying after, ‘before’, ‘after’).

The ‘distance’ component of a relative temporal expression may be encoded as a temporal element in its own right using either `<date>` or `<time>`, or with the more generic `<measure>` element. A special element, `<offset>`, is provided by this module for encoding the ‘offset’ component of a relative temporal expression. The absolute temporal expression contained within the relative expression may be encoded with a `<date>` or `<time>` element; in turn, those elements may of course be relative, and thus contain `<date>` or `<time>` elements within themselves. This allows for deeply nested structures such as ‘the third Sunday after the first Monday before Lammastide in the fifth year of the King’s second marriage ...’ but so does natural language.

In the following examples, the `when` and `dur` attributes have been used to simplify processing of variant forms of expression:

```
<date when="1786-12-11">
  <date dur="P14D">A fortnight</date>
  <offset>before</offset>
  <date when="1786-12-25" type="holiday">Christmas 1786</date>
</date>
```

```
I reached the station <time when="14:15:00">
  <time dur="PT30M0S">precisely half an hour</time>
  <offset>after</offset>
  <time when="13:45:00" type="occasion">the departure of the afternoon train to
Boston</time>
</time>
```

In the following example, a nested <date> element is used to show that ‘my birthday’ and the cited date are parts of the same temporal expression, and hence to disambiguate the phrase ‘A week before my birthday on 9th December’:

```
<date when="--12-02">
  <date>A week</date>
  <offset>before</offset>
  <date when="--12-09">
    <date type="occasion">my birthday</date>
    on <date>9th December</date>
  </date>
</date>
```

The alternative reading of this phrase could be encoded as follows:

```
<date when="--12-09">
  <date>A week</date>
  <offset>before</offset>
  <date type="occasion" when="--12-16">my birthday</date>
on <date>9th December</date>
</date>
```

Where more complex or ambiguous expressions are involved, and where it is desirable to make more explicit the interpretive processes required, the feature structure notation described in chapter 18. *Feature Structures* may be used. Consider, for example, the following temporal expression which occurs in the *Scottish Temperance Review* of August 1850, referring to the summer holiday known in Glasgow simply as ‘the Fair’:

```
Not only is the city, <date ana="#gf50">during the Fair</date>, a horrible nucleus of
immorality
and wickedness; it sends our multitudes to pollute and demoralize the
country.
```

For the definition of the *ana* attribute, see chapter 17. *Simple Analytic Mechanisms* (in particular 17.2. *Global Attributes for Simple Analyses*). It is used here to link the temporal phrase with an interpretation of it. Like most traditional fairs and market days, the Glasgow Fair was established by local custom and could vary from year to year. Consequently, in order to provide such an interpretation, it is necessary to draw upon additional information which may or may not be located in the particular text in question. In this case, it is necessary at least to know the spatial and temporal context (year and place) of the fair referred to. These and other features required for the analysis of this particular temporal expression may be combined together as one feature structure of type date-analysis:

```
<fs xml:id="gf50" type="date-analysis">
  <f name="event">
    <string>the Fair</string>
  </f>
```

```

<f name="place">
  <string>Glasgow</string>
</f>
<f name="year">
  <numeric value="1850"/>
</f>
<f name="from-value">
  <string>1850-08-08</string>
</f>
<f name="to-value">
  <string>1850-09-19</string>
</f>
</fs>

```

For further discussion of feature structure representation see chapter 18. *Feature Structures*.

### 13.3.6.2 Absolute Dates and Times

The following are examples of absolute temporal expressions.

The university's view of American affairs produced a stinging attack by Edmund Burke in the Commons debate of <date when="1775-10-26">26 October 1775</date>

<date when="1993-05-14">Friday, 14 May 1993</date>

It may be useful to categorize a temporal expression which is given in terms of a named event, such as a public holiday, or a named time such as 'tea time' or 'matins':

In New York, <date type="occasion" when="--01-01">New Year's Day</date> is the quietest of holidays, <date when="--07-04" type="occasion">Independence Day</date> the most turbulent.

Absolute temporal expressions denoting times which are given in terms of seconds, minutes, hours, or of well-defined events (e.g. 'noon', 'sunset') may similarly be represented using the <time> element.

The train leaves for Boston at  
<time type="twentyfourHour" when="13:45:00">13:45</time>

At <time type="occasion">sunset</time> we walked to the beach.

The train leaves for Boston at  
<time xml:lang="en-US" type="descriptive" when="13:45:00-05:00"> a quarter of two  
</time>

### 13.3.6.3 More Expressive Normalizations

The attributes for normalization of dates and times so far described use a standard format defined by *XML Schema Part 2: Datatypes Second Edition*. This format is widely accepted and has significant software support. It is essentially a profile of ISO 8601 *Data elements and interchange formats — Information interchange — Representation of dates and times*. The full ISO standard provides formats not available in the W3C recommendation, for example, the capability to refer to a date by its ordinal date or week date, or to refer to a century. It also provides ways of indicating duration and range.

When this module is included in a schema, the following additional attributes are provided:

**att.datable.iso** provides attributes for normalization of elements that contain datable events using the ISO 8601 standard.

**@when-iso** supplies the value of a date or time in a standard form.

**@notBefore-iso** specifies the earliest possible date for the event in standard form, e.g. yyyy-mm-dd.

**@notAfter-iso** specifies the latest possible date for the event in standard form, e.g. yyyy-mm-dd.

**@from-iso** indicates the starting point of the period in standard form.

**@to-iso** indicates the ending point of the period in standard form.

**att.duration.iso** provides attributes for recording normalized temporal durations.

**@dur-iso** (duration) indicates the length of this element in time.

These attributes may be used in preference to their W3C equivalent when it is necessary to provide a normalized value in some form not supported by the W3C attributes. For example, a century date in the W3C format must be expressed as a range, using the *from* attribute together with either the *to* attribute or the *dur* (duration) attribute:

```
<date from="1301" to="1400">fourteenth century</date>
<date from="1301" dur="P100Y">fourteenth century</date>
```

With the attribute *when-iso*, however, it is possible to express the same normalized value in any of the following additional ways:

```
<date when-iso="13">fourteenth century</date>
<date when-iso="1301/1400">fourteenth century</date>
<date when-iso="1301/P100Y">fourteenth century</date>
```

### 13.3.6.4 Using Non-Gregorian Calendars

All date-related encoding described above makes use of the Gregorian calendar, on which both the ISO and W3C datetime formats are based. However, historical texts often pre-date the invention of the Gregorian calendar in the 16th century, or its adoption in Europe over the following centuries, and many other calendars are used in texts from other cultures and contexts. Non-Gregorian dates can be encoded using methods described below.

First, a Calendar Description element needs to be supplied in the `<teiHeader>` as described in 2.4.5. *Calendar Description*:

```
<calendarDesc>
  <calendar xml:id="Julian_England">
    <p>The Julian calendar, as used in late 16th-century England.</p>
  </calendar>
</calendarDesc>
```

The following attributes can now be used to encode dates using this calendar:

**att.datable** provides attributes for normalization of elements that contain dates, times, or datable events.

**@calendar** indicates the system or calendar to which the date represented by the content of this element belongs.

**att.datable.custom** provides attributes for normalization of elements that contain datable events to a custom dating system (i.e. other than the Gregorian used by W3 and ISO).

*@when-custom* supplies the value of a date or time in some custom standard form.

*@notBefore-custom* specifies the earliest possible date for the event in some custom standard form.

*@notAfter-custom* specifies the latest possible date for the event in some custom standard form.

*@from-custom* indicates the starting point of the period in some custom standard form.

*@to-custom* indicates the ending point of the period in some custom standard form.

*@datingMethod* supplies a pointer to a <calendar> element or other means of interpreting the values of the custom dating attributes.

```
<p>The Poole by S. <hi>Giles</hi> Churchyarde was a
large water in the yeare <date calendar="#Julian_England">1244</date>.
</p>
```

Here, the *calendar* attribute points to the <calendar> element in the header which defines and describes the calendar used.

The *calendar* attribute is used to specify the calendar used in the *text content* of the dating element which bears it. However, just as we use, for instance, *when*, *notBefore*, *notAfter* etc. to provide more precise expressions of dates and times in a constrained and computable form, it is often necessary to express a date or a date-range from a non-Gregorian calendar in a more precise manner. The attributes whose names end in ‘-custom’ are provided for this purpose, and the *datingMethod* is used to identify the calendar used in the content of these attributes:

```
<head> The Tryumphs of Peace.<lb/>
That Celebrated the Solemnity of the right Honorable
Sr Francis Iones Knight, at his Inauguration into the
Maioraltie of London, on Monday being the
<date when-custom="1620-10-30"
    datingMethod="#Julian_England" calendar="#Julian_England"> 30. of October, 1620.
</date>
</head>
```

Here, the *calendar* attribute specifies the calendar used in the text content of the <date> element, as before, whereas the *datingMethod* attribute signifies that the calendar used in the *when-custom* attribute is also Julian. The schema could be customized in order to constrain the content of custom attributes in a manner similar to the constraints provided on regular Gregorian dating attributes such as *when*, to enforce consistency in the use of non-Gregorian dates.

Custom dating attributes can be combined with any of the standard dating attributes in order to provide a standardized Gregorian version of a non-Gregorian date. We might enhance the preceding example with the addition of *when*, providing the Gregorian calendar equivalent of the Julian date:

```
<date when-custom="1620-10-30"
    when="1620-11-09" datingMethod="#Julian_England"
    calendar="#Julian_England"> 30. of October, 1620.
</date>
```

## 13.4 Module for Names and Dates

The module described in this chapter makes available the following components:

Module `namesdates`: Names and dates

- *Elements defined:* addName affiliation age birth bloc climate country death district education event faith floruit forename genName geo geogFeat geogName langKnowledge langKnown listEvent listNym listOrg listPerson listPlace listRelation location nameLink nationality nym occupation offset org orgName persName person personGrp place placeName population region relation residence roleName settlement sex socecStatus state surname terrain trait
- *Classes defined:* att.dateable.custom att.dateable.iso model.persNamePart

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

## 14 Tables, Formulæ, Graphics and Notated Music

Many documents, both historical and contemporary, include not only text, but also graphics, artwork, and other images. Although some types of images can be represented directly with markup, it is more common practice to include such information by using a reference to an external entity (typically a URL) encoded in a suitable graphical notation.

In addition to graphic images, documents often contain material presented in graphical or tabular format. In such materials, details of layout and presentation may also be of comparatively greater significance or complexity than they are for running text. Indeed, it may often be difficult to make a clear distinction between details relating purely to the rendition of information and those relating to the information itself.

Documents may also contain mathematical formulæ or expressions in other formulaic notations, for which no notation is defined in these Guidelines.

Finally, documents may contain musical notation, embedded in a manner similar to tables, graphs and formulæ.

These areas (graphics, tabular material, and mathematical or other formulæ, and music) have in common that they have received considerable attention from many other standards bodies or similar professional groups. In part because of this, they may frequently be most conveniently encoded and processed using some notation not defined by these Guidelines. For these reasons, and others, we consider tables, formulæ, graphics and notated music together in this chapter.

As with text markup in general, many incompatible formats have been proposed for the representation of graphics, formulæ, and tables in electronic form. Unfortunately, no single format as effective as XML in the domain of text has yet emerged for their interchange, to some extent because of the difficulty of representing the information these data formats convey independently of the way it is rendered.

The module defined by this chapter defines special purpose ‘container’ elements that can be used to encapsulate occurrences of such data within a TEI-conformant document in a portable way. Specific recommendations for the encoding of tables are provided in section 14.1. *Tables*, recommendations for mathematical or other formulæ in section 14.2. *Formulæ and Mathematical Expressions*, and for the encoding of musical notation in section 14.3. *Notated Music in Written Text*. Specific recommendations for the encoding of graphic figures may be found in section 14.4. *Specific Elements for Graphic Images*. The rest of the chapter is devoted to general problems of encoding graphic information.

There is at the time of writing no consensus on formats for graphical images, and such formats vary in many ways. We therefore provide (in section 14.5. *Overview of Basic Graphics Concepts*) a brief discussion of the ways in which images may be represented, and (in section 14.6. *Graphic Image Formats*) a list of formal names for those representations most popular at this time. Each one includes a very brief description. These Guidelines recommend a few particular representations as being the most widely supported and understood.

### 14.1 Tables

A table is the least ‘graphic’ of the elements discussed in this chapter. Almost any text structure can be presented as a series of rows and columns: one might, for example, choose to show a glossary or other form of list in tabular form, without necessarily regarding it as a table. In such cases, the global *rend* attribute is an appropriate way of indicating that some element is being presented in tabular format, for example by using an appropriate display property in CSS. When tabular presentation is regarded as of less intrinsic importance, it is correspondingly simpler to encode descriptive or functional information about the contents of the table, for example to identify one cell as containing a name and another as containing a date, though the two methods may be combined.

When, however, particular elements are required to encode the tabular arrangement itself, then one or other of the various ‘table schemas’ now available may be preferable. The schemas in common use generally view a table as a special text element, made up of row elements, themselves composed of cells. Table cells generally appear in row-major order, with the first row from left to right, then the second row, and so on. Details of appearance such as column widths, border lines, and alignment are generally encoded by numerous attributes. Beyond this, however, such schemas differ greatly. This section begins by describing a table schema of this kind; a brief summary of some other widely available table schemas is also provided in section 14.1.2. *Other Table Schemas*.

#### 14.1.1 TEI Tables

For encoding tables of low to moderate complexity, these Guidelines provide the following special purpose elements:

**<table>** contains text displayed in tabular form, in rows and columns.

`@ROWS` indicates the number of rows in the table.

`@COLS` (columns) indicates the number of columns in each row of the table.

`<row>` contains one row of a table.

`<cell>` contains one cell of a table.

The `<table>` element is defined as a member of the class `model.inter`; it may therefore appear both within other components (such as paragraphs), or between them, provided that the module defined in this chapter has been enabled, as described at the beginning of this chapter.

It is to a large extent arbitrary whether a table should be regarded as a series of rows or as a series of columns. For compatibility with currently available systems, however, these Guidelines require a row-by-row description of a table. It is also possible to describe a table simply as a series of cells; this may be useful for tabular material which is not presented as a simple matrix.

The attributes `rows` and `cols` may be used to indicate the size of a table, or to indicate that a particular cell or row of a table spans more than one row or column. For both tables and cells, rows and columns are always given in top-to-bottom, left-to-right order, although formatting properties such as those provided by CSS may be used to specify that they should be displayed differently. These Guidelines do not require that the size of a table be specified; for most formatting and many other applications, it will be necessary to process the whole table in two passes in any case.

Where cells span more than one column or row, the encoder must determine whether this is a purely presentational effect (in which case the `rend` attribute may be more appropriate), whether the part of the table affected would be better treated as a nested table, or whether to use the spanning attributes listed above.

The `role` attribute may be used to categorize a single cell, or set a default for all the cells in a given row. The present Guidelines distinguish the roles of `label` and `data` only, but the encoder may define other roles, such as 'derived', 'numeric', etc., as appropriate.

These three attributes are provided by the attribute class `att.tableDecoration` of which both `<cell>` and `<row>` are members; see further 1.3.1. *Attribute Classes*.

The following simple example demonstrates how the data presented as a labelled list in section 3.7. *Lists* might be represented by an encoder wishing to preserve its original appearance as a table:

```
<table rend="boxed" rows="2" cols="2">
  <head rend="it">Report of the conduct and progress of Ernest
    Pontifex. Upper Vth form – half term ending Midsummer 1851</head>
  <row>
    <cell role="label">Classics</cell>
    <cell>Idle listless and unimproving</cell>
  </row>
  <row>
    <cell role="label">Mathematics</cell>
    <cell>ditto</cell>
  </row>
  <row>
    <cell role="label">Divinity</cell>
    <cell>ditto</cell>
  </row>
  <row>
    <cell role="label">Conduct in house</cell>
    <cell>Orderly</cell>
  </row>
  <row>
    <cell role="label">General conduct</cell>
    <cell>Not satisfactory, on account of his great unpunctuality and
      inattention to duties</cell>
  </row>
</table>
```

Note that this encoding makes no attempt to represent the full significance of the ‘ditto’ cells above; these might be regarded as simple links between the cells containing them and that to which they refer, or as virtual copies of it. For ways of representing either interpretation, see chapter 16. *Linking, Segmentation, and Alignment*.

The following example demonstrates how a simple statistical table may be represented using this scheme:

```
<table rows="4" cols="4">
  <head>Poor Man's Lodgings in Norfolk (Mayhew, 1843)</head>
  <row role="label">
    <cell/>
    <cell>Dossing Cribs or Lodging Houses</cell>
    <cell>Beds</cell>
    <cell>Needys or Nightly Lodgers</cell>
  </row>
  <row>
    <cell role="label">Bury St Edmund's</cell>
    <cell>5</cell>
    <cell>8</cell>
    <cell>128</cell>
  </row>
  <row>
    <cell role="label">Thetford</cell>
    <cell>3</cell>
    <cell>6</cell>
    <cell>36</cell>
  </row>
  <row>
    <cell role="label">Attleboro'</cell>
    <cell>3</cell>
    <cell>5</cell>
    <cell>20</cell>
  </row>
  <row>
    <cell role="label">Wymondham</cell>
    <cell>1</cell>
    <cell>11</cell>
    <cell>22</cell>
  </row>
</table>
```

Note the use of a blank cell in the first row to ensure that the column labels are correctly aligned with the data. Again, this encoding does not explicitly represent the alignment between column and row labels and the data to which they apply. Where the primary emphasis of an encoding is on the semantic content of a table, a more explicit mechanism for the representation of structured information such as that provided by the feature structure mechanism described in chapter 18. *Feature Structures* may be preferred. Alternatively, the general purpose linkage and alignment mechanisms described in chapter 16. *Linking, Segmentation, and Alignment* may also be applied to individual cells of a table.

The content of a table cell need not be simply character data. It may also contain any sequence of the phrase-level elements described in chapter 3. *Elements Available in All TEI Documents*, thus allowing for the encoding of potentially more useful semantic information, as in the following example, where the fact that one cell contains a number and the other contains a place name has been explicitly recorded:

```
<table>
  <head>US State populations, 1990</head>
  <row>
    <cell>
```

```

        <name>Wyoming</name>
    </cell>
    <cell>
        <num>453,588</num>
    </cell>
</row>
<row>
    <cell>
        <name>Alaska</name>
    </cell>
    <cell>
        <num>550,043</num>
    </cell>
</row>
<row>
    <cell>
        <name>Montana</name>
    </cell>
    <cell>
        <num>799,065</num>
    </cell>
</row>
<row>
    <cell>
        <name>Rhode Island</name>
    </cell>
    <cell>
        <num>1,003,464</num>
    </cell>
</row>
</table>

```

The use of semantically marked elements within a <cell> enables the encoder to convey something about the nature and significance of the information, rather than merely suggesting how to display it in rows and columns.

Alternatively, the *role* attribute might be used to convey such information:

```

<table>
  <head>US State populations, 1990</head>
  <row>
    <cell role="statename">Wyoming </cell>
    <cell role="pop">453,588 </cell>
  </row>
  <row>
    <cell role="statename">Alaska </cell>
    <cell role="pop">550,043 </cell>
  </row>
  <row>
    <cell role="statename">Montana </cell>
    <cell role="pop">799,065 </cell>
  </row>
  <row>
    <cell role="statename">Rhode Island</cell>
    <cell role="pop">1,003,464</cell>
  </row>
</table>

```

The content of table elements is not limited to <head> and <row>. Milestone elements such as <cb> and <lb> allow breaks to be signalled inside tables; <figure> provides an option for including data which is not amenable to normal row/cell analysis; and other elements such as <epigraph> and <trailer> provide options for including text which is clearly part of the table, but outside the actual tabular layout. This example shows the use of <trailer>:

```
<table>
  <head>The Table of Battallions, reduced out of the grand square of
    men.</head>
  <row>
    <cell>1</cell>
    <cell>2</cell>
    <cell>3</cell>
    <cell>4</cell>
  </row>
  <!-- ... -->
  <row>
    <cell>841</cell>
    <cell>3</cell>
    <cell>289 289 256</cell>
    <cell>7</cell>
  </row>
  <trailer>The end of the Table of Battallions reduced out of the
    battels of g. and squares of men: vpon the right side of euery
    leafe.</trailer>
</table>
```

### 14.1.2 Other Table Schemas

Many authoring systems include built-in support for their own or for public table schemas. These provide an enhanced user interface and good formatting capabilities, but are often product-specific, despite their use of a XML markup language.

The DTD developed by the Association of American Publishers (AAP) and standardized in ANSI Z39.59 provided a very simple encoding for correspondingly simple tables. This has been further developed, together with the table DTD documented in ISO Technical Report 9537, and now forms part of ISO 12083. The TEI table model described above has functionality very similar to that defined by ISO 12083.

For more complex tables, the most effective publicly-available DTD is probably that developed by the US Department of Defense CALS project. This supports vertical and horizontal spanning and various kinds of text rotation and justification within cells and is also directly supported by a number of existing XML software systems.

The CALS table model is much too complex to describe fully here; for historical background see <http://archive.is/gGzsZ>; for more recent simplifications of it and current implementations see <https://www.oasis-open.org/specs/tablemodels.php>. As with any other XML vocabulary, the XML version of the CALS model may readily be included in a TEI schema, using the techniques described in 23.3. *Personalization and Customization*.

The XHTML table model (XHTML™ 1.0 The Extensible HyperText Markup Language (Second Edition) (2000)) is based on the HTML table model (Ragget et al. (eds.) (1999)). Both models support arrangement of arbitrary data into rows and columns of cells. Table rows and columns may be grouped to convey additional structural information and may be rendered by user agents in ways that emphasize this structure. Support for incremental rendering of tables and for rendering on ‘non-visual’ user agents is also available. Special elements and attributes are provided to associate metadata with tables. They indicate the table’s purpose, or are for the benefit of people using speech or Braille-based user agents. Tables are not recommended for use purely as a means to lay out document content, as this leads to many accessibility problems (see further <http://www.w3.org/TR/WCAG10-HTML-TECHS/#tables>). Stylesheets provide a far more effective means of controlling layout and other visual characteristics in both HTML and XML documents.

## 14.2 Formulæ and Mathematical Expressions

Mathematical and chemical formulæ pose problems similar to those posed by tables in that rendition may be of great significance and hard to disentangle from content. They also require access to a wide range of special characters, for most of which standard entity names already exist in the documented ISO entity sets (see further chapters *vi Languages and Character Sets* and *5. Characters, Glyphs, and Writing Modes*).

Formulæ and tables are also similar in that well-researched and detailed DTD fragments have already been developed for them independently of the TEI. They differ in that (for mathematics at least) there also exists a richly detailed text-based but non-XML notation which is very widely used: this is the TeX system, and the sets of descriptive macros developed for it such as LaTeX, AMS-TeX, and AMS-LaTeX.

The AAP and ISO standards mentioned in section 14.1. *Tables* above both provide DTDs for equations as well as for tables, which now form part of ISO 12083. The European Mathematical Trust, an organization set up specifically to enhance research support for European mathematicians, has also defined a general purpose mathematical DTD known as EuroMath (<http://xml.coverpages.org/emt-ukc-index.html>), for which it provides both software and services.

Most if not all of the functionality provided by these DTDs can now be found in the OpenMath and MathML XML-based systems briefly described below.

As with tables, in all the XML solutions a tension exists between the need to encode the way a formula is written (its appearance) and the need to represent its semantics. If the object of the encoding is purely to act as an interchange format among different formatting programs, then there is no need to represent the mathematical meaning of an expression. If however the object is to use the encoding as input to an algebraic manipulation system (such as Mathematica or Maple) or a database system, clearly simply representing superscripts and subscripts will be inadequate.

The `<formula>` element provided by these Guidelines makes no attempt to represent the internal structure of formulæ.

**`<formula>`** contains a mathematical or other formula.

By default, a `<formula>` is assumed to contain character data which is not validated in any way. The notation used may however be named, using the *notation* attribute provided by the `att.notated` class.

```
<formula notation="TeX">$e=mc^2$</formula>
```

The character data must still be well-formed, of course, which means that `<` and `&` must be escaped with entity references or numeric character references, e.g.

```
<formula notation="TeX">${\matrix{0 & \\ 1\cr & 1}}$</formula>
```

Alternatively, if more detailed markup is desired, the content of the `<formula>` element may be redefined to include elements defined by some other XML vocabulary, such as that of ISO 12083, or to use elements from the OpenMath or MathML schemas.

When the content of a `<formula>` element is not expressed in XML the notation used should always be specified using the *notation* attribute as above, and in the following longer example:

```
<p>Achilles runs ten times faster than the tortoise and gives the animal a headstart of ten meters. Achilles runs those ten meters, the tortoise one; Achilles runs that meter, the tortoise runs a decimeter; Achilles runs that decimeter, the tortoise runs a centimeter; Achilles runs that centimeter, the tortoise, a millimeter; Fleet-footed Achilles, the millimeter, the tortoise, a tenth of a millimeter, and so on to infinity, without the tortoise ever being overtaken. . . Such is the customary version.
<!-- ... --> The problem does not change, as
```

you can see; but I would like to know the name of the poet who provided it with a hero and a tortoise. To those magical competitors and to the series `<formula notation="TeX">$$ {1 \over 10} + {1 \over 100} + {1 \over 1000} + {1 \over 10, \!000} + \dots $$</formula>` the argument owes its fame.</p>

The *notation* attribute supplies the name of a notation ('TeX'), which is expected to be identified somewhere in document metadata.

Mathematical Markup Language (MathML) (Carlisle et al. (eds.) (2003)) is a vocabulary for describing mathematical notation, capturing both its structure and content. It provides two types of markup: Presentation Markup, which captures the *notational* structure of an expression and could be seen as the 'TeX for the Web' and Content Markup, which captures the *mathematical* structure of an expression. Most of its content elements correspond with the range of operators, relations, and named functions typically found at the high-school level of mathematics. The tortoise example given above in TeX can be re-expressed in MathML as

```
<m:math>
  <m:mfrac>
    <m:mrow>
      <m:mn>1</m:mn>
    </m:mrow>
    <m:mrow>
      <m:mn>10</m:mn>
    </m:mrow>
  </m:mfrac>
  <m:mo>+</m:mo>
  <m:mfrac>
    <m:mrow>
      <m:mn>1</m:mn>
    </m:mrow>
    <m:mrow>
      <m:mn>100</m:mn>
    </m:mrow>
  </m:mfrac>
  <m:mo>+</m:mo>
  <m:mfrac>
    <m:mrow>
      <m:mn>1</m:mn>
    </m:mrow>
    <m:mrow>
      <m:mn>1000</m:mn>
    </m:mrow>
  </m:mfrac>
  <m:mo>+</m:mo>
  <m:mfrac>
    <m:mrow>
      <m:mn>1</m:mn>
    </m:mrow>
    <m:mrow>
      <m:mn>10000</m:mn>
    </m:mrow>
  </m:mfrac>
  <m:mo>+</m:mo>
  <m:mo>...</m:mo>
</m:math>
```

MathML 2.0 provides support for a ‘Semantic Math-Web’, XML namespaces, and other current XML standards, such as XML DOM, OMG IDL, ECMAScript, and Java. It also provides a modularized version of the MathML DTD so that MathML fragments ‘embedded’ in XHTML 1.1 documents can be correctly validated.

The OpenMath (<http://www.nag.co.uk/projects/OpenMath.html>) project is coordinated by the OpenMath Society (<http://www.openmath.org/>) and funded by the European Commission under the Esprit Multimedia Standards Initiative that commenced in September 1997. It is likely to become a key standard for communicating semantically rich representations of mathematical objects both on and off the Web in a platform-independent manner.

The OpenMath Standard (<http://www.openmath.org/standard/om20-2004-06-30/>) consists of specifications for

1. OpenMath objects, representing the structure of formulæ ([http://www.openmath.org/standard/om20-2004-06-30/omstd20html-2.xml#cha\\_obj](http://www.openmath.org/standard/om20-2004-06-30/omstd20html-2.xml#cha_obj));
2. Content Dictionaries, providing semantic context ([http://www.openmath.org/standard/om20-2004-06-30/omstd20html-4.xml#cha\\_cd](http://www.openmath.org/standard/om20-2004-06-30/omstd20html-4.xml#cha_cd));
3. Encodings, both binary ([http://www.openmath.org/standard/om20-2004-06-30/omstd20html-3.xml#sec\\_binary](http://www.openmath.org/standard/om20-2004-06-30/omstd20html-3.xml#sec_binary)) and XML ([http://www.openmath.org/standard/om20-2004-06-30/omstd20html-3.xml#sec\\_xml](http://www.openmath.org/standard/om20-2004-06-30/omstd20html-3.xml#sec_xml)).

OpenMath and MathML have certain common aspects. They both use prefix operators, both are XML-based and they both construct their objects by applying certain rules recursively. Such similarities facilitate mapping between the two standards. There are also some key differences between MathML and OpenMath. OpenMath does not provide support for presentation of mathematical objects and its scope of semantically-oriented elements is much broader than that of MathML, with the expressive power to cover virtually all areas of computational mathematics. In fact, a particular set of Content Dictionaries, the ‘MathML CD Group’, covers the same areas of mathematics as the Content Markup elements of MathML 2.0.

Finally, OMDoc (<http://omdoc.org/>) is an extension of the OpenMath standard that supplies markup for structures such as axioms, theorems, proofs, definitions, texts (mixing formal content with mathematical text).

In-line versus block placement for an equation can be distinguished if desired, via the global *rend* attribute. The global *n* and *xml:id* attributes may also be used to label or identify the formula, as in the following example:

```
<p>The volume of a sphere
is given by the formula: <formula xml:id="f12" n="12" rend="inline">
  <m:math>
    <m:mi>V</m:mi>
    <m:mo>=</m:mo>
    <m:mfrac>
      <m:mrow>
        <m:mn>4</m:mn>
      </m:mrow>
      <m:mrow>
        <m:mn>3</m:mn>
      </m:mrow>
    </m:mfrac>
    <m:mi>π</m:mi>
    <m:msup>
      <m:mrow>
        <m:mi>r</m:mi>
      </m:mrow>
      <m:mrow>
        <m:mn>3</m:mn>
      </m:mrow>
    </m:msup>
  </m:math>
```

```

</formula> which is readily calculated.</p>
<p>As we have seen in equation <ptr target="#f12"/>, ... </p>

```

## 14.3 Notated Music in Written Text

Music, like many other art forms, is often mentioned, discussed and described in writings of various kinds. This applies to both historical and contemporary documents, even though methods of notating music have changed considerably in western history. In most cases, music notation enters the text flow in a way similar to figures, images or graphs. On other occasions, elements of music notation are treated as inline characters in running text.

<notatedMusic> provides a way to signal the presence of music notation in text, but defer to other representations, which are not covered by the TEI guidelines, to describe the music notation itself. In fact, several commercial, academic and standard bodies have developed digital representations of music notation, and given the topic's complexity, these representations often focus on different aspects and adopt different methodologies. Therefore, <notatedMusic> only defines a container element to encode the occurrence of music notation and allows linking to the data format preferred by the encoder. (Note: <notatedMusic> is not the same as <musicNotation>, a metadata element, which is used to describe musical notation that appears in a manuscript. See *10. Manuscript Description*.)

The following elements can be used for encoding music notation in text:

**<notatedMusic>** encodes the presence of music notation in a text

**<ptr>** (pointer) defines a pointer to another location.

**<desc>** (description) contains a brief description of the object documented by its parent element, including its intended usage, purpose, or application where this is appropriate.

**<graphic>** indicates the location of a graphic or illustration, either forming part of a text, or providing an image of it.

**<binaryObject>** provides encoded binary data representing an inline graphic, audio, video or other object.

groups elements representing or containing music notation.

can be used to indicate the location of a representation of the music notation.

- *contentType* supplies the MIME type of the data format, when available.

can be used to give a prose description of the notated music.

can be used to indicate the location of a graphical representation of the music notation.

provides encoded binary data which constitutes another representation of the music notation (e.g. audio).

The <notatedMusic> element may contain a textual description and pointers to various representations of the music notation in different media. An external representation of the notated music is specified using the <ptr> element, whose *target* attribute provides its electronically-accessible location. The attribute *contentType* supplies the MIME type of the data format when available. For example:

```

<notatedMusic>
  <ptr target="bar1.xml"/>
</notatedMusic>

```

A textual description of the notation can be provided within the <desc> element; alternatively, a <label> may be supplied. For example:

```

<notatedMusic>
  <ptr target="bar1.xml"/>
  <desc>First bar of Chopin's Scherzo No.3 Op.39</desc>
</notatedMusic>

```

It is possible to link to any kind of music notation data format. However, when a MIME type is not available, it is recommended that the format be specified in the description. See the following examples.

MIME type available:

```
<notatedMusic>
  <ptr target="bar1.xml"
    mimeType="application/vnd.recordare.musicxml"/>
  <desc>First bar of Chopin's Scherzo No.3 Op.39. Encoded in
    MusicXML.</desc>
</notatedMusic>
```

MIME type not available:

```
<notatedMusic>
  <ptr target="bar1.ly"/>
  <desc>First bar of Chopin's Scherzo No.3 Op.39. Encoded in
    Lilypond.</desc>
</notatedMusic>
```

Application format:

```
<notatedMusic>
  <ptr target="bar1.mscz"
    mimeType="application/x-musescore"/>
  <desc>First bar of Chopin's Scherzo No.3 Op.39. MuseScore Notation
    Software format.</desc>
</notatedMusic>
```

It is possible to specify the location of digital objects representing the notated music in other media such as images or audio-visual files. The interpretation of the correspondence between the notated music and these digital objects is not encoded explicitly. We recommend the use of `<graphic>` and `<binaryObject>` mainly as a fallback mechanism when the notated music format is not displayable by the application using the encoding. The alignment of encoded notated music, images carrying the notation, and audio files is a complex matter for which we refer the reader to other formats and specifications such as MPEG-SMR.

```
<notatedMusic>
  <ptr target="bar1.xml"/>
  <graphic url="bar1.jpg"/>
  <desc>First bar of Chopin's Scherzo No.3 Op.39</desc>
</notatedMusic>
```

In modern printing, music notation positioned between blocks of text for illustrative purposes is usually referred to as a 'figure' or 'example'. In this cases, we recommend the inclusion of `<notatedMusic>` in `<figure>` in order to encode possible captions and headers. For example:

```
<div n="67">
  <p> We now give some examples, from the works of the great masters, of
    some of the most frequently used bowings. </p>
  <figure n="Ex. 3">
    <head>SCHUBERT: Symphony in B minor.</head>
    <notatedMusic>
      <ptr target="example_schubert.xml"/>
    </notatedMusic>
  </figure>
</div>
```

67. We now give some examples, from the works of the great masters, of some of the most frequently used bowings.

## 14.4 Specific Elements for Graphic Images

The following special purpose elements are used to indicate the presence of graphic images within a document: **<figure>** groups elements representing or containing graphic information such as an illustration, formula, or figure.

**<graphic>** indicates the location of a graphic or illustration, either forming part of a text, or providing an image of it.

**<binaryObject>** provides encoded binary data representing an inline graphic, audio, video or other object.

**<figDesc>** (description of figure) contains a brief prose description of the appearance or content of a graphic figure, for use when documenting an image without displaying it.

The **<graphic>** and **<binaryObject>** elements form part of the common core module, and are discussed in section 3.9. *Graphics and Other Non-textual Components*.

The **<figure>** element is used to contain images, captions, and textual descriptions of the pictures. The images themselves are specified using the **<graphic>** element, whose *url* attribute provides the location of an image. For example:

```
<figure>
  <graphic url="Fig1.pdf"/>
</figure>
```

Three kinds of content may be supplied inside a **<figure>** element: the element **<head>** may be used to transcribe (or supply) a descriptive heading or title for the graphic itself as in this example:

```
<figure>
  <graphic url="Fig1.pdf"/>
  <head>The View from the Bridge</head>
</figure>
```

Figures are often accompanied not only by a title or heading (a caption), but by a paragraph or so of commentary (a legend) following the caption. One or more **<p>** or **<ab>** elements may be used to transcribe any commentary on the figure in the source:

```
<figure>
  <graphic url="pullman.png"/>
  <head>Above:</head>
  <p>The drawing room of the Pullman house, the white and gold saloon
    where the magnate delighted in giving receptions for several hundred
    people.</p>
  <figDesc>The figure shows an elaborately decorated room, at least
    twenty-five feet side to side and fifty feet long, with ornate
```

```

    mouldings and Corinthian columns on the walls, overstuffed armchairs
    and loveseats arranged in several conversational groupings, and two
    large chandeliers.</figDesc>
</figure>

```

Here, the figure contains a heading 'Above' which is complemented by a paragraph of description 'The drawing room ... several hundred people'. Both of these are transcribed from the source, while the description is provided by the encoder, for use by applications which cannot display the graphic directly. In documents created in electronic form with the needs of print-handicapped readers in mind, the <figDesc> element may be provided by the author rather than a subsequent encoder.

```

<figure>
  <graphic url="Fig1.jpg"/>
  <head>Figure One: The View from the Bridge</head>
  <figDesc>A Whistleresque view showing four or five sailing boats in
    the foreground, and a series of buoys strung out between
    them.</figDesc>
</figure>

```

Where the graphic itself contains large amounts of text, perhaps with a complex structure, and perhaps difficult to distinguish from the graphic, the encoder should choose whether to regard the graphic as containing the text (in which case, a nested <floatingText> element may be included within the <figure> element) or to regard the enclosed text as being a separate division of the <text> element in which the graphic appears. In this latter case, an appropriate <div> or <div1> (etc.) element may be used for the text represented within the graphic, and the <figure> element embedded within it. The choice will depend to a large degree on the encoder's understanding of the relationship between the graphic and the surrounding text.

A figure which is internally divided, or contains sub-figures, may be encoded with nested <figure> elements, as in the following example.

```

<figure n="6.45">
  <figure n="a">
    <graphic url="./figs/6.45a.png"/>
    <ab type="caption">Parallel</ab>
  </figure>
  <figure n="b">
    <graphic url="./figs/6.45b.png"/>
    <ab type="caption">Perspective</ab>
  </figure>
  <ab type="caption">The two canonical view volumes, for the (a)
    parallel and (b) perspective projections. Note that -z is to the
    right.</ab>
</figure>

```

Like any other element in the TEI scheme, figures may be given identifiers so that they can be aligned with other elements, and linked to or from them, as described in chapter 16. *Linking, Segmentation, and Alignment*. Some common examples are discussed briefly here; full information is provided in that chapter.

It is often desirable to maintain two versions of an image in an electronic file: one a low resolution or 'thumbnail' version which, when selected by the user, causes the other, high resolution, version to be accessed. In TEI terms, the thumbnail image acts as a *reference* to the other. Supposing that a thumbnail version of the figure discussed above is available as `fig1th.png`, we might embed a reference to the image using the simple <ref> element discussed in section 3.6. *Simple Links and Cross-References*:

```
<ref target="#IM1">Click
here <graphic url="fig1th.png"/> for enlightenment </ref>
<figure xml:id="IM1">
  <graphic url="fig1.jpg"/>
</figure>
```

Another common requirement is to associate part or the whole of an image with a textual element not necessarily contiguous to it in the text; this is sometimes known as a *callout*. When the module for transcription is included in a schema, specific attributes for parts of a text and parts (or all) of a digital image are available; these are discussed in 11.1. *Digital Facsimiles*. In addition, chapter 16. *Linking, Segmentation, and Alignment* may be consulted for other mechanisms available for this purpose.

The following example assumes that we wish to associate one portion of the image held as 'fig1' with chapter two of some text, and another portion of it with chapter three. The application may be thought of as a hypertext browser in which the user selects from a graphic image which part of a text to read next, but the mechanism is independent of this particular application.

The first requirement is some way of identifying and hence pointing to sub-parts of a graphic image. This may be done by pointing into an XML graphic representation, for example an SVG file. Thus

```
<ptr xml:id="PD1" target="Fig1.svg#object1"/>
<ptr xml:id="PD2" target="Fig1.svg#object2"/>
```

These <ptr> elements identify two areas within the image 'Fig1' by pointing at elements inside the XML file Fig1.svg, which contains the following.

```
<svg xmlns="http://www.w3.org/2000/svg" width="8cm" height="3cm"
  viewBox="2 1 8 3">
  <g id="object1">
    <ellipse style="fill: #ffffff" cx="3.875"
      cy="3.025" rx="1.175" ry="1.175"/>
  </g>
  <g id="object2">
    <rect style="fill: #a81616" x="7.8"
      y="1.9" width="2.17581" height="2.24833"/>
  </g>
</svg>
```

The next requirement is some way of identifying the parts of the document to which a link is to be made. The most obvious way of doing this is to use the global *xml:id* attribute:

```
<div1 type="chapter" xml:id="CHAP1">
<!-- ... -->
</div1>
<div1 type="chapter" xml:id="CHAP2">
<!-- ... -->
</div1>
```

Now, all that is needed to linking these areas to the relevant chapters is a <linkGrp> element, as described in section 16.1. *Links*:

```
<linkGrp type="callout">
  <link target="#CHAP1 #PD1"/>
  <link target="#CHAP2 #PD2"/>
</linkGrp>
```

In this example, the SVG representation of the graphic is stored externally to the TEI document and linked by means of a pointer. It is also possible to embed the SVG representation directly within the TEI by extending the content model of the <figure> element to permit an element <svg> from the SVG namespace. Like other customizations of the TEI scheme, this is carried out using the techniques documented in section 1.2. *Defining a TEI Schema*; further examples are provided in chapter 16. *Linking, Segmentation, and Alignment*.

## 14.5 Overview of Basic Graphics Concepts

The first major distinction in graphic representation is that between raster graphics and vector graphics. A *raster image* is a list of points, or dots. Scanners, fax machines and other simple devices easily produce digital raster images, and such images are therefore quite common. A *vector image*, in contrast, is a list of geometrical objects, such as lines, circles, arcs, or even cubes. These are much more difficult to produce, and so are mainly encountered as the output of sophisticated systems such as architectural and engineering CAD programs.

Raster images are difficult to modify because by definition they only encode single points: a line, for example, cannot grow or shrink as such, since it is not identified as such. Only its component parts are identified, and only they can be manipulated. Therefore the resolution or dot-size of a raster image is important, which is not the case with vector images. It is also far more difficult to convert raster images to vector images than to perform the opposite conversion. Raster images generally require more storage space than vector images, and a wide variety of methods exists for compressing them; the variation in these methods leads to corresponding variations in representations for storage and transmission of raster images.

Motion video usually consists of a long series of raster images. Data compression is even more effective on video than on single raster images (mainly owing to redundancy which arises from the usual similarity of adjacent frames). Notations for representing full-motion video are hotly debated at this time, and any user of these Guidelines would do well to obtain up-to-date expert advice before undertaking a project using them.

The compression methods used with any of these image types may be 'lossy' or 'lossless'. Methods for *lossy compression* save space by discarding a small portion of the image's detail, such as fine distinctions of shading. When decompressed, therefore, such an image will be only a close approximation of the original. In contrast, *lossless compression* guarantees that the exact uncompressed image will be reproducible from the compressed form: only truly redundant information is removed. In general, therefore, lossless compression does not save quite so much space as lossy compression, though it does guarantee fidelity to the original uncompressed image.

Raster images may be characterized by their *resolution*, which is the number of dots per inch used to represent the image. Doubling the resolution will give a more precise image, but also quadruple the storage requirement (before compression), and affect processing time for any operations to be performed, such as displaying an image for a reader. Motion video also has resolution in time: the number of frames to be shown per second. Encoders should consider carefully what resolution(s) and frame rate(s) to use for particular applications; these Guidelines express no recommendation in this matter, save the universal ones of consistency and documentation.

Within any image, it is typical to refer to locations via Cartesian coordinate axes: values for x, y, and sometimes z and/or time. However, graphic notations vary in whether coordinates count from left-to-right and top-to-bottom, or another way. They also vary in whether coordinates are considered real (inches, millimeters, and so on), or virtual (dots). These Guidelines do not recommend any of these methods over another, but all decisions made should be applied consistently, and documented in the <encodingDesc> section of the TEI header.<sup>87</sup>

Methods of aligning images and text are discussed in 11.1. *Digital Facsimiles*.

The chromatic values of an image may be rendered in many different ways. In monochrome images every displayed point is either black or white. In *grayscale* images, each point is rendered in some shade of gray, the number of shades varying from system to system. In true polychrome images, points are rendered in different hues, again with varying limitations affecting the number of distinct shades and the means by which they are displayed.

<sup>87</sup>Since no special purpose element is provided for this purpose by the current version of these Guidelines, such information should be provided as one or more distinct paragraphs at the end of the <encodingDesc> element described in section 2.3. *The Encoding Description*.

## 14.6 Graphic Image Formats

As noted above, there exists a wide variety of different graphics formats, and the following list is in no way exhaustive. Moreover, inclusion of any format in this list should not be taken as indicating endorsement by the TEI of this format or any products associated with it. Some of the formats listed here are proprietary to a greater or lesser extent and cannot therefore be regarded as standards in any meaningful sense. They are however widely used by many different vendors.

