The contents of the `<desc>` element provide a brief characterization of the intended function of the object being documented in a form that permits its quotation out of context, as in the following example:

```xml
<elementSpec module="core" ident="foreign">
  <desc xml:lang="en" versionDate="2007-07-21">identifies a word or phrase as belonging to some language other than that of the surrounding text. </desc>
</elementSpec>
```

By convention, a `<desc>` element begins with a verb such as contains, indicates, specifies, etc. and contains a single clause.

Both the `<gloss>` and `<desc>` elements (in addition to `<exemplum>`, `<remarks>`, and `<valDesc>`) are members of `att.translatable`, and thus carry the `versionDate` attribute. Where specifications are supplied in multiple languages, these elements may be repeated as often as needed. Each such element should carry both an `xml:lang` and a `versionDate` attribute to indicate the language used and the date on which the translated text was last checked against its source.

The `<equiv>` element is used to document equivalencies between the concept represented by this object and the same concept as described in other schemes or ontologies. The `uri` attribute is used to supply a pointer to some location where such external concepts are defined. For example, to indicate that the TEI `<death>` element corresponds to the concept defined by the CIDOC CRM category E69, the declaration for the former might begin as follows:

```xml
<elementSpec module="namesdates" ident="death">
  <equiv name="E69" url="http://cidoc.ics.forth.gr/"/>
  <desc>
</desc>
</elementSpec>
```

The `<equiv>` element may also be used to map newly-defined elements onto existing constructs in the TEI, using the `filter` and `name` attributes to point to an implementation of the mapping. This is useful when a TEI customization
(see 23.3. Customization) defines ‘shortcuts’ for convenience of data entry or markup readability. For example, suppose that in some TEI customization an element `<bo>` has been defined which is conceptually equivalent to the standard markup construct `<hi rend="bold">`. The following declarations would additionally indicate that instances of the `<bo>` element can be converted to canonical TEI by obtaining a filter from the URI specified, and running the procedure with the name `bold`. The `mimeType` attribute specifies the language (in this case XSL) in which the filter is written:

```xml
<elementSpec ident="bo"
    ns="http://www.example.com/ns/nonTEI">
    <equiv filter="http://www.example.com/equiv-filter.xsl"
        mimeType="text/xsl" name="bold"/>
    <gloss>bold</gloss>
    <desc>contains a sequence of characters rendered in a bold face.</desc>
</elementSpec>
```

The `<altIdent>` element is used to provide an alternative name for an object, for example using a different natural language. Thus, the following might be used to indicate that the `<abbr>` element should be identified using the German word *Abkürzung*:

```xml
<elementSpec ident="abbr" mode="change">
    <altIdent xml:lang="de">Abkürzung</altIdent>
</elementSpec>
```

In the same way, the following specification for the `<graphic>` element indicates that the attribute `url` may also be referred to using the alternate identifier `href`:

```xml
<elementSpec ident="graphic" mode="change">
    <attList>
        <attDef mode="change" ident="url">
            <altIdent>href</altIdent>
        </attDef>
    </attList>
</elementSpec>
```

By default, the `<altIdent>` of a component is identical to the value of its `ident` attribute.

The `<remarks>` element contains any additional commentary about how the item concerned may be used, details of implementation-related issues, suggestions for other ways of treating related information etc., as in the following example:

```xml
<elementSpec module="core" ident="foreign">
</elementSpec>
<remarks>
    <p>This element is intended for use only where no other element is available to mark the phrase or words concerned. The global `<att xml:lang>` attribute should be used in preference to this element where it is intended to mark the language of the whole of some text element.</p>
    <p>The `<gi>` distinct element may be used to identify phrases belonging to
```
A specification element will usually conclude with a list of references, each tagged using the standard `<ptr>` element, and grouped together into a `<listRef>` element: in the case of the `<foreign>` element discussed above, the list is as follows:

```
<listRef>
  <ptr target="#COHQHF"/>
</listRef>
```

where the value COHQHF is the identifier of the section in these Guidelines where this element is fully documented.

### 22.4.2 Exemplification of Components

- `<exemplum>` (exemplum) groups an example demonstrating the use of an element along with optional paragraphs of commentary.
- `<eg>` (example) contains any kind of illustrative example.
- `<egXML>` (example of XML) a single XML fragment demonstrating the use of some XML, such as elements, attributes, or processing instructions, etc., in which the `<egXML>` element functions as the root element.
  - `@valid` indicates the intended validity of the example with respect to a schema.
  - `@source [att.global.source]` specifies the source from which some aspect of this element is drawn.