The following formats are widely used at the present time, and likely to remain supported by more than one vendor's software:

- BMP: Microsoft bitmap format
- CGM: Computer Graphics Metafile
- GIF: Graphics Interchange Format
- JPEG: Joint Photographic Expert Group
- PBM: Portable Bit Map
- PCX: IBM PC raster format
- PICT: Macintosh drawing format
- PNG: Portable Network Graphics format
- Photo-CD: Kodak Photo Compact Disk format
- QuickTime: Apple real-time image system
- SMIL: Synchronized Multimedia Integration Language format
- SVG: Scalable Vector Graphics format
- TIFF: Tagged Image File Format

Brief descriptions of all the above are given below. Where possible, current addresses or other contact information are shown for the originator of each format. Many formal standards, especially those promulgated by ISO and many related national organizations (ANSI, DIN, BSI, and many more), are available from those national organizations. Addresses may be found in any standard organizational directory for the country in question.

### 14.6.1 Vector Graphic Formats

**CGM: Computer Graphics Metafile** This vector graphics format is specified by an ISO standard, ISO 8632:1987, amended in 1990. It defines binary, character, and plain-text encodings; the non-binary forms are safer for blind interchange, especially over networks. Documentation on CGM is available from ISO and from its member national bodies such as AFNOR, ANSI, BSI, DIN, JIS, etc.

**SVG: Scalable Vector Graphics format** SVG is a language for describing two-dimensional vector and mixed vector or raster graphics in XML. It is defined by the Scalable Vector Graphics (SVG) 1.0 Specification, W3C Recommendation, 04 September 2001, and is available at <http://www.w3.org/TR/2001/REC-SVG-20010904/>.

**PICT: Macintosh drawing format** This format is universally supported on Macintosh (tm) systems, and readable by a limited range of software for other systems. Documentation is available from Apple Computer Company, Cupertino, California USA.

### 14.6.2 Raster Graphic Formats

**PNG: Portable Network Graphics format** PNG is a non-proprietary raster format currently widely available. It provides an extensible file format for the lossless, portable, well-compressed storage of raster images. Indexed-color, grayscale, and truecolor images are supported, plus an optional alpha channel. Sample depths range from 1 to 16 bits. It is defined by IETF RFC 2083, March 1997.

**TIFF: Tagged Image File Format** Currently the most widely supported raster image format, especially for black and white images, TIFF is also one of the few formats commonly supported on more than one operating system. The drawback to TIFF is that it actually is a wrapper for several formats, and some TIFF-supporting software does not support all variants. TIFF files may use LZW, CCITT Group 4, or PackBits compression methods, or may use no compression at all. Also, TIFF files may be monochrome, grayscale, or polychromatic. All such options should

be specified in prose at the end of the <encodingDesc> section of the TEI header for any document including TIFF images. TIFF is owned by Aldus Corporation. Documentation on TIFF is available from them at Craigcook Castle, Craigcook Road, Edinburgh EH4 3UH, Scotland, or 411 First Avenue South, Seattle, Washington 98104 USA.

**GIF: Graphics Interchange Format** Raster images are widely available in this form, which was created by CompuServe Information Services, but has by now been implemented for many other systems as well. Documentation on GIF is copyright by, and is available from, CompuServe Incorporated, Graphics Technology Department, 5000 Arlington Center Boulevard, Columbus, Ohio 43220 USA.

**PBM: Portable Bit Map** PBM files are easy to process, eschewing all compression in favor of transparency of file format. PBM files can, of course, be compressed by generic file-compression tools for storage and transfer. Public domain software exists which will convert many other formats to and from PBM. Documentation on PBM is copyright by Jeff Poskanzer, and is available widely on the Internet.

**PCX: IBM PC raster format** This format is used by most IBM PC paint programs, and supports both monochrome and polychromatic images. Documentation is available from ZSoft Corporation, Technical Support Department, ATTN: Technical Reference Manual, 450 Franklin Rd. Suite 100, Marietta, GA 30067 USA.

**BMP: Microsoft bitmap format** This format is the standard raster format for computer using Microsoft Windows (tm) or Presentation Manager (tm). Documentation is available from Microsoft Corporation.

### 14.6.3 Photographic and Motion Video Formats

**JPEG: Joint Photographic Experts Group** This standard is sponsored by CCITT and by ISO. It is ISO/IEC Draft International Standard 10918-1, and CCITT T.81. It handles monochrome and polychromatic images with a variety of compression techniques. JPEG per se, like CCITT Group IV, must be encapsulated before transmission; this can be done via TIFF, or via the JPEG File Interchange Format (JFIF), as commonly done for Internet delivery.

**QuickTime: Apple real-time image system** QuickTime is a proprietary method introduced by Apple Computer Company to synchronize the display of various data. The data can include frames of video, sound, lighting control mechanisms, and other things. Viewers for QuickTime productions are available for Apple and other computers. Further information is available from Apple Computer Incorporated, 10201 North de Anza Boulevard MS 23AQ, Cupertino, California 95014 USA.

**Photo-CD: Kodak Photo Compact Disk format** This format was introduced by Kodak for rasterizing photographs and storing them on CD-ROMs (about one hundred 35mm file images fit on one disk), for display on televisions or CD-I systems. Information on Photo-CD is available from Kodak Limited, Research and Development, Headstone Drive, Harrow, Middlesex HA1 4TY, UK.

**SMIL: Synchronized Multimedia Integration Language format** SMIL is a W3C Recommendation which supports the integration of independent multimedia objects into a synchronized multimedia presentation. It provides multimedia authors with easily-defined basic timing relationships, fine-tuned synchronization, spatial layout, direct inclusion of non-text and non-image media objects, hyperlink support for time-based media, and adaptiveness to varying user and system characteristics. SMIL 1.0 (<http://www.w3.org/TR/REC-smil/>) became a W3C Recommendation on June 15, 1998, and was further developed in SMIL 2.0. SMIL 2.0 adds native support for transitions, animation, event-based interaction, extended layout facilities, and more sophisticated timing and synchronization primitives to the SMIL 1.0 language. It also allows reuse of SMIL syntax and semantics in other XML-based languages, in particular those who need to represent timing and synchronization. For example, SMIL 2.0 components are used for integrating timing into XHTML Document Types and into SVG. SMIL 2.0 also provides recommendations for Document Types based on SMIL 2.0 Modules (<http://www.w3.org/TR/2005/REC-SMIL2-20050107/smil-modules.html>). One such Document Type is the SMIL 2.0 Language Profile (<http://www.w3.org/TR/2005/REC-SMIL2-20050107/smil20-profile.html>). It contains support for all of the major SMIL 2.0 features including animation, content control, layout, linking, media object, meta-information, structure, timing, and transition effects and is designed for Web clients that support direct playback from SMIL 2.0 markup. SMIL 2.0 (<http://www.w3.org/TR/2001/REC-smil20-20010807/>) became a W3C Recommendation on August 7, 2001, becoming the first vocabulary to provide XML Schema support and to have reached such status.

As noted above, the reader will encounter many, many other graphics formats.

## 14.7 Module for Tables, Formulæ, Notated Music, and Graphics

The module described in this chapter provides the following features:

**Module figures: Tables, formulæ, notated music, and figures**

- *Elements defined:* cell figDesc figure formula notatedMusic row table

The selection and combination of modules to form a TEI schema is described in *1.2. Defining a TEI Schema*.

## 15 Language Corpora

The term *language corpus* is used to mean a number of rather different things. It may refer simply to any collection of linguistic data (for example, written, spoken, signed, or multimodal), although many practitioners prefer to reserve it for collections which have been organized or collected with a particular end in view, generally to characterize a particular state or variety of one or more languages. Because opinions as to the best method of achieving this goal differ, various subcategories of corpora have also been identified. For our purposes however, the distinguishing characteristic of a corpus is that its components have been selected or structured according to some conscious set of design criteria.

These design criteria may be very simple and undemanding, or very sophisticated. A corpus may be intended to represent (in the statistical sense) a particular linguistic variety or sublanguage, or it may be intended to represent all aspects of some assumed ‘core’ language. A corpus may be made up of whole texts or of fragments or text samples. It may be a ‘closed’ corpus, or an ‘open’ or ‘monitor’ corpus, the composition of which may change over time. However, since an open corpus is of necessity finite at any particular point in time, the only likely effect of its expansibility from the encoding point of view may be some increased difficulty in maintaining consistent encoding practices (see further section 15.5. *Recommendations for the Encoding of Large Corpora*). For simplicity, therefore, our discussion largely concerns ways of encoding closed corpora, regarded as single but composite texts.

Language corpora are regarded by these Guidelines as *composite texts* rather than *unitary texts* (on this distinction, see chapter 4. *Default Text Structure*). This is because although each discrete sample of language in a corpus clearly has a claim to be considered as a text in its own right, it is also regarded as a subdivision of some larger object, if only for convenience of analysis. Corpora share a number of characteristics with other types of composite texts, including anthologies and collections. Most notably, different components of composite texts may exhibit different structural properties (for example, some may be composed of verse, and others of prose), thus potentially requiring elements from different TEI modules.

Aside from these high-level structural differences, and possibly differences of scale, the encoding of language corpora and the encoding of individual texts present identical sets of problems. Any of the encoding techniques and elements presented in other chapters of these Guidelines may therefore prove relevant to some aspect of corpus encoding and may be used in corpora. Therefore, we do not repeat here the discussion of such fundamental matters as the representation of multiple character sets (see chapter *vi Languages and Character Sets*); nor do we attempt to summarize the variety of elements provided for encoding basic structural features such as quoted or highlighted phrases, cross-references, lists, notes, editorial changes and reference systems (see chapter 3. *Elements Available in All TEI Documents*). In addition to these general purpose elements, these Guidelines offer a range of more specialized sets of tags which may be of use in certain specialized corpora, for example those consisting primarily of verse (chapter 6. *Verse*), drama (chapter 7. *Performance Texts*), transcriptions of spoken text (chapter 8. *Transcriptions of Speech*), etc. Chapter 1. *The TEI Infrastructure* should be reviewed for details of how these and other components of these Guidelines should be tailored to create a document type definition appropriate to a given application. In sum, it should not be assumed that only the matters specifically addressed in this chapter are of importance for corpus creators.

This chapter does however include some other material relevant to corpora and corpus-building, for which no other location appeared suitable. It begins with a review of the distinction between unitary and composite texts, and of the different methods provided by these Guidelines for representing composite texts of different kinds (section 15.1. *Varieties of Composite Text*). Section 15.2. *Contextual Information* describes a set of additional header elements provided for the documentation of contextual information, of importance largely though not exclusively to language corpora. This is the additional module for language corpora proper. Section 15.3. *Associating Contextual Information with a Text* discusses a mechanism by which individual parts of the TEI header may be associated with different parts of a TEI-conformant text. Section 15.4. *Linguistic Annotation of Corpora* reviews various methods of providing linguistic annotation in corpora, with some specific examples of relevance to current practice in corpus linguistics. Finally, section 15.5. *Recommendations for the Encoding of Large Corpora* provides some general recommendations about the use of these Guidelines in the building of large corpora.

### 15.1 Varieties of Composite Text

Both unitary and composite texts may be encoded using these Guidelines; composite texts, including corpora, will typically make use of the following tags for their top-level organization.

**<teiCorpus>** contains the whole of a TEI encoded corpus, comprising a single corpus header and one or more TEI elements, each containing a single text header and a text.

**<TEI>** (TEI document) contains a single TEI-conformant document, combining a single TEI header with one or more members of the `model.resourceLike` class. Multiple TEI elements may be combined to form a `<teiCorpus>` element.

**<teiHeader>** (TEI header) supplies descriptive and declarative metadata associated with a digital resource or set of resources.

`@type` specifies the kind of document to which the header is attached, for example whether it is a corpus or individual text.

**<text>** contains a single text of any kind, whether unitary or composite, for example a poem or drama, a collection of essays, a novel, a dictionary, or a corpus sample.

**<group>** contains the body of a composite text, grouping together a sequence of distinct texts (or groups of such texts) which are regarded as a unit for some purpose, for example the collected works of an author, a sequence of prose essays, etc.

Full descriptions of these may be found in chapter 2. *The TEI Header* (for `<teiHeader>`), and chapter 4. *Default Text Structure* (for `<teiCorpus>`, `<TEI>`, `<text>` and `<group>`); this section discusses their application to composite texts in particular.

In these Guidelines, the word *text* refers to any stretch of discourse, whether complete or incomplete, unitary or composite, which the encoder chooses (perhaps merely for purposes of analytic convenience) to regard as a unit. The term *composite text* refers to texts within which other texts appear; the following common cases may be distinguished:

- language corpora
- collections or anthologies
- poem cycles and epistolary works (novels or essays written in the form of collections or series of letters)
- otherwise unitary texts, within which one or more subordinate texts are embedded

The elements listed above may be combined to encode each of these varieties of composite text in different ways.

In corpora, the component samples are clearly distinct texts, but the systematic collection, standardized preparation, and common markup of the corpus often make it useful to treat the entire corpus as a unit, too. Some corpora may become so well established as to be regarded as texts in their own right; the Brown and LOB corpora are now close to achieving this status.

The `<teiCorpus>` element is intended for the encoding of language corpora, though it may also be useful in encoding newspapers, electronic anthologies, and other disparate collections of material. The individual samples in the corpus are encoded as separate `<TEI>` elements, and the entire corpus is enclosed in a `<teiCorpus>` element. Each sample has the usual structure for a `<TEI>` document, comprising a `<teiHeader>` followed by a `<text>` element. The corpus, too, has a corpus-level `<teiHeader>` element, in which the corpus as a whole, and encoding practices common to multiple samples may be described. The overall structure of a TEI-conformant corpus is thus:

```
<teiCorpus xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader/>
  <TEI>
    <teiHeader/>
    <text/>
  </TEI>
  <TEI>
    <teiHeader/>
    <text/>
  </TEI>
</teiCorpus>
```

Header information which relates to the whole corpus rather than to individual components of it should be factored out and included in the `<teiHeader>` element prefixed to the whole. This two-level structure allows for contextual information to be specified at the corpus level, at the individual text level, or at both. Discussion of the kinds of

information which may thus be specified is provided below, in section 15.2. *Contextual Information*, as well as in chapter 2. *The TEI Header*. Information of this type should in general be specified only once: a variety of methods are provided for associating it with individual components of a corpus, as further described in section 15.3. *Associating Contextual Information with a Text*.

In some cases, the design of a corpus is reflected in its internal structure. For example, a corpus of newspaper extracts might be arranged to combine all stories of one type (reportage, editorial, reviews, etc.) into some higher-level grouping, possibly with sub-groups for date, region, etc. The <teiCorpus> element provides no direct support for reflecting such internal corpus structure in the markup: it treats the corpus as an undifferentiated series of components, each tagged <TEI>.

If it is essential to reflect a single permanent organization of a corpus into sub- and sub-sub-corpora, then the corpus or the high-level subcorpora may be encoded as composite texts, using the <group> element described below and in section 4.3.1. *Grouped Texts*. The mechanisms for corpus characterization described in this chapter, however, are designed to reduce the need to do this. Useful groupings of components may easily be expressed using the text classification and identification elements described in section 15.2.1. *The Text Description*, and those for associating declarations with corpus components described in section 15.3. *Associating Contextual Information with a Text*. These methods also allow several different methods of text grouping to co-exist, each to be used as needed at different times. This helps minimize the danger of cross-classification and misclassification of samples, and helps improve the flexibility with which parts of a corpus may be characterized for different applications.

Anthologies and collections are often treated as texts in their own right, if only for historical reasons. In conventional publishing, at least, anthologies are published as units, with single editorial responsibility and common front and back matter which may need to be included in their electronic encodings. The texts collected in the anthology, of course, may also need to be identifiable as distinct individual objects for study.

Poem cycles, epistolary novels, and epistolary essays differ from anthologies in that they are often written as single works, by single authors, for single occasions; nevertheless, it can be useful to treat their constituent parts as individual texts, as well as the cycle itself. Structurally, therefore, they may be treated in the same way as anthologies: in both cases, the body of the text is composed largely of other texts.

The <group> element is provided to simplify the encoding of collections, anthologies, and cyclic works; as noted above, the <group> element can also be used to record the potentially complex internal structure of language corpora. For a full description, see chapter 4. *Default Text Structure*.

Some composite texts, finally, are neither corpora, nor anthologies, nor cyclic works: they are otherwise unitary texts within which other texts are embedded. In general, they may be treated in the same way as unitary texts, using the normal <TEI> and <body> elements. The embedded text itself may be encoded using the <text> element, which may occur within quotations or between paragraphs or other chunk-level elements inside the sections of a larger text. For further discussion, see chapter 4. *Default Text Structure*.

All composite texts share the characteristic that their different component texts may be of structurally similar or dissimilar types. If all component texts may all be encoded using the same module, then no problem arises. If however they require different modules, then these must be included in the schema. This process is described in more detail in section 1.1. *TEI Modules*.

## 15.2 Contextual Information

Contextual information is of particular importance for collections or corpora composed of samples from a variety of different kinds of text. Examples of such contextual information include: the age, sex, and geographical origins of participants in a language interaction, or their socio-economic status; the cost and publication data of a newspaper; the topic, register or factuality of an extract from a textbook. Such information may be of the first importance, whether as an organizing principle in creating a corpus (for example, to ensure that the range of values in such a parameter is evenly represented throughout the corpus, or represented proportionately to the population being sampled), or as a selection criterion in analysing the corpus (for example, to investigate the language usage of some particular vector of social characteristics).

Such contextual information is potentially of equal importance for unitary texts, and these Guidelines accordingly make no particular distinction between the kinds of information which should be gathered for unitary and for composite texts. In either case, the information should be recorded in the appropriate section of a TEI header, as described in chapter 2. *The TEI Header*. In the case of language corpora, such information may be gathered together in the overall corpus header, or split across all the component texts of a corpus, in their individual headers, or divided between the two. The association between an individual corpus text and the contextual information applicable to

it may be made in a number of ways, as further discussed in section 15.3. *Associating Contextual Information with a Text* below.

Chapter 2. *The TEI Header*, which should be read in conjunction with the present section, describes in full the range of elements available for the encoding of information relating to the electronic file itself, for example its bibliographic description and those of the source or sources from which it was derived (see section 2.2. *The File Description*); information about the encoding practices followed with the corpus, for example its design principles, editorial practices, reference system, etc. (see section 2.3. *The Encoding Description*); more detailed descriptive information about the creation and content of the corpus, such as the languages used within it and any descriptive classification system used (see section 2.4. *The Profile Description*); and version information documenting any changes made in the electronic text (see section 2.6. *The Revision Description*).

In addition to the elements defined by chapter 2. *The TEI Header*, several other elements can be used in the TEI header if the additional module defined by this chapter is invoked. These additional tags make it possible to characterize the social or other situation within which a language interaction takes place or is experienced, the physical setting of a language interaction, and the participants in it. Though this information may be relevant to, and provided for, unitary texts as well as for collections or corpora, it is more often recorded for the components of systematically developed corpora than for isolated texts, and thus this module is referred to as being ‘for language corpora’.

When the module defined in this chapter is included in a schema, a number of additional elements become available within the <profileDesc> element of the TEI header (discussed in section 2.4. *The Profile Description*).

**<textDesc>** (text description) provides a description of a text in terms of its situational parameters.

**<particDesc>** (participation description) describes the identifiable speakers, voices, or other participants in any kind of text or other persons named or otherwise referred to in a text, edition, or metadata.

**<settingDesc>** (setting description) describes the setting or settings within which a language interaction takes place, or other places otherwise referred to in a text, edition, or metadata.

These elements, members of the `model.profileDescPart`, are discussed in the remainder of the chapter.

### 15.2.1 The Text Description

The <textDesc> element provides a full description of the situation within which a text was produced or experienced, and thus characterizes it in a way relatively independent of any *a priori* theory of text-types. It is provided as an alternative or a supplement to the common use of descriptive taxonomies used to categorize texts, which is fully described in section 2.4.3. *The Text Classification*, and section 2.3.7. *The Classification Declaration*.

The description is organized as a set of values and optional prose descriptions for the following eight *situational parameters*, each represented by one of the following eight elements:

**<channel>** (primary channel) describes the medium or channel by which a text is delivered or experienced.

For a written text, this might be print, manuscript, email, etc.; for a spoken one, radio, telephone, face-to-face, etc.

**@mode** specifies the mode of this channel with respect to speech and writing.

**<constitution>** describes the internal composition of a text or text sample, for example as fragmentary, complete, etc.

**@type** specifies how the text was constituted.

**<derivation>** describes the nature and extent of originality of this text.

**@type** categorizes the derivation of the text.

**<domain>** (domain of use) describes the most important social context in which the text was realized or for which it is intended, for example private vs. public, education, religion, etc.

**@type** categorizes the domain of use.

**<factuality>** describes the extent to which the text may be regarded as imaginative or non-imaginative, that is, as describing a fictional or a non-fictional world.

**@type** categorizes the factuality of the text.

**<interaction>** describes the extent, cardinality and nature of any interaction among those producing and experiencing the text, for example in the form of response or interjection, commentary, etc.

**@type** specifies the degree of interaction between active and passive participants in the text.

`@active` specifies the number of active participants (or *addressors*) producing parts of the text.

`@passive` specifies the number of passive participants (or *addressees*) to whom a text is directed or in whose presence it is created or performed.

**<preparedness>** describes the extent to which a text may be regarded as prepared or spontaneous.

`@type` a keyword characterizing the type of preparedness.

**<purpose>** characterizes a single purpose or communicative function of the text.

`@type` specifies a particular kind of purpose.

`@degree` specifies the extent to which this purpose predominates.

These elements constitute a model class called `model.textDescPart`; new parameters may be defined by defining new elements and adding them to that class, as further described in 23.3. *Personalization and Customization*.

By default, a text description will contain each of the above elements, supplied in the order specified. Except for the `<purpose>` element, which may be repeated to indicate multiple purposes, no element should appear more than once within a single text description. Each element may be empty, or may contain a brief qualification or more detailed description of the value expressed by its attributes. It should be noted that some texts, in particular literary ones, may resist unambiguous classification in some of these dimensions; in such cases, the situational parameter in question should be given the content 'not applicable' or an equivalent phrase.

Texts may be described along many dimensions, according to many different taxonomies. No generally accepted consensus as to how such taxonomies should be defined has yet emerged, despite the best efforts of many corpus linguists, text linguists, sociolinguists, rhetoricians, and literary theorists over the years. Rather than attempting the task of proposing a single taxonomy of *text-types* (or the equally impossible one of enumerating all those which have been proposed previously), the closed set of *situational parameters* described above can be used in combination to supply useful distinguishing descriptive features of individual texts, without insisting on a system of discrete high-level text-types. Such text-types may however be used in combination with the parameters proposed here, with the advantage that the internal structure of each such text-type can be specified in terms of the parameters proposed. This approach has the following analytical advantages:<sup>88</sup>

- it enables a relatively continuous characterization of texts (in contrast to discrete categories based on type or topic)
- it enables meaningful comparisons across corpora
- it allows analysts to build and compare their own text-types based on the particular parameters of interest to them
- it is equally applicable to spoken, written, or signed texts

Two alternative approaches to the use of these parameters are supported by these Guidelines. One is to use pre-existing taxonomies such as those used in subject classification or other types of text categorization. Such taxonomies may also be appropriate for the description of the topics addressed by particular texts. Elements for this purpose are described in section 2.4.3. *The Text Classification*, and elements for defining or declaring such classification schemes in section 2.3.7. *The Classification Declaration*. A second approach is to develop an application-specific set of *feature structures* and an associated *feature system declaration*, as described in chapters 18. *Feature Structures* and 18.11. *Feature System Declaration*.

Where the organizing principles of a corpus or collection so permit, it may be convenient to regard a particular set of values for the situational parameters listed in this section as forming a *text-type* in its own right; this may also be useful where the same set of values applies to several texts within a corpus. In such a case, the set of text-types so defined should be regarded as a *taxonomy*. The mechanisms described in section 2.3.7. *The Classification Declaration* may be used to define hierarchic taxonomies of such text-types, provided that the `<catDesc>` component of the `<category>` element contains a `<textDesc>` element rather than a prose description. Particular texts may then be associated with such definitions using the mechanisms described in sections 2.4.3. *The Text Classification*.

Using these situational parameters, an informal domestic conversation might be characterized as follows:

---

<sup>88</sup>Schemes similar to that proposed here were developed in the 1960s and 1970s by researchers such as Hymes, Halliday, and Crystal and Davy, but have rarely been implemented; one notable exception being the pioneering work on the Helsinki Diachronic Corpus of English, on which see Kytö and Rissanen (1988)

```

<textDesc n="Informal domestic conversation">
  <channel mode="s">informal face-to-face conversation</channel>
  <constitution type="single">each text represents a continuously
    recorded interaction among the specified participants
  </constitution>
  <derivation type="original"/>
  <domain type="domestic">plans for coming week, local affairs</domain>
  <factuality type="mixed">mostly factual, some jokes</factuality>
  <interaction type="complete"
    active="plural" passive="many"/>
  <preparedness type="spontaneous"/>
  <purpose type="entertain" degree="high"/>
  <purpose type="inform" degree="medium"/>
</textDesc>

```

The following example demonstrates how the same situational parameters might be used to characterize a novel:

```

<textDesc n="novel">
  <channel mode="w">print; part issues</channel>
  <constitution type="single"/>
  <derivation type="original"/>
  <domain type="art"/>
  <factuality type="fiction"/>
  <interaction type="none"/>
  <preparedness type="prepared"/>
  <purpose type="entertain" degree="high"/>
  <purpose type="inform" degree="medium"/>
</textDesc>

```

### 15.2.2 The Participant Description

The <particDesc> element in the <profileDesc> element provides additional information about the participants in a spoken text or, where this is judged appropriate, the persons named or depicted in a written text. When the detailed elements provided by the *namesdates* module described in *13. Names, Dates, People, and Places* are included in a schema, this element can contain detailed demographic or descriptive information about individual speakers or groups of speakers, such as their names or other personal characteristics. Individually identified persons may also be identified by a code which can then be used elsewhere within the encoded text, for example as the value of a *who* attribute.

It should be noted that although the terms *speaker* or *participant* are used throughout this section, it is intended that the same mechanisms may be used to characterize fictional personæ or ‘voices’ within a written text, except where otherwise stated. For the purposes of analysis of language usage, the information specified here should be equally applicable to written, spoken, or signed texts.

The element <particDesc> contains a description of the participants in an interaction, which may be supplied as straightforward prose, possibly containing a list of names, encoded using the usual <list> and <name> elements, or alternatively using the more specific and detailed <listPerson> element provided by the *namesdates* module described in *13. Names, Dates, People, and Places*.

For example, a participant in a recorded conversation might be described informally as follows:

```

<particDesc xml:id="p2">
  <p>Female informant, well-educated, born in Shropshire UK, 12 Jan
    1950, of unknown occupation. Speaks French fluently.
    Socio-Economic status B2 in the PEP classification scheme.</p>
</particDesc>

```

Alternatively, when the `namesdates` module is included in a schema, information about the same participant described above might be provided in a more structured way as follows:

```
<person sex="2" age="mid">
  <birth when="1950-01-12">
    <date>12 Jan 1950</date>
    <name type="place">Shropshire, UK</name>
  </birth>
  <langKnowledge tags="en fr">
    <langKnown level="first" tag="en">English</langKnown>
    <langKnown tag="fr">French</langKnown>
  </langKnowledge>
  <residence>Long term resident of Hull</residence>
  <education>University postgraduate</education>
  <occupation>Unknown</occupation>
  <socecStatus scheme="#pep" code="#b2"/>
</person>
```

An identified character in a drama or a novel may also be regarded as a participant in this sense, and encoded using the same techniques:<sup>89</sup>

```
<particDesc>
  <p>The chief speaking characters in this novel are
  <list>
    <item xml:id="EMWOO">
      <name>Emma Woodhouse</name>
    </item>
    <item xml:id="DARCY">
      <name>Mr Darcy</name>
    </item>
  <!-- ... -->
  </list>
</p>
</particDesc>
```

Here, the characters are simply listed without the detailed structure which use of the `<listPerson>` element permits.

### 15.2.3 The Setting Description

The `<settingDesc>` element is used to describe the setting or settings in which language interaction takes place. It may contain a prose description, analogous to a stage description at the start of a play, stating in broad terms the locale, or a more detailed description of a series of such settings.

Each distinct setting is described by means of a `<setting>` element.

**<setting>** describes one particular setting in which a language interaction takes place.

Individual settings may be associated with particular participants by means of the optional *who* attribute which this element inherits as a member of the `att.ascribed` if, for example, participants are in different places. This attribute identifies one or more individual participants or participant groups, as discussed earlier in section 15.2.2. *The Participant Description*. If this attribute is not specified, the setting details provided are assumed to apply to all participants represented in the language interaction. Note however that it is not possible to encode different settings for the same participant: a participant is deemed to be a person within a specific setting.

The `<setting>` element may contain either a prose description or a selection of elements from the classes `model.nameLike.agent`, `model.dateLike`, or `model.settingPart`. By default, when the module defined by this chapter is included in a schema, these classes thus provide the following elements:

<sup>89</sup>It is particularly useful to define participants in a dramatic text in this way, since it enables the *who* attribute to be used to link `<sp>` elements to definitions for their speakers; see further section 7.2.2. *Speeches and Speakers*.

- <name>** (name, proper noun) contains a proper noun or noun phrase.
- <date>** contains a date in any format.
- <time>** contains a phrase defining a time of day in any format.
- <locale>** contains a brief informal description of the kind of place concerned, for example: a room, a restaurant, a park bench, etc.
- <activity>** contains a brief informal description of what a participant in a language interaction is doing other than speaking, if anything.
- Additional more specific naming elements such as **<orgName>** or **<persName>** may also be available if the **namesdates** module is also included in the schema.
- The following example demonstrates the kind of background information often required to support transcriptions of language interactions, first encoded as a simple prose narrative:

```
<settingDesc>
  <p>The time is early spring, 1989. P1 and P2 are playing on the rug
    of a suburban home in Bedford. P3 is doing the washing up at the
    sink. P4 (a radio announcer) is in a broadcasting studio in
    London.</p>
</settingDesc>
```

The same information might be represented more formally in the following way:

```
<settingDesc>
  <setting who="#p1 #p2">
    <name type="city">Bedford</name>
    <name type="region">UK: South East</name>
    <date>early spring, 1989</date>
    <locale>rug of a suburban home</locale>
    <activity>playing</activity>
  </setting>
  <setting who="#p3">
    <name type="city">Bedford</name>
    <name type="region">UK: South East</name>
    <date>early spring, 1989</date>
    <locale>at the sink</locale>
    <activity>washing-up</activity>
  </setting>
  <setting who="#p4">
    <name type="place">London, UK</name>
    <time>unknown</time>
    <locale>broadcasting studio</locale>
    <activity>radio performance</activity>
  </setting>
</settingDesc>
```

Again, a more detailed encoding for places is feasible if the **namesdates** module is included in the schema. The above examples assume that only the general purpose **<name>** element supplied in the core module is available.

## 15.3 Associating Contextual Information with a Text

This section discusses the association of the contextual information held in the header with the individual elements making up a TEI text or corpus. Contextual information is held in elements of various kinds within the TEI header, as discussed elsewhere in this section and in chapter 2. *The TEI Header*. Here we consider what happens when different parts of a document need to be associated with different contextual information of the same type, for example when one part of a document uses a different encoding practice from another, or where one part relates to a different

setting from another. In such situations, there will be more than one instance of a header element of the relevant type.

The TEI scheme allow for the following possibilities:

- A given element may appear in the corpus header only, in the header of one or more texts only, or in both places
- There may be multiple occurrences of certain elements in either corpus or text header.

To simplify the exposition, we deal with these two possibilities separately in what follows; however, they may be combined as desired.

### 15.3.1 Combining Corpus and Text Headers

A TEI-conformant document may have more than one header only in the case of a TEI corpus, which must have a header in its own right, as well as the obligatory header for each text. Every element specified in a corpus-header is understood as if it appeared within every text header in the corpus. An element specified in a text header but not in the corpus header supplements the specification for that text alone. If any element is specified in both corpus and text headers, the corpus header element is over-ridden for that text alone.

The `<titleStmt>` for a corpus text is understood to be prefixed by the `<titleStmt>` given in the corpus header. All other optional elements of the `<fileDesc>` should be omitted from an individual corpus text header unless they differ from those specified in the corpus header. All other header elements behave identically, in the manner documented below. This facility makes it possible to state once for all in the corpus header each piece of contextual information which is common to the whole of the corpus, while still allowing for individual texts to vary from this common denominator.

For example, the following schematic shows the structure of a corpus comprising three texts, the first and last of which share the same encoding description. The second one has its own encoding description.

```
<teiCorpus xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <fileDesc>
<!-- corpus file description-->
    </fileDesc>
    <encodingDesc>
<!-- default encoding description -->
    </encodingDesc>
    <revisionDesc>
<!-- corpus revision description -->
    </revisionDesc>
  </teiHeader>
  <TEI>
    <teiHeader>
      <fileDesc>
<!-- file description for this corpus text -->
      </fileDesc>
    </teiHeader>
    <text>
<!-- first corpus text -->
    </text>
  </TEI>
  <TEI>
    <teiHeader>
      <fileDesc>
<!-- file description for this corpus text -->
      </fileDesc>
      <encodingDesc>
<!-- encoding description for this corpus
text, over-riding the default -->
      </encodingDesc>
    </teiHeader>
```

```

<text>
<!-- second corpus text -->
</text>
</TEI>
<TEI>
  <teiHeader>
    <fileDesc>
<!-- file description for third corpus text -->
    </fileDesc>
  </teiHeader>
  <text>
<!-- third corpus text -->
  </text>
</TEI>
</teiCorpus>

```

### 15.3.2 Declarable Elements

Certain of the elements which can appear within a TEI header are known as *declarable elements*. These elements have in common the fact that they may be linked explicitly with a particular part of a text or corpus by means of a *decls* attribute on that element. This linkage is used to over-ride the default association between declarations in the header and a corpus or corpus text. The only header elements which may be associated in this way are those which would not otherwise be meaningfully repeatable.

Declarable elements are all members of the class `att.declarable`; the corresponding declaring elements are all members of the class `att.declaring`.

**att.declarable** provides attributes for those elements in the TEI header which may be independently selected by means of the special purpose *decls* attribute.

*@default* indicates whether or not this element is selected by default when its parent is selected.

**att.declaring** provides attributes for elements which may be independently associated with a particular declarable element within the header, thus overriding the inherited default for that element.

*@decls* identifies one or more *declarable elements* within the header, which are understood to apply to the element bearing this attribute and its content.

An alphabetically ordered list of declarable elements follows:

**<availability>** supplies information about the availability of a text, for example any restrictions on its use or distribution, its copyright status, any licence applying to it, etc.

**<bibl>** (bibliographic citation) contains a loosely-structured bibliographic citation of which the sub-components may or may not be explicitly tagged.

**<biblFull>** (fully-structured bibliographic citation) contains a fully-structured bibliographic citation, in which all components of the TEI file description are present.

**<biblStruct>** (structured bibliographic citation) contains a structured bibliographic citation, in which only bibliographic sub-elements appear and in a specified order.

**<broadcast>** describes a broadcast used as the source of a spoken text.

**<correction>** (correction principles) states how and under what circumstances corrections have been made in the text.

**<editorialDecl>** (editorial practice declaration) provides details of editorial principles and practices applied during the encoding of a text.

**<equipment>** provides technical details of the equipment and media used for an audio or video recording used as the source for a spoken text.

**<hyphenation>** summarizes the way in which hyphenation in a source text has been treated in an encoded version of it.

**<interpretation>** describes the scope of any analytic or interpretive information added to the text in addition to the transcription.

**<langUsage>** (language usage) describes the languages, sublanguages, registers, dialects, etc. represented within a text.

**<listBibl>** (citation list) contains a list of bibliographic citations of any kind.

**<normalization>** indicates the extent of normalization or regularization of the original source carried out in converting it to electronic form.

**<particDesc>** (participation description) describes the identifiable speakers, voices, or other participants in any kind of text or other persons named or otherwise referred to in a text, edition, or metadata.

**<projectDesc>** (project description) describes in detail the aim or purpose for which an electronic file was encoded, together with any other relevant information concerning the process by which it was assembled or collected.

**<quotation>** specifies editorial practice adopted with respect to quotation marks in the original.

**<recording>** (recording event) provides details of an audio or video recording event used as the source of a spoken text, either directly or from a public broadcast.

**<samplingDecl>** (sampling declaration) contains a prose description of the rationale and methods used in sampling texts in the creation of a corpus or collection.

**<scriptStmnt>** (script statement) contains a citation giving details of the script used for a spoken text.

**<segmentation>** describes the principles according to which the text has been segmented, for example into sentences, tone-units, graphemic strata, etc.

**<sourceDesc>** (source description) describes the source from which an electronic text was derived or generated, typically a bibliographic description in the case of a digitized text, or a phrase such as "born digital" for a text which has no previous existence.

**<stdVals>** (standard values) specifies the format used when standardized date or number values are supplied.

**<textClass>** (text classification) groups information which describes the nature or topic of a text in terms of a standard classification scheme, thesaurus, etc.

**<textDesc>** (text description) provides a description of a text in terms of its situational parameters.

**<xenoData>** (outside metadata) provides a container element into which metadata in non-TEI formats may be placed.

All of the above elements may be multiply defined within a single header, that is, there may be more than one instance of any declarable element type at a given level. When this occurs, the following rules apply:

- every declarable element must bear a unique identifier
- for each different type of declarable element which occurs more than once within the same parent element, exactly one element must be specified as the default, by means of the *default* attribute

In the following example, an editorial declaration contains two possible **<correction>** policies, one identified as CorPol1 and the other as CorPol2. Since there are two, one of them (in this case CorPol1) must be specified as the default:

```
<editorialDecl>
  <correction xml:id="CorPol1"
    default="true">
    <p> ... </p>
  </correction>
  <correction xml:id="CorPol2">
    <p> ... </p>
  </correction>
  <normalization xml:id="n1">
    <p> ... </p>
    <p> ... </p>
  </normalization>
</editorialDecl>
```

For texts associated with the header in which this declaration appears, correction method CorPol1 will be assumed, unless they explicitly state otherwise. Here is the structure for a text which does state otherwise:

```

<text>
  <body>
    <div1 n="d1" />
    <div1 n="d2" decls="#CorPol2" />
    <div1 n="d3" />
  </body>
</text>

```

In this case, the contents of the divisions D1 and D3 will both use correction policy CorPol1, and those of division D2 will use correction policy CorPol2.

The *decls* attribute is defined for any element which is a member of the class *declaring*. This includes the major structural elements <text>, <group>, and <div>, as well as smaller structural units, down to the level of paragraphs in prose, individual utterances in spoken texts, and entries in dictionaries. However, TEI recommended practice is to limit the number of multiple declarable elements used by a document as far as possible, for simplicity and ease of processing.

The identifier or identifiers specified by the *decls* attribute are subject to two further restrictions:

- An identifier specifying an element which contains multiple instances of one or more other elements should be interpreted as if it explicitly identified the elements identified as the default in each such set of repeated elements
- Each element specified, explicitly or implicitly, by the list of identifiers must be of a different kind.

To demonstrate how these rules operate, we now expand our earlier example slightly:

```

<encodingDesc>
  <editorialDecl xml:id="ED1" default="true">
    <correction xml:id="C1A" default="true">
      <p> ... </p>
    </correction>
    <correction xml:id="C1B">
      <p> ... </p>
    </correction>
    <normalization xml:id="N1">
      <p> ... </p>
      <p> ... </p>
    </normalization>
  </editorialDecl>
  <editorialDecl xml:id="ED2">
    <correction xml:id="C2A" default="true">
      <p> ... </p>
    </correction>
    <correction xml:id="C2B">
      <p> ... </p>
    </correction>
    <normalization xml:id="N2A">
      <p> ... </p>
    </normalization>
    <normalization xml:id="N2B"
      default="true">
      <p> ... </p>
    </normalization>
  </editorialDecl>
</encodingDesc>

```

This encoding description now has two editorial declarations, identified as ED1 (the default) and ED2. For texts not specifying otherwise, ED1 will apply. If ED1 applies, correction method C1A and normalization method N1 apply, since these are the specified defaults within ED1. In the same way, for a text specifying *decls* as 'ED2', correction C2A, and normalization N2B will apply.

A finer grained approach is also possible. A text might specify `<text decls='C2B N2A'>`, to 'mix and match' declarations as required. A tag such as `<text decls='ED1 ED2'>` would (obviously) be illegal, since it includes two elements of the same type; a tag such as `<text decls='ED2 C1A'>` is also illegal, since in this context ED2 is synonymous with the defaults for that editorial declaration, namely C2A N2B, resulting in a list that identifies two correction elements (C1A and C2A).

### 15.3.3 Summary

The rules determining which of the declarable elements are applicable at any point may be summarized as follows:

1. If there is a single occurrence of a given declarable element in a corpus header, then it applies by default to all elements within the corpus.
2. If there is a single occurrence of a given declarable element in the text header, then it applies by default to all elements of that text irrespective of the contents of the corpus header.
3. Where there are multiple occurrences of declarable elements within either corpus or text header,
  - each must have a unique value specified as the value of its *xml:id* attribute;
  - one only must bear a *default* attribute with the value YES.
4. It is a semantic error for an element to be associated with more than one occurrence of any declarable element.
5. Selecting an element which contains multiple occurrences of a given declarable element is semantically equivalent to selecting only those contained elements which are specified as defaults.
6. An association made by one element applies by default to all of its descendants.

## 15.4 Linguistic Annotation of Corpora

Language corpora often include analytic encodings or annotations, designed to support a variety of different views of language. The present Guidelines do not advocate any particular approach to linguistic annotation (or 'tagging'); instead a number of general analytic facilities are provided which support the representation of most forms of annotation in a standard and self-documenting manner. Analytic annotation is of importance in many fields, not only in corpus linguistics, and is therefore discussed in general terms elsewhere in the Guidelines.<sup>90</sup> The present section presents informally some particular applications of these general mechanisms to the specific practice of corpus linguistics.

### 15.4.1 Levels of Analysis

By *linguistic annotation* we mean here any annotation determined by an analysis of linguistic features of the text, excluding as borderline cases both the formal structural properties of the text (e.g. its division into chapters or paragraphs) and descriptive information about its context (the circumstances of its production, its genre, or medium). The structural properties of any TEI-conformant text should be represented using the structural elements discussed elsewhere in these Guidelines, for example in chapters 3. *Elements Available in All TEI Documents* and 4. *Default Text Structure*. The contextual properties of a TEI text are fully documented in the TEI header, which is discussed in chapter 2. *The TEI Header*, and in section 15.2. *Contextual Information* of the present chapter.

Other forms of linguistic annotation may be applied at a number of levels in a text. A code (such as a word-class or part-of-speech code) may be associated with each word or token, or with groups of such tokens, which may be continuous, discontinuous, or nested. A code may also be associated with relationships (such as cohesion) perceived as existing between distinct parts of a text. The codes themselves may stand for discrete non-decomposable categories, or they may represent highly articulated bundles of textual features. Their function may be to place the annotated part of the text somewhere within a narrowly linguistic or discorsal domain of analysis, or within a more general semantic field, or any combination drawn from these and other domains.

The manner by which such annotations are generated and attached to the text may be entirely automatic, entirely manual, or a mixture. The ease and accuracy with which analysis may be automated may vary with the level at which the annotation is attached. The method employed should be documented in the `<interpretation>` element within the encoding description of the TEI header, as described in section 2.3.3. *The Editorial Practices Declaration*.

---

<sup>90</sup>See in particular chapters 16. *Linking, Segmentation, and Alignment*, 17. *Simple Analytic Mechanisms*, and 18. *Feature Structures*.

Where different parts of a corpus have used different annotation methods, the *decls* attribute may be used to indicate the fact, as further discussed in section 15.3. *Associating Contextual Information with a Text*.

An extended example of one form of linguistic analysis commonly practised in corpus linguistics is given in section 17.4. *Linguistic Annotation*.

## 15.5 Recommendations for the Encoding of Large Corpora

These Guidelines include proposals for the identification and encoding of a far greater variety of textual features and characteristics than is likely to be either feasible or desirable in any one language corpus, however large and ambitious. The reasoning behind this catholic approach is further discussed in chapter *iv About These Guidelines*. For most large-scale corpus projects, it will therefore be necessary to determine a subset of TEI recommended elements appropriate to the anticipated needs of the project, as further discussed in chapter 23.3. *Personalization and Customization*; these mechanisms include the ability to exclude selected element types, add new element types, and change the names of existing elements. A discussion of the implications of such changes for TEI conformance is provided in chapter 23.4. *Conformance*.

Because of the high cost of identifying and encoding many textual features, and the difficulty in ensuring consistent practice across very large corpora, encoders may find it convenient to divide the set of elements to be encoded into the following four categories:

**required** texts included within the corpus will always encode textual features in this category, should they exist in the text

**recommended** textual features in this category will be encoded wherever economically and practically feasible; where present but not encoded, a note in the header should be made.

**optional** textual features in this category may or may not be encoded; no conclusion about the absence of such features can be inferred from the absence of the corresponding element in a given text.

**proscribed** textual features in this category are deliberately not encoded; they may be transcribed as unmarked up text, or represented as <gap> elements, or silently omitted, as appropriate.

## 15.6 Module for Language Corpora

The module described in this chapter makes available the following components:

**Module corpus:** Corpus texts

- *Elements defined:* activity channel constitution derivation domain factuality interaction locale particDesc preparedness purpose setting settingDesc textDesc

The selection and combination of modules to form a TEI schema is described in 1.2. *Defining a TEI Schema*.

## 16 Linking, Segmentation, and Alignment

This chapter discusses a number of ways in which encoders may represent analyses of the structure of a text which are not necessarily linear or hierarchic. The module defined by this chapter provides for the following common requirements:

- to link disparate elements using the *xml:id* attribute (section 16.1. *Links*);
- to link disparate elements without using the *xml:id* attribute (sections 16.2.1. *Pointing Elsewhere* and 16.2.4. *TEI XPointer Schemes*);
- to segment text into elements convenient for the encoder and to mark arbitrary points within documents (section 16.3. *Blocks, Segments, and Anchors*);
- to represent correspondence or alignment among groups of text elements, both those with content and those which are empty (section 16.4. *Correspondence and Alignment*);<sup>91</sup>
- to synchronize elements of a text, that is to represent temporal correspondences and alignments among text elements (section 16.5. *Synchronization*) and also to align them with specific points in time (section 16.5.2. *Placing Synchronous Events in Time*);
- to specify that one text element is identical to or a copy of another (section 16.6. *Identical Elements and Virtual Copies*);
- to aggregate possibly noncontiguous elements (section 16.7. *Aggregation*);
- to specify that different elements are alternatives to one another and to express preferences among the alternatives (section 16.8. *Alternation*);
- to store markup separately from the data it describes (section 16.9. *Stand-off Markup*);
- to associate segments of a text with interpretations or analyses of their significance (section 16.10. *Connecting Analytic and Textual Markup*).

These facilities all use the same set of techniques based on the W3C XPointer framework (Grosso et al. (eds.) (2003)) This provides a variety of *schemes*; the most convenient of which, and that recommended by these Guidelines, makes use of the global *xml:id* attribute, as defined in section 1.3.1.1. *Global Attributes*, and introduced in the section of *v A Gentle Introduction to XML* titled *v.5.2 Identifiers and Indicators*. When the **linking** module is included in a schema, the attribute class **att.global** is extended to include eight additional attributes to support the various kinds of linking listed above. Each of these attributes is introduced in the appropriate section below. In addition, for many of the topics discussed, a choice of methods of encoding is offered, ranging from simple but less general ones, which use attribute values only, to more elaborate and more general ones, which use specialized elements.

### 16.1 Links

We say that one element *points* to others if the first has an attribute whose value is a reference to the others: such an element is called a *pointer element*, or simply a *pointer*. Among the pointers that have been introduced up to this point in these Guidelines are `<note>`, `<ref>`, and `<ptr>`. These elements all indicate an association between one place in the document (the location of the pointer itself) and one or more others (the elements whose identifiers are specified by the pointer's *target* attribute). The module described in this chapter introduces a variation on this basic kind of pointer, known as a *link*, which specifies both 'ends' of an association. In addition, we define a syntax for representing locations in a document by a variety of means not dependent on the use of *xml:id* attributes.

#### 16.1.1 Pointers and Links

In section 3.6. *Simple Links and Cross-References* we introduced the simplest pointer elements, `<ptr>` and `<ref>`. Here we introduce additionally the `<link>` element, which represents an association between two (or more) locations by specifying each location explicitly. Its own location is irrelevant to the intended linkage. All three elements use the attribute *target*, provided by the **att.pointing** class as a means of indicating the location or locations referenced or pointed to.

<sup>91</sup>We use the term *alignment* as a special case for the more general notion of correspondence. Using A as a short form for 'an element with its attribute *xml:id* set to the value A', and suppose elements A1, A2, and A3 occur in that order and form one group, while elements B1, B2, and B3 occur in that order and form another group. Then a relation in which A1 corresponds to B1, A2 corresponds to B2, and A3 corresponds to B3 is an alignment. On the other hand, a relation in which A1 corresponds to B2, B1 to C2, and C1 to A2 is not an alignment.

**att.pointing** provides a set of attributes used by all elements which point to other elements by means of one or more URI references.

**@target** specifies the destination of the reference by supplying one or more URI References

**<link>** defines an association or hypertextual link among elements or passages, of some type not more precisely specifiable by other elements.

The **<ptr>** element may be called a ‘pure pointer’, because its primary function is simply to point. A pointer sets up a *connection* between an element (which, in the case of a pure pointer, is simply a location in a document), and one or more others, known collectively as its *target*. The **<ptr>** and **<ref>** elements point, conceptually, at a single target, even if that target may be discontinuous in the document. The **<link>** element specifies at least two targets and represents an association between them, independent of its own location.

These three elements also share a common set of attributes, derived from the **att.pointing** and **att.typed** classes:

**att.pointing** provides a set of attributes used by all elements which point to other elements by means of one or more URI references.

**@evaluate** specifies the intended meaning when the target of a pointer is itself a pointer.

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

**@type** characterizes the element in some sense, using any convenient classification scheme or typology.

**@subtype** provides a sub-categorization of the element, if needed

Double connection among elements could also be expressed by a combination of pointer elements, for example, two **<ptr>** elements, or one **<ptr>** element and one **<note>** element. All that is required is that the value of the *target* (or other pointing) attribute of the one be the value of the *xml:id* attribute of the other. What the **<link>** element accomplishes is the handling of double connection by means of a single element. Thus, in the following encoding:

```
<ptr xml:id="sa-p1" target="#sa-p2"/>
<ptr xml:id="sa-p2" target="#sa-p1"/>
```

sa-p1 points to sa-p2, and sa-p2 points to sa-p1. This is logically equivalent to the more compact encoding:

```
<link target="#sa-p1 #sa-p2"/>
```

As noted elsewhere, the *target* attribute may take as value one or more URI reference. In the simplest case, each such reference will indicate an element in the current document (or in some other document), for example by supplying the value used for its global *xml:id* attribute. It may however carry as value any form of URI, such as a URL pointing to some other document or location on the Internet. Pointing or linking to external documents and pointing and linking where identifiers are not available is described below in section 16.2. *Pointing Mechanisms*.

### 16.1.2 Using Pointers and Links

As an example of the use of mechanisms which establish connections among elements, consider the practice (common in 18th century English verse and elsewhere) of providing footnotes citing parallel passages from classical authors. Such footnotes can of course simply be encoded using the **<note>** element (see section 3.8. *Notes, Annotation, and Indexing*) without a *target* attribute, placed adjacent to the passage to which the note refers:<sup>92</sup>

```
<l>(Diff'rent our parties, but with equal grace</l>
<l>The Goddess smiles on Whig and Tory race,</l>
```

<sup>92</sup>The *type* attribute on the note is used to classify the notes using the typology established in the Advertisement to the work: ‘The *Imitations* of the Ancients are added, to gratify those who either never read, or may have forgotten them; together with some of the Parodies, and Allusions to the most excellent of the Moderns.’ In the source text, the text of the poem shares the page with two sets of notes, one headed ‘Remarks’ and the other ‘Imitations’.

Book III. The D U N C I A D. 73

Their full-fed Heroes, their pacific May's,  
 280 Their annual trophies, and their monthly wars.  
 Tho' long my Party built on me their hopes,  
 For writing pamphlets, and for burning Popes;  
 (Diff'rent our parties, but with equal grace  
 The Goddess smiles on Whig and Tory race,  
 285 'Tis the same rope at sev'ral ends they twist,  
 To Dulness, Ridpath is as dear as Mift.)  
 Yet lo! in me what authors have to brag on!  
 Reduc'd at last to hiss in my own dragon.  
 Avert it, heav'n! that thou or Cibber e'er  
 290 Should wag two serpent tails in Smithfield fair.  
 Like the vile straw that's blown about the streets  
 The needy Poet sticks to all he meets,  
 Coach'd, carted, trod upon, now loose, now fast,  
 In the Dog's tail his progress ends at last.

R E M A R K S.

VERSE 280. Annual trophies, on the *Lord Mayor's Day*; and monthly wars, in the *Artillery Ground*.  
 VERSE 281. *Tho' long my Party.*] *Settle*, like most Party-writers, was very uncertain in his political principles. He was employ'd to hold the pen in the *Character of a Popish successor*, but afterwards printed his *Narrative* on the contrary side. He had managed the Ceremony of a famous Pope-burning on Nov. 17, 1680: then became a Trooper of King *James's* army at *Hounslow-beath*: After the Revolution he kept a Booth at *Bartlemew-fair*, where in his Dröll call'd *St. George for England*, he acted in his old age in a Dragon of green leather of his own invention. He was at last taken into the Charter-house, and there dyed, aged about 60 years.  
 V. 285. *To Dulness, Ridpath is as dear as Mift.*] *George Ridpath*, author for several years of the *Flying-Post*, a Whig-paper; *Nathaniel Mift*, publisher of the *Weekly Journal*, a Tory-paper.

I M I T A T I O N S.

VERSE 283-84. — *With equal grace* | *Tros Ratuſue ſuat, nullo discrimine babet.*  
*Our Goddess smiles on Whig and Tory race.* | — *Rex Jupiter omnibus idem.*  
 Virg. *Æn.* 10.

P

```

<l>
  <note type="imitation" place="bottom"
    anchored="false">
    <bibl>Virg. Æn. 10.</bibl>
    <quote>
      <l>Tros Rutulusve fuat; nullo discrimine habebo.</l>
      <l>— Rex Jupiter omnibus idem.</l>
    </quote>
  </note>'Tis the same rope at sev'ral ends they twist,
</l>
<l>To Dulness, Ridpath is as dear as Mist)</l>

```

This use of the `<note>` element can be called *implicit pointing* (or *implicit linking*). It relies on the juxtaposition of the note to the text being commented on for the connection to be understood. If it is felt that the mere juxtaposition of the note to the text does not make it sufficiently clear exactly what text segment is being commented on (for example, is it the immediately preceding line, or the immediately preceding two lines, or what?), or if it is decided to place the note at some distance from the text, then the pointing or the linking must be made explicit. We now consider various methods for doing that.

Firstly, a `<ptr>` element might be placed at an appropriate point within the text to link it with the annotation:

```

<l>(Diff'rent our parties, but with equal grace</l>
<l>The Goddess smiles on Whig and Tory race,
<ptr rend="unmarked" target="#note3.284"/>
</l>
<l>'Tis the same rope at sev'ral ends they twist,</l>
<l>To Dulness, Ridpath is as dear as Mist)</l>
<note xml:id="note3.284" type="imitation"
  place="bottom" anchored="false">
  <bibl>Virg. Æn. 10.</bibl>
  <quote>
    <l>Tros Rutulusve fuat; nullo discrimine habebo.</l>
    <l>— Rex Jupiter omnibus idem.</l>
  </quote>
</note>

```

The `<note>` element has been given an arbitrary identifier (`note3.284`) to enable it to be specified as the target of the pointer element. Because there is nothing in the text to signal the existence of the annotation, the `rend` attribute has been given the value `unmarked`.

Secondly, the `target` attribute of the `<note>` element can be used to point at its associated text, provided that an `xml:id` attribute has been supplied for the associated text:

```

<l xml:id="L3.283">(Diff'rent our parties, but with equal grace</l>
<l xml:id="L3.284">The Goddess smiles on Whig and Tory race,</l>
<l xml:id="L3.285">'Tis the same rope at sev'ral ends they twist,</l>
<l xml:id="L3.286">To Dulness, Ridpath is as dear as Mist)</l>
<!-- ... -->

```

Given this encoding of the text itself, we can now link the various notes to it. In this case, the note itself contains a pointer to the place in the text which it is annotating; this could be encoded using a `<ref>` element, which bears a `target` attribute of its own and contains a (slightly misquoted) extract from the text marked as a `<quote>` element:

```

<note type="imitation" place="bottom"
  anchored="false" target="#L3.284">
  <ref rend="sc" target="#L3.284">Verse 283–84.
  <quote>
    <l>—. With equal grace</l>
    <l>Our Goddess smiles on Whig and Tory race.</l>
  </quote>
</ref>
<bibl>Virg. Æn. 10.</bibl>
<quote>
  <l>Tros Rutulusve fuat; nullo discrimine habeo.</l>
  <l>— Rex Jupiter omnibus idem. </l>
</quote>
</note>

```

Combining these two approaches gives us the following associations:

- a pointer within one line indicates the note
- the note indicates the line
- a pointer within the note indicates the line

Note that we do not have any way of pointing from the line itself to the note: the association is implied by containment of the pointer. We do not as yet have a true double link between text and note. To achieve that we will need to supply identifiers for the annotations as well as for the verse lines, and use a <link> element to associate the two. Note that the <ptr> element and the *target* attribute on the <note> may now be dispensed with:

```

<note xml:id="n3.284" type="imitation"
  place="bottom" anchored="false">
  <ref rend="sc" target="#L3.284">Verse 283–84.
  <quote>
    <l>—. With equal grace</l>
    <l>Our Goddess smiles on Whig and Tory race.</l>
  </quote>
</ref>
<bibl>Virg. Æn. 10.</bibl>
<quote>
  <l>Tros Rutulusve fuat; nullo discrimine habeo.</l>
  <l>— Rex Jupiter omnibus idem. </l>
</quote>
</note>
<link target="#n3.284 #L3.284"/>

```

The *target* attribute of the <link> element here bears the identifier of the note followed by that of the verse line. We could also allocate an identifier to the reference within the note and encode the association between it and the verse line in the same way:

```

<note type="imitation" place="bottom"
  anchored="false">
  <ref rend="sc" xml:id="r3.284"
    target="#L3.284">Verse 283–84.
  <quote>
    <l>—. With equal grace</l>
    <l>Our Goddess smiles on Whig and Tory race.</l>
  </quote>

```

```

</ref>
<!-- ... -->
</note>
<!-- ... -->
<link target="#r3.284 #L3.284"/>

```

Indeed, the two `<link>`s could be combined into one, as follows:

```
<link target="#n3.284 #r3.284 #L3.284"/>
```

### 16.1.3 Groups of Links

Clearly, there are many reasons for which an encoder might wish to represent a link or association between different elements. For some of them, specific elements are provided in these Guidelines; some of these are discussed elsewhere in the present chapter. The `<link>` element is a general purpose element which may be used for any kind of association. The element `<linkGrp>` may be used to group links of a particular type together in a single part of the document; such a collection may be used to represent what is sometimes referred to in the literature of Hypertext as a *web*, a term introduced by the Brown University FRESS project in 1969, and not to be confused with the World Wide Web.

**<linkGrp>** (link group) defines a collection of associations or hypertextual links.

As a member of the class `att.pointing.group`, this element shares the following attributes with other members of that class:

**att.pointing.group** provides a set of attributes common to all elements which enclose groups of pointer elements.

**@domains** optionally specifies the identifiers of the elements within which all elements indicated by the contents of this element lie.

**@targetFunc** (target function) describes the function of each of the values of the *target* attribute of the enclosed `<link>`, `<join>`, or `<alt>` tags.

It is also a member of the `att.pointing` and `att.typed` classes, and therefore also carries the attributes specified in section 16.1.1. *Pointers and Links* above, in particular the *type* attribute.

The `<linkGrp>` element provides a convenient way of establishing a default for the *type* attribute on a group of links of the same type: by default, the *type* attribute on a `<link>` element has the same value as that given for *type* on the enclosing `<linkGrp>`.

Typical software might hide a web entirely from the user, but use it as a source of information about links, which are displayed independently at their referenced locations. Alternatively, software might provide a direct view of the link collection, along with added functions for manipulating the collection, as by filtering, sorting, and so on. To continue our previous example, this text contains many other notes of a kind similar to the one shown above. Here are a few more of the lines to which annotations have to be attached, followed by the annotations themselves:

```

<l xml:id="L2.79">A place there is, betwixt earth, air and seas</l>
<l xml:id="L2.80">Where from Ambrosia, Jove retires for ease.</l>
<!-- ... -->
<l xml:id="L2.88">Sign'd with that Ichor which from Gods distills.</l>
<!-- ... -->
<note xml:id="n2.79" place="bottom"
  anchored="false">
  <bibl>Ovid Met. 12.</bibl>
  <quote xml:lang="la">
    <l>Orbe locus media est, inter terrasq; fretumq;</l>
    <l>Cælestesq; plagas —</l>
  </quote>
</note>

```

```
<note xml:id="n2.88" place="bottom"
  anchored="false"> Alludes to <bibl>Homer, Iliad 5</bibl> ...
</note>
```

To avoid having to repeat the specification of *type* as imitation on each <note>, we may specify it once for all on a <linkGrp> element containing all links of this type.

```
<linkGrp type="imitation">
  <link target="#n2.79 #L2.79"/>
  <link target="#n2.88 #L2.88"/>
  <link target="#n3.284 #L3.284"/>
</linkGrp>
```

Additional information for applications that use <linkGrp> elements can be provided by means of special attributes. First, the *domains* attribute can be used to identify the text elements within which the individual targets of the links are to be found. Suppose that the text under discussion is organized into a <body> element, containing the text of the poem, and a <back> element containing the notes. Then the *domains* attribute can have as its value the identifiers of the <body> and the <back>, to enable an application to verify that the link targets are in fact contained by appropriate elements, or to limit its search space:

```
<!-- ... --><linkGrp type="imitation"
  domains="#dunclad #dunnotes">
  <link target="#n2.79 #L2.79"/>
  <link target="#n2.88 #L2.88"/>
<!-- ... -->
  <link target="#n3.284 #L3.284"/>
<!-- ... -->
</linkGrp>
```

Note that there must be a single parent element for each ‘domain’; if some notes are contained by a section with identifier *dunnotes*, and others by a section with identifier *dunimits*, an intermediate pointer must be provided (as described in section 16.1.4. *Intermediate Pointers*) within the <linkGrp> and its identifier used instead.

Next, the *targFunc* attribute can be used to provide further information about the role or function of the various targets specified for each link in the group. The value of the *targFunc* attribute is a list of names (formally, name tokens), one for each of the targets in the link; these names can be chosen freely by the encoder, but their significance should be documented in the encoding description in the header.<sup>93</sup> In the current example, we might think of the note as containing the *source* of the imitation and the verse line as containing the *goal* of the imitation. Accordingly, we can specify the <linkGrp> in the preceding example thus:

```
<linkGrp type="imitation"
  domains="#dunclad #dunnotes" targFunc="source goal">
  <link target="#n2.79 #L2.79"/>
  <link target="#n2.88 #L2.88"/>
<!-- ... -->
  <link target="#n3.284 #L3.284"/>
<!-- ... -->
</linkGrp>
```

<sup>93</sup>Since no special element is provided for this purpose in the present version of these Guidelines, the information should be supplied as a series of paragraphs at the end of the <encodingDesc> element described in section 2.3. *The Encoding Description*.

### 16.1.4 Intermediate Pointers

In the preceding examples, we have shown various ways of linking an annotation and a single verse line. However, the example cited in fact requires us to encode an association between the note and a *pair* of verse lines (lines 284 and 285); we call these two lines a *span*.

There are a number of possible ways of correcting this error: one could use the *target* attribute to indicate one end of the span and the special purpose *targetEnd* attribute on the <note> element to point to the other. Another possibility might be to create an element which represents the whole span itself and assign that an *xml:id* attribute, which can then be linked to the <note> and <ref> elements. This could be done using for example the <lg> element defined in section 3.12.1. *Core Tags for Verse* or the ‘virtual’ <join> element discussed in section 16.7. *Aggregation*.

A third possibility would be to use an ‘intermediate pointer’ as follows:

```
<ptr xml:id="L3.283-284"
  target="#L3.283 #L3.284"/>
```

When the *target* attribute of a <ptr> or <ref> element specifies more than one element, the indicated elements are intended to be combined or aggregated in some way to produce the object of the pointer. (Such aggregation is however the task of a processing application, and cannot be defined simply by the markup). The *xml:id* attribute of the <ptr> then provides an identifier which can be linked to the <note> and <ref> elements:

```
<link evaluate="all"
  target="#n3.284 #r3.284 #L3.283-284"/>
```

The all value of *evaluate* is used on the <link> element to specify that any pointer encountered as a target of that element is itself evaluated. If *evaluate* had the value none, the link target would be the pointer itself, rather than the objects it points to.

Where a <linkGrp> element is used to group a collection of <link> elements, any intermediate pointer elements used by those <link> elements should be included within the <linkGrp>.

## 16.2 Pointing Mechanisms

This section introduces more formally the pointing mechanisms available in the TEI. In addition to those discussed so far, the TEI provides methods of pointing:

- into documents other than the current document;
- to a particular element in a document other than the current document using its *xml:id*;
- to a particular element whether in the current document or not, using its position in the XML element tree;
- at arbitrary content in any XML document using TEI-defined XPointer schemes.

All TEI attributes used to point at something else are declared as having the datatype `data.pointer`, which is defined as a URI reference<sup>94</sup>; the cases so far discussed are all simple examples of a URI reference. Another familiar example is the mechanism used in XHTML to create represent hypertext links by means of the XHTML *href* attribute. A URI reference can reference the whole of an XML resource such as a document or an XML element, or a sub-portion of such a resource, identified by means of an appropriate *fragment identifier*. Technically speaking, the ‘fragment identifier’ is that portion of a URI reference following the first unescaped ‘#’ character; in practice, it provides a means of accessing some part of the resource described by the URI which is less than the whole.

The first three of the following subsections provide only a brief overview and some examples of the W3C mechanisms recommended. More detailed information on the use of these mechanisms is readily available elsewhere.

### 16.2.1 Pointing Elsewhere

Like the ubiquitous if misnamed XHTML pointing attribute *href*, the TEI pointing attributes can point to a document that is not the current document (the one that contains the pointing element) whether it is in the same local filesystem as the current document, or on a different system entirely. In either case, the pointing can be accomplished absolutely

<sup>94</sup>The URI (Universal Resource Indicator) is defined in RFC 3986

(using the entire address of the target document) or relatively (using an address relative to the current base URI in force). The 'current base URI' is defined according to Marsh 2001. If there is none, the base URI is that of the current document. In common practice the current base URI in force is likely to be the value of the *xml:base* attribute of the closest ancestor that has one. However this may not be the case, since *xml:base* attributes are accumulated through the hierarchy by concatenation of path segments, beginning at the top of the hierarchy and proceeding down to the context node.

The following example demonstrates an absolute URI reference that points to a remote document:

```
The current base URI in force is as defined in the
W3C <ref target="http://www.w3.org/TR/xmlbase/">XML
Base</ref> recommendation.
```

This example points explicitly to a location on the Web, accessible via HTTP. Suppose however that we wish to access a document stored locally in a file. Again we will supply an absolute URI reference, but this time using a different protocol:

```
This Debian package is distributed under the terms
of the <ref target="file:///usr/share/common-licenses/GPL-2">GNU General Public Li-
cense</ref>.
```

In the following example, we use a relative URI reference to point to a local document:

```
<figure rend="float fullpage">
  <graphic url="Images/compic.png"/>
  <figDesc>The figure shows the page from the <title>Orbis
    pictus</title> of Comenius which is discussed in the text.</figDesc>
</figure>
```

Since no *xml:base* is specified here, the location of the resource `Figures/compic.png` is determined relative to the resource indicated by the current base URI, which is the current document.

In the following example, however, we first change the current base URI by setting a new value for *xml:base*. The resource required is then identified by means of a relative URI:

```
<div type="chap"
  xml:base="http://classics.mit.edu/">
  <head>On Ancient Persian Manners</head>
  <p>In the very first story of <ref target="Sadi/gulistan.2.i.html">
    <title>The Gulistan of
      Sa'di</title>
    </ref>,
    Sa'di relates moral advice worthy of Miss Minners ...</p>
  <!-- ... -->
</div>
```

As noted above, the current base URI is found on the nearest ancestor. This provides a useful way of abbreviating URIs within a given scope:

```
<body>
  <div n="A">
    <p>The base URI here is the current document. A URI such as
```

```

<code>a.xml</code> is equivalent to
<code>./a.xml</code>.</p>
</div>
<div n="B"
  xml:base="http://www.example.org/">
  <p>The base URI here is
  <code>http://www.example.org/</code>. A
  URI such as <code>a.xml</code> is equivalent to
  <code>http://www.example.org/a.xml</code>.</p>
</div>
<div n="C"
  xml:base="ftp://ftp.example.net/mirror/">
  <p>The base URI here is
  <code>ftp://ftp.example.net/mirror/</code>. A URI such
  as
  <code>a.xml</code> is equivalent to
  <code>ftp://ftp.example.net/mirror/a.xml</code>.</p>
</div>
<div n="D">
  <p>The base URI here is the current document. A URI such as
  <code>a.xml</code> is equivalent to
  <code>./a.xml</code>.</p>
</div>
</body>

```

### 16.2.2 Pointing Locally

Because the default base URI is the current document, a pointer that is specified as a *bare name* fragment identifier<sup>95</sup> alone acts as a pointer to an element in the current document, as in the following example.

```

<div type="section" xml:id="sect106">
<!-- ... -->
</div>
<div type="section" n="107" xml:id="sect107">
  <head>Limitations on exclusive rights: Fair use</head>
  <p>Notwithstanding the provisions of
  <ref target="#sect106">section 106</ref>, the fair use of a
  copyrighted work, including such use by reproduction in copies
  or phonorecords or by any other means specified by that section,
  for purposes such as criticism, comment, news reporting,
  teaching (including multiple copies for classroom use),
  scholarship, or research, is not an infringement of copyright.
  In determining whether the use made of a work in any particular
  case is a fair use the factors to be considered shall
  include –
  <list rend="bulleted">
    <item n="(1)">the purpose and character of the use, including
      whether such use is of a commercial nature or is for nonprofit
      educational purposes;</item>
    <item n="(2)">the nature of the copyrighted work;</item>
    <item n="(3)">the amount and substantiality of the portion
      used in relation to the copyrighted work as a whole;
      and</item>
    <item n="(4)">the effect of the use upon the potential market

```

<sup>95</sup>In more recent W3C documents, the term ‘bare name’ is deprecated in favour of the more explicit *shorthand pointer*.

```

        for or value of the copyrighted work.</item>
    </list>
    The fact that a work is unpublished shall not itself bar a
    finding of fair use if such finding is made upon consideration
    of all the above factors.</p>
</div>

```

This method of pointing, by referring to the *xml:id* of the target element as a bare name only (e.g., #sect106) is the simplest and often the best approach where it can be applied, i.e. where both the source element and target element are in the same XML document, and where the target element carries an identifier. It is the method used extensively in previous sections of this chapter and elsewhere in these Guidelines.

### 16.2.3 Using Abbreviated Pointers

*xml:base* is a useful way of handling the repeated use of long external URIs. However, it is less convenient when your text contain many references to a variety of different sources in different locations. Even in the case of relative links on the local file system, *ref* or *target* attributes may become quite lengthy and make XML code difficult to read. To deal with this problem, the TEI provides a useful method of using abbreviated pointers and documenting a way to dereference them automatically.

Imagine a project which has a large collection of XML documents organized like this:

- anthology
  - poetry
    - \* poem.xml
  - prose
    - \* novel.xml
- references
  - people
    - \* personography.xml

If you want to link a <name> in the novel.xml file to a <person> in the personography.xml file, the link will look like this:

```
<name ref="../../references/people/personography.xml#fred">Fred</name>
```

If there are many names to tag in a single paragraph, the XML encoding will be congested, and such lengthy links are prone to typographical error. In addition, if the project organization is changed, every relative link will have to be found and altered.

One way to deal with this is to use what is often referred to as a "magic token". You could make such links using the *key* attribute:

```
<name key="fred">Fred</name>
```

and document the meaning of the key using (for instance) a <taxonomy> element in the TEI header, as described in 3.5.1. *Referring Strings*. However, such a link cannot be mechanically processed by an external system that does not know how to interpret it; a human will have to read the header explanation and write code explicitly to reconstruct the intended link.

A more robust alternative is to use a *private URI scheme*. This is a method of constructing a simple, key-like token which functions as a **data pointer**, and can therefore be used as the value of any attribute which has that datatype, such as *ref* and *target*. Such a scheme consists of a prefix with a colon, and then a value. You might, for example, use the prefix psn (for "person"), and structure your name tags like this:

```
<name ref="psn:fred">Fred</name>
```

How is this different from a ‘magic token’? Essentially, it isn't, except that TEI provides a structured method of dereferencing it (turning it into a computable path, such as `../../references/people/personography.xml#fred`) by means of a declaration inside `<encodingDesc>` in the TEI header, using the elements and attributes for prefix declaration:

**<listPrefixDef>** (list of prefix definitions) contains a list of definitions of prefixing schemes used in `data.pointer` values, showing how abbreviated URIs using each scheme may be expanded into full URIs.

**<prefixDef>** (prefixing scheme used in `data.pointer` values) defines a prefixing scheme used in `data.pointer` values, showing how abbreviated URIs using the scheme may be expanded into full URIs.

*@ident* supplies a name which functions as the prefix for an abbreviated pointing scheme such as a private URI scheme. The prefix constitutes the text preceding the first colon.

**att.patternReplacement** provides attributes for regular-expression matching and replacement.

*@matchPattern* specifies a regular expression against which the values of other attributes can be matched.

*@replacementPattern* specifies a ‘replacement pattern’, that is, the skeleton of a relative or absolute URI containing references to groups in the *matchPattern* which, once subpattern substitution has been performed, complete the URI.

This is how you might document a private URI scheme using the `psn:` prefix:

```
<listPrefixDef>
  <prefixDef ident="psn"
    matchPattern="([a-z]+)"
    replacementPattern="../../references/people/personography.xml#$1">
    <p> In the context of this project, private URIs with the prefix
      "psn" point to <gi>person</gi> elements in the project's
      personography.xml file.
    </p>
  </prefixDef>
</listPrefixDef>
```

This specifies that where a `data.pointer` value is constructed with a `psn:` prefix, a regular-expression replace operation can be performed on it to construct the full or relative URI to the target document or fragment. `<listPrefixDef>` is a child of `<encodingDesc>`, and it contains any number of `<prefixDef>` elements. Each `<prefixDef>` element provides a method of dereferencing or expanding an abbreviated pointer, based on a regular expression. The *ident* attribute specifies the prefix to which the expansion applies (without the colon). The *matchPattern* attribute contains a regular expression which is matched against the component of the pointer following the first colon, and the *replacementPattern* provides the string which will be used as a replacement. In this example, using `psn:fred`, the value `fred` would be matched by the *matchPattern*, and also captured (through the parentheses in the regular expression); it would then be replaced by the value `../../references/people/personography.xml#fred` (with the `$1` in the *replacementPattern* being replaced by the captured value). The `<p>` element inside the `<prefixDef>` can be used to provide a human-readable explanation of the usage of this prefix.

Through this mechanism, any processor which encounters a `data.pointer` with a protocol unknown to it can check the `<listPrefixDef>` in the header to see if there is an available expansion for it, and if there is, it can automatically provide the expansion and generate a full or relative URI.

For any given prefix, it may be useful to supply more than one expansion. For instance, in addition to pointing at the `<person>` element in the `personography` file, it might also be useful to point to an external source which is available on the network, representing the same information in a different way. So there might be a second `<prefixDef>` like this:

```

<prefixDef ident="psn"
  matchPattern="([a-z]+)"
  replacementPattern="http://www.example.com/personography.html#$1">
  <p> Private URIs with the prefix "psn" can be converted to point
    to a fragment on the Personography page of the project Website.
  </p>
</prefixDef>

```

Any number of <prefixDef> elements may be provided for the same prefix. A processor may decide to process one or all of them; if it processes only one, it should choose the first one with the correct *ident* value, so the primary or most important <prefixDef> for any given prefix should appear first in its parent <listPrefixDef>.

When creating private URI schemes, it is recommended that you avoid using any existing registered prefix. A list of registered prefixes is maintained by IANA at <http://www.iana.org/assignments/uri-schemes.html>.

Note that this mechanism can also be used to dereference other abbreviated pointing systems which are based on prefixes, such as Tag URIs.

The *matchPattern* and *replacementPattern* attributes are also used in dereferencing canonical reference patterns, and further examples of the use of regular expressions are shown in 16.2.5. *Canonical References*.

## 16.2.4 TEI XPointer Schemes

The pointing schemes described in this chapter are part of a number of such schemes envisaged by the W3C, which together constitute a framework for addressing data within XML documents, known as the XPointer Framework (Grosso et al 2003). This framework permits the definition of many other named addressing methods, each of which is known as an *XPointer Scheme*. The W3C has predefined a set of such schemes, and maintains a register for their expansion.

One important scheme, also defined by the W3C, and recommended by these Guidelines is the `xpath()` pointer scheme, which allows for any part of an XML structure to be selected using the syntax defined by the XPath specification. This is further discussed below, 16.2.4.2. *xpath()*. These Guidelines also define six other pointer schemes, which provide access to parts of an XML document such as points within data content or stretches of data content. These additional TEI pointer schemes are defined in sections 16.2.4.3. *left()* to 16.2.4.8. *match()* below.

### 16.2.4.1 Introduction to TEI Pointers

Before discussing the TEI pointer schemes, we introduce slightly more formally the terminology used to define them. So far, we have discussed only ways of pointing at components of the XML information set node such as elements and attributes. However, there is often a need in text analysis to address additional types of location such as the 'point' locations *between* 'nodes', and 'sequences' that may arbitrarily cross the boundaries of nodes in a document. The content of an XML document is organized sequentially as well as hierarchically, and it makes sense to consider ranges of characters within a document independently of the nodes to which they belong. From the perspective of most of the pointer schemes discussed below, a TEI document is a tree structure superimposed upon a character stream. Nodes are entities available only in the tree, while points are available only in the stream. For this reason, the schemes below that rely upon character positions (`string-index()`, `string-range()`, and `match()`) cannot take nodes into account. Similarly, XPath, being a method for locating nodes in the tree, treats those nodes as atomic, and is unable to address parts of nodes in their document context.

The TEI pointer scheme thus distinguishes the following kinds of object:

**Node** A node is an instance of one of the node kinds defined in the XQuery 1.0 and XPath 2.0 Data Model (Second Edition). It represents a single item in the XML information set for a document. For pointing purposes, the only nodes that are of interest are Text Nodes, Element Nodes, and Attribute nodes.

**Sequence** A Sequence follows the definition in the XPath 2.0 Data Model, with one alteration. A Sequence is an ordered collection of zero or more items, where an item is either a node or a partial text node.

**Text Stream** A Text Stream is the concatenation of the text nodes in a document and behaves as though all tags had been removed. A text stream begins at a reference node and encompasses all of the text inside that node (if any) and all the text following it in document order. In XPath terms, this would encompass all of the text nodes beginning at a particular node, and following it on the following axis.

**Point** A Point represents a dimensionless point between nodes or characters in a document. Every point is adjacent to either characters or elements, and never to another point. Points can only be referenced in relation to an element or text node in the document (i.e. something addressable by either an XPath or a fragment identifier). Points occur either immediately before or after an element, or at a numbered position inside a text stream. Position zero in the stream would be immediately before the first character. Note that points within attribute values cannot mark the beginning or end of a range extending beyond the attribute value, because points indicate a position within a document. Since attribute nodes are by definition un-ordered, they cannot be said to have a fixed position.

The TEI recommends the following seven pointer schemes:

**xpath()** Addresses a node or nodeset using the XPath syntax. (16.2.4.2. *xpath()*)

**left() and right()** addresses the point before (left) or after (right) a node or node set (16.2.4.3. *left()* and 16.2.4.4. *right()*)

**string-index()** addresses a point inside a text node (16.2.4.5. *string-index()*)

**range()** addresses the range between two points (16.2.4.6. *range()*)

**string-range()** addresses a range of a specified length starting from a specified point (16.2.4.7. *string-range()*)

**match()** addresses a range which matches a specified string within a node (16.2.4.8. *match()*)

The *xpath()* scheme refers to the existing XPath specification which is adopted with one modification: the default namespace for any XPath used as a parameter to this scheme is assumed to be the TEI namespace <http://www.tei-c.org/ns/1.0>.

The other six schemes overlap in functionality with a W3C draft specification known as the XPointer scheme draft, but are individually much simpler. At the time of this writing, there is no current or scheduled activity at the W3C towards revising this draft or issuing it as a recommendation.

**A note on namespaces:** The W3C defines an *xmlns()* scheme (see XPointer *xmlns()* Scheme) which when prepended to a resolvable pointer allows for the definition of namespace prefixes to be used in XPaths in subsequent pointers. TEI Pointer schemes assume that un-prefixed element names in TEI Pointer XPaths are in the TEI namespace, <http://www.tei-c.org/ns/1.0>. The use of *xmlns()* is thus optional, provided no new prefixes need to be defined. If the schemes described here are used to address non-TEI elements, then any new prefixes to be used in pointer XPaths may be defined using the *xmlns()* scheme.

### 16.2.4.2 *xpath()*

#### Sequence *xpath*(XPATH)

The *xpath()* scheme locates a node within an XML Information Set. The single argument XPATH is an XPath path expression, following the latest scheme adopted by the W3C (currently XPath 2.0), that returns a sequence. XPaths returning atomic values (e.g. *substring()*) are illegal in the *xpath()* scheme because they represent extracted values rather than locations in the source document. XPath expressions that address attribute nodes are only advisable in the *xpath()* scheme.

The example below, and all subsequent examples in this section refer to the following TEI fragment:

```
<div xml:lang="la" type="edition"
  xml:space="preserve"><ab>
<lb n="1" xml:id="line1"/><supplied reason="lost">si</supplied> non <choice><reg>habui</reg><orig>
<lb n="2"/><si><gap reason="illegible" quantity="3"
  unit="character"/><b><gap reason="illegible" quantity="3"
  unit="character"/>
  cohort<unclear>e</unclear> mi rescribas
<lb n="3"/><unclear>s</unclear>emp<unclear>er</unclear> in <choice><reg>mente</reg><orig>mentem</orig>
  <choice><reg>habe</reg><orig>abe</orig></choice> supra res
<lb n="4"/><scriptas><gap reason="lost" extent="unknown"
  unit="character"/>
<lb n="5"/>auge et opto u<unclear>t</unclear> bene valeas</ab>
</div>
```

A TEI Pointer that referenced the "normalized" form in the `choice` in line 1 of the example might look like: `#xpath(//lb[@n='1']/following-sibling::choice/reg)`.

When an XPath is interpreted by a TEI processor, the information set of the referenced document is interpreted without any additional information supplied by any schema processing that may or may not be present. In particular this means that no whitespace normalization is applied to a document before the XPath is interpreted.

This pointer scheme allows easy, direct use of the most widely-implemented XML query method. It is probably the most robust pointing mechanism for the common situation of selecting an XML element or its contents where an *xml:id* is not present. The ability to use element names and attribute names and values makes `xpath()` pointers more robust than the other mechanisms discussed in this section even if the designated document changes. For durability in the presence of editing, use of *xml:id* is always recommended when possible.

#### 16.2.4.3 `left()`

Point `left( IDREF | XPATH )`

The `left()` scheme locates the point immediately preceding the node addressed by its argument, which is either an XPATH as defined above or an IDREF, the value of an *xml:id* occurring in the document addressed by the base URI in effect for the pointer.

Example: the pointer `#left(//gap[1])` indicates the point between the first `lb` and the first `gap` in the example above.

Example: `#left(line1)` indicates the point immediately before the `<lb n="1"/>` element.

#### 16.2.4.4 `right()`

Point `right( IDREF | XPATH )`

The `right()` scheme locates the point immediately following the node addressed by its argument.

Example: the pointer `#right(//lb[@n='3'])` indicates the point between the third `lb` and the `<unclear>s</unclear>` element in the example.

#### 16.2.4.5 `string-index()`

Point `string-index( IDREF | XPATH, OFFSET )`

The `string-index()` scheme locates a point based on character positions in a text stream relative to the node identified by the IDREF or XPATH parameter. The OFFSET parameter is a positive, negative, or zero integer which determines the position of the point. An offset of 0 represents the position immediately before the first character in either the first text node descendant of the node addressed in the first parameter or the first following text node, if the addressed element contains no text node descendants.

Example: `#string-index(//lb[@n='2'],1)` indicates the point between the 's' and the 'i' in the word 'si' in line 2.

**Note:** The OFFSET parameter (and similarly the LENGTH parameter found below in the `string-range()` scheme) are measured in characters. What is considered a single character will depend (assuming the document being evaluated is in Unicode) on the Normalization Form in use (see UNICODING NORMALIZATION FORMS). A letter followed by a combining diacritic counts as two characters, but the same diacritic precombined with a letter would count as a single character. Compare, for example, é (\u0060 followed by \u0301) and é (\u00E9). These are equivalent, and a conversion between Normalization Forms C and D will transform one into the other. This specification does not mandate a particular Normalization Form (see *Precomposed and Combining Characters and Normalization*), but users and implementers should be aware that it affects the character count and therefore the result of evaluating pointers that rely on character counting.

#### 16.2.4.6 `range()`

Sequence `range( POINTER, POINTER[, POINTER, POINTER ...])`

The `range()` scheme takes as parameters one or more pairs of POINTERS, which are each members of the set IDREF, XPATH, `left()`, `right()`, or `string-index()`. A `range()` locates a (possibly non-contiguous) sequence beginning at the first POINTER parameter and ending at the last. If the POINTER locates a node (i.e. is an XPATH or IDREF), then that node is a member of the addressed sequence. If a sequence addressed by a range pointer overlaps, but does not wholly contain, an element (i.e. it contains only the start but not the end tag or vice-versa), then that element is not part of the sequence.

Range(s) may address sequences of non-contiguous nodes. For example, a `range()` might select text beginning before an `<app>`, encompassing the content of a single `<rdg>` and continuing after the `<app>`.

Example: `#range(left(//lb[@n='3']),left(//lb[@n='4']))` indicates the whole of line 4 from the `<lb n="3"/>` to the point right before the following `<lb n="4"/>`.

Example: `#range(right(//lb[@n='3']),string-index(//lb[@n='3'],15))` indicates the sequence `<unclear>s</unclear>emp<unclear>er</unclear>` in `mente`.

Example: `#range(string-index(//lb[@n='3'],7),string-index(//lb[@n='3'],10),string-index(//lb[@n='3'],15),string-index(//lb[@n='3'],21))` indicates the non-contiguous sequence `'in mentem'`.

#### 16.2.4.7 string-range()

Sequence `string-range(IDREF | XPATH, OFFSET, LENGTH[, OFFSET, LENGTH ...])`

The `string-range()` scheme locates a sequence based on character positions in a text stream relative to the node identified by the first parameter. The location of the beginning of the addressed sequence is determined precisely as for `string-index()`. The `OFFSET` parameter is defined as above in `string-index()`. The `LENGTH` parameter is a positive integer that denotes the length of the text stream captured by the sequence. As with `range()`, the addressed sequence may contain text nodes and/or elements. The `string-range()` scheme, can accept multiple `OFFSET, LENGTH` pairs to address a non-contiguous sequence in much the same way that `range()` can accept multiple pairs of pointers.

Because `string-range()` addresses points in the text stream, tags are invisible to it. For example, if an empty tag like `<lb>` is encountered while processing a `string-range()`, it will be included in the resulting sequence, but the `LENGTH` count will not increment when it is captured.

Example: `#string-range(//lb[@n='5'],0,27)` indicates the whole of line 5 from the text immediately following the `lb` to the point right before the closing `ab` tag.

Example: `#string-range(//lb[@n='3'],7,8)` indicates the sequence `'in mente'`.

Example: `#string-range(//lb[@n='3'],7,3,15,6)` indicates the non-contiguous sequence `'in mentem'`.

#### 16.2.4.8 match()

Sequence `match(IDREF | XPATH, 'REGEX' [, INDEX])`

The `match` scheme locates a sequence based on matching the `REGEX` parameter against a text stream relative to the reference node identified by the first parameter. `REGEX` is a regular expression as defined by XQuery 1.0 and XPath 2.0 Functions and Operators (Second Edition), with some modifications:

- Because the regular expression is delimited by apostrophe characters, any such characters (`'` or `\u0027`) occurring inside the expression must be escaped using the URI percent-encoding scheme `%27`.
- Regular expressions in `match()` are assumed to operate in multi-line mode. The end of the string to be matched against is either the end of the text contained by the element in the first parameter or the end of the document, if that parameter indicates an empty element. The meta-character `^` therefore matches the beginning of the text stream inside or following the reference node, and the meta-character `$` matches the end of that stream.

The optional `INDEX` parameter is an integer greater than 0 which specifies which match should be chosen when there is more than one possibility. If omitted, the first match in the text stream will be used.

Like `string-range()`, `match()` may capture elements in the returned sequence, even though they are ignored for purposes of evaluating the match.

Example: `#match(//lb[@n='5'],'opto.*valeas')` indicates the sequence `opto <unclear>t</unclear> bene valeas` in line 5.

Example: `#match(//lb[@n='3'],'semper')` would indicate the word `'semper'`, but would not capture the `unclear` elements in `<unclear>s</unclear>emp<unclear>er</unclear>`, just their text children.

### 16.2.5 Canonical References

By 'canonical' reference we mean any means of pointing into documents, specific to a community or corpus. For example, biblical scholars might understand `'Matt 5:7'` to mean 'the book called *Matthew*, chapter 5, verse 7.' They might then wish to translate the string `'Matt 5:7'` into a pointer into a TEI-encoded document, selecting the element which corresponds to the seventh `<div>` element within the fifth `<div>` element within the `<div>` element with the `n` attribute valued `'Matt'`.