The `<exemplum>` element is used to combine a single illustrative example with an optional paragraph of commentary following or preceding it. The illustrative example itself may be marked up using either the `<eg>` or the `<egXML>` element.

The `source` attribute may be used on either element to indicate the source from which an example is taken, typically by means of a pointer to an entry in an associated bibliography, as in the following example:

```
<exemplum versionDate="2008-04-06" xml:lang="fr">
  <p>L'element <gi>foreign</gi> s'applique également aux termes considered étrangers.</p>
  <egXML xmlns="http://www.tei-c.org/ns/Examples" source="#fr-ex-Queneau_Journ">
    <p>Pendant ce temps-là, dans le bureau du rez- de-chaussée, les secrétaires faisaient du <foreign xml:lang="en">hulla-hoop</foreign>.</p>
  </egXML>
</exemplum>
```

When, as here, an example contains valid XML markup, the `<egXML>` element should be used. In such a case, it will clearly be necessary to distinguish the markup within the example from the markup of the document itself. In an XML environment, this is easily done by using a different name space for the content of the `<egXML>` element. For example:

```
<p>The <gi>term</gi> element may be used to mark any technical term, thus:
  <egXML xmlns="http://www.tei-c.org/ns/Examples">
    This <term>recursion</term> is giving me a headache.</egXML></p>
```
Alternatively, the XML tagging within an example may be 'escaped', either by using entity references to represent the opening angle bracket, or by wrapping the whole example in a CDATA marked section:

```xml
<p>The <gi>term</gi> element may be used to mark any technical term, thus:
<egXML xmlns="http://www.tei-c.org/ns/Examples">
This &lt;term&gt;recursion&lt;/term&gt; is giving me a headache.</egXML></p>
```

or, equivalently:

```xml
<p>The <gi>term</gi> element may be used to mark any technical term, thus:
<egXML xmlns="http://www.tei-c.org/ns/Examples"><![CDATA[
This <term>recursion</term> is giving me a headache.]]>"</egXML></p>
```

However, escaping the markup in this way will make it impossible to validate, and should therefore generally be avoided.

If the XML contained in an example is not well-formed then it must either be enclosed in a CDATA marked section, or 'escaped' as above: this applies whether the `<eg>` or `<egXML>` is used. The `valid` attribute on `<egXML>` may be used to indicate the XML validity of the example with respect to some schema, as being valid, invalid, or feasibly valid.

The `<egXML>` element should not be used to tag non-XML examples: the general purpose `<eg>` or `<q>` elements should be used for such purposes.

### 22.4.3 Classification of Components

In the TEI scheme elements are assigned to one or more classes, which may themselves have subclasses. The following elements are used to indicate class membership:

- `<classes>` (classes) specifies all the classes of which the documented element or class is a member or subclass.
- `<memberOf>` specifies class membership of the documented element or class.
  - `@key` specifies the identifier for a class of which the documented element or class is a member or subclass.

The `<classes>` element appears within either the `<elementSpec>` or `<classSpec>` element. It specifies the classes of which the element or class concerned is a member by means of one or more `<memberOf>` child elements. Each such element references a class by means of its `key` attribute. Classes themselves are defined by the `<classSpec>` element described in section 22.6. Class Specifications below.

For example, to show that the element `<gi>` is a member of the class `model.phrase.xml`, the `<elementSpec>` which documents this element contains the following `<classes>` element:

```xml
<classes>
  <memberOf key="model.phrase.xml"/>
</classes>
```

### 22.5 Element Specifications

The `<elementSpec>` element is used to document an element type, together with its associated attributes. In addition to the elements listed above, it may contain the following subcomponents:
<content> (content model) contains a declaration of the intended content model for the element (or other construct) being specified.
@autoPrefix controls whether or not pattern names generated in the corresponding RELAX NG schema source are automatically prefixed to avoid potential nameclashes.