Several elements in the TEI scheme (`<gloss>`, `<ptr>`, `<ref>`, and `<term>`) bear a special attribute, `cRef`, just for this purpose. Using the system described in this section, an encoder may specify references to canonical works in a discipline-familiar format, and expect software to derive a complete URI from it. The value of the `cRef` attribute is

processed as described in this section, and the resulting URI reference is treated as if it were the value of the *target* attribute. The *cRef* and *target* attributes are mutually exclusive: only one or the other may be specified on any given occurrence of an element.

For the *cRef* attribute to function as required, a mechanism is needed to define the mapping between (for example) ‘the book called *Matt*’ and the part of the XML structure which corresponds with it. This is provided by the `<refsDecl>` element in the TEI header, which contains an algorithm for translating a canonical reference string (like *Matt 5:7*) into a URI such as `#xpath(//div[@n='Matt']/div[5]/div[7])`. The `<refsDecl>` element is described in section 2.3.6. *The Reference System Declaration*; the following example is discussed in more detail below in section 16.2.5.1. *Worked Example*.

```
<refsDecl xml:id="biblical">
  <cRefPattern matchPattern="(.) (.):(.)"
    replacementPattern="#xpath(//div[@n='$1']/div[@n='$2']/div[@n='$3'])">
    <p>This pointer pattern extracts and references the <q>book,</q>
      <q>chapter,</q> and <q>verse</q> parts of a biblical reference.</p>
  </cRefPattern>
  <cRefPattern matchPattern="(.) (.)"
    replacementPattern="#xpath(//div[@n='$1']/div[$2])">
    <p>This pointer pattern extracts and references the <q>book</q> and
      <q>chapter</q> parts of a biblical reference.</p>
  </cRefPattern>
  <cRefPattern matchPattern="(.)"
    replacementPattern="#xpath(//div[@n='$1'])">
    <p>This pointer pattern extracts and references just the <q>book</q>
      part of a biblical reference.</p>
  </cRefPattern>
</refsDecl>
```

When an application encounters a canonical reference as the value of *cRef* attribute, it might follow this sequence of specific steps to transform it into a URI reference:

1. Ascertain the correct `<refsDecl>` following the rules summarized in section 15.3.3. *Summary*.
2. For each `<cRefPattern>` element encountered in the appropriate `<refsDecl>`, in the order encountered:
  - (a) match the value of the *cRef* attribute to the regular expression found as the value of the *matchPattern* attribute
  - (b) if the value of the *cRef* attribute matches:
    - i. take the value of the *replacementPattern* attribute and substitute the back references (\$1, \$2, etc.) with the corresponding matched substrings
    - ii. the result is taken as if it were a relative or absolute URI reference specified on the *target* attribute; i.e., it should be used as is or combined with the current *xml:base* attribute value as usual
    - iii. no further processing of this value of the *cRef* attribute against the `<refsDecl>` should take place
  - (c) if, however, the value of the *cRef* attribute does not match the regular expression specified in the value of the *matchPattern* attribute, proceed to the next `<cRefPattern>`
3. If all the `<cRefPattern>` elements are examined in turn and none matches, the pointer fails.

The regular expression language used as the value of the *matchPattern* attribute is that used for the *pattern* facet of the World Wide Web Consortium's XML Schema Language in an Appendix to XML Schema Part 2.<sup>96</sup> The value of the *replacementPattern* attribute is simply a string, except that occurrences of ‘\$1’ through ‘\$9’ are replaced by the corresponding substring match. Note that since a maximum of nine substring matches are permitted, the string ‘\$18’ means ‘the value of the first matched substring followed by the character ‘8’ as opposed to ‘the eighteenth matched

<sup>96</sup>As always seems to be the case, no two regular expression languages are precisely the same. For those used to Perl regular expressions, be warned that while in Perl the pattern `tei` matches any string that contains *tei*, in the W3C language it only matches the string ‘tei’.

substring'. If there is a need for an actual string including a dollar sign followed by a digit that is not supposed to be replaced, the dollar sign should be written as `$$`. Implementations must convert `$$` to `$` during processing.

### 16.2.5.1 Worked Example

Let us presume that with the example `<refsDecl>` above, an application comes across a `cRef` value of `Matt 5:7` inside a `<div>` which has an `xml:base` of `http://www.example.org/resources/books/Bible.xml`. The application would first apply the regular expression `(.+) (.+):(.)` to `'Matt 5:7'`. This regular expression would successfully match. The first matched substring would be `'Matt'`, the second `'5'`, and the third `'7'`. The application would then apply these substrings to the pattern `#xpath(//div[@n='$1']/div[$2]/div[$3])`, producing `#xpath(//div[@n='Matt']/div[5]/div[7])`. It would append this to the `xml:base` in force, thus generating the complete URI Reference `http://www.example.org/resources/books/Bible.xml#xpath(//div[@n='Matt']/div[5]/div[7])`.

If, however, the input string had been `'Matt 5'`, the first regular expression would not have matched. The application would have then tried the second, `(.+) (.+)`, producing a successful match, and the matched substrings `'Matt'` and `'5'`. It would then have substituted those matched substrings into the pattern `#xpath(//div[@n='$1']/div[$2])` to produce a fragment identifier, which when appended to the `xml:base` in force produces the absolute URI reference `http://www.example.org/resources/books/Bible.xml#xpath(//div[@n='Matt']/div[5])`.

If the input string had been `'Matt'`, neither the first nor the second regular expressions would have successfully matched. The application would have then tried the third, `(.+)`, producing the matched substring `'Matt'`, and the URI Reference `http://www.example.org/resources/books/Bible.xml#xpath(//div[@n='Matt'])`.

a `<cRefPattern>` should not reference more matched substrings. For example:

```
<cRefPattern matchPattern="(.) (.+):(.)"
replacementPattern="//div[@n='$1']/div[$2]/div[$3]/p[$4]"/>
```

is faulty, since only three matched substrings would have been produced, but a fourth (`$4`) was referenced.

### 16.2.5.2 Complete and Partial URI Examples

In the above example, the value of `cRef` was used to generate a Fragment Identifier, which in turn was used to generate a complete URI. The complete URI could be generated directly, as in the following example.

```
<refsDecl xml:id="USC">
  <cRefPattern matchPattern="([0-9][0-9])\s*U\.?S\.?C\.?s*[Cc](h(\.|ap(ter|\.)?)?)?
\s*([1-9][0-9]*)"
  replacementPattern="http://uscode.house.gov/download/pls/$1C$5.txt">
    <p>Matches most standard references to particular
      chapters of the United States Code, e.g.
    <val>11USCC7</val>, <val>17 U.S.C. Chapter 3</val>, or
    <val>14 USC Ch. 5</val>. Note that a leading zero is
      required for the title (must be two digits), but is not
      permitted for the chapter number.</p>
  </cRefPattern>
  <cRefPattern matchPattern="([0-9][0-9])\s*U\.?S\.?C\.?s*[Pp](re(lim(inary)?)?)?
\s*[Mm](at(erial)?)?"
  replacementPattern="http://uscode.house.gov/download/pls/$1T.txt">
    <p>Matches references to the preliminary material for a
      given title, e.g. <val>11USCP</val>, <val>17 U.S.C.
      Prelim Mat</val>, or <val>14 USC pm</val>.</p>
  </cRefPattern>
  <cRefPattern matchPattern="([0-9][0-9])\s*U\.?S\.?C\.?s*[Aa](ppend(ix)?)?"
  replacementPattern="http://uscode.house.gov/download/pls/$1A.txt">
    <p>Matches references to the appendix of a given title,
      e.g. <val>05USCA</val>, <val>11 U.S.C. Appendix</val>,</p>
```

```

    or <val>18 USC Append</val>.</p>
  </cRefPattern>
</refsDecl>
<!-- ... -->
<p>The example in section 10 is taken
from <ref cRef="17 USC Ch 1">Subject Matter and Scope of
  Copyright</ref>.</p>

```

See 16.2.3. *Using Abbreviated Pointers* for another related use of the *matchPattern* and *replacementPattern* attributes.

### 16.2.5.3 Miscellaneous Usages

Canonical reference pointers are intended for use by TEI encoders. However, this specification might be useful to the development of a process for recognizing canonical references in non-TEI documents (such as plain text documents), possibly as part of their conversion to TEI.

## 16.3 Blocks, Segments, and Anchors

In this section, we discuss three general purposes elements which may be used to mark and categorize both a span of text and a point within one. These elements have several uses, most notably to provide elements which can be given identifiers for use when aligning or linking to parts of a document, as discussed elsewhere in this chapter. They also provide a convenient way of extending the semantics of the TEI markup scheme in a theory-neutral manner, by providing for two neutral or ‘anonymous’ elements to which the encoder can add any meaning not supplied by other TEI defined elements.

**<anchor>** (anchor point) attaches an identifier to a point within a text, whether or not it corresponds with a textual element.

**<ab>** (anonymous block) contains any arbitrary component-level unit of text, acting as an anonymous container for phrase or inter level elements analogous to, but without the semantic baggage of, a paragraph.

**<seg>** (arbitrary segment) represents any segmentation of text below the ‘chunk’ level.

The elements **<anchor>**, **<ab>**, and **<seg>** are members of the class **att.typed**, from which they inherit the following attributes:

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

**@type** characterizes the element in some sense, using any convenient classification scheme or typology.

**@subtype** provides a sub-categorization of the element, if needed

The elements **<ab>**, and **<seg>** are members of the class **att.fragmentable**, from which they inherit the following attribute:

**att.fragmentable** provides an attribute for representing fragmentation of a structural element, typically as a consequence of some overlapping hierarchy.

**@part** specifies whether or not its parent element is fragmented in some way, typically by some other overlapping structure: for example a speech which is divided between two or more verse stanzas, a paragraph which is split across a page division, a verse line which is divided between two speakers.

The **<seg>** element is also a member of the class **att.segLike** from which it inherits the following attribute:

**att.segLike** provides attributes for elements used for arbitrary segmentation.

**@function** characterizes the function of the segment.

The **<anchor>** element may be thought of as an empty **<seg>**, or as an artifice enabling an identifier to be attached to any position in a text. Like the **<milestone>** element discussed in section 3.10. *Reference Systems*, it is useful where multiple views of a document are to be combined, for example, when a logical view based on paragraphs or verse lines is to be mapped on to a physical view based on manuscript lines. Like those elements, it is a member of the class **model.global** and can therefore appear anywhere within a document when the module defined by this chapter is included in a schema. Unlike the other elements in its class, the **<anchor>** element is primarily intended

to mark an arbitrary point used for alignment, or as the target of a spanning element such as those discussed in section 11.3.1.4. *Additions and Deletions*, rather than as a means of marking segment boundaries for some arbitrary segmentation of a text.

For example, suppose that we wish to mark the end of the fifth word following each occurrence of some term in a particular text, perhaps to assist with some collocational analysis. This can most easily be done with the help of the `<anchor>` element, as follows:

```
English language. Except for not very<anchor xml:id="eng1"/>
English at all at the time<anchor xml:id="eng2"/>
English was still full of flaws<anchor xml:id="eng3"/>
English. This was revised by young
<anchor xml:id="eng4"/>
```

In section 16.4.1. *Correspondence* we discuss ways in which these `<anchor>` points might be used to represent an alignment such as one might get in a keyword-in-context concordance.

The `<seg>` element may be used at the encoder's discretion to mark almost any segment of the text of interest for processing. One use of the element is to mark text features for which no appropriate markup is otherwise defined, i.e. as a simple extension mechanism. Another use is to provide an identifier for some segment which is to be pointed at by some other element, i.e. to provide a target, or a part of a target, for a `<ptr>` or other similar element.

Several examples of uses for the `<seg>` element are provided elsewhere in these Guidelines. For example:

- as a means of marking segments significant in a metrical or rhyming analysis (see section 6.4. *Rhyme and Metrical Analysis*)
- as a means of marking typographic lines in drama (see section 7.2. *The Body of a Performance Text*) or title pages (see section 4.6. *Title Pages*)
- as a means of marking prosody- or pause-defined units in transcribed speech (see section 8.4.1. *Segmentation*)
- as a means of marking linguistic or other analyses in a theory-neutral manner (see chapter 17. *Simple Analytic Mechanisms* passim)

In the following simple example, the `<seg>` element simply delimits the extent of a stutter, a textual feature for which no element is provided in these Guidelines.

```
<q>Don't say <q>
  <seg type="stutter">I-I-I</seg>'m afraid,</q> Melvin, just say <q>I'm
  afraid.</q>
</q>
```

The `<seg>` element is particularly useful for the markup of linguistically significant constituents such as the phrases that may be the output of an automatic parsing system. This example also demonstrates the use of the `xml:id` attribute to carry an identifier which other parts of a document may use to point to, or align with:

```
<seg xml:id="bl0034" type="sentence">
  <seg xml:id="bl0034.1" type="phrase">Literate and illiterate speech</seg>
  <seg xml:id="bl0034.2" type="phrase">in a language like English</seg>
  <seg xml:id="bl0034.3" type="phrase">are plainly different.</seg>
</seg>
```

As the above example shows, `<seg>` elements may be nested directly within one another, to any degree of analysis considered appropriate. This is taken a little further in the following example, where the `type` and `subtype` attributes have been used to further categorize each word of the sentence (the `xml:id` attributes have been removed to reduce the complexity of the example):

```

<seg type="sentence" subtype="declarative">
  <seg type="phrase" subtype="noun">
    <seg type="word" subtype="adjective">Literate</seg>
    <seg type="word" subtype="conjunction">and</seg>
    <seg type="word" subtype="adjective">illiterate</seg>
    <seg type="word" subtype="noun">speech</seg>
  </seg>
  <seg type="phrase" subtype="preposition">
    <seg type="word" subtype="preposition">in</seg>
    <seg type="word" subtype="article">a</seg>
    <seg type="word" subtype="noun">language</seg>
    <seg type="word" subtype="preposition">like</seg>
    <seg type="word" subtype="noun">English</seg>
  </seg>
  <seg type="phrase" subtype="verb">
    <seg type="word" subtype="verb">are</seg>
    <seg type="word" subtype="adverb">plainly</seg>
    <seg type="word" subtype="adjective">different</seg>
  </seg>
  <seg type="punct">.</seg>
</seg>

```

(The example values shown are chosen for simplicity of comprehension, rather than verisimilitude). It should also be noted that specialized segment elements are defined in section 17.1. *Linguistic Segment Categories* to facilitate this particular kind of analysis. These allow for the explicit markup of units called *s-units*, *clauses*, *phrases*, *words*, *morphemes*, and *characters*, which may be felt preferable to the more generic approach typified by use of the `<seg>` element. Using these, the first phrase above might be encoded simply as

```

<phr type="noun">
  <w type="adjective">Literate</w>
  <w type="conjunction">and</w>
  <w type="adjective">illiterate</w>
  <w type="noun">speech</w>
</phr>

```

Note the way in which the *type* attribute of these specialized elements now carries the value carried by the *subtype* attribute of the more general `<seg>` element. For an analysis not using these traditional linguistic categories however, the `<seg>` element provides a simple but powerful mechanism.

In language corpora and similar material, the `<seg>` element may be used to provide an end-to-end segmentation as an alternative to the more specific `<s>` element proposed in chapter 17.1. *Linguistic Segment Categories* for the markup of orthographic sentences, or *s-units*. However, it may be more useful to use the `<s>` element for this purpose, since this means that the `<seg>` element can then be used to mark both features within *s-units* and segments composed of *s-units*, as in the following example:<sup>97</sup>

```

<seg xml:id="s1s3" type="narrative_unit">
  <s xml:id="s1">Sigmund, the <seg type="patronymic">son of Volsung</seg>,
    was a king in Frankish country.</s>
  <s xml:id="s2">Sinfiotli was the eldest of his sons.</s>
  <s xml:id="s3"> ... </s>
</seg>

```

<sup>97</sup>See section 17.3. *Spans and Interpretations*, where the text from which this fragment is taken is analyzed.

Like other elements, the `<seg>` tag must be properly enclosed within other elements. Thus, a single `<seg>` element can be used to group together words in different sentences only if the sentences are not themselves tagged. The first of the following two encodings is legal, but the second is not.

```
Give me <seg type="phrase">a dozen. Or two or three.</seg>
```

```
<!-- Illegal! -->
<s>Give me <seg type="phrase">a dozen.</s>
<s>Or two or three.</s></seg>
```

The `part` attribute may be used as one simple method of overcoming this restriction:

```
<s>Give me <seg type="phrase" part="I">a dozen.</seg>
</s>
<s>
  <seg part="F">Or two or three.</seg>
</s>
```

Another solution is to use the `<join>` element discussed in section 16.7. *Aggregation*; this requires that each of the `<seg>` elements be given an identifier. For further discussion of this generic encoding problem, see also chapter 20. *Non-hierarchical Structures*.

The `<seg>` element has the same content as a paragraph in prose: it can therefore be used to group together consecutive sequences of `model.inter` class elements, such as lists, quotations, notes, stage directions, etc. as well as to contain sequences of phrase-level elements. It cannot however be used to group together sequences of paragraphs or similar text units such as verse lines; for this purpose, the encoder should use intermediate pointers, as described in section 16.1.4. *Intermediate Pointers* or the methods described in section 16.7. *Aggregation*. It is particularly important that the encoder provide a clear description of the principles by which a text has been segmented, and the way in which that segmentation is represented. This should include a description of the method used and the significance of any categorization codes. The description should be provided as a series of paragraphs within the `<segmentation>` element of the encoding description in the TEI header, as described in section 2.3.3. *The Editorial Practices Declaration*.

The `<seg>` element may also be used to encode simultaneous or mutually exclusive variants of a text when the more special purpose elements for simple editorial changes, abbreviation and expansion, addition and deletion, or for a critical apparatus are not appropriate. In these circumstances, one `<seg>` is encoded for each possible variant, and the set of them is enclosed in a `<choice>` element.

For example, if one were writing dual-platform instructions for installation of software, it might be useful to use `<seg>` to record platform-specific pieces of mutually exclusive text.

```
...pressing <choice>
  <seg type="platform" subtype="Mac">option</seg>
  <seg type="platform" subtype="PC">alt</seg>
</choice>-f will ...
```

Elsewhere in this chapter we provide a number of examples where the `<seg>` element is used simply to provide an element to which an identifier may be attached, for example so that another segment may be linked or related to it in some way.

The `<ab>` (anonymous block) element performs a similar function to that of the `<seg>` element, but is used for portions of the text which occur not within paragraphs or other component-level elements, but at the component level themselves. It is therefore a member of the `model.pLike` class.

The `<ab>` element may be used, for example, to tag the canonical verse divisions of Biblical texts:

```

<div1 n="Gen" type="book">
  <head>The First Book of Moses, Called</head>
  <head type="main">Genesis</head>
  <div2 n="1" type="chapter">
    <ab n="1">In the beginning God created the heaven and the
      earth.</ab>
    <ab n="2">And the earth was without form, and void; and darkness
  <hi>was</hi> upon the face of the deep. And the Spirit of God
    moved upon the face of the waters.</ab>
    <ab n="3">And God said, Let there be light: and there was
      light.</ab>
  </div2>
</div1>

```

In other cases, where the text clearly indicates paragraph divisions containing one or more verses, the <p> element may be used to tag the paragraphs, and the <seg> element used to subdivide them. The <ab> element is provided as an alternative to the <p> element; it may *not* be used within paragraphs. The <seg> element, by contrast, may appear only within and not between paragraphs (or anonymous block elements).

```

<div1 n="Gen" type="book">
  <head>Das Erste Buch Mose.</head>
  <div2 n="1" type="chapter">
    <p>
      <seg n="1">Am Anfang schuff Gott Himel vnd Erden.</seg>
      <seg n="2">Vnd die Erde war wüst vnd leer / vnd es war
        finster auff der Tieffe / Vnd der Geist Gottes schwebet auff
        dem Wasser.</seg>
    </p>
    <p>
      <seg n="3">Vnd Gott sprach / Es werde Liecht / Vnd es ward
        Liecht.</seg>
    </p>
  </div2>
</div1>

```

The <ab> element is also useful for marking dramatic speeches when it is not clear whether the speech is to be regarded as prose or verse. If, for example, an encoder does not wish to express an opinion as to whether the opening lines of Shakespeare's *The Tempest* are to be regarded as prose or as verse, they might be tagged as follows:

```

<div1 n="I" type="act">
  <div2 n="1" type="scene">
    <head rend="italic">Actus primus, Scena prima.</head>
    <stage rend="italic" type="setting"> A tempestuous noise of
      Thunder and Lightning heard:
      Enter a Ship-master, and a Boteswaine.</stage>
    <sp>
      <speaker>Master.</speaker>
      <ab>Bote-swaine.</ab>
    </sp>
    <sp>
      <speaker>Botes.</speaker>
      <ab>Heere Master: What cheere?</ab>
    </sp>
  <sp>

```

```

    <speaker>Mast.</speaker>
    <ab>Good: Speake to th' Mariners: fall too't, yarely,
        or we run our selues a ground, bestirre, bestirre.
    <stage type="move">Exit.</stage>
    </ab>
</sp>
<stage type="move">Enter Mariners.</stage>
<sp>
    <speaker>Botes.</speaker>
    <ab>Heigh my hearts, cheerely, cheerely my harts: yare, yare:
        Take in the toppe-sale: Tend to th' Masters whistle: Blow
        till thou burst thy winde, if roome e-nough.</ab>
</sp>
</div2>
</div1>

```

See further 3.12.2. *Core Tags for Drama* and 7.2.5. *Speech Contents*.

## 16.4 Correspondence and Alignment

In this section we introduce the notions of *correspondence*, expressed by the *corresp* attribute, and of *alignment*, which is a special kind of correspondence involving an ordered set of correspondences. Both cases may be represented using the `<link>` and `<linkGrp>` elements introduced in section 16.1. *Links*. We also discuss the special case of alignment in time or *synchronization*, for which special purpose elements are proposed in section 16.5. *Synchronization*.

### 16.4.1 Correspondence

A common requirement in text analysis is to represent correspondences between two or more parts of a single document, or between places in different documents. Provided that explicit elements are available to represent the parts or places to be linked, then the global linking attribute *corresp* may be used to encode such correspondence, once it has been identified.

**att.global.linking** provides a set of attributes for hypertextual linking.

`@CORRESP` (corresponds) points to elements that correspond to the current element in some way.

This is one of the attributes made available by the mechanism described in the introduction to this chapter (16. *Linking, Segmentation, and Alignment*). Correspondence can also be expressed by means of the `<link>` element introduced in section 16.1. *Links*.

Where the correspondence is between *spans*, the `<seg>` element should be used, if no other element is available. Where the correspondence is between *points*, the `<anchor>` element should be used, if no other element is available.

The use of the *corresp* attribute with spans of content is illustrated by the following example:

```

<title xml:id="SHIRLEY">Shirley</title>, which made
its Friday night debut only a month ago, was
not listed on <name xml:id="NBC">NBC</name>'s new schedule,
although <seg corresp="#NBC" xml:id="NETWORK">the network</seg>
says <seg corresp="#SHIRLEY" xml:id="SHOW">the show</seg>
still is being considered.

```

Here the anaphoric phrases *the network* and *the show* have been associated directly with the elements to which they refer by means of *corresp* attributes. This mechanism is simple to apply, but has the drawback that it is not possible to specify more exactly what kind of correspondence is intended. Where this attribute is used, therefore, encoders are encouraged to specify their intent in the associated encoding description in the TEI header.

Essentially, what the *corresp* attribute does is to specify that elements bearing this attribute and those to which the attribute points are doubly linked. In the example above, the use of the *corresp* attribute indicates that the `<seg>` element containing ‘the show’ and the `<title>` element containing ‘Shirley’ correspond to each other: the correspondence relationship is not ‘from’ one to the other, but ‘between’ the two objects. It is thus different from

the *target* attribute, and provides functionality more similar to that of the `<link>` and `<linkGrp>` elements defined in section 16.1. *Links*, although it lacks the ability to indicate more precisely what kind of correspondence is intended as in the following retagging of the preceding example.

```
<title xml:id="shirley">Shirley</title>, which made
its Friday night debut only a month ago, was not
listed on <name xml:id="nbc">NBC</name>'s new schedule,
although <seg xml:id="network">the network</seg> says
<seg xml:id="show">the show</seg> still is being considered.

<linkGrp type="anaphoric_link"
  targFunc="antecedent anaphor">
  <link target="#shirley #show"/>
  <link target="#nbc #network"/>
</linkGrp>
```

In the following example, we use the same mechanism to express a correspondence amongst the anchors introduced following the fifth word after *English* in a text:

```
English language. Except for not very<anchor xml:id="en1"/>
<!-- ... -->
English at all at the time
<anchor xml:id="en2"/>
<!-- ... -->
English was still full of flaws
<anchor xml:id="en3"/>
<!-- ... -->
English. This was revised by young
<anchor xml:id="en4"/>
<!-- ... -->
<linkGrp type="five-word_collocates">
  <link type="collocates_of_ENGLISH"
    target="#en1 #en2 #en3 #en4"/>
<!-- ... -->
</linkGrp>
```

### 16.4.2 Alignment of Parallel Texts

One very important application area for the alignment of parallel texts is multilingual corpora. Consider, for example, the need to align ‘translation pairs’ of sentences drawn from a corpus such as the Canadian Hansard, in which each sentence is given in both English and French. Concerning this problem, Gale and Church write:

Most English sentences match exactly one French sentence, but it is possible for an English sentence to match two or more French sentences. The first two English sentences [in the example below] illustrate a particularly hard case where two English sentences align to two French sentences. No smaller alignments are possible because the clause ‘...sales...were higher...’ in the first English sentence corresponds to (part of) the second French sentence. The next two alignments ... illustrate the more typical case where one English sentence aligns with exactly one French sentence. The final alignment matches two English sentences to a single French sentence. These alignments [which were produced by a computer program] agreed with the results produced by a human judge.<sup>98</sup>

The alignment produced by Gale and Church's program can be expressed in four different ways. The encoder must first decide whether to represent the alignment in terms of points within each text (using the `<anchor>` element) or in terms of whole stretches of text, using the `<seg>` element. To some extent the choice will depend on the process by

<sup>98</sup>See Gale and Church (1993), from which the example in the text is taken.

which the software works out where alignment occurs, and the intention of the encoder. Secondly, the encoder may elect to represent the actual encoding using either *corresp* attributes attached to the individual `<anchor>` or `<seg>` elements, or using a free-standing `<linkGrp>` element.

We present first a solution using `<anchor>` elements bearing only *corresp* attributes:

```
<div xml:lang="en" type="subsection">
  <p>
    <anchor corresp="#fa1" xml:id="ea1"/>According to our survey, 1988
    sales of mineral water and soft drinks were much higher than in 1987,
    reflecting the growing popularity of these products. Cola drink
    manufacturers in particular achieved above-average growth rates.
    <anchor corresp="#fa2" xml:id="ea2"/>The higher turnover was largely
    due to an increase in the sales volume.
    <anchor corresp="#fa3" xml:id="ea3"/>Employment and investment levels also climbed.
    <anchor corresp="#fa4" xml:id="ea4"/>Following a two-year transitional period,
    the new Foodstuffs Ordinance for Mineral Water came into effect on
    April 1, 1988. Specifically, it contains more stringent requirements
    regarding quality consistency and purity guarantees.</p>
</div>
<div xml:lang="fr" type="subsection">
  <p>
    <anchor corresp="#ea1" xml:id="fa1"/>Quant aux eaux minérales
    et aux limonades, elles rencontrent toujours plus d'adeptes. En effet,
    notre sondage fait ressortir des ventes nettement supérieures
    à celles de 1987, pour les boissons à base de cola
    notamment. <anchor corresp="#ea2" xml:id="fa2"/>La progression des
    chiffres d'affaires résulte en grande partie de l'accroissement
    du volume des ventes. <anchor corresp="#ea3" xml:id="fa3"/>L'emploi et
    les investissements ont également augmenté.
    <anchor corresp="#ea4" xml:id="fa4"/>La nouvelle ordonnance fédérale
    sur les denrées alimentaires concernant entre autres les eaux
    minérales, entrée en vigueur le 1er avril 1988 après
    une période transitoire de deux ans, exige surtout une plus
    grande constance dans la qualité et une garantie de la
    pureté.</p>
</div>
```

There is no requirement that the *corresp* attribute be specified in both English and French texts, since (as noted above) this attribute is defined as representing a mutual association. However, it may simplify processing to do so, and also avoids giving the impression that the English is translating the French, or vice versa. More seriously, this encoding does not make explicit that it is in fact the entire stretch of text between the anchors which is being aligned, not simply the points themselves. If for example one text contained material omitted from the other, this approach would not be appropriate.

We now present the same passage using the alternative `<linkGrp>` mechanism and marking explicitly the segments which have been aligned:

```
<div xml:id="div-e" xml:lang="en"
  type="subsection">
  <p>
    <seg xml:id="e_1">According to our survey, 1988 sales of mineral
    water and soft drinks were much higher than in 1987,
    reflecting the growing popularity of these products. Cola
    drink manufacturers in particular achieved above-average
    growth rates.</seg>
    <seg xml:id="e_2">The higher turnover was largely due to an
```

```

        increase in the sales volume.</seg>
    <seg xml:id="e_3">Employment and investment levels also climbed.</seg>
    <seg xml:id="e_4">Following a two-year transitional period, the new
    Foodstuffs Ordinance for Mineral Water came into effect on
    April 1, 1988. Specifically, it contains more stringent
    requirements regarding quality consistency and purity
    guarantees.</seg>
</p>
</div>
<div xml:id="div-f" xml:lang="fr"
    type="subsection">
    <p>
    <seg xml:id="f_1">Quant aux eaux minérales et aux limonades,
    elles rencontrent toujours plus d'adeptes. En effet, notre
    sondage fait ressortir des ventes nettement
    supérieures à celles de 1987, pour les
    boissons à base de cola notamment.</seg>
    <seg xml:id="f_2">La progression des chiffres d'affaires
    résulte en grande partie de l'accroissement du volume
    des ventes.</seg>
    <seg xml:id="f_3">L'emploi et les investissements ont
    également augmenté.</seg>
    <seg xml:id="f_4">La nouvelle ordonnance fédérale sur
    les denrées alimentaires concernant entre autres les
    eaux minérales, entrée en vigueur le 1er avril
    1988 après une période transitoire de deux
    ans, exige surtout une plus grande constance dans la
    qualité et une garantie de la pureté.</seg>
    </p>
</div>
<linkGrp type="alignment"
    domains="#div-e #div-f">
    <link target="#e_1 #f_1"/>
    <link target="#e_2 #f_2"/>
    <link target="#e_3 #f_3"/>
    <link target="#e_4 #f_4"/>
</linkGrp>

```

Note that use of the `<ab>` element allows us to mark up the orthographic sentences in both languages independently of the alignment: the first translation pair in this example might be marked up as follows:

```

<div xml:id="english" xml:lang="en"
    type="subsection">
    <ab xml:id="english1">
    <s>According to our survey, 1988 sales of mineral water and soft
    drinks were much higher than in 1987, reflecting the growing popularity
    of these products.</s>
    <s>Cola drink manufacturers in particular achieved above-average
    growth rates.</s>
    </ab>
</div>
<div xml:id="french" xml:lang="fr"
    type="subsection">
    <ab xml:id="french1">
    <s xml:id="fs1">Quant aux eaux minérales et aux limonades, elles
    rencontrent toujours plus d'adeptes.</s>

```

```

<s xml:id="fs2">En effet, notre sondage fait ressortir des ventes nettement
supérieures à celles de 1987, pour les boissons à
base de cola notamment.</s>
</ab>
</div>

```

### 16.4.3 A Three-way Alignment

The preceding encoding of the alignment of parallel passages from two texts requires that those texts and the alignment all be part of the same document. If the texts are in separate documents, then complete URIs, whether absolute or relative (section 16. *Linking, Segmentation, and Alignment*), will be required. These external pointers may appear anywhere within the document, but if they are created solely for use in encoding links, they may for convenience be grouped within the <linkGrp> (or other grouping element that uses them for linking).

To demonstrate this facility, we consider how we might encode the alignments in an extract from Comenius' *Orbis Sensualium Pictus*, in the English translation of Charles Hoole (1659). Each topic covered in this work has three parts: a picture, a prose text in Latin describing the topic, and a carefully-aligned translation of the Latin into English, German, or some other vernacular. Key terms in the two texts are typographically distinct, and are linked to the picture by numbers, which appear in the two texts and within the picture as well.

First, we consider the text portions. The English and Latin portions have been encoded as distinct <div> elements. Identifiers have been attached to each typographic line, but no other encoding added, to simplify the example.

```

<div xml:id="e98" xml:lang="en"
type="lesson">
<head>The Study</head>
<p>
<seg xml:id="e9801">The Study</seg>
<seg xml:id="e9802">is a place</seg>
<seg xml:id="e9803">where a Student,</seg>
<seg xml:id="e9804">a part from men,</seg>
<seg xml:id="e9805">sitteth alone,</seg>
<seg xml:id="e9806">addicted to his Studies,</seg>
<seg xml:id="e9807">whilst he readeth</seg>
<seg xml:id="e9808">Books,</seg>
</p>
</div>
<div xml:id="l98" xml:lang="la"
type="lesson">
<head>Muséum</head>
<p>
<seg xml:id="l9801">Museum</seg>
<seg xml:id="l9802">est locus</seg>
<seg xml:id="l9803">ubi Studiosus,</seg>
<seg xml:id="l9804">secretus ab hominibus,</seg>
<seg xml:id="l9805">solus sedet,</seg>
<seg xml:id="l9806">Studiis deditus,</seg>
<seg xml:id="l9807">dum lectitat</seg>
<seg xml:id="l9808">Libros,</seg>
</p>
</div>

```

Next we consider the non-textual parts of the page. Encoding this requires providing two distinct components: firstly a digitized rendering of the page itself, and secondly a representation of the areas within that image which are to be aligned. In section 11.1. *Digital Facsimiles* we present a simple way of doing this using the TEI-defined markup for alignment of facsimiles. In the present chapter we demonstrate a more powerful means of aligning arbitrary polygons and points, which uses the XML notation SVG (see SVG). This provides appropriate facilities for both these requirements:

(200)

**XCVIII.**

The Study.

*Muséum.*

The Study 1.  
 is a place  
 where a Student, 2.  
 is apart from men,  
 sitteth alone,  
 addicted to his Studies,  
 whilst he readeth  
 Books, 3.  
 which being within  
 his reach, he layeth  
 open upon a Desk 4.  
 and picketh all the  
 best things out of  
 them into his own  
 Manual, 5.

*Muséum* 1.  
 est locus,  
 ubi *Studiosus*, 2.  
 secretus ab hominibus,  
 solus sedet,  
*Studiis* deditus,  
 dum lectitat  
*Libros*, 3.  
 quos penes se  
 super *Pluteum* 4.  
 exponit, & ex illis  
 in *Manuale* 5. suum  
 optima quæq; excerpit,  
 02

```
<svg xmlns="http://www.w3.org/2000/svg"
  xmlns:xlink="http://www.w3.org/1999/xlink">
  <image xlink:href="p1764.png" width="597"
    height="897" id="p981"/>
  <rect id="p982" x="75" y="75" width="25"
    height="10"/>
  <rect id="p983" x="55" y="42" width="25"
    height="10"/>
</svg>
```

This example of SVG defines two rectangles at the locations with the specified *x* and *y* coordinates. A view is defined on these, enabling them to be mapped by an SVG processor to the image found at the URL specified (*p1764.png*). It also defines unique identifiers for the whole image, and the two views of it, which we will use within our alignment, as shown next (for further discussion of the handling of images and graphics, see section 14.4. *Specific Elements for Graphic Images*; for further discussion of using non-TEI XML vocabularies such as SVG within a TEI document, see section 22.8.2. *Combining TEI and Non-TEI Modules*).

As printed, the Comenius text exhibits three kinds of alignment.

- 1 The English and Latin portions are printed in two parallel columns, with corresponding phrases, (represented above by `<seg>` elements), more or less next to each other.
- 2 Particular words or phrases are marked as terms in the two languages by a change of rendition: the English text, which otherwise uses black letter type throughout, has the words *The Study*, *a Student*, *Studies*, and *Books* in a roman font; in the Latin text, which is printed in roman, the corresponding words (*Museum*, *Studiosus*, *Studiis*, and *Libros*) are all in italic.
- 3 Numbered labels appear within the text portions, linking keywords to each other and to sections of the picture. These labels, which have been left out of the above encoding, are attached to the first, third, and last segments in each language quoted below, and also appear (rather indistinctly) within the picture itself. Thus, the images of the study, the student, and his books are each aligned with the correct term for them in the two languages.

The first kind of alignment might be represented by using the *corresp* attribute on the `<seg>` element. The second kind might be represented by using the `<gloss>` and `<term>` mechanism described in section 3.3.4. *Terms, Glosses, Equivalents, and Descriptions*. The third kind of alignment might be represented using pointers embedded within the texts, for example:

```
<!--... --><seg xml:id="xe9803">where a <ref n="2" tar-
get="#xp982">Student</ref>,</seg>
<seg xml:id="xl9803">ubi <ref n="2" target="#xp982">Studiosus</ref>,</seg>
<!--... -->
```

We choose however to use the `<link>` element, since this provides a more efficient way of representing the three-way alignment between English, Latin, and picture without redundancy.

```
<linkGrp type="alignment">
  <link target="#xe9801 #xl9801 #xp981"/>
  <link target="#xe9802 #xl9802"/>
  <link target="#xe9803 #xl9803 #xp982"/>
  <link target="#xe9804 #xl9804"/>
  <link target="#xe9805 #xl9805"/>
  <link target="#xe9806 #xl9806"/>
  <link target="#xe9807 #xl9807"/>
  <link target="#xe9808 #xl9808 #xp983"/>
</linkGrp>
```

This map, of course, only aligns whole segments and image portions, since these are the only parts of our encoding which bear identifiers and can therefore be pointed to. To add to it the alignment between the typographically distinct words mentioned above, new elements must be defined, either within the text itself or externally by using stand off techniques. Encoding these word pairs as <term> and <gloss>, although intuitively obvious, requires a non-trivial decision as to whether the Latin text is glossing the English, or vice versa. Tagging all the marked words as <term> avoids the difficult decision, but might be thought by some encoders to convey the wrong information about the words in question. Simply tagging them as additional embedded <seg> elements with identifiers that can be aligned like the others is also a possibility.

These solutions all require the addition of further markup to the text. This may pose no problems, or it may be infeasible, for example because the text is held on a read-only medium. If it is not feasible to add more markup to the original text, some form of stand-off markup will be needed. Any item within the text that can be pointed to using the various pointer schemes discussed in this chapter may be used, not simply those which rely on the existence of an *xml:id* attribute. Suppose our example had been more lightly tagged, as follows:

```
<div xml:id="E98" xml:lang="en"
  type="lesson">
  <head>The Study</head>
  <ab>The Study</ab>
  <ab>is a place</ab>
  <ab>where a Student,</ab>
</div>
<div xml:id="L98" xml:lang="la"
  type="lesson">
  <head>Muséum</head>
  <ab>Museum</ab>
  <ab>est locus</ab>
  <ab>ubi Studiosus,</ab>
</div>
```

To express the same alignment mentioned above, we could use an XPath expression to identify the required <seg> elements:

```
<linkGrp type="alignment">
  <link target="#xpath(//div[@xml:id='L98']/ab[1])" #xpath(//div[@xml:id='E98']/ab[1])"/>
  <link target="#xpath(//div[@xml:id='L98']/ab[2])" #xpath(//div[@xml:id='E98']/ab[2])"/>
</linkGrp>
```

In the absence of any markup around individual substrings of the element content, the string-range pointer scheme discussed in 16.2.4.7. *string-range()* may also be helpful: for example, to indicate that the words *Studies* and *Studiis* correspond, we might express the link between them as follows:

```
<link target="#string-range(e9806,16,7) #string-range(l9806,0,7)"/>
```

## 16.5 Synchronization

In the previous section we discussed two particular kinds of alignment: alignment of parallel texts in different languages; and alignment of texts and portions of an image. In this section we address another specialized form of alignment: synchronization. The need to mark the relative positions of text components with respect to time arises most naturally and frequently in transcribed spoken texts, but it may arise in any text in which quoted speech occurs, or events are described within a time frame. The methods described here are also generalizable for other kinds of alignment (for example, alignment of text elements with respect to space).

### 16.5.1 Aligning Synchronous Events

Provided that explicit elements are available to represent the parts or places to be synchronized, then the global linking attribute *synch* may be used to encode such synchronization, once it has been identified.

**att.global.linking** provides a set of attributes for hypertextual linking.

*@synch* (synchronous) points to elements that are synchronous with the current element.

This is another of the attributes made globally available by the mechanism described in the introduction to this chapter. Alternatively, the `<link>` and `<linkGrp>` elements may be used to make explicit the fact that the synchronous elements are aligned.

To illustrate the use of these mechanisms for marking synchrony, consider the following representation of a spoken text:

```
B: The first time in twenty five years, we've cooked Christmas
(unclear) for a blooming great load of people.
A: So you're [1] (unclear) [2]
B: [1] It will be [2] nice in a way, but, [3] be strange. [4]
A: [3] Yeah [4], yeah, cos it, it's [5] the [6]
B: [5] not [6]
```

This representation uses numbers in brackets to mark the points at which speakers overlap each other. For example, the *[1]* in A's first speech is to be understood as coinciding with the *[1]* in B's second speech.<sup>99</sup>

To encode this we use the spoken texts module, described in chapter 8. *Transcriptions of Speech*, together with the module described in the present chapter. First, we transcribe this text, marking the synchronous points with `<anchor>` elements, and providing a *synch* attribute on one of each of the pairs of synchronous anchors. As noted in the example given above (section 16.4.2. *Alignment of Parallel Texts*), correspondence, and hence synchrony, is a symmetric relation; therefore the attribute need only be specified on one of the pairs of synchronous anchors.

```
<div xml:id="BNC-d1" type="convers">
  <u xml:id="u2b" who="#b"> The first time in twenty five years,
    we've cooked Christmas <unclear> for a blooming great
    load of people.</unclear>
  </u>
  <u xml:id="u3a" who="#a">So you're
  <anchor synch="#t1b" xml:id="t1a"/>
  <unclear>
    <anchor synch="#t2b" xml:id="t2a"/>
  </unclear>
  </u>
  <u xml:id="u3b" who="#b">
    <anchor xml:id="t1b"/>It will be <anchor xml:id="t2b"/>
    nice in a way, but, <anchor xml:id="t3b"/>
    be strange.<anchor xml:id="t4b"/>
  </u>
  <u xml:id="u4a" who="#a">
    <anchor synch="#t3b" xml:id="t3a"/>Yeah
  <anchor synch="#t4b" xml:id="t4a"/>, yeah, cos it, its
  <anchor synch="#t5b" xml:id="t5a"/>the
  <anchor synch="#t6b" xml:id="t6a"/>
  </u>
  <u xml:id="u4b" who="#b">
    <anchor xml:id="t5b"/>not<anchor xml:id="t6b"/>
  </u>
```

<sup>99</sup>This sample is taken from a conversation collected and transcribed for the British National Corpus.

```
<!-- ... -->
</div>
```

We can encode this same example using `<link>` and `<linkGrp>` elements to make the temporal alignment explicit. A `<back>` element has been used to enclose the `<linkGrp>` element, but the links may be located anywhere the encoder finds convenient:

```
<back>
  <linkGrp xml:id="lg1"
    domains="#BNC-d1 #BNC-d1" targFunc="speaker.a speaker.b"
    type="synchronous_alignment">
    <link xml:id="L1" target="#t1a #t1b"/>
    <link xml:id="L2" target="#t2a #t2b"/>
    <link xml:id="L3" target="#t3a #t3b"/>
    <link xml:id="L4" target="#t4a #t4b"/>
    <link xml:id="L5" target="#t5a #t5b"/>
    <link xml:id="L6" target="#t6a #t6b"/>
  </linkGrp>
</back>
```

The *xml:id* attributes are provided for the `<link>` and `<linkGrp>` elements here for reasons discussed in the next section, 16.5.2. *Placing Synchronous Events in Time*.

As with other forms of alignment, synchronization may be expressed between stretches of speech as well as between points. When complete utterances are synchronous, for example, if one person says *What?* and another *No!* at the same time, that can be represented without `<anchor>` elements as follows.

```
<u synch="#u02" xml:id="u01" who="#a">What?</u>
<u xml:id="u02" who="#b">No!</u>
```

A simple way of expressing *overlap* (where one speaker starts speaking before another has finished) is thus to use the `<seg>` element to encode the overlapping portions of speech. For example,

```
<u who="#a"> So you're <unclear synch="#u-b1"/>
</u>
<u who="#b">
  <seg xml:id="u-b1"> It will be </seg> nice in a way, but,
<seg synch="#u-a3"> be strange. </seg>
</u>
<u who="#a">
  <seg xml:id="u-a3"> Yeah </seg>, yeah, cos it,
its <seg synch="#u-b2"> the </seg>
</u>
<u xml:id="u-b2" who="#b"> not </u>
```

Note in this encoding how synchronization has been effected between an empty `<unclear>` element and the content of a `<seg>` element, and between the content of an `<u>` element and that of another `<seg>`, using the *synch* attribute. Alternatively, a `<linkGrp>` could be used in the same way as above.

## 16.5.2 Placing Synchronous Events in Time

A synchronous alignment specifies which points in a spoken text occur at the same time, and the order in which they occur, but does not say at what time those points actually occur. If that information is available to the encoder it can be represented by means of the `<when>` and `<timeline>` elements, whose description and attributes are the following:

- <when>** indicates a point in time either relative to other elements in the same timeline tag, or absolutely.
- @absolute** supplies an absolute value for the time.
  - @interval** specifies a time interval either as a number or as one of the keywords defined by the datatype data.interval
  - @unit** specifies the unit of time in which the *interval* value is expressed, if this is not inherited from the parent <timeline>.
  - @since** identifies the reference point for determining the time of the current <when> element, which is obtained by adding the interval to the time of the reference point.
- <timeline>** provides a set of ordered points in time which can be linked to elements of a spoken text to create a temporal alignment of that text.
- @origin** designates the origin of the timeline, i.e. the time at which it begins.
  - @interval** specifies a time interval either as a positive integral value or using one of a set of predefined codes.
  - @unit** specifies the unit of time corresponding to the *interval* value of the timeline or of its constituent points in time.

Each <when> element indicates a point in time, either directly by means of the *absolute* attribute, whose value is a string which specifies a particular time, or indirectly by means of the *since* attribute, which points to another <when>. If the *since* is used, then the *interval* and *unit* attributes should also be used to indicate the amount of time that has elapsed since the time specified by the element pointed to by the *since* attribute; the value -1 can be given to indicate that the interval is unknown.

If the <when> elements are uniformly spaced in time, then the *interval* and *unit* values need be given once in the <timeline>, and not repeated in any of the <when> elements. If the intervals vary, but the units are all the same, then the *unit* attribute alone can be given in the <timeline> element, and the *interval* attribute given in the <when> element.

The *origin* attribute in the <timeline> element points to a <when> element which specifies the reference or origin for the timings within the <timeline>; this must, of course, specify its position in time absolutely. If the origin of a timeline is unknown, then this attribute may be omitted.

The following <timeline> might be used to accompany the marked up conversation shown in the preceding section:

```
<timeline xml:id="tL1" origin="#w0"
  unit="ms">
  <when xml:id="w0" absolute="11:30:00"/>
  <when xml:id="w1" interval="unknown"
    since="#w0"/>
  <when xml:id="w2" interval="100"
    since="#w1"/>
  <when xml:id="w3" interval="200"
    since="#w2"/>
  <when xml:id="w4" interval="150"
    since="#w3"/>
  <when xml:id="w5" interval="250"
    since="#w4"/>
  <when xml:id="w6" interval="100"
    since="#w5"/>
</timeline>
```

The information in this <timeline> could now be linked to the information in the <linkGrp> which provides the temporal alignment (synchronization) for the text, as follows:

```
<linkGrp type="temporal_specification"
  domains="#lg1 #tL1" targFunc="synch.points when">
  <link target="#L1 #w1"/>
```

```

<link target="#L2 #w2"/>
<link target="#L3 #w3"/>
<link target="#L4 #w4"/>
<link target="#L5 #w5"/>
<link target="#L6 #w6"/>
</linkGrp>

```

To avoid the need for two distinct link groups (one marking the synchronization of anchors with each other, and the other marking their alignment with points on the time line) it would be better to link the <when> elements with the synchronous points directly:

```

<linkGrp type="temporal_specification"
  domains="#BNC-d1 #BNC-d1 #tL1" targFunc="speaker.a speaker.b when">
  <link target="#t1a #t1b #w1"/>
  <link target="#t2a #t2b #w2"/>
  <link target="#t3a #t3b #w3"/>
  <link target="#t4a #t4b #w4"/>
  <link target="#t5a #t5b #w5"/>
  <link target="#t6a #t6b #w6"/>
</linkGrp>

```

Finally, suppose that a digitized audio recording is also available, and an XML file that assigns identifiers to the various temporal spans of sound is available. For example, the following Synchronized Multimedia Integration Language (SMIL, pronounced "smile") fragment:

```

<audio xmlns="http://www.w3.org/2001/SMIL20/Language" src="rtsp://
soundstage.pi.cnr.it:554/home/az/bncSound/xmas4lots.mp3"
  xml:id="au1" begin="05.2s"/>
<audio xmlns="http://www.w3.org/2001/SMIL20/Language" src="rtsp://
soundstage.pi.cnr.it:554/home/az/bncSound/xmas4lots.mp3"
  xml:id="au2" begin="05.7s"/>
<audio xmlns="http://www.w3.org/2001/SMIL20/Language" src="rtsp://
soundstage.pi.cnr.it:554/home/az/bncSound/xmas4lots.mp3"
  xml:id="au3" begin="05.9s"/>
<audio xmlns="http://www.w3.org/2001/SMIL20/Language" src="rtsp://
soundstage.pi.cnr.it:554/home/az/bncSound/xmas4lots.mp3"
  xml:id="au4" begin="06.3s"/>
<audio xmlns="http://www.w3.org/2001/SMIL20/Language" src="rtsp://
soundstage.pi.cnr.it:554/home/az/bncSound/xmas4lots.mp3"
  xml:id="au5" begin="06.9s"/>
<audio xmlns="http://www.w3.org/2001/SMIL20/Language" src="rtsp://
soundstage.pi.cnr.it:554/home/az/bncSound/xmas4lots.mp3"
  xml:id="au6" begin="07.4s"/>

```

URIs pointing to the <audio> elements could also be included as a fourth component in each of the above <link> elements, thus providing a synchronized audio track to complement the transcribed text.

For further discussion of this and related aspects of encoding transcribed speech, refer to chapter 8. *Transcriptions of Speech*.

## 16.6 Identical Elements and Virtual Copies

This section introduces the notion of a *virtual element*, that is, an element which is not explicitly present in a text, but the presence of which an application can infer from the encoding supplied. In this section, we are concerned

with virtual elements made by simply cloning existing elements. In the next section (16.7. *Aggregation*), we discuss virtual elements made by aggregating existing elements.

Provided that explicit elements are available to represent the parts or places to be linked, then the global linking attributes *sameAs* and *copyOf* may be used to encode this kind of equivalence:

**att.global linking** provides a set of attributes for hypertextual linking.

@*sameAs* points to an element that is the same as the current element.

@*copyOf* points to an element of which the current element is a copy.

It is useful to be able to represent the fact that one element of text is identical to others, for analytical purposes, or (especially if the elements have lengthy content) to obviate the need to repeat the content. For example, consider the repetition of the <date> element in the following material:

```
<p>In small clumsy letters he wrote:
<q  rend="centered italic">
  <date xml:id="d840404">April 4th,
    1984</date>.</q>
</p>
<p>He sat back. A sense of complete helplessness had
descended upon him. ...</p>
<p>His small but childish handwriting straggled up
and down the page, shedding first its capital letters
and finally even its full stops:
<q  rend="italic">
  <date>April 4th, 1984</date>.
  Last night to the flicks. ... </q>
</p>
```

Suppose now that we wish to encode the fact that the second <date> element above has identical content to the first. The *sameAs* attribute is provided for this purpose. Using it, we could recode the last line of the above example as follows:

```
<date sameAs="#d840404">April 4th,
1984</date>
Last night to the flicks ...
```

The *sameAs* attribute may be used to document the fact that two elements have identical content. It may be regarded as a special kind of link. It should only be attached to an element with identical content to that which it targets, or to one the content of which clearly designates it as a repetition, such as the word *repeat* or *bis* in the representation of the chorus of a song, the second time it is to be sung. The relation specified by the *sameAs* attribute is symmetric: if a chorus is repeated three times and each repetition bears a *sameAs* attribute indicating the first occurrence of the element concerned, it is implied that each chorus is identical, and there is no need for the first occurrence to specify any of its copies.

The *copyOf* attribute is used in a similar way to indicate that the content of the element bearing it is identical to that of another. The difference is that the content is not itself repeated. The effect of this attribute is thus to create a *virtual copy* of the element indicated. Using this attribute, the repeated date in the first example above could be recoded as follows:

```
<date  rend="italic"  copyOf="#d840404"/>
```

An application program should replace whatever is the actual content of an element bearing a *copyOf* attribute with the content of the element specified by it. If the content of the element specified includes other elements, these will become embedded within the element bearing the attribute. Care must be taken to ensure that the document is valid both before and after this embedding takes place. If, for example, the element bearing a *copyOf* attribute

requires a mandatory sub-component, then this component must be present (though possibly empty), even though it will be replaced by the content of the targetted element.

The following example demonstrates how the *copyOf* attribute may be used in conjunction with the `<seg>` element to highlight the differences between almost identical repetitions:

```
<sp>
  <speaker>Mikado</speaker>
  <l>My <seg xml:id="Mik-L1s">object all sublime</seg>
  </l>
  <l>I shall <seg xml:id="Mik-L2s">achieve in time</seg>—</l>
  <l xml:id="Mik-L3">To let <seg xml:id="L3s">the punishment fit the crime</seg>,</l>
  <l xml:id="Mik-l4">
    <seg copyOf="#Mik-L3s"/>;</l>
  <l xml:id="Mik-l5">And make each pris'ner pent</l>
  <l xml:id="Mik-l6">Unwillingly represent</l>
  <l xml:id="Mik-l7">A source <seg xml:id="Mik-l7s">of innocent merriment</seg>,</l>
  <l xml:id="Mik-l8">
    <seg copyOf="#Mik-l7s"/>!</l>
</sp>
<sp>
  <speaker>Chorus</speaker>
  <l>His <seg copyOf="#Mik-L1s"/>
  </l>
  <l>He will <seg copyOf="#Mik-L2s"/>
  </l>
  <l copyOf="#Mik-L3"/>
  <l copyOf="#Mik-l4"/>
  <l copyOf="#Mik-l5"/>
  <l copyOf="#Mik-l6"/>
  <l copyOf="#Mik-l7"/>
  <l copyOf="#Mik-l8"/>
</sp>
```

For further examples of the use of this attribute, see 16.8. *Alternation* and 19.3. *Another Tree Notation*.

## 16.7 Aggregation

Because of the strict hierarchical organization of elements, or for other reasons, it may not always be possible or desirable to include all the parts of a possibly fragmented text segment within a single element. In section 16.1.4. *Intermediate Pointers* we introduced the notion of an intermediate pointer as a way of pointing to discontinuous segments of this kind. In this section we first describe another way of linking the parts of a discontinuous whole, using a set of linking attributes, which are made available for any tag by following the procedure described at the beginning of this chapter. We then describe how the `<link>` element may be used to aggregate such segments, and finally introduce the `<join>` element, which is a special-purpose linking element specifically for representing the aggregation of parts, and the `<joinGrp>` for grouping `<join>` elements.

The linking attributes for aggregation are *next* and *prev*; each of these attributes has a single identifier as its value:

**att.global.linking** provides a set of attributes for hypertextual linking.

*@next* points to the next element of a virtual aggregate of which the current element is part.

*@prev* (previous) points to the previous element of a virtual aggregate of which the current element is part.

The `<join>` element is also a member of the class of **att.pointing** elements, and so may carry any of the attributes of that class; for the list, see section 16.1. *Links*.

Here is the material on which we base our first illustration of the use of these mechanisms. Our problem is to represent the s-units identified below as qs3 and qs4 as a single (but discontinuous) whole:

```

<q>
  <s xml:id="qs2">Monsieur Paul, after he has taken equal
    parts of goose breast and the finest pork, and
    broken a certain number of egg yolks into them,
    and ground them <emph>very</emph>, very fine,
    cooks all with seasoning for some three hours.</s>
  <s xml:id="qs3">
    <emph>But</emph>,</s>
</q>
<s xml:id="ps2">she pushed her face nearer, and looked with
ferocious gloating at the pâté
inside me, her eyes like X rays,</s>
<q>
  <s xml:id="qs4">he never stops stirring it!</s>
  <s xml:id="qs5">Figure to yourself the work of it -</s>
  <s xml:id="qs6">stir, stir, never stopping!</s>
</q>

```

Using the *prev* and *next* attributes, we can link the s-units with identifiers qs3 and qs4, either singly or doubly as follows:

```

<s xml:id="qs3" next="#qs4"><emph>But</emph>,</s>
<s xml:id="qs4">he never stops stirring it!</s>

```

```

<s xml:id="qs3"><emph>But</emph>,</s>
<s xml:id="qs4" prev="#qs3">he never stops stirring it!</s>

```

```

<s xml:id="qs3" next="#qs4"><emph>But</emph>,</s>
<s xml:id="qs4" prev="#qs3">he never stops stirring it!</s>

```

Double linking of the two s-units, as illustrated by the last of these encodings, is equivalent to specifying a `<link>` element:

```
<link type="join" target="#qs3 #qs4"/>
```

Such a `<link>` element must carry a *type* attribute with a value of *join* to specify that the link is to be understood as joining its targets into a single aggregate.

The `<join>` element is equivalent to a `<link>` element of type *join*. Unlike the `<link>` element, the `<join>` element can additionally specify information about the virtual element which it represents, by means of its *result* attribute. And finally, unlike the `<link>` element, the position of a `<join>` element within a text is significant: it must be supplied at a position where the element indicated by its *result* attribute would be contextually legal.

**<join>** identifies a possibly fragmented segment of text, by pointing at the possibly discontinuous elements which compose it.

*@result* specifies the name of an element which this aggregation may be understood to represent.

**<joinGrp>** (join group) groups a collection of join elements and possibly pointers.

*@result* supplies the default value for the *result* on each <join> included within the group.

To conclude the above example, we now use a <join> element to represent the virtual sentence formed by the aggregation of s1 and s2:

```
<join target="#qs3 #qs4" result="s"/>
```

As a further example, consider the following list of authors' names. The object of the <join> element here is to provide another list, composed of those authors from the larger list who happen to come from Heidelberg:

```
<list>
  <head>Authors</head>
  <item xml:id="a_uf">Figge, Udo </item>
  <item xml:id="a_ch">Heibach, Christiane </item>
  <item xml:id="a_gh">Heyer, Gerhard </item>
  <item xml:id="a_bp">Philipp, Bettina </item>
  <item xml:id="a_ms">Samiec, Monika </item>
  <item xml:id="a_ss">Schierholz, Stefan </item>
</list>
<join target="#a_ch #a_bp #a_ss"
  result="list">
  <desc>Authors from Heidelberg</desc>
</join>
```

The following example shows how <join> can be used to reconstruct a text cited in fragments presented out of order. The poem being remembered (an unusual translation of a well-known poem by Basho) runs 'When the old pond / gets a new frog, / it's a new pond.'

```
<sp>
  <speaker>Hughie</speaker>
  <p>How does it go?
  <q>
    <l xml:id="frog-x1">da-da-da</l>
    <l xml:id="frog-L2">gets a new frog</l>
    <l>...</l>
  </q>
</p>
</sp>
<sp>
  <speaker>Louie</speaker>
  <p>
    <q>
      <l xml:id="frog-L1">When the old pond</l>
      <l>...</l>
    </q>
  </p>
</sp>
<sp>
  <speaker>Dewey</speaker>
  <p>
    <q>...
    <l xml:id="frog-L3">It's a new pond.</l>
    </q>
  </p>
  <join target="#frog-L1 #frog-L2 #frog-L3">
```

```

    result="lg" scope="root"/>
</sp>

```

As with other forms of link, a grouping element `<joinGrp>` is available for use when a number of `<join>` elements of the same kind co-occur. This avoids the need to specify the *result* attribute for each `<join>` if they are all of the same type, and also allows us to restrict the domain within which their target elements are to be found, in the same way as for `<linkGrp>` elements (see 16.1.3. *Groups of Links*). Like a `<join>`, a `<joinGrp>` may appear only where the elements represented by its contents are legal. Thus if we had created many `<join>` tags of the sort just described, we could group them together, and require that their components are all contained by an element with the identifier MFKFhungry as follows:

```

<joinGrp domains="#mfkfhungry #mfkfhungry"
  result="s">
  <join target="#qs3 #qs4"/>
  <join target="#qs5 #qs6"/>
</joinGrp>

```

The `<join>` element is useful as a means of representing non-hierarchical structures (as further discussed in chapter 20. *Non-hierarchical Structures*). It may also be used as a convenient way of representing a variety of analytic units, like the `<span>` and `<interp>` elements discussed in chapter 17. *Simple Analytic Mechanisms*. As an example, consider the following famous Zen koan:

Zui-Gan called out to himself every day, ‘Master.’  
 Then he answered himself, ‘Yes, sir.’  
 And then he added, ‘Become sober.’  
 Again he answered, ‘Yes, sir.’  
 ‘And after that,’ he continued, ‘do not be deceived by others.’  
 ‘Yes, sir; yes, sir,’ he replied.

Suppose now that we wish to represent an interpretation of the above passage in which we distinguish between the various ‘voices’ adopted by Zui-Gan. In the following encoding, the *who* attribute has been used for this purpose; its value on each occasion supplies a pointer to the ‘voice’ to which each speech is attributed. (For convenience in this example, we use simply the first occurrence of the names used for each voice as the target for these pointers.) Note also that we add *xml:id* attributes to each distinct speech fragment, which we can then use to link the material spoken by each voice:

```

<text xml:id="zuitxt">
  <body>
    <p>
      <name xml:id="zuigan">Zui-Gan</name> called out to himself every day,
      <q next="#zuiq2" xml:id="zuiq1"
        who="#zuigan">
        <name xml:id="master">Master</name>.</q>
    </p>
    <p>Then he answered himself,
      <q next="#zuiq4" xml:id="zuiq2"
        who="#zuigan">Yes, sir.</q>
    </p>
    <p>And then he added,
      <q next="#zuiq5" xml:id="zuiq3"
        who="#master">Become sober.</q>

```

```

</p>
<p>Again he answered,
<q next="#zuiq7" xml:id="zuiq4"
  who="#zuigan">Yes, sir.</q>
</p>
<p>
  <q next="#zuiq6" xml:id="zuiq5"
    who="#master">And after that,</q>
    he continued,
  <q xml:id="zuiq6" who="#master">do not be deceived by others.</q>
</p>
<p>
  <q xml:id="zuiq7" who="#zuigan">Yes, sir; yes, sir,</q>
  he replied.</p>
</body>
</text>

```

However, by using the <join> element, we can directly represent the complete speech attributed to each voice:

```

<joinGrp result="q">
  <join target="#zuiq1 #zuiq2 #zuiq4 #zuiq7">
    <desc>what Zui-Gan said</desc>
  </join>
  <join target="#zuiq3 #zuiq5 #zuiq6">
    <desc>what Master said</desc>
  </join>
</joinGrp>

```

Note the use of the <desc> child element within the two <join>s making up the <q> element here. These enable us to document the speakers of the two virtual <q> elements represented by the <join> elements; this is necessary because there is no way of specifying the attributes to be associated with a virtual element, in particular there is no way to specify a *who* value for them.

Suppose now that *xml:id* attributes, for whatever reasons, are not available. Then <ptr> elements may be created using any of the methods described in section 16.2.4. *TEI XPointer Schemes*. The *xml:id* attributes of *these* elements may now be specified by the *target* attribute on the <join> elements.

```

<text>
  <body>
<!-- five div1 elements -->
  <div1>
    <p>Zui-Gan called out to himself every day, <q>Master.</q>
    </p>
    <p>Then he answered himself, <q>Yes, sir.</q>
    </p>
    <p>And then he added, <q>Become sober.</q>
    </p>
    <p>Again he answered, <q>Yes, sir.</q>
    </p>
    <p>
      <q>And after that,</q> he continued, <q>do not be deceived by others.</q>
    </p>
    <p>
      <q>Yes, sir; yes, sir,</q> he replied.</p>
  <ab type="aggregation">

```

```

<ptr xml:id="rzuiq1"
  target="./#xpath(//div1[6]/p[1]/q[1])"/>
<ptr xml:id="rzuiq2"
  target="./#xpath(//div1[6]/p[2]/q[1])"/>
<ptr xml:id="rzuiq3"
  target="./#xpath(//div1[6]/p[3]/q[1])"/>
<ptr xml:id="rzuiq4"
  target="./#xpath(//div1[6]/p[4]/q[1])"/>
<ptr xml:id="rzuiq5"
  target="./#xpath(//div1[6]/p[5]/q[1])"/>
<ptr xml:id="rzuiq6"
  target="./#xpath(//div1[6]/p[5]/q[2])"/>
<ptr xml:id="rzuiq7"
  target="./#xpath(//div1[6]/p[6]/q[1])"/>
<joinGrp evaluate="one" result="q">
  <join target="#rzuiq1 #rzuiq2 #rzuiq4 #rzuiq7">
    <desc>what Zui-Gan said</desc>
  </join>
  <join target="#rzuiq3 #rzuiq5 #rzuiq6">
    <desc>what Master said</desc>
  </join>
</joinGrp>
</ab>
</div1>
</body>
</text>

```

The extended pointer with identifier `rzuiq2`, for example, may be read as ‘the first `<q>` in the first `<p>`, within the sixth `<div1>` element of the current document.’

## 16.8 Alternation

This section proposes elements for the representation of alternation. We say that two or more elements are in *exclusive alternation* if any of those elements could be present in a text, but one and only one of them is; in addition, we say that those elements are *mutually exclusive*. We say that the elements are in *inclusive alternation* if at least one (and possibly more) of them is present. The elements that are in alternation may also be called *alternants*.

The need to mark exclusive alternation arises frequently in text encoding. A common situation is one in which it can be determined that exactly one of several different words appears in a given location, but it cannot be determined which one. One way to mark such an exclusive alternation is to use the linking attribute *exclude*. Having marked an exclusive alternation, it can sometimes later be determined which of the alternants actually appears in the given location. To preserve the fact that an alternation was posited, one can add the linking attribute *select* to a tag which hierarchically encompasses the alternants, which points to the one which actually appears. To assign responsibility and degree of certainty to the choice, one can use the `<certainty>` tag described in chapter 21. *Certainty, Precision, and Responsibility*. Also see that chapter for further discussion of certainty in general.

The *exclude* and *select* attributes may be used with any element assuming that they have been declared following the procedure discussed in the introduction to this chapter.

**att.global.linking** provides a set of attributes for hypertextual linking.

`@exclude` points to elements that are in exclusive alternation with the current element.

`@select` selects one or more alternants; if one alternant is selected, the ambiguity or uncertainty is marked as resolved. If more than one alternant is selected, the degree of ambiguity or uncertainty is marked as reduced by the number of alternants not selected.

A more general way to mark alternation, encompassing both exclusive and inclusive alternation, is to use the linking element `<alt>`. The description and attributes of this tag and of the associated grouping tag `<altGrp>` are as follows. These elements are also members of the `att.pointing` class and therefore have all the attributes associated with that class.

**<alt>** (alternation) identifies an alternation or a set of choices among elements or passages.

@*weights* If *mode* is `excl`, each weight states the probability that the corresponding alternative occurs. If *mode* is `incl` each weight states the probability that the corresponding alternative occurs given that at least one of the other alternatives occurs.

**<altGrp>** (alternation group) groups a collection of `<alt>` elements and possibly pointers.

To take a simple hypothetical example, suppose in transcribing a spoken text, we encounter an utterance that we can understand either as *We had fun at the beach today.* or as *We had sun at the beach today.* We can represent the exclusive alternation of these two possibilities by means of the *exclude* attribute as follows.

```
<div type="interview">
  <u exclude="#we.sun1" xml:id="we.fun1">We had fun at the beach today.</u>
  <u exclude="#we.fun1" xml:id="we.sun1">We had sun at the beach today.</u>
</div>
```

If it is then determined that the speaker said *fun*, not *sun*, the encoder could amend the text by deleting the alternant containing *sun* and the *exclude* attribute on the remaining alternant. Alternatively, the encoder could preserve the fact that there was uncertainty in the original transcription by retaining the alternants, and assigning the *we.fun* value to the *select* attribute value on the `<div>` element that encompasses the alternants, as in:

```
<div select="#we.fun2" type="interview">
  <u exclude="#we.sun2" xml:id="we.fun2">We had fun at the beach
    today.</u>
  <u exclude="#we.fun2" xml:id="we.sun2">We had sun at the beach today.</u>
</div>
```

The above alternation (including the *select* attribute) could be recoded by assigning the *exclude* attributes to tags that enclose just the words or even the characters that are mutually exclusive, as in:<sup>100</sup>

```
<div type="interview">
  <u select="#fun3">We had
    <seg exclude="#sun3" xml:id="fun3"
      type="word">fun</seg>
    <seg exclude="#fun3" xml:id="sun3"
      type="word">sun</seg>
    at the beach today.</u>
</div>
```

```
<div type="interview">
  <u>We had
    <seg select="#id-f" type="word">
      <seg exclude="#id-s" xml:id="id-f"
        type="character">f</seg>
      <seg exclude="#id-f" xml:id="id-s"
        type="character">s</seg>
      un</seg>
    at the beach today.</u>
</div>
```

<sup>100</sup>See section 17.1. *Linguistic Segment Categories* for discussion of the `<w>` and `<c>` tags that can be used in the following examples instead of the `<seg type="word">` and `<seg type="character">` tags.

Now suppose that the transcriber is uncertain whether the first word in the utterance is *We* or *Lee*, but is certain that if it is *Lee*, then the other uncertain word is definitely *fun* and not *sun*. The three utterances that are in mutual exclusion can be encoded as follows.

```
<div type="interview">
<!-- ... -->
  <u exclude="#we.sun4 #lee.fun4"
    xml:id="we.fun4">We had fun at the beach today.</u>
  <u exclude="#we.fun4 #lee.fun4"
    xml:id="we.sun4">We had sun at the beach today.</u>
  <u exclude="#we.fun4 #we.sun4"
    xml:id="lee.fun4">Lee had fun at the beach today.</u>
<!-- ... -->
</div>
```

The preceding example can also be encoded with *exclude* attributes on the word segments *We*, *Lee*, *fun*, and *sun*:

```
<u>
  <seg exclude="#lee" xml:id="we" type="word">We</seg>
  <seg exclude="#we #sun" xml:id="lee"
    type="word">Lee</seg>
had
  <seg exclude="#sun" xml:id="fun"
    type="word">fun</seg>
  <seg exclude="#fun #lee" xml:id="sun"
    type="word">sun</seg>
at the beach today.
</u>
```

The value of the *select* attribute is defined as a list of identifiers; hence it can also be used to narrow down the range of alternants, as in:

```
<div select="#we.fun5 #lee.fun5"
  type="interview">
  <u exclude="#we.sun5 #lee.fun5"
    xml:id="we.fun5">We had fun at the beach today.</u>
  <u exclude="#we.fun5 #lee.fun5"
    xml:id="we.sun5">We had sun at the beach today.</u>
  <u exclude="#we.fun5 #we.sun5"
    xml:id="lee.fun5">Lee had fun at the beach today.</u>
</div>
```

This is interpreted to mean that either the first or the third *<u>* element tag appears, and is thus equivalent to just the alternation of those two tags:

```
<div type="interview">
  <u exclude="#lee.fun6" xml:id="we.fun6">We had fun at the beach
    today.</u>
  <u exclude="#we.fun6" xml:id="lee.fun6">Lee had fun at the beach today.</u>
</div>
```

The *exclude* attribute can also be used in case there is uncertainty about the tag that appears in a certain position. For example, the occurrence of the word *May* in the s-unit *Let's go to May* can be interpreted, in the absence of other

information, either as a person's name or as a date. The uncertainty can be rendered as follows, using the *exclude* attribute.

```
<s>Let's go to
<name exclude="#mayn" xml:id="mayd">May</name>
  <date copyOf="#mayd" exclude="#mayd"
    xml:id="mayn"/>.</s>
```

Note the use of the *copyOf* attribute discussed in section 16.6. *Identical Elements and Virtual Copies*; this avoids having to repeat the content of the element whose correct tagging is in doubt.

The *copyOf* and the *exclude* attributes also provide for a simple way of indicating uncertainty about exactly where a particular element occurs in a document.<sup>101</sup> For example suppose that a particular <div2> element appears either as the third and last of the <div2> elements within the first <div1> element in the body of a document, or as the first <div2> of the second <div1>. One solution would be to record the <div2> in its entirety in the first of these positions, and a virtual copy of it in the second, and mark them as excluding each other as follows:

```
<body>
  <div1 xml:id="C1">
    <div2 xml:id="C1S3" exclude="#C2S1"/>
  </div1>
  <div1 xml:id="C2">
    <div2 xml:id="C2S1" copyOf="#C1S3"
      exclude="#C1S3"/>
  </div1>
</body>
```

In this case, the *select* attribute, if used, would appear on the <body> element.

Mutual exclusion can also be expressed using a <link>; the first example in this section can be recoded by removing the *exclude* attributes from the <u> elements, and adding a <link> element as follows:<sup>102</sup>

```
<div type="interview">
  <u xml:id="we.had.fun">We had fun at the beach today.</u>
  <u xml:id="we.had.sun">We had sun at the beach today.</u>
  <link type="exclusiveAlternation"
    target="#we.had.fun #we.had.sun"/>
</div>
```

Now we define the specialized linking element <alt>, making it a member of the class **att.pointing**, and assigning it a *mode* attribute, which can have either of the values *excl* (for exclusive) or *incl* (for inclusive). Then the following equivalence holds:

```
<alt target="#a #b" mode="excl"/>
```

=

```
<link target="#a #b"
  type="exclusive_alternation"/>
```

<sup>101</sup>An alternative way of representing this problem is discussed in chapter 21. *Certainty, Precision, and Responsibility*.

<sup>102</sup>In this example, we have placed the <link> next to the elements that represent the alternants. It could also have been placed elsewhere in the document, perhaps within a <linkGrp>.

The preceding <link> element may therefore be recoded as the following <alt> element.

```
<alt target="#we.had.fun #we.had.sun"
mode="excl"/>
```

Another attribute that is defined specifically for the <alt> element is *weights*, which is to be used if one wishes to assign *probabilistic weights* to the targets (alternants). Its value is a list of numbers, corresponding to the targets, expressing the probability that each target appears. If the alternants are mutually exclusive, then the weights must sum to 1.0.

Suppose in the preceding example that it is equiprobable whether *fun* or *sun* appears. Then the <alt> element that represents the alternation may be stated as follows:

```
<alt target="#we.fun #we.had.sun"
mode="excl" weights="0.5 0.5"/>
```

The assignment of a weight of 1.0 to one target (and weights of 0 to all the others) is equivalent to selecting that target. Thus the following encoding is equivalent to the second example at the beginning of this section.

```
<u xml:id="we.fun">We had fun at the beach today.</u>
<u xml:id="we.sun">We had sun at the beach today.</u>
<alt target="#we.fun #we.sun" mode="excl"
weights="1 0"/>
```

The sum of the weights for <alt mode="incl"> tags ranges from 0% to  $(100 \times k)\%$ , where  $k$  is the number of targets. If the sum is 0%, then the alternation is equivalent to exclusive alternation; if the sum is  $(100 \times k)\%$ , then all of the alternants must appear, and the situation is better encoded without an <alt> tag.

If it is desired, <alt> elements may be grouped together in an <altGrp> element, and attribute values shared by the individual <alt> elements may be identified on the <altGrp> element. The *targFunc* attribute defaults to the value *first.alternant next.alternant*.

To illustrate, consider again the example of a transcribed utterance, in which it is uncertain whether the first word is *We* or *Lee*, whether the third word is *fun* or *sun*, but that if the first word is *Lee*, then the third word is *fun*. Now suppose we have the following additional information: if *we* occurs, then the probability that *fun* occurs is 50% and that *sun* occurs is 50%; if *fun* occurs, then the probability that *we* occurs is 40% and that *Lee* occurs is 60%. This situation can be encoded as follows.

```
<u>
  <seg exclude="#lee2" xml:id="we2"
type="word">We</seg>
  <seg exclude="#we2" xml:id="lee2"
type="word">Lee</seg>
had
  <seg exclude="#sun2" xml:id="fun2"
type="word">fun</seg>
  <seg exclude="#fun2" xml:id="sun2"
type="word">sun</seg>
at the beach today.
</u>
<altGrp>
  <alt target="#we2 #lee2"/>
  <alt target="#fun2 #sun2"/>
  <alt target="#we2 #fun2" mode="incl"
weights="0.5 0.5"/>
```

```
<alt target="#lee2 #fun2" mode="incl"
  weights="1.0 0.6"/>
</altGrp>
```

As noted above, when the *mode* attribute on an `<alt>` has the value `incl`, then each weight states the probability that the corresponding alternative occurs, given that at least one of the other alternatives occurs.

From the information in this encoding, we can determine that the probability is about 28.5% that the utterance is ‘We had fun at the beach today’, 28.5% that it is *We had sun at the beach today*, and 43% that it is *Lee had fun at the beach today*.

Another very similar example is the following regarding the text of a Broadway song. In three different versions of the song, the same line reads ‘Her skin is tender as a leather glove’, ‘Her skin is tender as a baseball glove’, and ‘Her skin is tender as Dimaggio’s glove.’<sup>103</sup>

If we wish to express this textual variation using the `<alt>` element, we can record our relative confidence in the readings *Dimaggio’s* (with probability 50%), *a leather* (25%), and *a baseball* (25%).

Let us extend the example with a further (imaginary) variation, supposing for the sake of the argument that the next line is variously given as *and she bats from right to left* (with probability 50%) or *now ain’t that too damn bad* (with probability 50%). Using the `<alt>` element, we can express the conviction that if the first choice for the second line is correct, then the probability that the first line contains *Dimaggio’s* is 90%, and each of the others 5%; whereas if the second choice for the second line is correct, then the probability that the first line contains *Dimaggio’s* is 10%, and each of the others is 45%. This can be encoded, with an `<altGrp>` element containing a combination of exclusive and inclusive `<alt>` elements, as follows.

```
<div xml:id="bm" type="song">
  <l>Her skin is tender as
  <seg xml:id="dm">Dimaggio's</seg>
    <seg xml:id="lt">a leather</seg>
    <seg xml:id="bb">a baseball</seg>
    glove,</l>
  <l xml:id="rl">and she bats from right to left.</l>
  <l xml:id="db">now ain't that too damn bad.</l>
</div>
<altGrp>
  <alt target="#dm #lt #bb" mode="excl"

## 16.9 Stand-off Markup

### 16.9.1 Introduction

Most of the mechanisms defined in this chapter rely to a greater or lesser extent on the fact that tags in a marked-up document can both assert a property for a span of text which they enclose, and assert the existence of an association between themselves and some other span of text elsewhere. In stand-off markup, there is a clear separation of these

<sup>103</sup>The variant readings are found in the commercial sheet music, the performance score, and the Broadway cast recording.

two behaviours: the markup does not directly contain any part of the text, but instead includes it by reference. One specific mechanism recommended by these Guidelines for this purpose is the standard XInclude mechanism defined by the W3C; another is to use pointers as demonstrated elsewhere in this chapter.

There are many reasons for using stand-off markup: the source text might be read-only so that additional markup cannot be added, or a single text may need to be marked up according to several hierarchically incompatible schemes, or a single scheme may need to accommodate multiple hierarchical ambiguities, so that a single markup tree is not the most faithful representation of the source material.

This section describes a generic mechanism for expressing *all* kinds of markup externally as stand-off tags, for use whenever it is appropriate.

Throughout this section the following terms will be systematically used in specific senses.

**source document** a document to which the stand-off markup refers (a source document can be either XML or plain text); there may be more than one source document.

**internal markup** markup that is already present in an XML source document

**stand-off markup** markup that is either outside of the source document and points in to it to the data it describes, or alternatively is in another part of the source document and points elsewhere within the document to the data it describes

**external document** a document that contains stand-off markup that points to a different, source document

**internalize** the action of creating a new XML document with external markup and data integrated with the source document data, and possibly some source document markup as well

**externalize** a process applied to markup from a pre-existing XML document, which splits it into two documents, an XML (external) document containing some of the markup of the original document, and another (source) XML document containing whatever text content and markup has not been extracted into the stand-off document; if all markup has been externalized from a document, the new source may be a plain text document

The three major requirements satisfied by this scheme for stand-off markup are:

- a any valid TEI markup can be either internal or external,
- b external markup can be internalized by applying it to the document content by either substituting the existing markup or adding to it, to form a valid TEI document, and
- c the external markup itself specifies whether an internalized document is to be created by substituting the existing internal markup or by adding to it

## 16.9.2 Overview of XInclude

Stand-off markup which relies on the inclusion of virtual content is adequately supported by the W3C XInclude recommendation, which is also recommended for use by these Guidelines.<sup>104</sup> XInclude defines a namespace (<http://www.w3.org/2001/XInclude>), which in these Guidelines will be associated with the prefix *xi*; and exactly two elements, `<xi:include>` and `<xi:fallback>`. XInclude relies on the XPointer framework discussed elsewhere in this chapter to point to the actual fragments of text to be internalized. Although XInclude only requires support for the `element()` scheme of XPointer, these Guidelines permit the use of any of the pointing schemes discussed in section 16.2. *Pointing Mechanisms*.

XInclude is a W3C recommendation which specifies a syntax for the inclusion within an XML document of data fragments placed in different resources. Included resources can be either plain text or XML. XInclude instructions within an XML document are meant to be replaced by a resource targeted by a URI, possibly augmented by an XPointer that identifies the exact subresource to be included.

The `<xi:include>` element uses the *href* attribute to specify the location of the resource to be included; its value is an URI containing, if necessary, an XPointer. Additionally, it uses the *parse* attribute (whose only valid values are text and xml) to specify whether the included content is plain text or an XML fragment, and the *encoding* attribute to provide a hint, when the included fragment is text, of the character encoding of the fragment. An optional `<xi:fallback>` element is also permitted within an `<xi:include>`; it specifies alternative content to be used

<sup>104</sup>The version on which this text is based is the W3C Recommendation dated 20 December 2004..

when the external resource cannot be fetched for some reason. Its use is not however recommended for stand-off markup.

### 16.9.3 Stand-off Markup in TEI

The operations of internalizing and externalizing markup are very useful and practically important. XInclude processing as defined by the W3C is internalization of one or more source documents' content into a stand-off document. TEI use of XInclude for stand-off markup enables use of XInclude-conformant software to perform this useful operation. However, internalization is not clearly defined for all stand-off files, because the structure of the internal and external markup trees may overlap. In particular, when an external markup document selects a range that overlaps partial elements in the source document, it is not clear how the semantics of internalization (inclusion) should work, since partial elements are not XML objects.<sup>105</sup> XInclude defines a semantics for this case that involves only complete elements.

When a range selection partially overlaps a number of elements in a source document, XInclude specifies that the partially overlapping elements should be included as well as all completely overlapping elements and characters (partially overlapping characters are not possible). The effect of this is that elements that straddle the start or end of a selected range will be included as wrappers for those of their children that are completely or partially selected by the range. For example, given the following source document:

```
<body>
  <p xml:id="par1">home, <emph>home</emph> on Brokeback Mountain.</p>
  <p xml:id="par2">That was the <emph>song</emph> that I sang</p>
</body>
```

and the following external document:

```
<body>
<div><include href="example1.xml" xmlns="http://www.w3.org/2001/XInclude"
xpointer="range(xpath(id('par1'))//emph),xpath(id('par2'))//emph)"/>
</div>
</body>
```

the resulting document after XInclude processing of this external document would be:

```
<body>
<div>
<p xml:id="par1">home, <emph>home</emph> on Brokeback Mountain.</p>
<p xml:id="par2">That was the <emph>song</emph> that I sang</p>
</div>
</body>
```

The result of the inclusion is two paragraph elements, while the original range designated in the source document overlapped two paragraph fragments. The semantics of XInclude require the creation of well-formed XML results even though the pointing mechanisms it uses do not necessarily respect the hierarchical structure of XML documents, as in this case. While this is a good way to ensure that internalization is always possible, it has implications for the use of XInclude as a notation for the *description* of overlapping markup structures.

When overlapping hierarchies need to be represented for a single document, each hierarchy must be represented by a separate set of XInclude tags pointing to a common source document. This sort of structure corresponds to

<sup>105</sup>This corresponds to the observation that overlapping XML tags reflecting a textual version of such an inclusion would not even be well-formed XML. This kind of overlap in textual phenomena of interest is in fact the major reason that stand-off markup is needed.

common practice in work with linguistic text corpora. In such corpora, each potentially overlapping hierarchy of elements for the text is represented as a separate stream of stand-off markup. Generally the source text contains markup for the smallest significant units of analysis in the corpus, such as words or morphemes, this information and its markup representing a layer of common information that is shared by all the various hierarchies. As a way of organizing the representation of complex data, this technique generally allows a large number of *xml:id* attributes to be attached to the shared elements, providing robust anchors for links and facilitating adjustments to the source document without breaking external documents that reference it.

Any tag can be externalized by removing its content and replacing it with an `<xi:include>` element that contains an XPointer pointing to the desired content.

For instance the following portion of a TEI document:

```
<text>
  <body>
    <head>1755</head>
    <l>To make a prairie it takes a clover and one bee,</l>
    <l>One clover, and a bee,</l>
    <l>And revery.</l>
    <l>The revery alone will do,</l>
    <l>If bees are few.</l>
  </body>
</text>
```

can be externalized by placing the actual text in a separate document, and providing exactly the same markup with the `<xi:include>` elements:

**Source.xml**

```
<content>To make a prairie it takes a clover and one bee,\n
One clover, and a bee,\n
And revery.\n
The revery alone will do,\n
If bees are few.\n
</content>
```

**External.xml**

```
<text xmlns:xi="http://www.w3.org/2001/XInclude">
  <body>
    <head>1755</head>
    <l>
      <xi:include href="Source.xml" parse="xml"
        xpointer="string-range(element(/1), 0, 48)"/>
    </l>
    <l>
      <xi:include href="Source.xml" parse="xml"
        xpointer="string-range(element(/1), 49, 71)"/>
    </l>
    <l>
      <xi:include href="Source.xml" parse="xml"
        xpointer="string-range(element(/1), 72, 83)"/>
    </l>
  </body>
</text>
```

```

<l>
<xi:include href="Source.xml" parse="xml"
xpointer="string-range(element(/1), 84,109)"/>
</l>
<l>
<xi:include href="Source.xml" parse="xml"
xpointer="string-range(element(/1),110,126)"/>
</l>
</body>
</text>

```

Please note that this specification requires that the XInclude namespace declaration is present in all cases. The `<xi:fallback>` element contains text or XML fragments to be placed in the document if the inclusion fails for any reason (for instance due to inaccessibility of an external resource). The `<xi:fallback>` element is optional; if it is not present an XInclude processor must signal a fatal error when a resource is not found. This is the preferred behaviour for use with stand-off markup. These Guidelines recommend against the use of `<xi:fallback>` for stand-off markup.

#### 16.9.4 Well-formedness and Validity of Stand-off Markup

The whole source fragment identified by an XInclude element, as well as any markup therein contained is inserted in the position specified, and an XInclude processor is required to ensure that the resulting internalized document is well-formed. This has obvious implications when the external document contains XML markup. A plain text source document will always create a well-formed internalized document.

While a TEI customization may permit `<xi:include>` elements in various places in a TEI document instance, in general these Guidelines suggest that validity be verified after the resolution of all the `<xi:include>` elements.

#### 16.9.5 Including Text or XML Fragments

When the source text is plain text the overall form of the XPointer pointing to it is of minimal importance. The form of the XPointer matters considerably, on the other hand, when the source document is XML.

In this case, it is rather important to distinguish whether we intend to substitute the source XML with the new one, or just to add new markup to it. The XPointers used in the references can express both cases.

A simple way is to make sure to select only textual data in the XPointer. For instance, given the following document:

**Source.xhtml**

```

<xhtml:html>
  <xhtml:body>
    <xhtml:div>To make a prairie it takes a <xhtml:a href="clover.gif">clover</xhtml:a>
      and one <xhtml:a href="bee.gif">bee</xhtml:a>,</xhtml:div>
    <xhtml:div>One <xhtml:a href="clover.gif">clover</xhtml:a>, and
      a <xhtml:a href="bee.gif">bee</xhtml:a>,</xhtml:div>
    <xhtml:div>And revery.</xhtml:div>
    <xhtml:div>The revery alone will do,</xhtml:div>
    <xhtml:div>If bees are few.</xhtml:div>
  </xhtml:body>
</xhtml:html>

```

the expression `range(element(/1/2/1.0),element(/1/2/11.1))` will select the whole poem, text content *and* `<div>` elements *and* hypertext links (NB: in XPointer whitespace-only text nodes count).

On the contrary, the expressions `xpointer(//text()/range-to(.))` and `xpointer(string-range(//text(),"To")/range-to(//text(),"few."))` will only select the text of the poem, with no markup inside.

Thus, the following could be a valid stand-off document for the *Source.xhtml* document:

**External2.xml**

```

<text xmlns:xi="http://www.w3.org/2001/XInclude">
<body>
<head>1755</head>
<l>
<xi:include href="Source.xhtml"
xpointer='xpointer(string-range(//div[1]/text(),"To")/range-to(//div[1]/
text(),"bee,"))' />
</l>
<l>
<xi:include href="Source.xhtml"
xpointer='xpointer(string-range(//div[2]/text(),"One")/range-to(//div[2]/
text(),"bee,"))' />
</l>
<l>
<xi:include href="Source.xhtml"
xpointer='xpointer(string-range(//div[3]/text(),"And")/range-to(//div[3]/text(),".")' />
</l>
<l>
<xi:include href="Source.xhtml"
xpointer='xpointer(string-range(//div[4]/text(),"The")/range-to(//div[4]/text(),".")' />
</l>
<l>
<xi:include href="Source.xhtml"
xpointer='xpointer(string-range(//div[5]/text(),"If")/range-to(//div[5]/text(),".")' />
</l>
</body>
</text>

```

## 16.10 Connecting Analytic and Textual Markup

In chapters 17. *Simple Analytic Mechanisms* and 18. *Feature Structures* and elsewhere, provision is made for analytic and interpretive markup to be represented outside of textual markup, either in the same document or in a different document. The elements in these separate domains can be connected, either with the pointing attributes *ana* (for *analysis*) and *inst* (for *instance*), or by means of `<link>` and `<linkGrp>` elements. Numerous examples are given in these chapters.

## 16.11 Module for Linking, Segmentation, and Alignment

The module described in this chapter makes available the following components:

**Module linking: Linking, segmentation and alignment**

- *Elements defined:* ab alt altGrp anchor join joinGrp link linkGrp seg timeline when
- *Classes defined:* att.global.linking

The selection and combination of modules to form a TEI schema is described in 1.2. *Defining a TEI Schema*.

## 17 Simple Analytic Mechanisms

This chapter describes a module for associating simple analyses and interpretations with text elements. We use the term *analysis* here to refer to any kind of semantic or syntactic interpretation which an encoder wishes to attach to all or part of a text. Examples discussed in this chapter include familiar linguistic categorizations (such as ‘clause’, ‘morpheme’, ‘part-of-speech’ etc.) and characterizations of narrative structure (such as ‘theme’, ‘reconciliation’ etc.). The mechanisms presented in this chapter are simpler but less powerful than those described in chapter 18. *Feature Structures*.

Section 17.1. *Linguistic Segment Categories* introduces elements which can be used to characterize text segments according to the familiar linguistic categories of *sentence* or *s-unit*, *clause*, *phrase*, *word*, *morpheme*, *character*, and *punctuation mark*. These elements represent special cases of the generic `<seg>` element described in section 16.3. *Blocks, Segments, and Anchors*.

Section 17.2. *Global Attributes for Simple Analyses* introduces an additional global attribute which allows passages of text to be associated with specialized elements representing their interpretation. These ‘interpretative’ elements (`<span>` and `<interp>`) are described in detail in section 17.3. *Spans and Interpretations*. They allow the encoder to specify an analysis as a series of names and associated values,<sup>106</sup> each such pair being linked to one or more stretches of text, either directly, in the case of spans, or indirectly, in the case of interpretations.

Finally section 17.4. *Linguistic Annotation* revisits the topic of linguistic analysis, and illustrates how these interpretative mechanisms may be used to associate simple linguistic analysis with text segments.

### 17.1 Linguistic Segment Categories

In this section we introduce specialized *linguistic segment category* elements which may be used to represent the segmentation of a text into the traditional linguistic categories of *sentence*, *clause*, *phrase*, *word*, *morpheme*, *characters*, and *punctuation marks*.

#### 17.1.1 Words and Above

Although different languages have very different rules about what constitutes a ‘word’ or a ‘sentence’, these remain generally useful concepts. In this section we discuss elements provided for marking up linguistic units down to the word level, however defined.

`<s>` (s-unit) contains a sentence-like division of a text.

`<cl>` (clause) represents a grammatical clause.

`<phr>` (phrase) represents a grammatical phrase.

`<w>` (word) represents a grammatical (not necessarily orthographic) word.

`@lemma` provides a lemma for the word, such as an uninflected dictionary entry form.

`@lemmaRef` provides a pointer to a definition of the lemma for the word, for example in an online lexicon.

As members of the `att.segLike` class, these elements all share the following attribute:

**att.segLike** provides attributes for elements used for arbitrary segmentation.

`@function` characterizes the function of the segment.

They also share attributes from `att.typed`:

**att.typed** provides attributes which can be used to classify or subclassify elements in any way.

`@type` characterizes the element in some sense, using any convenient classification scheme or typology.

`@subtype` provides a sub-categorization of the element, if needed

These elements are also all members of the `model.segLike` class, which is a subclass of `model.phrase`. They may thus appear anywhere that text is permitted within a document, when the module defined by this chapter is included in a schema.

The `<s>` element may be used simply to segment a text end-to-end into a series of non-overlapping segments, referred to here and elsewhere as *s-units*, or *sentences*.

<sup>106</sup>Or, as they are widely known, *attribute-value pairs*; this term should not be confused, however, with XML attributes and their values, which are similar in concept but distinct in their formal definitions.