<constraintSpec> (constraint on schema) contains a formal constraint, typically expressed in a rule-based schema language, to which a construct must conform in order to be considered valid
@scheme supplies the name of the language in which the constraints are defined

<attList> (attribute list) contains documentation for all the attributes associated with this element, as a series of <attDef> elements.
@org (organization) specifies whether all the attributes in the list are available (org="group") or only one of them (org="choice")

<model> describes the processing intended for a specified element.
@behaviour names the process or function which this processing model uses in order to produce output.

These subcomponents are discussed in the following sections.

22.5.1 Defining Content Models

As described in 3.2 Content Models: an Example and Content Model, the content of the element being defined — that is, what elements are allowed inside it, and in what order they are permitted — is described by its content model. The content model is defined by the <content> child of <elementSpec>. There are three distinctly different ways of specifying a content model:

- The content model can be described using TEI elements defined by this chapter, as discussed in 22.5.1.1. Defining Content Models: TEI immediately below. Two such TEI elements that may be used to define a content model are <dataRef> and <valList>. But because these are most often used to define attribute values, they are discussed separately near the beginning and towards the end of 22.5.3.2. Value Specification, respectively.
- Alternatively, and primarily for backwards compatibility, the content model may be expressed using a RELAX NG pattern. This is discussed in 22.5.1.2. Defining Content Models: RELAX NG, below.
- Lastly, content models may be expressed using a schema language other than TEI or RELAX NG, but no further recommendations on doing so are provided by these Guidelines.

22.5.1.1 Defining Content Models: TEI

In the simplest case, the content model of an element may be expressed using a single <empty> element as the only child of <content>. This describes the element being defined as empty, meaning a valid instance of said element can not have any content.128

<empty> indicates the presence of an empty node within a content model.

More commonly, one or more of the following elements are used to define a content model:

<elementRef> points to the specification for some element which is to be included in a schema

<anyElement> indicates the presence of any elements in a content model

<classRef> points to the specification for an attribute or model class which is to be included in a schema

<macroRef> provides the name of a predefined macro, the expansion of which is to be inserted at a certain point in a content model.

An <elementRef> provides the name of an element which may appear at a certain point in a content model.
An <anyElement> also asserts that an element may appear at a certain point in a content model, but rather than providing the name of a particular element type that may appear, any element regardless of its name may appear (and may have any attributes). A <classRef> provides the name of a model class, members of which may appear at a certain point in content model. A <macroRef> provides the name of a predefined macro, the expansion of which is to be inserted at a certain point in a content model.

These three elements are all members of an attribute class which provides attributes that further modify their significance as follows:

att.repeatable provides attributes for the elements which define component parts of a content model.

128It would still be allowed to contain comments or processing instructions, as these are not considered part of the content model.
129The <classRef> element may be used to refer to attribute classes, but this should not be done within a <content>.
@minOccurs (minimum number of occurrences) indicates the smallest number of times this component may occur.
@maxOccurs (maximum number of occurrences) indicates the largest number of times this component may occur.

Additionally, two wrapper elements are provided to indicate whether the components listed as their children form a sequence or an alternation:

- `<sequence>` indicates that the constructs referenced by its children form a sequence
- `<alternate>` indicates that the constructs referenced by its children form an alternation

These two wrapper elements are also members of `att.repeatable`. References listed as children of `<sequence>` must appear in the order and cardinality specified. Only one of the references listed as children of `<alternate>` may appear, although the cardinality of the `<alternate>` itself applies. Thus the following fanciful content model permits either any number of `<ptr>` elements (except zero) or any number of `<ref>` elements (except zero); at least one element must be present, but having both a `<ptr>` and a `<ref>` would be invalid.

```xml
<content>
  <alternate minOccurs="1" maxOccurs="unbounded">
    <elementRef key="ptr" minOccurs="1" maxOccurs="unbounded"/>
    <elementRef key="ref" minOccurs="1" maxOccurs="unbounded"/>
  </alternate>
</content>
```

However, the following content model permits any number of either `<ptr>` or `<ref>` elements (except zero); one element must be present, and having both `<ptr>` elements and `<ref>` elements (even intermixed) would be valid.

```xml
<content>
  <alternate minOccurs="1" maxOccurs="unbounded">
    <elementRef key="ptr"/>
    <elementRef key="ref"/>
  </alternate>
</content>
```