```

<p>
  <s>Nineteen fifty-four, when I was eighteen years old,
    is held to be a crucial turning point in the history of
    the Afro-American – for the U.S.A. as a whole – the
    year segregation was outlawed by the U.S. Supreme Court.</s>
  <s>It was also a crucial year for me because on June 18,
    1954, I began serving a sentence in state prison for
    possession of marijuana.</s>
</p>

```

The <s> element is more restricted both in its content and its usage than the generic <seg> element. The <seg> unit may contain anything which can appear within a paragraph: thus it may be used to enclose members of the `model.inter` class (such as <bibl> or <list>) as well as other phrase elements; the <s> unit may only contain phrase-level elements or text. Also, unlike <seg> elements, <s> elements should not be nested within each other.<sup>107</sup> The <seg> element is intended for use as a generic segmentation element, the specific function of which may be indicated by its *type* attribute; the other members of the class are more specialized. Thus, the <s>, <cl>, and <phr> elements may be thought of as equivalent to <seg type="s-unit">, <seg type="clause"> and <seg type="phrase">, respectively, but with the above-mentioned restrictions.

The <s> element may be further subdivided into *clauses*, marked with the <cl> element, as in the following example:

```

<p>
  <s>
    <cl>It was about the beginning of September, 1664,
    <cl>that I, among the rest of my neighbours,
      heard in ordinary discourse
    <cl>that the plague was returned again to Holland; </cl>
    </cl>
  </s>
  <s>
    <cl>for it had been very violent there, and particularly at
      Amsterdam and Rotterdam, in the year 1663, </cl>
    <cl>whither, <cl>they say,</cl> it was brought,
    <cl>some said</cl> from Italy, others from the Levant, among some goods
    <cl>which were brought home by their Turkey fleet;</cl>
    </cl>
    <cl>others said it was brought from Candia;
      others from Cyprus. </cl>
  </s>
</p>

```

Clauses may be further divided into <phr> elements in the same way. A text may be segmented directly into clauses, or into phrases, with no need to include segmentation at a higher level as well.

For verse texts, the overlapping of metrical and syntactic structure requires that special care be given to representing both using an element hierarchy. One simple approach is to split the syntactic phrases into fragments when they cross verse boundaries, reuniting them with the *part* attribute:

<sup>107</sup>Neither this constraint, nor the requirement that the whole of the text be segmented by <s> elements is enforced by the current TEI schemas; such constraints may however be introduced in a later version of these Guidelines.

```

<div type="stanza">
  <l>
    <cl part="I">Tweedledum and Tweedledee</cl>
  </l>
  <l>
    <cl part="F">Agreed to have a battle;</cl>
  </l>
  <l>
    <cl part="I">For Tweedledum said <cl part="I">Tweedledee</cl>
    </cl>
  </l>
  <l>
    <cl part="F">
      <cl part="F">Had spoiled his nice new rattle.</cl>
    </cl>
  </l>
</div>
<div type="stanza">
  <l>
    <cl part="I">Just then flew down a monstrous crow,</cl>
  </l>
  <l>
    <cl part="F">As black as a tar barrel;</cl>
  </l>
  <l>
    <cl part="I">Which frightened both the heroes so,</cl>
  </l>
  <l>
    <cl part="F">
      <cl>They quite forgot their quarrel.</cl>
    </cl>
  </l>
</div>

```

Another approach is to use the *next* and *prev* attributes defined in the additional module for linking (chapter 16. *Linking, Segmentation, and Alignment*):

```

<l>
  <cl next="#c5" xml:id="c3" part="I">For Tweedledum said
  <cl next="#c6" xml:id="c4" part="I">Tweedledee</cl>
</cl>
</l>
<l>
  <cl prev="#c3" xml:id="c5" part="F">
    <cl prev="#c4" xml:id="c6" part="F">Had spoiled his nice new rattle.</cl>
  </cl>
</l>

```

Other methods are also possible; for discussion, see chapter 20. *Non-hierarchical Structures*.

The *type* attribute on linguistic segment categories can be used to provide additional interpretative information about the category. The *function* attribute on the `<cl>` and `<phr>` elements can be used to provide additional information about the function of the category. Legal values for these two attributes are not defined by these Guidelines, but should be documented in the `<segmentation>` element of the `<encodingDesc>` element within the document's header. A general approach to the encoding of linguistic categories for parts of a text is discussed in section 17.4. *Linguistic Annotation* below.

Using traditional terminology, these attributes provide a convenient way of specifying, for example, that the clause *from whence it came* is a relative clause modifying another, or that the phrase *by the U.S. Supreme Court* is a prepositional post-modifier:

```
<cl>It mattered not
<cl type="relative"
  function="clause_modifier">from whence it came;</cl>
</cl>
```

```
<phr type="NP">the year segregation</phr>
<phr>was outlawed</phr>
<phr type="PP"
  function="postmodifier-agent">by the U.S. Supreme Court.</phr>
```

Segmentation into clauses and phrases can, of course, be combined. Such detailed encodings as the following may require careful formatting if they are to be easily readable however.

```
<p>
  <s>
    <cl type="finite-declarative"
      function="independent">
      <phr type="NP" function="subject">Nineteen fifty-four,
      <cl type="finite-relative-declarative"
        function="appositive">when <phr type="NP" function="subject">I</phr>
        <phr type="VP" function="predicate">was eighteen years old</phr>
      </cl>
      </phr>,
    <phr type="VP" function="predicate">
      <phr type="V" function="verb-main">is held</phr>
      <phr type="NP" function="complement">
        <cl type="nonfinite"
          function="predicate-nom.">
          <phr type="V" function="copula">to be</phr>
          <phr type="NP"
            function="predicate-nom.">a crucial turning point
          <phr type="PP"
            function="postmodifier">in
            <phr type="NP" function="prep.obj.">the history
            <phr type="PP"
              function="postmodifier">of the Afro-American</phr>
            </phr>
          </phr>
        </cl>
      </phr>
      -
    <phr type="PP"
      function="postmodifier-appositive">for
      <phr type="NP" function="prep.obj.">the U.S.A.
      <phr type="PP"
        function="postmodifier">as a whole</phr>
      </phr>
    </phr>
    -
  <phr type="NP"
    function="appositive-predicate-nom.">the year
```

```

    <cl type="finite-relative"
      function="adjectival">
      <phr type="NP" function="subject">segregation</phr>
      <phr type="VP" function="predicate">
        <phr type="V" function="verb-main">was outlawed</phr>
        <phr type="PP"
          function="postmodifier">by the U.S. Supreme Court</phr>
      </phr>
    </cl>
  </phr>
</cl>
</phr>.</cl>
</s>
<s>
  <cl type="finite-declarative"
    function="independent">
    <phr type="NP" function="subject">It</phr>
    <phr type="VP" function="predicate">
      <phr type="V" function="verb-main">was</phr>
      also
    <phr type="NP"
      function="predicate-nom.">a crucial year for me</phr>
    </phr>
    <cl type="declarative-finite"
      function="dependent-causative">because
    <phr type="PP"
      function="sentence_adverb">on June 18, 1954</phr>,
    <phr type="NP" function="subject">I</phr>
    <phr type="VP" function="predicate">
      <phr type="V" function="verb-main">began serving</phr>
      <phr type="NP" function="complement">a sentence in state prison
      <phr type="PP" function="complement">for possession of marijuana</phr>
    </phr>
    </phr>
  </cl>
</cl>
</s>.
</p>

```

This style of markup may introduce spurious new lines and blanks into the text. If the original layout is important, it should be explicitly encoded, using such facilities as the `<lb>` element, the global *rend* or *rendition* attributes, etc.

The `<w>`, `<m>`, and `<c>` elements are identical in meaning to the `<seg>` element with a *type* attribute of 'w', 'm', or 'c' respectively, and may occur wherever `<seg>` is permitted to occur. However, their content is more constrained than `<seg>`: for example, the `<w>` element should only contain `<w>`, `<m>`, `<c>` elements or `<pc>` elements, or plain text; the `<m>` element should contain only `<c>` or `<pc>` elements or plain text; both the `<c>` and `<pc>` elements should contain only plain text, most often only a single character or a sequence of graphemes to be treated as a single character. Consequently, while these more specific elements can be translated directly into typed `<seg>` elements, the reverse is not necessarily the case.

The restriction on the content of the `<w>` element in particular requires that a certain care must be exercised when using it, especially in relation to the use of other tags that one may think of as *word level*, but which are in fact defined as *phrase level*. Consider the problem of segmenting an occurrence of the `<mentioned>` element as a word.

```
<mentioned>grandiloquent</mentioned>
```

The first of the following two encodings is legitimate; the second is not, since the `<mentioned>` element is not part of the content model of the `<w>` element:

```
<mentioned>
  <w>grandiloquent</w>
</mentioned>
```

```
<w>
  <mentioned>grandiloquent</mentioned>
</w>
```

On the other hand, both of the following encodings *are* legitimate:

```
<mentioned>
  <phr>grandiloquent speech</phr>
</mentioned>
```

```
<phr>
  <mentioned>grandiloquent speech</mentioned>
</phr>
```

The first encoding describes the citing of a phrase. The second describes a phrase which consists of something mentioned.

The `<w>` element carries additional attributes which may be of use in many indexing or analytic applications. The *lemma* attribute may be used to specify the *lemma*, that is the head- or uninflected form of an inflected verb or noun, for example:

```
<s xml:lang="la">
  <w lemma="timeo">timeo</w>
  <w lemma="danaii">Danaos</w>
  <w lemma="et">et</w>
  <w lemma="donum">dona</w>
  <w lemma="fero">ferentes</w>
</s>
```

In some situations it may be more convenient to use the *lemmaRef* pointer attribute than to supply an explicit uninflected form. This attribute assumes the existence of a list of uninflected forms, for example in an online lexicon, with which individual `w` entries can be associated using the usual TEI pointer mechanisms. Assuming that a standardized lexicon for Latin is available at the location <http://lexicon.org/latin.xml>, we might for example revise the above example as:

```
<s xml:lang="la">
  <w lemmaRef="http://lexicon.org/latin.xml#timeo">timeo</w>
  <w lemmaRef="http://lexicon.org/latin.xml#danaii">Danaos</w>
  <!-- ... -->
</s>
```

### 17.1.2 Below the Word Level

It is sometimes helpful to markup explicitly sub-word components such as morphemes, characters, or punctuation.

**<m>** (morpheme) represents a grammatical morpheme.

**<c>** (character) represents a character.

**<pc>** (punctuation character) contains a character or string of characters regarded as constituting a single punctuation mark.

The **<m>** element is used to mark up morphologically identified segmentation below the word level. Analogous to the *lemma* attribute for **<w>**, there is a *baseForm* attribute for the **<m>** element, which may be used to indicate the 'base form' of an inflected morpheme; where appropriate, **<m>** elements may also be organized hierarchically:

```
<w type="adjective">
  <m type="base">
    <m type="prefix" baseForm="con">com</m>
    <m type="root">fort</m>
  </m>
  <m type="suffix">able</m>
</w>
```

The distinction between **<m>** and **<w>** is provided as a convenience only; it may not be appropriate for all linguistic theories, nor is it meaningful in all languages. The intention is to provide a means for those cases where it is considered helpful to distinguish lexical from sub-lexical tokens, to complement the more general mechanism already provided by the **<seg>** element, using which the above example could alternatively be marked up as follows:

```
<seg type="adjective">
  <seg type="base">
    <seg type="prefix">com</seg>
    <seg type="morph">fort</seg>
  </seg>
  <seg type="suffix">able</seg>
</seg>
```

There is a substantial linguistic difference between characters like letters or diacritics and punctuation marks. The former are used to construct meaningful units like morphemes or words. The latter are functionally independent units acting at the level of syntactic units. A word may consist of a single letter (for example 'I' in English), but this does not mean that we should use **<c>** instead of **<w>** to mark it up.

The **<c>** (character) element should be used to mark up any non-lexical character, whether this appears within a word, or outside it. In the following example, the encoder wishes to indicate that the letters are not to be regarded as words:

```
<phr>
  <c>M</c>
  <c>0</c>
  <c>A</c>
  <c>I</c>
  <w>doth</w>
  <w>sway</w>
  <w>my</w>
  <w>life</w>
</phr>
```

The **<c>** element may be used for individual characters occurring within a **<w>** or **<m>** element which it is desired to distinguish for some reason, as in the following examples:

```
<m baseForm="not">
  <c>n</c>
  <c type="punct">'</c>
  <c>t</c>
</m>
```

This encoding represents the constituents of a common abbreviation, but does not indicate that it is in fact an abbreviation; the `<am>` element (11.3.1.2. *Abbreviation and Expansion*) may be preferred for the latter purpose. Generally speaking, the use of `<c>` to mark non-lexical punctuation marks is deprecated, since the `<pc>` element is provided specifically to distinguish these.

The `<pc>` (punctuation character) element should be used to mark up characters which are specifically regarded as providing punctuation, rather than constituting parts of a word. It may be particularly useful when transcribing older written materials, in which an encoding of the original punctuation may be useful for interpretive or analytic purposes, in much the same way as an encoding of the original orthography may be. For example, in the following extract from a Bodleian Library musical manuscript two different punctuation marks are used to distinguish kinds of

pause in the text. The *punctus elevatus* (which resembles an inverted semicolon) is not a Unicode character, but may still be encoded using the `<g>` element. As further described in chapter 5. *Characters, Glyphs, and Writing Modes*, this element points to a definition for the intended character which may be stored either locally or elsewhere.

```
deus qui regis omnia
<pc>
  <g ref="#pelev">;</g>
</pc> natus est in bethlehem
<pc>.</pc>o <pc>.</pc> mira gratia...

<!-- elsewhere -->
<char xml:id="pelev">
<!-- definition of the punctus elevatus character -->
</char>
```

The `<pc>` element carries special attributes to record analyses of the functional behaviour or classification of the punctuation mark it contains. The *unit* attribute may be used, as on the `<milestone>` element to name the kind of unit which the punctuation mark delimits, for example a paragraph or section. The *pre* attribute may be used to indicate whether the punctuation precedes or follows the unit it delimits. The *force* attribute indicates the strength of the association between the punctuation mark and its adjacent word.

In the following example, the paragraph marker (¶) has been tagged as a strong punctuation mark, preceding the unit it marks, which is named 'para':

```
<p>
  <pc unit="para" force="strong" pre="true">¶</pc>Incipit...
</p>
```

The `<w>`, `<m>`, `<c>`, and `<pc>` elements can be used together to give a fairly detailed low-level grammatical analysis of text. For example, consider the following segmentation of the English S-unit *I didn't do it*.

```

<w>I</w>
<w>
  <m baseForm="do">did</m>
  <m>n't</m>
</w>
<w lemma="do">do</w>
<w>it</w>
<pc>.</pc>

```

This segmentation, crude as it is, succeeds in representing the idea that *did* occurring as a morphological component of the word *didn't* has something in common with the word <do>. A further advantage of segmenting the text down to this level is that it becomes relatively simple to associate each such segment with a more detailed formal analysis, for example by providing a baseform, or morphological analysis at whichever level is appropriate. This matter is taken up in detail in section 17.4. *Linguistic Annotation*.

## 17.2 Global Attributes for Simple Analyses

When the module described by this chapter is selected, an additional attribute is defined for all elements: **att.global.analytic** provides additional global attributes for associating specific analyses or interpretations with appropriate portions of a text.

**@ana** (analysis) indicates one or more elements containing interpretations of the element on which the *ana* attribute appears.

The *ana* attribute may be specified for any element. Its effect is to associate the element with one or more others representing an analysis or interpretation of it. Its target should be one of the elements described in the section 17.3. *Spans and Interpretations* below, or some other interpretative element such as <note>, on which see section 3.8. *Notes, Annotation, and Indexing* or <fs>, on which see chapter 18. *Feature Structures*.

## 17.3 Spans and Interpretations

The simplest mechanisms for attaching analytic notes in some structured vocabulary to particular passages of text are provided by the <span> and <interp> elements, and their associated grouping elements <spanGrp> and <interpGrp>.

**<span>** associates an interpretative annotation directly with a span of text.

**<spanGrp>** (span group) collects together span tags.

**<interp>** (interpretation) summarizes a specific interpretative annotation which can be linked to a span of text.

**<interpGrp>** (interpretation group) collects together a set of related interpretations which share responsibility or type.

These elements are all members of the class **att.interpLike**, and thus share the following attributes:

**att.interpLike** provides attributes for elements which represent a formal analysis or interpretation.

**@type** indicates what kind of phenomenon is being noted in the passage.

**@inst** (instances) points to instances of the analysis or interpretation represented by the current element.

They also inherit the following attributes from **att.global.responsibility**:

**att.global.responsibility** provides attributes indicating the agent responsible for some aspect of the text, the markup or something asserted by the markup, and the degree of certainty associated with it.

**@cert** (certainty) signifies the degree of certainty associated with the intervention or interpretation.

**@resp** (responsible party) indicates the agency responsible for the intervention or interpretation, for example an editor or transcriber.

The *type* attribute of the <span> and <interp> elements may be used to indicate that the annotations are of specific types, for example thematic or structural. The annotation itself is supplied as the content of the <span> or <interp> element. In the case of the <span> element, the span of text being annotated is indicated by values of the *from*, *to* or

*target* attributes, used in combination as follows. If only the *from* attribute is supplied, then the span is coterminous with the element indicated by its value; if both *from* and *to* are supplied, the span runs from the start of the element indicated by the *from* attribute up to the end of the element indicated by the *to* attribute; if the *target* attribute is used, the span is defined by aggregating the contents of the (possibly non-contiguous) elements pointed to by its values. It is an error to supply only the *to* attribute; to supply more than one pointer value for either *to* or *from* attributes; or to supply either of these in conjunction with the *target* attribute. In the case of <interp> (see below), the span is indicated by a pointer from a <link> element or some similar mechanism. The *resp* attribute indicates the annotator responsible for this annotation.

The <span> element provides a simple way of indicating such features as phrasal verbs in a linguistic analysis, as in this example:

```
<s>
  <w>What</w>
  <w>did</w>
  <w>you</w>
  <w xml:id="mk01">make</w>
  <w xml:id="up01">up</w>
</s>
<span from="#mk01" to="#up01">phrasal verb "make up"</span>
```

Here the two components of the span follow each other, so the *to* and *from* attributes may be used. The same effect could however be achieved by using the *target* attribute:

```
<s>
  <w>What</w>
  <w>did</w>
  <w>you</w>
  <w xml:id="mk02">make</w>
  <w xml:id="up02">up</w>
</s>
<span target="#mk02 #up02">phrasal verb "make up"</span>
```

This second approach might be cumbersome if the number of components to be combined is very large. It is however essential if the components do not follow each other, as in this example:

```
<s>
  <w>Did</w>
  <w>you</w>
  <w xml:id="mk03">make</w>
  <w>it</w>
  <w xml:id="up03">up</w>
</s>
<span target="#mk03 #up03">phrasal verb "make up"</span>
```

The <span> element can be used for any kind of annotation. In this example it is used in a narratological analysis:

```
<p xml:id="MaQp1s2p114">
  <s xml:id="MaQp1s2p114s1">There was certainly a definite point at which the
    thing began.</s>
  <s xml:id="MaQp1s2p114s2">It was not; then it was suddenly inescapable,
    and nothing could have frightened it away.</s>
  <s xml:id="MaQp1s2p114s3">There was a slow integration, during which she,
```

```

and the little animals, and the moving grasses, and the sun-warmed
trees, and the slopes of shivering silvery mealies, and the great
dome of blue light overhead, and the stones of earth under her feet,
became one, shuddering together in a dissolution of dancing
atoms.</s>
<s xml:id="MaQp1s2p114s4">She felt the rivers under the ground forcing
themselves painfully along her veins, swelling them out in an
unbearable pressure; her flesh was the earth, and suffered growth
like a ferment; and her eyes stared, fixed like the eye of the
sun.</s>
<s xml:id="MaQp1s2p114s5">Not for one second longer (if the terms for time
apply) could she have borne it; but then, with a sudden movement
forwards and out, the whole process stopped; and <emph rend="italic">that</emph>
was <soCalled rend="dquo">the
moment</soCalled> which it was impossible to remember
afterwards.</s>
<span from="#MaQp1s2p114s3"
to="#MaQp1s2p114s5">the moment</span>
<s xml:id="MaQp1s2p114s6">For during that space of time (which was
timeless) she understood quite finally her smallness, the
unimportance of humanity.</s>
</p>

```

The `<span>` element may, as in this example, be placed in the text near the textual span it is associated with. Alternatively, it may be placed elsewhere in the same or a different document. Where several `<span>` or `<interp>` elements share the same attributes, for example having the same responsibility or type, it may be convenient to group them within a `<spanGrp>` or `<interpGrp>` element as follows:

```

<spanGrp resp="#DTL">
  <span from="#MaQp1s2p114s3"
to="#MaQp1s2p114s5">the moment</span>
<!-- other spans identified by DTL here -->
</spanGrp>

```

Spans may also be used to represent structural divisions within a narrative, particularly when these do not coincide with the structure implied by the element structure. Consider the following narrative:

Sigmund, the son of Volsung, was a king in Frankish country. Sinfiotli was the eldest of his sons, the second was Helgi, the third Hamund. Borghild, Sigmund's wife, had a brother named — But Sinfiotli, her stepson, and — both wooed the same woman and Sinfiotli killed him over it.<sup>108</sup> And when he came home, Borghild asked him to go away, but Sigmund offered her weregild, and she was obliged to accept it. At the funeral feast Borghild was serving beer. She took poison, a big drinking horn full, and brought it to Sinfiotli. When Sinfiotli looked into the horn, he saw that poison was in it, and said to Sigmund ‘This drink is cloudy, old man.’ Sigmund took the horn and drank it off. It is said that Sigmund was hardy and that poison did him no harm, inside or out. And all his sons could tolerate poison on their skin. Borghild brought another horn to Sinfiotli, and asked him to drink, and everything happened as before. And a third time she brought him a horn, and reproachful words as well, if he didn't drink from it. He spoke again to Sigmund as before. He said ‘Filter it through your mustache, son!’ Sinfiotli drank it off and at once fell dead.

Sigmund carried him a long way in his arms and came to a long, narrow fjord, and there was a small boat there and a man in it. He offered to ferry Sigmund over the fjord. But when Sigmund carried the body out to the boat, it was fully laden. The man said Sigmund should go around the fjord inland. The man pushed the boat out and then suddenly vanished.

<sup>108</sup>The rule marks spaces left for the missing name in the manuscript.

King Sigmund lived a long time in Denmark in the kingdom of Borghild, after he married her. Then he went south to Frankish lands, to the kingdom he had there. Then he married Hiordis, the daughter of King Eylimi. Their son was Sigurd. King Sigmund fell in a battle with the sons of Hunding. And then Hiordis married Alf, the son of King Hialprec. Sigurd grew up there as a boy.

Sigmund and all his sons were tall and outstanding in their strength, their growth, their intelligence, and their accomplishments. But Sigurd was the most outstanding of all, and everyone who knows about the old days says he was the most outstanding of men and the noblest of all the warrior kings.

A structural analysis of this text, dividing it into narrative units in a pattern shared with other texts from the same literature, might look like this:

```
<p xml:id="P1">
  <s xml:id="S1">Sigmund ... was a king in Frankish country.</s>
  <s xml:id="S2">Sinfiotli was the eldest of his sons.</s>
  <s xml:id="S3">Borghild, Sigmund's wife, had a brother ...</s>
  <s xml:id="S4A">But Sinfiotli ... wooed the same woman</s>
  <s xml:id="S4B">and Sinfiotli killed him over it.</s>
  <s xml:id="S5">And when he came home, ... she was obliged to accept it.</s>
  <s xml:id="S6">At the funeral feast Borghild was serving beer.</s>
  <s xml:id="S7">She took poison ... and brought it to Sinfiotli.</s>
  <s xml:id="S17">Sinfiotli drank it off and at once fell dead.</s>
  <anchor xml:id="E0S17"/>
</p>
<p xml:id="P2">Sigmund carried him a long way in his arms ... </p>
<p xml:id="P3">King Sigmund lived a long time in Denmark ... </p>
<p xml:id="P4">Sigmund and all his sons were tall ... </p>
<spanGrp resp="#TMA"
  type="narrative-structure">
  <span from="#S1" to="#S3">introduction</span>
  <span from="#S4A">conflict</span>
  <span from="#S4B">climax</span>
  <span from="#S5" to="#S17">revenge</span>
  <span from="#E0S17">reconciliation</span>
  <span from="#P2" to="#P4">aftermath</span>
</spanGrp>
```

Note the use of an empty `<anchor>` element to provide a target for the ‘reconciliation’ unit which is normally part of the narrative pattern but which is not realized in the text shown.

The same analysis may be expressed with the `<interp>` element instead of the `<span>` element; this element provide attributes for recording an interpretive category and its value, as well as the identity of the interpreter, but does not itself indicate which passage of text is being interpreted; the same interpretive structures can thus be associated with many passages of the text. The association between text passages and `<interp>` elements must be made either by pointing from the text to the `<interp>` element with the *ana* attribute defined in section 17.2. *Global Attributes for Simple Analyses*, or by pointing at both text and interpretation from a `<link>` element, as described in chapter 16. *Linking, Segmentation, and Alignment*.

To encode the first example above using `<interp>`, it is necessary to create a text element which contains—or corresponds to—the third, fourth, and fifth orthographic sentences (S-units) in the paragraph. This can be done either with the `<seg>` element, described in 16.3. *Blocks, Segments, and Anchors*, or the `<join>` element, described in 16.7. *Aggregation*. The resulting element can then be associated with the `<interp>` element using the *ana* attribute described in section 17.2. *Global Attributes for Simple Analyses*. We illustrate using the `<seg>` element.

```
<p xml:id="MarQp1s2p114">
  <s xml:id="MarQp1s2p114s1">There was certainly a definite point ... </s>
  <s xml:id="MarQp1s2p114s2">It was not; then it was suddenly inescapable ... </s>
```

```

<seg xml:id="MarQpls2p114s3-5"
  ana="#moment">
  <s xml:id="MarQpls2p114s3">There was a slow integration ... </s>
  <s xml:id="MarQpls2p114s4">She felt the rivers under the ground ... </s>
  <s xml:id="MarQpls2p114s5">Not for one second longer ... </s>
</seg>
<s xml:id="MarQpls2p114s6">For during that space of time ... </s>
</p>
<interp xml:id="moment">the moment</interp>

```

The second example above can be recoded using <interp> and <interpGrp> tags in a similar manner. The interpretation itself can be expressed in an <interpGrp> element, which would replace the <spanGrp> in the example shown above:

```

<interpGrp resp="#TMA"
  type="structuralUnit">
  <interp xml:id="INTRO">introduction</interp>
  <interp xml:id="CONFLICT">conflict</interp>
  <interp xml:id="CLIMAX">climax</interp>
  <interp xml:id="REVENGE">revenge</interp>
  <interp xml:id="RECONCIL">reconciliation</interp>
  <interp xml:id="AFTERM">aftermath</interp>
</interpGrp>

```

Any of these <interp> elements may be linked to the text either by means of the *ana* attribute, or by means of <link> elements. Using the *ana* attribute (on <seg> elements introduced specifically for this purpose), the text would be encoded as follows:

```

<p xml:id="PP1">
  <seg xml:id="SS1-SS3" ana="#INTRO">
    <s xml:id="SS1">Sigmund ... was a king in Frankish country.</s>
    <s xml:id="SS2">Sinfiotli was the eldest of his sons.</s>
    <s xml:id="SS3">Borghild, Sigmund's wife, had a brother ... </s>
  </seg>
  <s xml:id="SS4A" ana="#CONFLICT">But Sinfiotli ... wooed the same woman</s>
  <s xml:id="SS4B" ana="#CLIMAX">and Sinfiotli killed him over it.</s>
  <seg xml:id="SS5-SS17" ana="#REVENGE">
    <s xml:id="SS5">And when he came home, ... she was obliged to accept it.</s>
    <s xml:id="SS6">At the funeral feast Borghild was serving beer.</s>
    <s xml:id="SS17">Sinfiotli drank it off and at once fell dead.</s>
  </seg>
</p>
<anchor xml:id="NIL1" ana="#RECONCIL"/>
<p xml:id="PP2">Sigmund carried him a long way in his arms ... </p>
<p xml:id="PP3">King Sigmund lived a long time in Denmark ... </p>
<p xml:id="PP4">Sigmund and all his sons were tall ... </p>
<join xml:id="PP2-PP4"
  target="#PP2 #PP3 #PP4" ana="#AFTERM"/>

```

The linkage may also be accomplished using a <linkGrp> element, whose content is a set of <link> elements which point to each interpretive element and its corresponding text unit. This method does not require the use of the *ana* attribute on the text units.

```
<linkGrp targFunc="interpretation text">
  <link target="#INTRO #SS1-SS3"/>
  <link target="#CONFLICT #SS4A"/>
  <link target="#CLIMAX #SS4B"/>
  <link target="#REVENGE #SS5-SS17"/>
  <link target="#RECONCIL #NIL1"/>
  <link target="#AFTERM #PP2-PP4"/>
</linkGrp>
```

One obvious advantage of using `<interp>` rather than `<span>` elements for the Sigmund text is that the `<interp>` elements can be reused for marking up other texts in the same document, whereas the `<span>` elements cannot. On the other hand, the use of `<interp>` elements may require the creation of special text elements not otherwise needed (e.g. the `<seg>` and the `<join>` in the revised encoding of the text), whereas the use of `<span>` elements does not.

## 17.4 Linguistic Annotation

By *linguistic annotation* we mean here any annotation determined by an analysis of linguistic features of the text, excluding as borderline cases both the formal structural properties of the text (e.g. its division into chapters or paragraphs) and descriptive information about its context (the circumstances of its production, its genre or medium). The structural properties of any TEI-conformant text should be represented using the structural elements discussed elsewhere in this chapter and in chapters 3. *Elements Available in All TEI Documents*, 4. *Default Text Structure*, and the various chapters of Part III. The contextual properties of a TEI text are fully documented in the TEI header, which is discussed in chapter 2. *The TEI Header*, and in section 15.2. *Contextual Information*.

Other forms of linguistic annotation may be applied at a number of levels in a text. A code (such as a word-class or part-of-speech code) may be associated with each word or token, or with groups of such tokens, which may be continuous, discontinuous, or nested. A code may also be associated with relationships (such as cohesion) perceived as existing between distinct parts of a text. The codes themselves may stand for discrete and non-decomposable categories, or they may represent highly articulated bundles of textual features. Their function may be to place the annotated part of the text somewhere within a narrowly linguistic or discoursal domain of analysis, or within a more general semantic field, or any combination drawn from these and other domains.

The manner by which such annotations are generated and attached to the text may be entirely automatic, entirely manual or a mixture. The ease and accuracy with which analysis may be automated may vary with the level at which the annotation is attached. The method employed should be documented in the `<interpretation>` element within the encoding description of the TEI header, as described in section 2.3.3. *The Editorial Practices Declaration*. Where different parts of a language corpus have used different annotation methods, the `decls` attribute may be used to indicate the fact, as further discussed in section 15.3. *Associating Contextual Information with a Text*.

As one example of such types of analysis, consider the following sentence, taken from the Lancaster/IBM Treebank Project (Leech and Garside (1991)).

The victim's friends told police that Kruger drove into the quarry and never surfaced.

Our discussion focuses on the way that this sentence might be analysed using the CLAWS system developed at the University of Lancaster but exactly the same principles may be applied to a wide variety of other systems.<sup>109</sup> Output from the system consists of a segmented and tokenized version of the text, in which word class codes have been associated with each token. CLAWS offers outputs in a variety of non-XML and XML formats: for example, the simplest format for the sample sentence would be:

```
The_ AT0 victim_ NN1 's_ POS friends_ NN2 told_ VVD police_ NN2 that_ CJT Kruger_ NP0
drove_ VVD into_ PRP the_ AT0 quarry_ NN1 and_ CJC never_ AV0 surfaced_ VVD
```

<sup>109</sup>For the word-class tagging method used by CLAWS see Marshall (1983); For an overview of the system see Garside et al. (1991). The example sentence was processed using an online version of the CLAWS tagger at <http://ucrel.lancs.ac.uk/claws/>

This may be easily transformed into an equivalent TEI XML representation:

```
<s>
  <w ana="#AT0">The </w>
  <w ana="#NN1">victim</w>
  <w ana="#POS">'s</w>
  <w ana="#NN2">friends </w>
  <w ana="#VVD">told </w>
  <w ana="#NN2">police </w>
  <w ana="#CJT">that </w>
  <w ana="#NP0">Kruger </w>
  <w ana="#VVD">drove </w>
  <w ana="#PRP">into </w>
  <w ana="#AT0">the </w>
  <w ana="#NN1">quarry </w>
  <w ana="#CJC">and </w>
  <w ana="#AV0">never </w>
  <w ana="#VVD">surfaced</w>
</s>
```

Although the names used for the attribute values here may have some significance for the human reader (AT0 for *article*, NN1 for *singular noun*, NN2 for *plural noun*, etc.) they are arbitrary codes, used in this case as pointers to other elements which define their significance more precisely. If the codes are considered to be *atomic*, then the `<interp>` element described in section 17.3. *Spans and Interpretations* might be used to supply brief definitions in the header:

```
<interpGrp type="POS">
  <interp xml:id="AT0">Definite article</interp>
  <interp xml:id="AV0">Adverb</interp>
  <interp xml:id="CJC">Conjunction</interp>
  <interp xml:id="CJT">Relative that</interp>
  <interp xml:id="NN1">Noun singular</interp>
  <interp xml:id="NN2">Noun plural</interp>
  <interp xml:id="NP0">Proper noun</interp>
  <interp xml:id="POS">Genitive marker</interp>
  <interp xml:id="PRP">Preposition</interp>
  <interp xml:id="VVD">Verb past tense</interp>
</interpGrp>
```

If the codes are considered to be compositional (for example that NN1 and NN2 have something in common, namely their *noun-ness*, which they do not share with, say, VVD), then this compositionality may be most clearly expressed using a mechanism based on the `<fs>` element defined in chapter 18. *Feature Structures*.

This approach requires the text to be fully segmented, using the linguistic segment elements described in section 17.1. *Linguistic Segment Categories*, so that the scope of the *ana* attribute used to point to each interpretation is clearly defined. A further analysis into phrase and clause elements can be superimposed on the word and morpheme tagging in the preceding illustration. For example, CLAWS provides the following constituent analysis of the sample sentence (the word class codes have been deleted):

```
[N [G The victim's G] friends N] [V told [N police N] [Fn that
[N Krueger N] [V [V& drove [P into [N the quarry N]P]V&] and
[V+ never surfaced V+]V]Fn]V]
```

Treating the labels on the brackets as phrase or clause interpretations, this analysis of the structure of the example sentence can be combined with the word class analysis and represented as follows (the symbol V&"/> representing

the first part of a coordinate phrase, has been replaced by V1, and V+, representing the second part, has been replaced by V2).

```
<s type="sentence">
  <phr ana="#n">
    <phr ana="#gn">
      <w ana="#AT0">The</w>
      <w ana="#NN1">victim</w>
      <m ana="#POS">'s</m>
    </phr>
    <w ana="#NN2">friends</w>
  </phr>
  <phr ana="#v">
    <w ana="#VVD">told</w>
    <phr ana="#n">
      <w ana="#NN2">police</w>
    </phr>
  </phr>
  <cl ana="#fn">
    <w ana="#CJT">that</w>
    <phr ana="#n">
      <w ana="#NP0">Krueger</w>
    </phr>
    <phr ana="#v">
      <phr ana="#v1">
        <w ana="#VVD">drove</w>
        <phr ana="#pr">
          <w ana="#PRP">into</w>
          <phr ana="#n">
            <w ana="#AT0">the</w>
            <w ana="#NN1">quarry</w>
          </phr>
        </phr>
      </phr>
    </phr>
    <w ana="#CJC">and</w>
    <phr ana="#v2">
      <w ana="#AV0">never</w>
      <w ana="#VVD">surfaced</w>
    </phr>
  </cl>
</phr>
<c ana="#pun">.</c>
</s>
```

This approach requires the definition of further <interp> (or <fs>) elements to provide targets for the pointers used to represent the constituent analysis:

```
<interpGrp type="constituentFunction">
  <interp xml:id="v2">coordinate continuation</interp>
  <interp xml:id="v">verbal</interp>
  <interp xml:id="no">nominal</interp>
  <interp xml:id="gn">genitive</interp>
  <interp xml:id="fn">finite clause</interp>
  <interp xml:id="pr">prepositional</interp>
  <interp xml:id="v1">coordinate start</interp>
</interpGrp>
```

Alternatively, a ‘stand-off’ representation for these analyses might be created using the <linkGrp> element. In this case, each linguistic segment must be supplied with its own *xml:id* attribute:

```
<s>
  <w xml:id="word-1">The</w>
  <w xml:id="word-2">victim</w>
  <w xml:id="word-3">'s</w>
  <w xml:id="word-4">friends</w>
  <w xml:id="word-5">told</w>
  <w xml:id="word-6">police</w>
  <w xml:id="word-7">that</w>
  <w xml:id="word-8">Kruger</w>
  <w xml:id="word-9">drove</w>
  <w xml:id="word10">into</w>
  <w xml:id="word11">the</w>
  <w xml:id="word12">quarry</w>
  <w xml:id="word13">and</w>
  <w xml:id="word14">never</w>
  <w xml:id="word15">surfaced</w>
</s>
```

Each segment-interpretation pair may now be represented by means of a <link> element inside an appropriate <linkGrp> element:

```
<linkGrp type="POS-annotation">
  <link target="#word-1 #AT0"/>
  <link target="#word-2 #NN1"/>
  <link target="#word-3 #POS"/>
  <link target="#word-4 #NN2"/>
  <link target="#word-5 #VVD"/>
  <link target="#word-6 #NN2"/>
<!--... -->
</linkGrp>
```

Each linguistic segment so far discussed has been well-behaved with respect to the basic document hierarchy, having only a single parent. Moreover, the segmentation has been complete, in that each part of the text is accounted for by some segment at each level of analysis, without discontinuities or overlap. This state of affairs does not of course apply in all types of analysis, and these Guidelines provide a number of mechanisms to support the representation of discontinuities or multiple analyses. A brief overview of these facilities is provided in chapter 20. *Non-hierarchical Structures*; also see 16. *Linking, Segmentation, and Alignment*. These mechanisms all depend to a greater or lesser degree on the use of pointing elements of various kinds.

The mechanisms proposed in this chapter may also be used to encode analyses of an entirely different kind, for example discourse function. Here is an application of the span technique to record details of a sales transaction in a spoken text.

```
<u xml:id="u1">Can I have ten oranges and a kilo of bananas please?</u>
<u xml:id="u2">Yes, anything else?</u>
<u xml:id="u3">No thanks.</u>
<u xml:id="u4">That'll be dollar forty.</u>
<u xml:id="u5">Two dollars</u>
<u xml:id="u6">Sixty, eighty, two dollars. Thank you.</u>
<spanGrp type="transactions">
  <span from="#u1">sale request</span>
  <span from="#u2" to="#u3">sale compliance</span>
</spanGrp>
```

```
<span from="#u4">sale</span>
<span from="#u5">purchase</span>
<span from="#u6">purchase closure</span>
</spanGrp>
```

For further discussion of the <u> (utterance) element and other elements recommended for transcriptions of spoken language, see chapter 8. *Transcriptions of Speech*.

## 17.5 Module for Analysis and Interpretation

The module described in this chapter makes available the following components:

**Module analysis: Simple analytic mechanisms**

- *Elements defined:* c cl interp interpGrp m pc phr s span spanGrp w
- *Classes defined:* att.global.analytic

The selection and combination of modules to form a TEI schema is described in 1.2. *Defining a TEI Schema*.

## 18 Feature Structures

A *feature structure* is a general purpose data structure which identifies and groups together individual *features*, each of which associates a name with one or more values. Because of the generality of feature structures, they can be used to represent many different kinds of information, but they are of particular usefulness in the representation of linguistic analyses, especially where such analyses are partial, or *underspecified*. Feature structures represent the interrelations among various pieces of information, and their instantiation in markup provides a *metalanguage* for the generic representation of analyses and interpretations. Moreover, this instantiation allows feature values to be of specific *types*, and for restrictions to be placed on the values for particular features, by means of *feature system declarations*.<sup>110</sup>

### 18.1 Organization of this Chapter

This chapter is organized as follows. Following this introduction, section 18.2. *Elementary Feature Structures and the Binary Feature Value* introduces the elements `<fs>` and `<f>`, used to represent feature structures and features respectively, together with the elementary *binary* feature value. Section 18.3. *Other Atomic Feature Values* introduces elements for representing other kinds of atomic feature values such as *symbolic*, *numeric*, and *string* values. Section 18.4. *Feature Libraries and Feature-Value Libraries* introduces the notion of predefined *libraries* or groups of features or feature values along with methods for referencing their components. Section 18.5. *Feature Structures as Complex Feature Values* introduces complex values, in particular feature-structures as values, thus enabling feature structures to be recursively defined. Section 18.7. *Collections as Complex Feature Values* discusses other complex values, in particular values which are collections, organized as *sets*, *bags*, and *lists*. Section 18.8. *Feature Value Expressions* discusses how the operations of alternation, negation, and collection of feature values may be represented. Section 18.9. *Default Values* discusses ways of representing underspecified, default, or uncertain values. Section 18.10. *Linking Text and Analysis* discusses how analyses may be linked to other parts of an encoded text. Section 18.11. *Feature System Declaration* describes the *feature system declaration*, a construct which provides for the validation of typed feature structures. Formal definitions for all the elements introduced in this chapter are provided in section 18.12. *Formal Definition and Implementation*.

### 18.2 Elementary Feature Structures and the Binary Feature Value

The fundamental elements used to represent a feature structure analysis are `<f>` (for *feature*), which represents a feature-value pair, and `<fs>` (for *feature structure*), which represents a structure made up of such feature-value pairs. The `<fs>` element has an optional *type* attribute which may be used to represent typed feature structures, and may contain any number of `<f>` elements. An `<f>` element has a required *name* attribute and an associated *value*. The value may be simple: that is, a single binary, numeric, symbolic (i.e. taken from a restricted set of legal values), or string value, or a collection of such values, organized in various ways, for example, as a list; or it may be complex, that is, it may itself be a feature structure, thus providing a degree of recursion. Values may be under-specified or defaulted in various ways. These possibilities are all described in more detail in this and the following sections.

Feature and feature-value representations (including feature structure representations) may be embedded directly at any point in an XML document, or they may be collected together in special-purpose feature or feature-value *libraries*. The components of such libraries may then be referenced from other feature or feature-value representations, using the *feats* or *fVal* attribute as appropriate.

We begin by considering the simple case of a feature structure which contains binary-valued features only. The following three XML elements are needed to represent such a feature structure:

- <fs>** (feature structure) represents a *feature structure*, that is, a collection of feature-value pairs organized as a structural unit.
  - @type** specifies the type of the feature structure.
  - @feats** (features) references the feature-value specifications making up this feature structure.
- <f>** (feature) represents a *feature value specification*, that is, the association of a name with a value of any of several different types.

<sup>110</sup>The recommendations of this chapter have been adopted as ISO Standard 24610-1 *Language Resource Management – Feature Structures – Part One: Feature Structure Representation*

*@name* a single word which follows the rules defining a legal XML name (see <http://www.w3.org/TR/REC-xml/#dt-name>), providing a name for the feature.

*@fVal* (feature value) references any element which can be used to represent the value of a feature.

**<binary>** (binary value) represents the value part of a feature-value specification which can contain either of exactly two possible values.

The attributes *feats* and the *fVal* are not discussed in this section: they provide an alternative way of indicating the content of an element, as further discussed in section 18.4. *Feature Libraries and Feature-Value Libraries*.

An *<fs>* element containing *<f>* elements with binary values can be straightforwardly used to encode the *matrices* of feature-value specifications for phonetic segments, such as the following for the English segment [s].

```
+--- ---+ | consonantal + | | vocalic - | | voiced - | | anterior + | | coronal + | |
continuant + | | strident + | +--- ---+
```

This representation may be encoded in XML as follows:

```
<fs type="phonological_segments">
  <f name="consonantal">
    <binary value="true"/>
  </f>
  <f name="vocalic">
    <binary value="false"/>
  </f>
  <f name="voiced">
    <binary value="false"/>
  </f>
  <f name="anterior">
    <binary value="true"/>
  </f>
  <f name="coronal">
    <binary value="true"/>
  </f>
  <f name="continuant">
    <binary value="true"/>
  </f>
  <f name="strident">
    <binary value="true"/>
  </f>
</fs>
```

Note that *<fs>* elements may have an optional *type* attribute to indicate the kind of feature structure in question, whereas *<f>* elements must have a *name* attribute to indicate the name of the feature. Feature structures need not be typed, but features must be named. Similarly, the *<fs>* element may be empty, but the *<f>* element must have (or reference) some content.

The restriction of specific features to specific types of values (e.g. the restriction of the feature *strident* to a binary value) requires additional validation, as does any restriction on the features available within a feature structure of a particular type (e.g. whether a feature structure of type *phonological segment* necessarily contains a feature *voiced*). Such validation may be carried out at the document level, using special purpose processing, at the schema level using additional validation rules, or at the declarative level, using an additional mechanism such as the *feature-system declaration* discussed in 18.11. *Feature System Declaration*.

Although we have used the term *binary* for this kind of value, and its representation in XML uses values such as **true** and **false** (or, equivalently, **1** and **0**), it should be noted that such values are not restricted to propositional assertions. As this example shows, this kind of value is intended for use with any binary-valued feature.

## 18.3 Other Atomic Feature Values

Features may take other kinds of atomic value. In this section, we define elements which may be used to represent: *symbolic values*, *numeric values*, and *string values*. The module defined by this chapter allows for the specification of additional datatypes if necessary, by extending the underlying class `model.featureVal.single`. If this is done, it is recommended that only the basic W3C datatypes should be used; more complex datotyping should be represented as feature structures.

**<symbol>** (symbolic value) represents the value part of a feature-value specification which contains one of a finite list of symbols.

`@value` supplies a symbolic value for the feature, one of a finite list that may be specified in a feature declaration.

**<numeric>** (numeric value) represents the value part of a feature-value specification which contains a numeric value or range.

**<string>** (string value) represents the value part of a feature-value specification which contains a string.

The `<symbol>` element is used for the value of a feature when that feature can have any of a small, finite set of possible values, representable as character strings. For example, the following might be used to represent the claim that the Latin noun form *mensas* (tables) has accusative case, feminine gender, and plural number:

```
<fs>
  <f name="case">
    <symbol value="accusative"/>
  </f>
  <f name="gender">
    <symbol value="feminine"/>
  </f>
  <f name="number">
    <symbol value="plural"/>
  </f>
</fs>
```

More formally, this representation shows a structure in which three features (*case*, *gender*, and *number*) are used to define morpho-syntactic properties of a word. Each of these features can take one of a small number of values (for example, case can be *nominative*, *genitive*, *dative*, *accusative*, etc.) and it is therefore appropriate to represent the values taken in this instance as `<symbol>` elements. Note that, instead of using a symbolic value for grammatical number, one could have named the feature *singular* or *plural* and given it an appropriate binary value, as in the following example:

```
<fs>
  <f name="case">
    <symbol value="accusative"/>
  </f>
  <f name="gender">
    <symbol value="feminine"/>
  </f>
  <f name="singular">
    <binary value="false"/>
  </f>
</fs>
```

Whether one uses a binary or symbolic value in situations like this is largely a matter of taste.

The `<string>` element is used for the value of a feature when that value is a string drawn from a very large or potentially unbounded set of possible strings of characters, so that it would be impractical or impossible to use the `<symbol>` element. The string value is expressed as the content of the `<string>` element, rather than as an attribute value. For example, one might encode a street address as follows:

```
<fs>
  <f name="address">
    <string>3418 East Third Street</string>
  </f>
</fs>
```

The `<numeric>` element is used when the value of a feature is a numeric value, or a range of such values. For example, one might wish to regard the house number and the street name as different features, using an encoding like the following:

```
<fs>
  <f name="houseNumber">
    <numeric value="3418"/>
  </f>
  <f name="streetName">
    <string>East Third Street</string>
  </f>
</fs>
```

If the numeric value to be represented falls within a specific range (for example an address that spans several numbers), the `max` attribute may be used to supply an upper limit:

```
<fs>
  <f name="houseNumber">
    <numeric value="3418" max="3440"/>
  </f>
  <f name="streetName">
    <string>East Third Street</string>
  </f>
</fs>
```

It is also possible to specify that the numeric value (or values) represented should (or should not) be truncated. For example, assuming that the daily rainfall in mm is a feature of interest for some address, one might represent this by an encoding like the following:

```
<fs>
  <f name="dailyRainFall">
    <numeric value="0.0" max="1.3"
      trunc="false"/>
  </f>
</fs>
```

This represents any of the infinite number of numeric values falling between 0 and 1.3; by contrast

```
<fs>
  <f name="dailyRainFall">
    <numeric value="0.0" max="1.3"
      trunc="true"/>
  </f>
</fs>
```

represents only two possible values: 0 and 1.

Some communities of practice, notably those with a strong computer-science bias, prefer to dissociate the information on the value of the given feature from the specification of the data type that this value represents. In such cases, feature values can be provided directly as textual content of <f>, with the assumption that the data type is specified by the schema. The following is an example taken from ISO 24612, presenting the symbolic values for Active Voice and Simple Present Tense in the untyped form:

```
<fs>
  <f name="voice">active</f>
  <f name="tense">SimPre</f>
</fs>
```

As noted above, additional processing is necessary to ensure that appropriate values are supplied for particular features, for example to ensure that the feature `singular` is not given a value such as <symbol value="feminine"/>. There are two ways of attempting to ensure that only certain combinations of feature names and values are used. First, if the total number of legal combinations is relatively small, one can predefine all of them in a construct known as a *feature library*, and then reference the combination required using the *feats* attribute in the enclosing <fs> element, rather than give it explicitly. This method is suitable in the situation described above, since it requires specifying a total of only ten (5 + 3 + 2) combinations of features and values. Similarly, to ensure that only feature structures containing valid combinations of feature values are used, one can put definitions for all valid feature structures inside a *feature value library* (so called, since a feature structure may be the value of a feature). A total of 30 feature structures (5 × 3 × 2) is required to enumerate all the possible combinations of individual case, gender and number values in the preceding illustration. We discuss the use of such libraries and their representation in XML further in section 18.4. *Feature Libraries and Feature-Value Libraries* below.

However, the most general method of attempting to ensure that only legal combinations of feature names and values are used is to provide a *feature-system declaration* discussed in 18.11. *Feature System Declaration*.

Whether at the level of feature-system declarations, feature- and feature-value libraries, or individual features, it is possible to align both feature names and their values with standardized external data category repositories such as ISOcat.<sup>111</sup> In the following example, both the feature `part_of_speech` and its value `#commonNoun` are aligned with the respective definitions provided by ISO DCR (Data Category Registry), as implemented by ISOcat.

```
<fs
  xmlns:dcr="http://www.isocat.org/ns/dcr">
<!-- . . . -->
  <f name="part_of_speech"
    dcr:datcat="http://www.isocat.org/datcat/DC-1345" fVal="#commonNoun"
    dcr:valueDatcat="http://www.isocat.org/datcat/DC-1256"/>
<!-- . . . -->
</fs>
```

## 18.4 Feature Libraries and Feature-Value Libraries

As the examples in the preceding section suggest, the direct encoding of feature structures can be verbose. Moreover, it is often the case that particular feature-value combinations, or feature structures composed of them, are re-used in different analyses. To reduce the size and complexity of the task of encoding feature structures, one may use the *feats* attribute of the <fs> element to point to one or more of the feature-value specifications for that element. This indirect method of encoding feature structures presumes that the <f> elements are assigned unique *xml:id* values, and are collected together in <fLib> elements (*feature libraries*). In the same way, feature values of whatever type can be collected together in <fvLib> elements (*feature-value libraries*). If a feature has as its value a feature structure or other value which is predefined in this way, the *fVal* attribute may be used to point to it, as discussed in the next section. The following elements are used for representing feature libraries and feature-value libraries:

<sup>111</sup>See section 9.5.2. *Lexical View* for more discussion of the need and rationale for ISOcat references.

**<fLib>** (feature library) assembles a library of feature elements.

**<fvLib>** (feature-value library) assembles a library of reusable feature value elements (including complete feature structures).

For example, suppose a feature library for phonological feature specifications is set up as follows.

```
<fLib n="phonological features">
  <f xml:id="CNS1" name="consonantal">
    <binary value="true"/>
  </f>
  <f xml:id="CNS0" name="consonantal">
    <binary value="false"/>
  </f>
  <f xml:id="VOC1" name="vocalic">
    <binary value="true"/>
  </f>
  <f xml:id="VOC0" name="vocalic">
    <binary value="false"/>
  </f>
  <f xml:id="VOI1" name="voiced">
    <binary value="true"/>
  </f>
  <f xml:id="VOI0" name="voiced">
    <binary value="false"/>
  </f>
  <f xml:id="ANT1" name="anterior">
    <binary value="true"/>
  </f>
  <f xml:id="ANT0" name="anterior">
    <binary value="false"/>
  </f>
  <f xml:id="COR1" name="coronal">
    <binary value="true"/>
  </f>
  <f xml:id="COR0" name="coronal">
    <binary value="false"/>
  </f>
  <f xml:id="CNT1" name="continuant">
    <binary value="true"/>
  </f>
  <f xml:id="CNT0" name="continuant">
    <binary value="false"/>
  </f>
  <f xml:id="STR1" name="strident">
    <binary value="true"/>
  </f>
  <f xml:id="STR0" name="strident">
    <binary value="false"/>
  </f>
<!-- ... -->
</fLib>
```

Then the feature structures that represent the analysis of the phonological segments (phonemes) /t/, /d/, /s/, and /z/ may be defined as follows.

```
<fs feats="#CNS1 #VOC0 #VOI0 #ANT1 #COR1 #CNT0 #STR0"/>
<fs feats="#CNS1 #VOC0 #VOI1 #ANT1 #COR1 #CNT0 #STR0"/>
```

```
<fs feats="#CNS1 #VOC0 #VOI0 #ANT1 #COR1 #CNT1 #STR1"/>
<fs feats="#CNS1 #VOC0 #VOI1 #ANT1 #COR1 #CNT1 #STR1"/>
```

The preceding are but four of the 128 logically possible fully specified phonological segments using the seven binary features listed in the feature library. Presumably not all combinations of features correspond to phonological segments (there are no strident vowels, for example). The legal combinations, however, can be collected together, each one represented as an identifiable <fs> element within a *feature-value library*, as in the following example:

```
<fvLib xml:id="fsl1"
  n="phonological segment definitions">
<!-- ... -->
  <fs xml:id="T.DF"
    feats="#CNS1 #VOC0 #VOI0 #ANT1 #COR1 #CNT0 #STR0"/>
  <fs xml:id="D.DF"
    feats="#CNS1 #VOC0 #VOI1 #ANT1 #COR1 #CNT0 #STR0"/>
  <fs xml:id="S.DF"
    feats="#CNS1 #VOC0 #VOI0 #ANT1 #COR1 #CNT1 #STR1"/>
  <fs xml:id="Z.DF"
    feats="#CNS1 #VOC0 #VOI1 #ANT1 #COR1 #CNT1 #STR1"/>
<!-- ... -->
</fvLib>
```

Once defined, these feature structure values can also be reused. Other <f> elements may invoke them by reference, using the *fVal* attribute; for example, one might use them in a feature value pair such as:

```
<f name="dental-fricative" fVal="#T.DF"/>
```

rather than expanding the hierarchy of the component phonological features explicitly.

Feature structures stored in this way may also be associated with the text which they are intended to annotate, either by a link from the text (for example, using the TEI global *ana* attribute), or by means of stand-off annotation techniques (for example, using the TEI <link> element): see further section 18.10. *Linking Text and Analysis* below.

Note that when features or feature structures are linked to in this way, the result is effectively a copy of the item linked to into the place from which it is linked. This form of linking should be distinguished from the phenomenon of *structure-sharing*, where it is desired to indicate that some part of an annotation structure appears simultaneously in two or more places within the structure. This kind of annotation should be represented using the <vLabel> element, as discussed in 18.6. *Re-entrant Feature Structures* below.

## 18.5 Feature Structures as Complex Feature Values

Features may have complex values as well as atomic ones; the simplest such complex value is represented by supplying a <fs> element as the content of an <f> element, or (equivalently) by supplying the identifier of an <fs> element as the value for the *fVal* attribute on the <f> element. Structures may be nested as deeply as appropriate, using this mechanism. For example, an <fs> element may contain or point to an <f> element, which may contain or point to an <fs> element, which may contain or point to an <f> element, and so on.

To illustrate the use of complex values, consider the following simple model of a word, as a structure combining surface form information, a syntactic category, and semantic information. Each word analysis is represented as a <f type='word'> element, containing three features named **surface**, **syntax**, and **semantics**. The first of these has an atomic string value, but the other two have complex values, represented as nested feature structures of types **category** and **act** respectively:

```

<fs type="word">
  <f name="surface">
    <string>love</string>
  </f>
  <f name="syntax">
    <fs type="category">
      <f name="pos">
        <symbol value="verb"/>
      </f>
      <f name="val">
        <symbol value="transitive"/>
      </f>
    </fs>
  </f>
  <f name="semantics">
    <fs type="act">
      <f name="rel">
        <symbol value="LOVE"/>
      </f>
    </fs>
  </f>
</fs>

```

This analysis does not tell us much about the meaning of the symbols `verb` or `transitive`. It might be preferable to replace these atomic feature values by feature structures. Suppose therefore that we maintain a feature-value library for each of the major syntactic categories (N, V, ADJ, PREP):

```

<fvLib n="Major category definitions">
  <!-- ... -->
  <fs xml:id="N" type="noun">
    <!-- noun features defined here -->
  </fs>
  <fs xml:id="V" type="verb">
    <!-- verb features defined here -->
  </fs>
</fvLib>

```

This library allows us to use shortcut codes (N, V, etc.) to reference a complete definition for the corresponding feature structure. Each definition may be explicitly contained within the `<fs>` element, as a number of `<f>` elements. Alternatively, the relevant features may be referenced by their identifiers, supplied as the value of the *feats* attribute, as in these examples:

```

<!-- ... -->
<fs xml:id="ADJ" type="adjective" feats="#F1 #F2"/>
<fs xml:id="PREP" type="preposition" feats="#F1 #F3"/>
<!-- ... -->

```

This ability to re-use feature definitions within multiple feature structure definitions is an essential simplification in any realistic example. In this case, we assume the existence of a feature library containing specifications for the basic feature categories like the following:

```

<fLib n="categorical features">
  <f xml:id="NN-1" name="nominal">
    <binary value="true"/>
  </f>
  <f xml:id="NN-0" name="nominal">
    <binary value="false"/>
  </f>
  <f xml:id="VV-1" name="verbal">
    <binary value="true"/>
  </f>
  <f xml:id="VV-0" name="verbal">
    <binary value="false"/>
  </f>
<!-- ... -->
</fLib>

```

With such libraries in place, and assuming the availability of similarly predefined feature structures for transitivity and semantics, the preceding example could be considerably simplified:

```

<fs type="word">
  <f name="surface">
    <string>love</string>
  </f>
  <f name="syntax">
    <fs type="category">
      <f name="pos" fVal="#V"/>
      <f name="val" fVal="#TRNS"/>
    </fs>
  </f>
  <f name="semantics">
    <fs type="act">
      <f name="rel" fVal="#LOVE"/>
    </fs>
  </f>
</fs>

```

Although in principle the *fVal* attribute could point to any kind of feature value, its use is not recommended for simple atomic values.

## 18.6 Re-entrant Feature Structures

Sometimes the same feature value is required at multiple places within a feature structure, in particular where the value is only partially specified at one or more places. The `<vLabel>` element is provided as a means of labelling each such re-entrancy point:

**<vLabel>** (value label) represents the value part of a feature-value specification which appears at more than one point in a feature structure.

For example, suppose one wishes to represent noun-verb agreement as a single feature structure. Within the representation, the feature indicating (say) number appears more than once. To represent the fact that each occurrence is another appearance of the same feature (rather than a copy) one could use an encoding like the following:

```

<fs xml:id="NVA">
  <f name="nominal">
    <fs>

```

```

    <f name="nm-num">
      <vLabel name="L1">
        <symbol value="singular"/>
      </vLabel>
    </f>
  <!-- other nominal features -->
</fs>
</f>
<f name="verbal">
  <fs>
    <f name="vb-num">
      <vLabel name="L1"/>
    </f>
  </fs>
  <!-- other verbal features -->
</f>
</fs>

```

In the above encoding, the features named `vb-num` and `nm-num` exhibit structure sharing. Their values, given as `vLabel` elements, are understood to be references to the same point in the feature structure, which is labelled by their *name* attribute.

The scope of the names used to label re-entrancy points is that of the outermost `<fs>` element in which they appear. When a feature structure is imported from a feature value library, or referenced from elsewhere (for example by using the *fVal* attribute) the names of any sharing points it may contain are implicitly prefixed by the identifier used for the imported feature structure, to avoid name clashes. Thus, if some other feature structure were to reference the `<fs>` element given in the example above, for example in this way:

```
<f name="class" fVal="#NVA"/>
```

then the labelled points in the example would be interpreted as if they had the name `NVAL1`.

## 18.7 Collections as Complex Feature Values

Complex feature values need not always be represented as feature structures. Multiple values may also be organized as sets, bags or multisets, or lists of atomic values of any type. The `<vColl>` element is provided to represent such cases:

**<vColl>** (collection of values) represents the value part of a feature-value specification which contains multiple values organized as a set, bag, or list.

A feature whose value is regarded as a set, bag, or list may have any positive number of values as its content, or none at all, (thus allowing for representation of the empty set, bag, or list). The items in a list are ordered, and need not be distinct. The items in a set are not ordered, and must be distinct. The items in a bag are neither ordered nor distinct. Sets and bags are thus distinguished from lists in that the order in which the values are specified does not matter for the former, but does matter for the latter, while sets are distinguished from bags and lists in that repetitions of values do not count for the former but do count for the latter.

If no value is specified for the *org* attribute, the assumption is that the `<vColl>` defines a list of values. If the `<vColl>` element is empty, the assumption is that it represents the null list, set, or bag.

To illustrate the use of the *org* attribute, suppose that a feature structure analysis is used to represent a genealogical tree, with the information about each individual treated as a single feature structure, like this:

```

<fs xml:id="p027" type="person">
  <f name="forenames">
    <vColl>
      <string>Daniel</string>
    </vColl>
  </f>
</fs>

```

```

    <string>Edouard</string>
  </vColl>
</f>
<f name="mother" fVal="#p002"/>
<f name="father" fVal="#p009"/>
<f name="birthDate">
  <fs type="date" feats="#y1988 #m04 #d17"/>
</f>
<f name="birthPlace" fVal="#austintx"/>
<f name="siblings">
  <vColl org="set">
    <fs copyOf="#pnb005"/>
    <fs copyOf="#prb001"/>
  </vColl>
</f>
</fs>

```

In this example, the <vColl> element is first used to supply a list of ‘name’ feature values, which together constitute the ‘forenames’ feature. Other features are defined by reference to values which we assume are held in some external feature value library (not shown here). For example, the <vColl> element is used a second time to indicate that the persons's siblings should be regarded as constituting a set rather than a list. Each sibling is represented by a feature structure: in this example, each feature structure is a copy of one specified in the feature value library.

If a specific feature contains only a single feature structure as its value, the component features of which are organized as a set, bag, or list, it may be more convenient to represent the value as a <vColl> rather than as a <fs>. For example, consider the following encoding of the English verb form *sinks*, which contains an *agreement* feature whose value is a feature structure which contains *person* and *number* features with symbolic values.

```

<fs type="word">
  <f name="category">
    <symbol value="verb"/>
  </f>
  <f name="tense">
    <symbol value="present"/>
  </f>
  <f name="agreement">
    <fs>
      <f name="person">
        <symbol value="third"/>
      </f>
      <f name="number">
        <symbol value="singular"/>
      </f>
    </fs>
  </f>
</fs>

```

If the names of the features contained within the *agreement* feature structure are of no particular significance, the following simpler representation may be used:

```

<fs type="word">
  <f name="category">
    <symbol value="verb"/>
  </f>
  <f name="tense">

```

```

    <symbol value="present"/>
  </f>
  <f name="agreement">
    <vColl org="set">
      <symbol value="third"/>
      <symbol value="singular"/>
    </vColl>
  </f>
</fs>

```

The `<vColl>` element is also useful in cases where an analysis has several components. In the following example, the French word *auxquels* has a two-part analysis, represented as a list of two values. The first specifies that the word contains a preposition; the second that it contains a masculine plural relative pronoun:

```

<fs>
  <f name="lex">
    <symbol value="auxquels"/>
  </f>
  <f name="maf">
    <vColl org="list">
      <fs>
        <f name="cat">
          <symbol value="prep"/>
        </f>
      </fs>
      <fs>
        <f name="cat">
          <symbol value="pronoun"/>
        </f>
        <f name="kind">
          <symbol value="rel"/>
        </f>
        <f name="num">
          <symbol value="pl"/>
        </f>
        <f name="gender">
          <symbol value="masc"/>
        </f>
      </fs>
    </vColl>
  </f>
</fs>

```

The set, bag, or list which has no members is known as the null (or empty) set, bag, or list. A `<vColl>` element with no content and with no value for its *feats* attribute is interpreted as referring to the null set, bag, or list, depending on the value of its *org* attribute.

If, for example, the individual described by the feature structure with identifier `p027` (above) had no siblings, we might specify the *siblings* feature as follows.

```

<f name="siblings">
  <vColl org="set"/>
</f>

```

A `<vColl>` element may also collect together one or more other `<vColl>` elements, if, for example one of the members of a set is itself a set, or if two lists are concatenated together. Note that such collections pay no attention

to the contents of the nested <vColl> elements: if it is desired to produce the union of two sets, the <vMerge> element discussed below should be used to make a new collection from the two sets.

## 18.8 Feature Value Expressions

It is sometimes desirable to express the value of a feature as the result of an operation over some other value (for example, as 'not green', or as 'male or female', or as the concatenation of two collections). Three special purpose elements are provided to represent disjunctive alternation, negation, and collection of values:

**<vAlt>** (value alternation) represents the value part of a feature-value specification which contains a set of values, only one of which can be valid.

**<vNot>** (value negation) represents a feature value which is the negation of its content.

**<vMerge>** (merged collection of values) represents a feature value which is the result of merging together the feature values contained by its children, using the organization specified by the *org* attribute.

### 18.8.1 Alternation

The <vAlt> element can be used wherever a feature value can appear. It contains two or more feature values, any one of which is to be understood as the value required. Suppose, for example, that we are using a feature system to describe residential property, using such features as *number.of.bathrooms*. In a particular case, we might wish to represent uncertainty as to whether a house has two or three bathrooms. As we have already shown, one simple way to represent this would be with a numeric maximum:

```
<f name="number.of.bathrooms">
  <numeric value="2" max="3"/>
</f>
```

A more general way would be to represent the alternation explicitly, in this way:

```
<f name="number.of.bathrooms">
  <vAlt>
    <numeric value="2"/>
    <numeric value="3"/>
  </vAlt>
</f>
```

The <vAlt> element represents alternation over feature values, not feature-value pairs. If therefore the uncertainty relates to two or more feature value specifications, each must be represented as a feature structure, since a feature structure can always appear where a value is required. For example, suppose that it is uncertain as to whether the house being described has two bathrooms or two bedrooms, a structure like the following may be used:

```
<f name="rooms">
  <vAlt>
    <fs>
      <f name="number.of.bathrooms">
        <numeric value="2"/>
      </f>
    </fs>
    <fs>
      <f name="number.of.bedrooms">
        <numeric value="2"/>
      </f>
    </fs>
  </vAlt>
</f>
```

Note that alternation is always regarded as *exclusive*: in the case above, the implication is that having two bathrooms excludes the possibility of having two bedrooms and vice versa. If inclusive alternation is required, a `<vColl>` element may be included in the alternation as follows:

```
<f name="rooms">
  <vAlt>
    <fs>
      <f name="number.of.bathrooms">
        <numeric value="2"/>
      </f>
    </fs>
    <fs>
      <f name="number.of.bedrooms">
        <numeric value="2"/>
      </f>
    </fs>
    <vColl>
      <fs>
        <f name="number.of.bathrooms">
          <numeric value="2"/>
        </f>
      </fs>
      <fs>
        <f name="number.of.bedrooms">
          <numeric value="2"/>
        </f>
      </fs>
    </vColl>
  </vAlt>
</f>
```

This analysis indicates that the property may have two bathrooms, two bedrooms, or both two bathrooms and two bedrooms.

As the previous example shows, the `<vAlt>` element can also be used to indicate alternations among values of features organized as sets, bags or lists. Suppose we use a feature `selling.points` to describe items that are mentioned to enhance a property's sales value, such as whether it has a pool or a good view. Now suppose for a particular listing, the selling points include an alarm system and a good view, and either a pool or a jacuzzi (but not both). This situation could be represented, using the `<vAlt>` element, as follows.

```
<fs type="real_estate_listing">
  <f name="selling.points">
    <vColl org="set">
      <string>alarm system</string>
      <string>good view</string>
      <vAlt>
        <string>pool</string>
        <string>jacuzzi</string>
      </vAlt>
    </vColl>
  </f>
</fs>
```

Now suppose the situation is like the preceding except that one is also uncertain whether the property has an alarm system or a good view. This can be represented as follows.

```

<fs type="real_estate_listing">
  <f name="selling.points">
    <vColl org="set">
      <vAlt>
        <string>alarm system</string>
        <string>good view</string>
      </vAlt>
      <vAlt>
        <string>pool</string>
        <string>jacuzzi</string>
      </vAlt>
    </vColl>
  </f>
</fs>

```

If a large number of ambiguities or uncertainties need to be represented, involving a relatively small number of features and values, it is recommended that a stand-off technique, for example using the general-purpose <alt> element discussed in section 16.8. *Alternation* be used, rather than the special-purpose <vAlt> element.

### 18.8.2 Negation

The <vNot> element can be used wherever a feature value can appear. It contains any feature value and returns the complement of its contents. For example, the feature *number.of.bathrooms* in the following example has any whole numeric value other than 2:

```

<f name="number.of.bathrooms">
  <vNot>
    <numeric value="2"/>
  </vNot>
</f>

```

Strictly speaking, the effect of the <vNot> element is to provide the complement of the feature values it contains, rather than their negation. If a feature system declaration is available which defines the possible values for the associated feature, then it is possible to say more about the negated value. For example, suppose that the available values for the feature *CASE* are declared to be nominative, genitive, dative, or accusative, whether in a TEI feature system declaration or by some other means. Then the following two specifications are equivalent:

```

(i) <f name="case">
  <vNot>
    <symbol value="genitive"/>
  </vNot>
</f>
(ii)
<f name="case">
  <vAlt>
    <symbol value="nominative"/>
    <symbol value="dative"/>
    <symbol value="accusative"/>
  </vAlt>
</f>

```

If however no such system declaration is available, all that one can say about a feature specified via negation is that its value is something other than the negated value.

Negation is always applied to a feature value, rather than to a feature-value pair. The negation of an atomic value is the set of all other values which are possible for the feature.

Any kind of value can be negated, including collections (represented by a <vColl> elements) or feature structures (represented by <fs> elements). The negation of any complex value is understood to be the set of values which cannot be unified with it. Thus, for example, the negation of the feature structure F is understood to be the set of feature structures which are not unifiable with F. In the absence of a constraint mechanism such as the Feature System Declaration, the negation of a collection is anything that is not unifiable with it, including collections of different types and atomic values. It will generally be more useful to require that the organization of the negated value be the same as that of the original value, for example that a negated set is understood to mean the set which is a complement of the set, but such a requirement cannot be enforced in the absence of a constraint mechanism.

### 18.8.3 Collection of Values

The <vMerge> element can be used wherever a feature value can appear. It contains two or more feature values, all of which are to be collected together. The organization of the resulting collection is specified by the value of the *org* attribute, which need not necessarily be the same as that of its constituent values if these are collections. For example, one can change a list to a set, or vice versa.

As an example, suppose that we wish to represent the range of possible values for a feature 'genders' used to describe some language. It would be natural to represent the possible values as a set, using the <vColl> element as in the following example:

```
<fs>
  <f name="genders">
    <vColl org="set">
      <symbol value="masculine"/>
      <symbol value="feminine"/>
    </vColl>
  </f>
</fs>
```

Suppose however that we discover for some language it is necessary to add a new possible value, and to treat the value of the feature as a list rather than as a set. The <vMerge> element can be used to achieve this:

```
<fs>
  <f name="genders">
    <vMerge org="list">
      <vColl org="set">
        <symbol value="masculine"/>
        <symbol value="feminine"/>
      </vColl>
      <symbol value="neuter"/>
    </vMerge>
  </f>
</fs>
```

## 18.9 Default Values

The value of a feature may be underspecified in a number of different ways. It may be null, unknown, or uncertain with respect to a range of known possibilities, as well as being defined as a negation or an alternation. As previously noted, the specification of the range of known possibilities for a given feature is not part of the current specification: in the TEI scheme, this information is conveyed by the *feature system declaration*. Using this, or some other system, we might specify (for example) that the range of values for an element includes symbols for masculine, feminine, and neuter, and that the default value is neuter. With such definitions available to us, it becomes possible to say that some feature takes the default value, or some unspecified value from the list. The following special element is provided for this purpose:

**<default>** (default feature value) represents the value part of a feature-value specification which contains a defaulted value.

The value of an empty `<f>` element which also lacks a *fVal* attribute is understood to be the most general case, i.e. any of the available values. Thus, assuming the feature system defined above, the following two representations are equivalent.

```
<f name="gender"/>
<f name="gender">
  <vAlt>
    <symbol value="feminine"/>
    <symbol value="masculine"/>
    <symbol value="neuter"/>
  </vAlt>
</f>
```

If, however, the value is explicitly stated to be the default one, using the `<default>` element, then the following two representations are equivalent:

```
<f name="gender">
  <default/>
</f>
```

```
<f name="gender">
  <symbol value="neuter"/>
</f>
```

Similarly, if the value is stated to be the negation of the default, then the following two representations are equivalent:

```
<f name="gender">
  <vNot>
    <default/>
  </vNot>
</f>
```

```
<f name="gender">
  <vAlt>
    <symbol value="feminine"/>
    <symbol value="masculine"/>
  </vAlt>
</f>
```

### 18.10 Linking Text and Analysis

Text elements can be linked with feature structures using any of the linking methods discussed elsewhere in these Guidelines (see for example sections 17.2. *Global Attributes for Simple Analyses* and 17.4. *Linguistic Annotation*). In the simplest case, the *ana* attribute may be used to point from any element to an annotation of it, as in the following example:

```

<s n="00741">
  <w ana="#at0">The</w>
  <w ana="#ajs">closest</w>
  <w ana="#pnp">he</w>
  <w ana="#vvd">came</w>
  <w ana="#prp">to</w>
  <w ana="#nn1">exercise</w>
  <w ana="#vbd">was</w>
  <w ana="#to0">to</w>
  <w ana="#vvi">open</w>
  <w ana="#crd">one</w>
  <w ana="#nn1">eye</w>
  <phr ana="#av0">
    <w>every</w>
    <w>so</w>
    <w>often</w>
  </phr>
  <c ana="#pun">,</c>
  <w ana="#cjs">if</w>
  <w ana="#pni">someone</w>
  <w ana="#vvd">entered</w>
  <w ana="#at0">the</w>
  <w ana="#nn1">room</w>
<!-- ... -->
</s>

```

The values specified for the *ana* attribute reference components of a feature-structure library, which represents all of the grammatical structures used by this encoding scheme. (For illustrative purposes, we cite here only the structures needed for the first six words of the sample sentence):

```

<fvLib xml:id="C6" n="Claws 6 tags">
<!-- ... -->
  <fs xml:id="ajs"
    type="grammatical_structure" feats="#wj #ds"/>
  <fs xml:id="at0"
    type="grammatical_structure" feats="#wl"/>
  <fs xml:id="pnp"
    type="grammatical_structure" feats="#wr #rp"/>
  <fs xml:id="vvd"
    type="grammatical_structure" feats="#wv #bv #fd"/>
  <fs xml:id="prp"
    type="grammatical_structure" feats="#wp #bp"/>
  <fs xml:id="nnn"
    type="grammatical_structure" feats="#wn #tc #ns"/>
<!-- ... -->
</fvLib>

```

The components of each feature structure in the library are referenced in much the same way, using the *feats* attribute to identify one or more <f> elements in the following feature library (again, only a few of the available features are quoted here):

```

<fLib>
<!-- ... -->
  <f xml:id="fl-bv" name="verbbase">

```

```

    <symbol value="main"/>
  </f>
  <f xml:id="fl-bp" name="prebase">
    <symbol value="lexical"/>
  </f>
  <f xml:id="fl-ds" name="degree">
    <symbol value="superlative"/>
  </f>
  <f xml:id="fl-fd" name="verbform">
    <symbol value="ed"/>
  </f>
  <f xml:id="fl-ns" name="number">
    <symbol value="singular"/>
  </f>
  <f xml:id="fl-rp" name="prontype">
    <symbol value="personal"/>
  </f>
  <f xml:id="fl-tc" name="nountype">
    <symbol value="common"/>
  </f>
  <f xml:id="fl-wj" name="class">
    <symbol value="adjective"/>
  </f>
  <f xml:id="fl-wl" name="class">
    <symbol value="article"/>
  </f>
  <f xml:id="fl-wn" name="class">
    <symbol value="noun"/>
  </f>
  <f xml:id="fl-wp" name="class">
    <symbol value="preposition"/>
  </f>
  <f xml:id="fl-wr" name="class">
    <symbol value="pronoun"/>
  </f>
  <f xml:id="fl-wv" name="class">
    <symbol value="verb"/>
  </f>
<!-- ... -->
</fLib>

```

Alternatively, a stand-off technique may be used, as in the following example, where a <linkGrp> element is used to link selected characters in the text *Caesar seized control* with their phonological representations.

```

<s>
  <w xml:id="S1W1">
    <c xml:id="S1W1C1">C</c>ae<c xml:id="S1W1C2">s</c>ar</w>
  <w xml:id="S1W2">
    <c xml:id="S1W2C1">s</c>ei<c xml:id="S1W2C2">z</c>e<c xml:id="S1W2C3">d</c>
  </w>
  <w xml:id="S1W3">con<c xml:id="S1W3C1">t</c>rol</w>.
</s>
<fvLib xml:id="FSL1"
  n="phonological segment definitions">
<!-- as in previous example -->

```

```

</fvLib>
<linkGrp type="phonology">
<!-- ... -->
  <link target="#S.DF #S1W3C1"/>
  <link target="#Z.DF #S1W2C3"/>
  <link target="#S.DF #S1W2C1"/>
  <link target="#Z.DF #S1W2C2"/>
<!-- ... -->
</linkGrp>

```

As this example shows, a stand-off solution requires that every component to be linked to must be addressable in some way, by means of an XPointer. To handle the POS tagging example above, for example, each annotated element might be given an identifier of some sort, as follows:

```

<s xml:id="mds09" n="00741">
  <w xml:id="mds0901">The</w>
  <w xml:id="mds0902">closest</w>
  <w xml:id="mds0903">he</w>
  <w xml:id="mds0904">came</w>
  <w xml:id="mds0905">to</w>
  <w xml:id="mds0906">exercise</w>
<!-- ... -->
</s>

```

It would then be possible to link each word to its intended annotation in the feature library quoted above, as follows:

```

<linkGrp type="POS-codes">
<!-- ... -->
  <link target="#mds0901 #at0"/>
  <link target="#mds0902 #ajs"/>
  <link target="#mds0903 #pnp"/>
  <link target="#mds0904 #vvd"/>
  <link target="#mds0905 #prp"/>
  <link target="#mds0906 #nn1"/>
  <link target="#mds0907 #vbd"/>
  <link target="#mds0908 #to0"/>
  <link target="#mds0909 #vvi"/>
  <link target="#mds0910 #crd"/>
<!-- ... -->
</linkGrp>

```

## 18.11 Feature System Declaration

The Feature System Declaration (FSD) is intended for use in conjunction with a TEI-conforming text that makes use of <fs> (that is, feature structure) elements. The FSD serves three purposes:

- It provides a mechanism by which the encoder can list all of the feature names and feature values and give a prose description as to what each represents.
- It provides a mechanism by which the encoder can define constraints not only what it means to be a well-formed feature structure, but also *valid* feature structure, relative to a given theory stated in typed feature logic. These constraints may involve constraints on the range of a feature value, constraints on what features are valid within certain types of feature structures, or constraints that prevent the co-occurrence of certain feature-value pairs.
- It provides a mechanism by which the encoder can define the intended interpretation of underspecified feature structures. This involves defining default values (whether literal or computed) for missing features.

The scheme described in this chapter may be used to document any feature structure system, but is primarily intended for use with the feature structure representation defined by the ISO 24610-1:2006 standard, which corresponds with the recommendations presented in these Guidelines, *18. Feature Structures*. This chapter relies upon, but does not reproduce, formal definitions and descriptions presented more thoroughly in the ISO standard, which should be consulted in case of ambiguity or uncertainty.

The FSD serves an important function in documenting precisely what the encoder intended by the system of feature structure markup used in an XML-encoded text. The FSD is also an important resource which standardizes the rules of inference used by software to validate the feature structure markup in a text, and to infer the full interpretation of underspecified feature structures.

The reader should be aware the terminology used in this document does not always closely follow conventional practice in formal logic, and may also diverge from practice in some linguistic applications of typed feature structures. In particular, the term ‘interpretation’ when applied to a feature structure is not an interpretation in the model-theoretic sense, but is instead a minimally informative (or equivalently, most general) extension of that feature structure that is consistent with a set of constraints declared by an FSD. In linguistic application, such a system of constraints is the principal means by which the grammar of some natural language is expressed. There is a great deal of disagreement as to what, if any, model-theoretic interpretation feature structures have in such applications, but the status of this formal kind of interpretation is not germane to the present document. Similarly, the term ‘valid’ is used here as elsewhere in these Guidelines to identify the syntactic state of well-formedness in the sense defined by the logic of typed feature structures itself, as distinct from and in addition to the ‘well-formedness’ that pertains at the level of this encoding standard. No appeal to any notion from formal semantics should be inferred.

We begin by describing how an encoded text is associated with one or more feature system declarations. The second, third, and fourth sections describe the overall structure of a feature system declaration and give details of how to encode its components. The final section offers a full example; fuller discussion of the reasoning behind FSDs and another complete example are provided in Langendoen and Simons (1995).

### 18.11.1 Linking a TEI Text to Feature System Declarations

In order for application software to use feature system declarations to aid in the automatic interpretation of encoded texts, or even for human readers to find the appropriate declarations which document the feature system used in markup, there must be a formal link from the encoded texts to the declarations. However, the schema which declares the syntax of the Feature System itself should be kept distinct from the feature structure schema, which is an application of that system.

A document containing typed feature structures may simply include a feature system declaration documenting those feature structures. A more usual scenario, however, is that the same feature system declaration (or parts of it) will be shared by many documents. In either case, an `<fsDecl>` element for each distinct type of feature structure used must be provided and associated with the type, which is the value used within each feature structure for its *type* attribute.

When the module defined in this chapter is included in an XML schema, the following elements become available:

**<fsdDecl>** (feature system declaration) provides a feature system declaration comprising one or more feature structure declarations or feature structure declaration links.

**<fsdLink>** (feature structure declaration link) associates the name of a typed feature structure with a feature structure declaration for it.

**<fsDecl>** (feature structure declaration) declares one type of feature structure.

The `<fsdDecl>` element may be supplied either within the header of a standard TEI document, or as a standalone document in its own right. It contains one or more `<fsdLink>` or `<fsDecl>` elements.

For example, suppose that a document `doc.xml` contains feature structures of two types: `gpsg` and `lex`. We might simply embed an `<fsDecl>` element for each within the header attached to the document as follows:

```
<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <fileDesc>
<!-- example -->
    </fileDesc>
```

```

    <encodingDesc>
<!-- ... -->
      <fsdDecl>
        <fsDecl type="gpsg">
<!-- information about this type -->
          </fsDecl>
        <fsDecl type="lex">
<!-- information about this type -->
          </fsDecl>
        </fsdDecl>
      </encodingDesc>
    </teiHeader>
    <text>
      <body>
<!-- ... -->
        <fs type="lex">
<!-- an instance of the typed feature structure "lex" -->
          </fs>
        </body>
      </text>
    </TEI>

```

In this case there is an implicit link between the `<fs>` element and the corresponding `<fsDecl>` element because they share the same value for their *type* attribute and appear within the same document. This is a short cut for the more general case which requires a more explicit link provided by means of the `<fsdLink>` element, as demonstrated below.

Now suppose that we wish to create a second document which includes feature structures of the same type. Rather than duplicate the corresponding declarations, we will need to provide a means of pointing to them from this second document. The easiest<sup>112</sup> way of accomplishing this is to add an XML identifier to each `<fsDecl>` element in `example.xml`:

```

<!-- ... --><fsdDecl>
  <fsDecl type="gpsg" xml:id="GPSG">
<!-- information about this type -->
    </fsDecl>
  <fsDecl type="lex" xml:id="LEX">
<!-- information about this type -->
    </fsDecl>
  </fsdDecl>

```

(Although in this case the XML identifier is simply an uppercase version of the type name, there is no necessary connection between the two names. The only requirement is that the XML identifier conform to the standards required for identifiers, and that it be unique within the document containing it.)

In the `<fsdDecl>` for the second document, we can now include pointers to the `<fsDecl>` elements in the first:

```

<TEI xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <fileDesc>
<!-- doc2 -->

```

<sup>112</sup>Ways of pointing to components of a TEI document without using an XML identifier are discussed in *16.2.1. Pointing Elsewhere*

```

    </fileDesc>
    <encodingDesc>
<!-- ... -->
      <fsdDecl>
        <fsdLink type="gpsg"
          target="example.xml#GPSG"/>
        <fsdLink type="lexx"
          target="example.xml#GPSG"/>
      </fsdDecl>
<!-- ... -->
    </encodingDesc>
  </teiHeader>
  <text>
    <body>
<!-- ... -->
      <fs type="lexx">
<!-- an instance of the typed feature structure "lex" -->
        </fs>
<!-- ... -->
    </body>
  </text>
</TEI>

```

Note that in `doc2.xml` there is no requirement for the local name for a given type of feature structures to be the same as that used by `example.xml`. We assume in this encoding that the type called `lexx` in `doc2.xml` is declared as having identical constraints and other properties to those declared for the type called `lex` in `example.xml`.

A `<fsdDecl>` may be given, as above, within the encoding description of the `<teiHeader>` element of a TEI document containing typed feature structures. Alternatively, it may appear independently of any feature structures, as a document in its own right, possibly with its own `<teiHeader>`. These options are both possible because the element is a member of both the `model.encodingDescPart` class and the `model.resourceLike` class.

The current recommendations provide no way of enforcing uniqueness of the *type* values among `<fsdDecl>` elements, nor of requiring that every *type* value specified on a `<fs>` element be also declared on an `<fsdDecl>` element. Encoders requiring such constraints (which might have some obvious utility in assisting the consistency and accuracy of tagging) are recommended to develop tools to enforce them, using such mechanisms as Schematron assertions.

### 18.11.2 The Overall Structure of a Feature System Declaration

A feature system declaration contains one or more feature structure declarations, each of which has up to three parts: an optional description (which gives a prose comment on what that type of feature structure encodes), an obligatory set of feature declarations (which specify range constraints and default values for the features in that type of structure), and optional feature structure constraints (which specify co-occurrence restrictions on feature values).

**<fsDescr>** (feature system description (in FSD)) describes in prose what is represented by the type of feature structure declared in the enclosing `fsDecl`.

**<fDecl>** (feature declaration) declares a single feature, specifying its name, organization, range of allowed values, and optionally its default value.

**<fsConstraints>** (feature-structure constraints) specifies constraints on the content of valid feature structures.

Feature declarations and feature structure constraints are described in the next two sections. Note that the specification of similar `<fsDecl>` elements can be simplified by devising an inheritance hierarchy for the feature structure types. Each `<fsDecl>` element may name one or more ‘baseTypes’ from which it inherits feature declarations and constraints (these are often called ‘supertypes’). For instance, suppose that `<fsDecl type="Basic">` contains `<fDecl name="One">` and `<fDecl name="Two">`, and that `<fsDecl type="Derived" baseTypes="Basic">` contains just `<fDecl name="Three">`. Then any instance of `<fs type="Derived">` must include all three features. This is because

`<fsDecl type="Derived">` inherits the two feature declarations from `<fsDecl type="Basic">` when it specifies a base type of Basic.

The following sample shows the overall structure of a complete feature structure declaration:

```
<fsDecl type="SomeName">
  <fsDescr>Describes what this type of fs represents</fsDescr>
  <fDecl name="featureOne">
<!-- The declaration for featureOne -->
  </fDecl>
  <fDecl name="featureTwo">
<!-- The declaration for featureTwo -->
  </fDecl>
  <fsConstraints>
<!-- The feature structure constraints go here -->
  </fsConstraints>
</fsDecl>
```

The attribute *baseTypes* gives the name of one or more types from which this type inherits feature specifications and constraints; if this type includes a feature specification with the same name as one inherited from any of the types specified by this attribute, or if more than one specification of the same name is inherited, then the possible values of that feature is determined by unification. Similarly, the set of constraints applicable is derived by conjoining those specified explicitly within this element with those implied by the *baseTypes* attribute. When no base type is specified, no feature specification or constraint is inherited.

Although the present standard does provide for default feature values, feature inheritance is defined to be monotonic.

The process of combining constraints may result in a contradiction, for example if two specifications for the same feature specify disjoint ranges of values, and at least one such specification is mandatory. In such a case, there is no valid feature structure of the type being defined.

Every type specified by *baseTypes* must be a single word which is a legal XML name; for example, they cannot include whitespace or begin with digits. Multiple base types are separated with spaces, e.g. `<fsDecl type="Sub" baseTypes="Super1 Super2">`.

### 18.11.3 Feature Declarations

Each feature is declared in an `<fDecl>` element whose *name* attribute identifies the feature being declared; this matches the *name* attribute of the `<f>` elements it declares. An `<fDecl>` has three parts: an optional prose description (which should explain what the feature and its values represent), an obligatory range specification (which declares what values the feature is allowed to have), and an optional default specification (which declares what default value should be supplied when the named feature does not appear in an `<fs>`). If, in a feature structure, a feature:

- is not optional (i.e., is obligatory),
- has no value provided, or the value `<default>` is provided (see ISO 24610-1, Subclause 5.10, Default Values, and
- either has no default specified, or has conditional defaults, none of the conditions on which is met,

then the value of this feature in the feature structure's most general valid extension is the most general value provided in its `<vRange>`, in the case of a unit organization, or the singleton set, bag, or list containing that element, in the case of a complex organization. If the feature:

- is optional,
- has no value provided, or the value `<default>` is provided, and
- either has a default specified, or has conditional defaults, one of the conditions on which is met,

then this feature does have a value in the feature structure's most general valid extension when it exists, namely the default value that pertains.

It is possible that a feature structure will not have a valid extension because the default value that pertains to a feature is not consistent with that feature's declared range. Additional tools are required for the enforcement of such criteria.

The following elements are used in feature system declarations:

**<fDecl>** (feature declaration) declares a single feature, specifying its name, organization, range of allowed values, and optionally its default value.

**@name** a single word which follows the rules defining a legal XML name (see <http://www.w3.org/TR/REC-xml/#dt-name>), indicating the name of the feature being declared; matches the *name* attribute of <f> elements in the text.

**@optional** indicates whether or not the value of this feature may be present.

**<fDescr>** (feature description (in FSD)) describes in prose what is represented by the feature being declared and its values.

**<vRange>** (value range) defines the range of allowed values for a feature, in the form of an <fs>, <vAlt>, or primitive value; for the value of an <f> to be valid, it must be subsumed by the specified range; if the <f> contains multiple values (as sanctioned by the *org* attribute), then each value must be subsumed by the <vRange>.

**<vDefault>** (value default) declares the default value to be supplied when a feature structure does not contain an instance of <f> for this name; if unconditional, it is specified as one (or, depending on the value of the *org* attribute of the enclosing <fDecl>) more <fs> elements or primitive values; if conditional, it is specified as one or more <if> elements; if no default is specified, or no condition matches, the value none is assumed.

**<if>** defines a conditional default value for a feature; the condition is specified as a feature structure, and is met if it subsumes the feature structure in the text for which a default value is sought.

**<then>** separates the condition from the default in an <if>, or the antecedent and the consequent in a <cond> element.

The logic for validating feature values and for matching the conditions for supplying default values is based on the operation of *subsumption*. Subsumption is a standard operation in feature-structure-based formalisms. Informally, a feature structure FS subsumes all feature structures that are at least as informative as itself; that is, all feature structures that specify all of the feature values that FS does with values that are subsumed by the values that FS has, and that have all of the re-entrancies (see 18.6. *Re-entrant Feature Structures*) that FS does. (Carpenter (1992); see also Pereira (1987) and Shieber (1986)) A more formal definition is provided in ISO 24610-1:2006 .

Following the spirit of the informal definition above, we can extend subsumption in a straightforward way to cover alternation, negation, special primitive values, and the use of attributes in the markup. For instance, a <vAlt> containing the value *v* subsumes *v*. The negation of a value *v* (represented by means of the <vNot> element discussed in section 18.8.2. *Negation*) subsumes any value that is not *v*; for example <vNot><numeric value='0' /></vNot> subsumes any numeric value other than zero. The value <fs type="X"/> subsumes any feature structure of type X, even if it is not valid.

As an example of feature declarations, consider the following extract from Gazdar et al.'s *Generalized Phrase Structure Grammar*. In the appendix to their book, they propose a feature system for English of which this is just a sampling:

| feature | value range                                     |
|---------|---|
| INV     | {+, -}  |
| CONJ    | {and, both, but, either, neither, nor, or, NIL} |
| COMP    | {for, that, whether, if, NIL}                   |
| AGR     | CAT   |
| PFORM   | {to, by, for, ...}                              |

#### Feature specification defaults

FSD 1: [-INV]  
 FSD 2: ~[CONJ]  
 FSD 9: [INF, +SUBJ] --> [COMP for]

The INV feature, which encodes whether or not a sentence is inverted, allows only the values plus (+) and minus (-). If the feature is not specified, then the default rule (FSD 1 above) says that a value of minus is always assumed. The feature declaration for this feature would be encoded as follows:

```
<fDecl name="INV">
  <fDescr>inverted sentence</fDescr>
  <vRange>
    <vAlt>
      <binary value="true"/>
      <binary value="false"/>
    </vAlt>
  </vRange>
  <vDefault>
    <binary value="false"/>
  </vDefault>
</fDecl>
```

The value range is specified as an alternation (more precisely, an exclusive disjunction), which can be represented by the <binary> feature value. That is, the value must be either true or false, but cannot be both or neither.

The CONJ feature indicates the surface form of the conjunction used in a construction. The ~ in the default rule (see FSD 2 above) represents negation. This means that by default the feature is not applicable, in other words, no conjunction is taking place. Note that CONJ not being present is distinct from CONJ being present but having the NIL value allowed in the value range. In their analysis, NIL means that the phenomenon of conjunction is taking place but there is no explicit conjunction in the surface form of the sentence. The feature declaration for this feature would be encoded as follows:

```
<fDecl name="CONJ">
  <fDescr>surface form of the conjunction</fDescr>
  <vRange>
    <vAlt>
      <symbol value="and"/>
      <symbol value="both"/>
      <symbol value="but"/>
      <symbol value="either"/>
      <symbol value="neither"/>
      <symbol value="nor"/>
      <symbol value="or"/>
      <symbol value="NIL"/>
    </vAlt>
  </vRange>
  <vDefault>
    <binary value="false"/>
  </vDefault>
</fDecl>
```

Note that the <vDefault> is not strictly necessary in this case, since the binary value of false only serves to convey the information that the feature has no other legitimate value.

The COMP feature indicates the surface form of the complementizer used in a construction. In value range, it is analogous to CONJ. However, its default rule (see FSD 9 above) is conditional. It says that if the verb form is infinitival (the VFORM feature is not mentioned in the rule since it is the only feature that can take INF as a value), and the construction has a subject, then a *for* complement must be used. For instance, to make John the subject of the infinitive in *It is necessary to go*, a *for* complement must be used; that is, *It is necessary for John to go*. The feature declaration for this feature would be encoded as follows:

```

<fDecl name="COMP">
  <fDescr>surface form of the complementizer</fDescr>
  <vRange>
    <vAlt>
      <symbol value="for"/>
      <symbol value="that"/>
      <symbol value="whether"/>
      <symbol value="if"/>
      <symbol value="NIL"/>
    </vAlt>
  </vRange>
  <vDefault>
    <if>
      <fs>
        <f name="VFORM">
          <symbol value="INF"/>
        </f>
        <f name="SUBJ">
          <binary value="true"/>
        </f>
      </fs>
      <then/>
      <symbol value="for"/>
    </if>
  </vDefault>
</fDecl>

```

The AGR feature stores the features relevant to subject-verb agreement. Gazdar et al. specify the range of this feature as CAT. This means that the value is a *category*, which is their term for a feature structure. This is actually too weak a statement. Not just any feature structure is allowable here; it must be a feature structure for agreement (which is defined in the complete example at the end of the chapter to contain the features of person and number). The following feature declaration encodes this constraint on the value range:

```

<fDecl name="AGR">
  <fDescr>agreement for person and number</fDescr>
  <vRange>
    <fs type="Agreement"/>
  </vRange>
</fDecl>

```

That is, the value must be a feature structure of type Agreement. The complete example at the end of this chapter includes the <fsDecl type="Agreement"> which includes <fDecl name="PERS"> and <fDecl name="NUM">.

The PFORM feature indicates the surface form of the preposition used in a construction. Since PFORM is specified above as an open set, <string> is used in the range specification below rather than <symbol>.

```

<fDecl name="PFORM">
  <fDescr>word form of a preposition</fDescr>
  <vRange>
    <vNot>
      <string/>
    </vNot>
  </vRange>
</fDecl>

```

This example makes use of a negated value: `<vNot><string/></vNot>` subsumes any string that is not the empty string.

Note that the class `model.featureVal` includes all possible single feature values, including feature structures, alternations (`<vAlt>`) and complex collections (`<vColl>`).

#### 18.11.4 Feature Structure Constraints

Ensuring the validity of feature structures may require much more than simply specifying the range of allowed values for each feature. There may be constraints on the co-occurrence of one feature value with the value of another feature in the same feature structure or in an embedded feature structure.

Such constraints on valid feature structures are expressed as a series of conditional and biconditional tests in the `<fsConstraints>` part of an `<fsDecl>`. A particular feature structure is valid only if it meets all the constraints. The `<cond>` element encodes the conventional if-then conditional of boolean logic which succeeds when both the antecedent and consequent are true, or whenever the antecedent is false. The `<bicond>` element encodes the biconditional (if and only if) operation of boolean logic. It succeeds only when the corresponding if-then conditionals in both directions are true. In feature structure constraints the antecedent and consequent are expressed as feature structures; they are considered true if they *subsume* (see section 18.11.3. *Feature Declarations*) the feature structure in question, but in the case of consequents, this truth is asserted rather than simply tested. That is to say, a conditional is enforced by determining that the antecedent does not (and will never) subsume the given feature structure, or by determining that the antecedent does subsume the given feature structure, and then unifying the consequent with it (the result of which, if successful, will be subsumed by the consequent). In practice, the enforcement of such constraints can result in periods in which the truth of a constraint with respect to a given feature structure is simply not known; in this case, the constraint must be persistently monitored as the feature structure becomes more informative until either its truth value is determined or computation fails for some other reason.

The following elements make up the `<fsConstraints>` part of an FSD:

**<fsConstraints>** (feature-structure constraints) specifies constraints on the content of valid feature structures.

**<cond>** (conditional feature-structure constraint) defines a conditional feature-structure constraint; the consequent and the antecedent are specified as feature structures or feature-structure collections; the constraint is satisfied if both the antecedent and the consequent subsume a given feature structure, or if the antecedent does not.

**<bicond>** (bi-conditional feature-structure constraint) defines a biconditional feature-structure constraint; both consequent and antecedent are specified as feature structures or groups of feature structures; the constraint is satisfied if both subsume a given feature structure, or if both do not.

**<then>** separates the condition from the default in an `<if>`, or the antecedent and the consequent in a `<cond>` element.

**<iff>** (if and only if) separates the condition from the consequence in a `bicond` element.

For an example of feature structure constraints, consider the following ‘feature co-occurrence restrictions’ extracted from the feature system for English proposed by Gazdar, et al. (1985:246–247):

```
[FCR 1: [+INV] → [+AUX, FIN]
```

```
FCR 7: [BAR 0] ≡ [N] & [V] & [SUBCAT]
```

```
FCR 8: [BAR 1] → ~ [SUBCAT]
```

The first constraint says that if a construction is inverted, it must also have an auxiliary and a finite verb form. That is,

```
<cond>
  <fs>
    <f name="INV">
      <binary value="true"/>
    </f>
  </fs>
  <then/>
  <fs>
    <f name="AUX">
      <binary value="true"/>
    </f>
    <f name="VFORM">
      <symbol value="FIN"/>
    </f>
  </fs>
</cond>
```

The second constraint says that if a construction has a BAR value of zero (i.e., it is a sentence), then it must have a value for the features N, V, and SUBCAT. By the same token, because it is a biconditional, if it has values for N, V, and SUBCAT, it must have BAR='0'. That is,

```
<bicond>
  <fs>
    <f name="BAR">
      <symbol value="0"/>
    </f>
  </fs>
  <iff/>
  <fs>
    <f name="N">
      <binary value="true"/>
    </f>
    <f name="V">
      <binary value="true"/>
    </f>
    <f name="SUBCAT">
      <binary value="true"/>
    </f>
  </fs>
</bicond>
```

The final constraint says that if a construction has a BAR value of 1 (i.e., it is a phrase), then the SUBCAT feature should be absent (-). This is not biconditional, since there are other instances under which the SUBCAT feature is inappropriate. That is,

```
<cond>
  <fs>
    <f name="BAR">
      <symbol value="1"/>
    </f>
  </fs>
  <then/>
  <fs>
    <f name="SUBCAT">
      <symbol value="-"/>
    </f>
  </fs>
</cond>
```

```

<then/>
<fs>
  <f name="SUBCAT">
    <binary value="false"/>
  </f>
</fs>
</cond>

```

Note that `<cond>` and `<bicond>` use the empty tags `<then>` and `<iff>`, respectively, to separate the antecedent and consequent. These are primarily for the sake of enhancing human readability.

### 18.11.5 A Complete Example

To summarize this chapter, the complete FSD for the example that has run through the chapter is reproduced below:

```

<TEI xmlns="http://www.tei-c.org/ns/1.0">

## 18.12 Formal Definition and Implementation

This elements discussed in this chapter constitute a module of the TEI scheme which is formally defined as follows:

**Module iso-fs: Feature structures**

- *Elements defined:* bicond binary cond default f fDecl fDescr fLib fs fsConstraints fsDecl fsDescr fsdDecl fsdLink fvLib if iff numeric string symbol then vAlt vColl vDefault vLabel vMerge vNot vRange

The selection and combination of modules to form a TEI schema is described in 1.2. *Defining a TEI Schema*.

## 19 Graphs, Networks, and Trees

Graphical representations are widely used for displaying relations among informational units because they help readers to visualize those relations and hence to understand them better. Two general types of graphical representations may be distinguished.

- *Graphs*, in the strictly mathematical sense, consist of points, often called *nodes* or *vertices*, and connections among them, called *arcs*, or under certain conditions, *edges*. Among the various types of graphs are *networks* and *trees*. Graphs generally and networks in particular are dealt with directly below. Trees are dealt with separately in sections 19.2. *Trees* and 19.3. *Another Tree Notation*.<sup>113</sup>
- *Charts*, which typically plot data in two or more dimensions, including plots with orthogonal or radial axes, bar charts, pie charts, and the like. These can be described using the elements defined in the module for figures and graphics; see chapter 14. *Tables, Formulæ, Graphics and Notated Music*.

Among the types of qualitative relations often represented by graphs are organizational hierarchies, flow charts, genealogies, semantic networks, transition networks, grammatical relations, tournament schedules, seating plans, and directions to people's houses. In developing recommendations for the encoding of graphs of various types, we have relied on their formal mathematical definitions and on the most common conventions for representing them visually. However, it must be emphasized that these recommendations do not provide for the full range of possible graphical representations, and deal only partially with questions of design, layout, and placement.

### 19.1 Graphs and Digraphs

Broadly speaking, graphs can be divided into two types: *undirected* and *directed*. An undirected graph is a set of *nodes* (or *vertices*) together with a set of pairs of those vertices, called *arcs* or *edges*. Each node in an arc of an undirected graph is said to be *incident* with that arc, and the two vertices (nodes) which make up an arc are said to be *adjacent*. A directed graph is like an undirected graph except that the arcs are *ordered pairs* of nodes. In the case of directed graphs, the term *edge* is not used; moreover, each arc in a directed graph is said to be *adjacent from* the node from which the arc emanates, and *adjacent to* the node to which the arc is directed. We use the element <graph> to encode graphs as a whole, <node> to encode nodes or vertices, and <arc> to encode arcs or edges; arcs can also be encoded by attributes on the <node> element. These elements have the following descriptions and attributes:

<graph> encodes a graph, which is a collection of nodes, and arcs which connect the nodes.

<node> encodes a node, a possibly labeled point in a graph.

<arc> encodes an arc, the connection from one node to another in a graph.

Before proceeding, some additional terminology may be helpful. We define a *path* in a graph as a sequence of nodes  $n_1, \dots, n_k$  such that there is an arc from each  $n_i$  to  $n_{i+1}$  in the sequence. A *cyclic path*, or *cycle* is a path leading from a particular node back to itself. A graph that contains at least one cycle is said to be *cyclic*; otherwise it is *acyclic*. We say, finally, that a graph is *connected* if there is a path from some node to every other node in the graph; any graph that is not connected is said to be *disconnected*.

Here is an example of an undirected, cyclic disconnected graph, in which the nodes are annotated with three-letter codes for airports, and the arcs connecting the nodes are represented by horizontal and vertical lines, with 90 degree bends used simply to avoid having to draw diagonal lines.

Next is a markup of the graph, using <arc> elements to encode the arcs.

```
<graph type="undirected" xml:id="CUG1"
  order="5" size="4">
```

<sup>113</sup>The treatment here is largely based on the characterizations of graph types in Chartrand and Lesniak (1986)

```

<label>Airline Connections in Southwestern USA</label>
<node xml:id="LAX" degree="2">
  <label>LAX</label>
</node>
<node xml:id="LVG" degree="2">
  <label>LVG</label>
</node>
<node xml:id="PHX" degree="3">
  <label>PHX</label>
</node>
<node xml:id="TUS" degree="1">
  <label>TUS</label>
</node>
<node xml:id="CIB" degree="0">
  <label>CIB</label>
</node>
<arc from="#LAX" to="#LVG"/>
<arc from="#LAX" to="#PHX"/>
<arc from="#LVG" to="#PHX"/>
<arc from="#PHX" to="#TUS"/>
</graph>

```

The first child element of <graph> may be a <label> to record a label for the graph; similarly, the <label> child of each <node> element records the labels of that node. The *order* and *size* attributes on the <graph> element record the number of nodes and number of arcs in the graph respectively; these values are optional (since they can be computed from the rest of the graph), but if they are supplied, they must be consistent with the rest of the encoding. They can thus be used to help check that the graph has been encoded and transmitted correctly. The *degree* attribute on the <node> elements record the number of arcs that are incident with that node. It is optional (because redundant), but can be used to help in validity checking: if a value is given, it must be consistent with the rest of the information in the graph. Finally, the *from* and *to* attributes on the <arc> elements provide pointers to the nodes connected by those arcs. Since the graph is undirected, no directionality is implied by the use of the *from* and *to* attributes; the values of these attributes could be interchanged in each arc without changing the graph.

The *adj*, *adjFrom*, and *adjTo* attributes of the <node> element provide an alternative method of representing unlabeled arcs, their values being pointers to the nodes which are adjacent to or from that node. The *adj* attribute is to be used for undirected graphs, and the *adjFrom* and *adjTo* attributes for directed graphs. It is a semantic error for the directed adjacency attributes to be used in an undirected graph, and vice versa. Here is a markup of the preceding graph, using the *adj* attribute to represent the arcs.

```

<graph type="undirected" xml:id="CUG2"
  order="5" size="4">
  <label>Airline Connections in Southwestern USA</label>
  <node xml:id="LAX2" degree="2"
    adj="#LVG2 #PHX2">
    <label>LAX2</label>
  </node>
  <node xml:id="LVG2" degree="2"
    adj="#LAX2 #PHX2">
    <label>LVG2</label>
  </node>
  <node xml:id="PHX2" degree="3"
    adj="#LAX2 #LVG2 #TUS2">
    <label>PHX2</label>
  </node>
  <node xml:id="TUS2" degree="1" adj="#PHX2">
    <label>TUS2</label>
  </node>
</graph>

```

```

</node>
<node xml:id="CIB2" degree="0">
  <label>CIB2</label>
</node>
</graph>

```

Note that each arc is represented twice in this encoding of the graph. For example, the existence of the arc from LAX to LVG can be inferred from each of the first two <node> elements in the graph. This redundancy, however, is not required: it suffices to describe an arc in any one of the three places it can be described (either adjacent node, or in a separate <arc> element). Here is a less redundant representation of the same graph.

```

<graph type="undirected" xml:id="CUG3"
  order="5" size="4">
  <label>Airline Connections in Southwestern USA</label>
  <node xml:id="LAX3" degree="2">
    adj="#LVG3 #PHX3">
    <label>LAX3</label>
  </node>
  <node xml:id="LVG3" degree="2" adj="#PHX3">
    <label>LVG3</label>
  </node>
  <node xml:id="PHX3" degree="3" adj="#TUS3">
    <label>PHX3</label>
  </node>
  <node xml:id="TUS3" degree="1">
    <label>TUS3</label>
  </node>
  <node xml:id="CIB3" degree="0">
    <label>CIB3</label>
  </node>
</graph>

```

Although in many cases the <arc> element is redundant (since arcs can be described using the adjacency attributes of their adjacent nodes), it has nevertheless been included in this module, in order to allow the convenient specification of identifiers, display or rendition information, and labels for each arc (using the attributes *xml:id*, *rend*, and a child <label> element).

Next, let us modify the preceding graph by adding directionality to the arcs. Specifically, we now think of the arcs as specifying selected routes from one airport to another, as indicated by the direction of the arrowheads in the following diagram.

Here is an encoding of this graph, using the <arc> element to designate the arcs.

```

<graph type="directed" xml:id="RDG1"
  order="5" size="5">

```

```

<label>Selected Airline Routes in Southwestern USA</label>
<node xml:id="LAX4" inDegree="1"
  outDegree="1">
  <label>LAX4</label>
</node>
<node xml:id="LVG4" inDegree="1"
  outDegree="1">
  <label>LVG4</label>
</node>
<node xml:id="PHX4" inDegree="2"
  outDegree="2">
  <label>PHX4</label>
</node>
<node xml:id="TUS4" inDegree="1"
  outDegree="1">
  <label>TUS4</label>
</node>
<node xml:id="CIB4" inDegree="0"
  outDegree="0">
  <label>CIB4</label>
</node>
<arc from="#LAX4" to="#LVG4"/>
<arc from="#LVG4" to="#PHX4"/>
<arc from="#PHX4" to="#LAX4"/>
<arc from="#PHX4" to="#TUS4"/>
<arc from="#TUS4" to="#PHX4"/>
</graph>

```

The attributes *inDegree* and *outDegree* indicate the number of nodes which are adjacent to and from the node concerned respectively.

Here is another encoding of the graph, using the *adjTo* and *adjFrom* attributes on nodes to designate the arcs.

```

<graph type="directed" xml:id="RDG2"
  order="5" size="5">
  <label>Selected Airline Routes in Southwestern USA</label>
  <node xml:id="LAX5" inDegree="1"
    outDegree="1" adjTo="#LVG5" adjFrom="#PHX5">
    <label>LAX5</label>
  </node>
  <node xml:id="LVG5" inDegree="1"
    outDegree="1" adjFrom="#LAX5" adjTo="#PHX5">
    <label>LVG5</label>
  </node>
  <node xml:id="PHX5" inDegree="2"
    outDegree="2" adjTo="#LAX5 #TUS" adjFrom="#LVG5 #TUS5">
    <label>PHX5</label>
  </node>
  <node xml:id="TUS5" inDegree="1"
    outDegree="1" adjTo="#PHX5" adjFrom="#PHX5">
    <label>TUS5</label>
  </node>
  <node xml:id="CIB5" inDegree="0"
    outDegree="0">
    <label>CIB5</label>
  </node>
</graph>

```

If we wish to label the arcs, say with flight numbers, then `<arc>` elements must be used to hold the `<label>` elements, as in the following example.

```
<graph type="directed" xml:id="RDG3"
  order="5" size="5">
  <label>Selected Airline Routes in Southwestern USA</label>
  <node xml:id="LAX6">
    <label>LAX6</label>
  </node>
  <node xml:id="LVG6">
    <label>LVG6</label>
  </node>
  <node xml:id="PHX6">
    <label>PHX6</label>
  </node>
  <node xml:id="TUS6">
    <label>TUS6</label>
  </node>
  <node xml:id="CIB6">
    <label>CIB6</label>
  </node>
  <arc from="#LAX6" to="#LVG6">
    <label>SW117</label>
  </arc>
  <arc from="#LVG6" to="#PHX6">
    <label>SW711</label>
  </arc>
  <arc from="#PHX6" to="#LAX6">
    <label>AA218</label>
  </arc>
  <arc from="#PHX6" to="#TUS6">
    <label>AW229</label>
  </arc>
  <arc from="#TUS6" to="#PHX6">
    <label>AW225</label>
  </arc>
</graph>
```

### 19.1.1 Transition Networks

For encoding transition networks and other kinds of directed graphs in which distinctions among types of nodes must be made, the `type` attribute is provided for `<node>` elements. In the following example, the *initial* and *final* nodes (or *states*) of the network are distinguished. It can be understood as accepting the set of strings obtained by traversing it from its initial node to its final node, and concatenating the labels.

```

<graph type="network-transition"
  xml:id="558" order="5" size="6">
  <label>(8)</label>
  <node xml:id="Q0" inDegree="0"
    outDegree="1" type="initial"/>
  <node xml:id="Q1" inDegree="2"
    outDegree="3"/>
  <node xml:id="Q2" inDegree="1"
    outDegree="1"/>
  <node xml:id="Q3" inDegree="1"
    outDegree="1"/>
  <node xml:id="Q4" inDegree="2"
    outDegree="0" type="final"/>
  <arc from="#Q0" to="#Q1">
    <label>THE</label>
  </arc>
  <arc from="#Q1" to="#Q1">
    <label>OLD</label>
  </arc>
  <arc from="#Q1" to="#Q2">
    <label>MAN</label>
  </arc>
  <arc from="#Q1" to="#Q3">
    <label>MEN</label>
  </arc>
  <arc from="#Q2" to="#Q4">
    <label>COMES</label>
  </arc>
  <arc from="#Q3" to="#Q4">
    <label>COME</label>
  </arc>
</graph>

```

A finite state transducer has two labels on each arc, and can be thought of as representing a mapping from one sequence of labels to the other. The following example represents a transducer for translating the English strings accepted by the network in the preceding example into French. The nodes have been annotated with numbers, for convenience.

```

<graph type="transducer" order="7" size="10">
  <node xml:id="T0" inDegree="0"
    outDegree="3" type="initial">
    <label>0</label>
  </node>
  <node xml:id="T1" inDegree="2"
    outDegree="1">
    <label>1</label>
  </node>
  <node xml:id="T2" inDegree="2"
    outDegree="2">
    <label>2</label>
  </node>
  <node xml:id="T3" inDegree="2"
    outDegree="2">
    <label>3</label>
  </node>
  <node xml:id="T4" inDegree="1"
    outDegree="1">
    <label>4</label>
  </node>
  <node xml:id="T5" inDegree="1"
    outDegree="1">
    <label>5</label>
  </node>
  <node xml:id="T6" inDegree="2"
    outDegree="0" type="final">
    <label>6</label>
  </node>
  <arc from="#T0" to="#T1">
    <label>THE</label>
    <label>L'</label>
  </arc>
  <arc from="#T0" to="#T2">
    <label>THE</label>
    <label>LE</label>
  </arc>
  <arc from="#T0" to="#T3">
    <label>THE</label>

```

```

    <label>LES</label>
  </arc>
  <arc from="#T1" to="#T4">
    <label>MAN</label>
    <label>HOMME</label>
  </arc>
  <arc from="#T2" to="#T1">
    <label>OLD</label>
    <label>VIEIL</label>
  </arc>
  <arc from="#T2" to="#T2">
    <label>OLD</label>
    <label>VIEIL</label>
  </arc>
  <arc from="#T3" to="#T3">
    <label>OLD</label>
    <label>VIEUX</label>
  </arc>
  <arc from="#T3" to="#T5">
    <label>MEN</label>
    <label>HOMMES</label>
  </arc>
  <arc from="#T4" to="#T6">
    <label>COMES</label>
    <label>VIENT</label>
  </arc>
  <arc from="#T5" to="#T6">
    <label>COME</label>
    <label>VIENNENT</label>
  </arc>
</graph>

```

### 19.1.2 Family Trees

The next example provides an encoding a portion of a family tree<sup>114</sup> in which nodes are used to represent individuals and parents of individuals, and arcs are used to represent common parentage and descent links. Let us suppose, further, that information about individuals is contained in feature structures, which are contained in feature-structure libraries elsewhere (see 18.4. *Feature Libraries and Feature-Value Libraries*). We can use the *value* attribute on <node> elements to point to those feature structures. In this particular representation of the graph, nodes representing females are framed by ovals, nodes representing males are framed by boxes, and nodes representing parents are framed by diamonds.

<sup>114</sup>The family tree is that of the mathematician and philosopher Bertrand Russell, whose third wife was commonly known as Peter. The information presented here is taken from Pereira and Shieber (1987).

```

<graph type="family_tree" order="13"
  size="12">
  <node xml:id="KATHR"

### 19.1.3 Historical Interpretation

For our final example, we represent graphically the relationships among various geographic areas mentioned in a seventeenth-century Scottish document. The document itself is a 'sasine', which records a grant of land from the earl of Argyll to one Donald McNeill, and reads in part as follows (abbreviations have been expanded silently, and '[...]' marks illegible passages):

Item instrument of Sasine given the said Hector Mcneil confirmed and dated 28 May 1632 [...] at Edinburgh upon the 15 June 1632

Item ane charter granted by Archibald late earl of Argyle and Donald McNeill of Gallachalzie wh makes mention that ... the said late Earl yields and grants to the said Donald MacNeill ...

All and hail the two merk land of old extent of Gallachalzie with the pertinents by and in the lordship of Knapdale within the sherrifdome of Argyll

[description of other lands granted follows ...]

This Charter is dated at Inverary the 15th May 1669

In this example, we are concerned with the land and pertinents (i.e. accompanying sources of revenue) described as ‘the two merk land of old extent of Gallachalzie with the pertinents by and in the lordship of Knapdale within the sherrifdom of Argyll’.

The passage concerns the following pieces of land:

- the Earl of Argyll's land (i.e. the lands granted by this clause of the sasine)
- two mark of land in Gallachalzie
- the pertinents for this land
- the Lordship of Knapdale
- the sherrifdom of Argyll

We will represent these geographic entities as nodes in a graph. Arcs in the graph will represent the following relationships among them:

- containment (INCLUDE)
- location within (IN)
- contiguity (BY)
- constituency (PART OF)

Note that these relationships are logically related: ‘include’ and ‘in’, for example, are inverses of each other: the Earl of Argyll's land includes the parcel in Gallachalzie, and the parcel is therefore in the Earl of Argyll's land. Given an explicit set of inference rules, an appropriate application could use the graph we are constructing to infer the logical consequences of the relationships we identify.

Let us assume that feature-structure analyses are available which describe Gallachalzie, Knapdale, and Argyll. We will link to those feature structures using the *value* attribute on the nodes representing those places. However, there may be some uncertainty as to which noun phrase is modified by the phrase ‘within the sherrifdome of Argyll’: perhaps the entire lands (land and pertinents) are in Argyll, perhaps just the pertinents are, or perhaps only Knapdale is (together with the portion of the pertinents which is in Knapdale). We will represent all three of these interpretations in the graph; they are, however, mutually exclusive, which we represent using the *exclude* attribute defined in chapter 16. *Linking, Segmentation, and Alignment*.<sup>115</sup>

We represent the graph and its encoding as follows, where the dotted lines in the graph indicate the mutually exclusive arcs; in the encoding, we use the *exclude* attribute to indicate those arcs.

<sup>115</sup>That is, the three syntactic interpretations of the clause are mutually exclusive. The notion that the pertinents are in Argyll is clearly not inconsistent with the notion that both the land in Gallachalzie and the pertinents are in Argyll. The graph given here describes the possible interpretations of the clause itself, not the sets of inferences derivable from each syntactic interpretation, for which it would be convenient to use the facilities described in chapter 18. *Feature Structures*.

The graph formalizes the following relationships:

- the Earl of Argyll's land *includes* (the parcel of land in) Gallachalzie
- the Earl of Argyll's land *includes* the pertinents of that parcel
- the pertinents are (in part) *by* the Lordship of Knapdale
- the pertinents are (in part) *part of* the Lordship of Knapdale
- the Earl of Argyll's land, or the pertinents, or the Lordship of Knapdale, is *in* the Sherrifdom of Argyll

We encode the graph thus:

```

<graph type="directed" order="7" size="9">
  <node xml:id="EARL">
    <label>Earl of Argyll's land</label>
  </node>
  <node xml:id="GALL"
    value="http://example.com/people/scots#gall">

</arc>
</graph>

```

## 19.2 Trees

A *tree* is a connected acyclic graph. That is, it is possible in a tree graph to follow a path from any vertex to any other vertex, but there are no paths that lead from any vertex to itself. A rooted tree is a directed graph based on a tree; that is, the arcs in the graph correspond to the arcs of a tree such that there is exactly one node, called the *root*, for which there is a path from that node to all other nodes in the graph. For our purposes, we may ignore all trees except for rooted trees, and hence we shall use the <tree> element for rooted trees, and the <root> element for its root. The nodes adjacent to a given node are called its *children*, and the node adjacent from a given node is called its *parent*. Nodes with both a parent and children are called *internal nodes*, for which we use the <iNode> element. A node with no children is tagged as a <leaf>. If the children of a node are ordered from left to right, then we say that that node is *ordered*. If all the nodes of a tree are ordered, then we say that the tree is an *ordered tree*. If some of the nodes of a tree are ordered and others are not, then the tree is a *partially ordered tree*. The ordering of nodes and trees may be specified by an attribute; we take the default ordering for trees to be ordered, that roots inherit their ordering from the trees in which they occur, and internal nodes inherit their ordering from their

parents. Finally, we permit a node to be specified as following other nodes, which (when its parent is ordered) it would be assumed to precede, giving rise to crossing arcs. The elements used for the encoding of trees have the following descriptions and attributes.

**<tree>** encodes a tree, which is made up of a root, internal nodes, leaves, and arcs from root to leaves.

*@arity* gives the maximum number of children of the root and internal nodes of the tree.

*@ord* (ordered) indicates whether or not the tree is ordered, or if it is partially ordered.

*@order* gives the order of the tree, i.e., the number of its nodes.

**<root>** (root node) represents the root node of a tree.

*@value* identifies the root node of the network by pointing to a feature structure or other analytic element.

*@children* identifies the elements which are the children of the root node.

*@ord* (ordered) indicates whether or not the root is ordered.

*@outDegree* gives the out degree of the root, the number of its children.

**<iNode>** (intermediate (or internal) node) represents an intermediate (or internal) node of a tree.

*@value* indicates an intermediate node, which is a feature structure or other analytic element.

*@children* provides a list of identifiers of the elements which are the children of the intermediate node.

*@parent* provides the identifier of the element which is the parent of this node.

*@ord* (ordered) indicates whether or not the internal node is ordered.

*@follow* provides the identifier of an element which this node follows.

*@outDegree* gives the out degree of an intermediate node, the number of its children.

**<leaf>** encodes the leaves (terminal nodes) of a tree.

*@value* provides a pointer to a feature structure or other analytic element.

*@parent* provides the identifier of parent of a leaf.

*@follow* provides an identifier of an element which this leaf follows.

Here is an example of a tree. It represents the order in which the operators of addition (symbolized by +), exponentiation (symbolized by \*\*) and division (symbolized by /) are applied in evaluating the arithmetic formula  $((a^{**2})+(b^{**2}))/((a+b)^{**2})$ . In drawing the graph, the root is placed on the far right, and directionality is presumed to be to the left.

```

<tree n="ex1" arity="2" ord="true" order="12">
  <root xml:id="G-DIV1"
    children="#PLU1 #EXP1">
    <label>/</label>
  </root>
  <iNode xml:id="PLU1" parent="#G-DIV1"
    children="#EXP2 #EXP3">
    <label>+</label>
  </iNode>
  <iNode xml:id="EXP1" parent="#G-DIV1"
    children="#PLU2 #NUM2.3">
    <label>**</label>
  </iNode>
  <iNode xml:id="EXP2" parent="#PLU1"
    children="#VARA1 #NUM2.1">
    <label>**</label>
  </iNode>
  <iNode xml:id="EXP3" parent="#PLU1"
    children="#VARB1 #NUM2.2">
    <label>**</label>
  </iNode>
  <iNode xml:id="PLU2" parent="#EXP1"
    children="#VARA2 #VARB2">
    <label>+</label>
  </iNode>
  <leaf xml:id="VARA1" parent="#EXP2">
    <label>a</label>
  </leaf>
  <leaf xml:id="NUM2.1" parent="#EXP2">
    <label>2</label>
  </leaf>

```

```

<leaf xml:id="VARB1" parent="#EXP3">
  <label>b</label>
</leaf>
<leaf xml:id="NUM2.2" parent="#EXP3">
  <label>2</label>
</leaf>
<leaf xml:id="VARA2" parent="#PLU2">
  <label>a</label>
</leaf>
<leaf xml:id="VARB2" parent="#PLU2">
  <label>b</label>
</leaf>
<leaf xml:id="NUM2.3" parent="#EXP1">
  <label>2</label>
</leaf>
</tree>

```

In this encoding, the *arity* attribute represents the *arity* of the tree, which is the greatest value of the *outDegree* attribute for any of the nodes in the tree. If, as in this case, *arity* is 2, we say that the tree is a *binary* tree.

Since the left-to-right (or top-to-bottom!) order of the children of the two + nodes does not affect the arithmetic result in this case, we could represent in this tree all of the arithmetically equivalent formulas involving its leaves, by specifying the attribute *ord* as false on those two <iNode> elements, the attribute *ord* as true on the <root> and other <iNode> elements, and the attribute *ord* as partial on the <tree> element, as follows.

```

<tree n="ex2" ord="partial" arity="2"
  order="13">
  <root xml:id="div1" ord="true"
    children="#plu1 #exp1">
    <label>/</label>
  </root>
  <iNode xml:id="plu1" ord="false"
    parent="#div1" children="#exp2 #exp3">
    <label>+</label>
  </iNode>
  <iNode xml:id="exp1" ord="true"
    parent="#div1" children="#plu2 #num2.3">
    <label>**</label>
  </iNode>
  <iNode xml:id="exp2" ord="true"
    parent="#plu1" children="#var1 #num2.1">
    <label>**</label>
  </iNode>
  <iNode xml:id="exp3" ord="true"
    parent="#plu1" children="#varb1 #num2.2">
    <label>**</label>
  </iNode>
  <iNode xml:id="plu2" ord="false"
    parent="#exp1" children="#vara2 #varb2">
    <label>+</label>
  </iNode>
  <leaf xml:id="var1" parent="#exp2">
    <label>a</label>
  </leaf>
  <leaf xml:id="num2.1" parent="#exp2">
    <label>2</label>
  </leaf>

```

```

<leaf xml:id="varb1" parent="#exp3">
  <label>b</label>
</leaf>
<leaf xml:id="num2.2" parent="#exp3">
  <label>2</label>
</leaf>
<leaf xml:id="vara2" parent="#plu2">
  <label>a</label>
</leaf>
<leaf xml:id="varb2" parent="#plu2">
  <label>b</label>
</leaf>
<leaf xml:id="num2.3" parent="#exp1">
  <label>2</label>
</leaf>
</tree>

```

This encoding represents all of the following:

- $((a^{**2})+(b^{**2}))/((a+b)^{**2})$
- $((b^{**2})+(a^{**2}))/((a+b)^{**2})$
- $((a^{**2})+(b^{**2}))/((b+a)^{**2})$
- $((b^{**2})+(a^{**2}))/((a+b)^{**2})$

Linguistic phrase structure is very commonly represented by trees. Here is an example of phrase structure represented by an ordered tree with its root at the top, and a possible encoding.

```

<tree n="ex3" ord="true" arity="2" order="8">
  <root xml:id="GD-PP1"
    children="#GD-P1 #GD-NP1">
    <label>PP</label>
  </root>
  <iNode xml:id="GD-P1" parent="#GD-PP1"
    children="#GD-WITH1">
    <label>P</label>
  </iNode>
  <leaf xml:id="GD-WITH1" parent="#GD-P1">
    <label>with</label>
  </leaf>
  <iNode xml:id="GD-NP1" parent="#GD-PP1"

```

```

    children="#GD-THE1 #GD-PER11">
    <label>NP</label>
  </iNode>
  <iNode xml:id="GD-ART1" parent="#GD-NP1"
    children="#GD-THE1">
    <label>Art</label>
  </iNode>
  <leaf xml:id="GD-THE1" parent="#GD-ART1">
    <label>the</label>
  </leaf>
  <iNode xml:id="GD-N1" parent="#GD-NP1"
    children="#GD-PER11">
    <label>N</label>
  </iNode>
  <leaf xml:id="GD-PER11" parent="#GD-N1">
    <label>periscope</label>
  </leaf>
</tree>

```

Finally, here is an example of an ordered tree, in which a particular node which ordinarily would precede another is specified as following it. In the drawing, the XXX symbol indicates that the arc from VB to PT crosses the arc from VP to PN.

```

<tree n="ex4" arity="2" order="8" ord="true">
  <leaf xml:id="GD-LOOK1" parent="#GD-VB2">
    <label>look</label>
  </leaf>
  <leaf xml:id="GD-THEM1" parent="#GD-PN1">
    <label>them</label>
  </leaf>
  <leaf xml:id="GD-UP1" parent="#GD-PT1">
    <label>up</label>
  </leaf>
  <iNode xml:id="GD-VB2" parent="#GD-VB1"
    children="#GD-LOOK1">
    <label>VB</label>
  </iNode>
  <iNode xml:id="GD-PN1" parent="#GD-VP1"

```

```

    children="#GD-THEM1">
    <label>PN</label>
  </iNode>
  <iNode xml:id="GD-PT1" parent="#GD-VB1"
    children="#GD-UP1" follow="#GD-PN1">
    <label>PT</label>
  </iNode>
  <iNode xml:id="GD-VB1" parent="#GD-VP1"
    children="#GD-VB2 #GD-PT1">
    <label>VB</label>