The `<sequence>` and `<alternate>` elements may be used in combination with great expressive power. For example, in the following example, which might be imagined as a clean replacement for the content of the `<choice>` element, one and only one of the element pairs `<sic>` and `<corr>`, `<orig>` and `<reg>`, or `<abbr>` and `<expan>` is allowed.

```xml
<content>
  <alternate>
    <sequence>
      <elementRef key="sic"/>
      <elementRef key="corr"/>
    </sequence>
    <sequence>
      <elementRef key="orig"/>
      <elementRef key="reg"/>
    </sequence>
    <sequence>
      <elementRef key="abbr"/>
      <elementRef key="expan"/>
    </sequence>
  </alternate>
</content>
```
In the following example, which might be imagined as a clean replacement for the content of the `<address>` element, the encoder is given a choice of either:

- a single `<street>` followed by a single `<placeName>` followed by a single `<postCode>` followed by an optional `<country>`, or
- 2, 3, or 4 `<addrLine>` elements.

```xml
<content>
  <alternate>
    <sequence>
      <elementRef key="street"/>
      <elementRef key="placeName"/>
      <elementRef key="postCode"/>
      <elementRef key="country" minOccurs="0" maxOccurs="1"/>
    </sequence>
    <elementRef key="addrLine" minOccurs="2" maxOccurs="4"/>
  </alternate>
</content>
```

In addition to expressing where certain elements, members of a class of elements, or constructs matching a predefined macro may occur inside an element, a content model may permit a string of zero or more Unicode characters to occur at a certain point in the content model. This is indicated by supplying the element `<textNode>` within the `<content>` element.

`<textNode>` indicates the presence of a text node in a content model.

If nothing but a `<textNode>` element is present inside a `<content>` element, valid instances of the element being defined may contain a sequence of zero or more Unicode characters, but may not contain any elements.

22.5.1.2 Defining Content Models: RELAX NG

Element content models may also be defined using RELAX NG patterns. Here is a very simple example:

```xml
<content>
  <rng:text/>
</content>
```

The element within whose specification element this `<content>` element appears will have a content model which is expressed in RELAX NG as `text`, using the RELAX NG namespace. This model will be copied unchanged to the output when RELAX NG schemas are being generated. When an XML DTD is being generated, an equivalent declaration (in this case `(#PCDATA)`) will be output.

Here is a more complex example:

```xml
<content>
  <rng:group>
    <rng:ref name="fileDesc"/>
    <rng:zeroOrMore>
      <rng:ref name="model.teiHeaderPart"/>
    </rng:zeroOrMore>
    <rng:optional>
      <rng:ref name="revisionDesc"/>
    </rng:optional>
  </rng:group>
</content>
```

---

130 This content model is not used very often in the TEI scheme. Because only Unicode characters are permitted, there is no way to record characters that are not (yet) represented in Unicode. Thus in TEI instead of `<textNode>` we often use a reference to `macro.xText` which permits both Unicode characters and the `<g>` element.
This is the content model for the `teiHeader` element, expressed in the RELAX NG syntax, which again is copied unchanged to the output during schema generation. The equivalent DTD notation generated from this is `(fileDesc, (%model.teiHeaderPart;)*, revisionDesc?)`.

The RELAX NG language does not formally distinguish element names, attribute names, class names, or macro names: all names are patterns which are handled in the same way, as the above example shows. Within the TEI scheme, however, different naming conventions are used to distinguish amongst the objects being named. Unqualified names (fileDesc, revisionDesc) are always element names. Names prefixed with model. or att. (e.g. `model.teiHeaderPart` and `att.typed`) are always class names. In DTD language, classes are represented by parameter entities (%model.teiHeaderPart; in the above example); see further 1. The TEI Infrastructure.

The RELAX NG pattern names generated by an ODD processor by default include a special prefix, the default value for which is set using the `prefix` attribute on `<schemaSpec>`. The purpose of this is to ensure that the pattern name generated is uniquely identified as belonging to a particular schema, and thus avoid name clashes. For example, in a RELAX NG schema combining the TEI element `<ident>` with another element called `<ident>` from some other vocabulary, the former will be defined by a pattern called `TEI_ident` rather than simply `ident`. Most of the time, this behaviour is entirely transparent to the user; the one occasion when it is not will be where a content model (expressed using RELAX NG syntax) needs explicitly to reference either the TEI `<ident>` or the other one. In such a situation, the `autoPrefix` attribute on `<content>` may be used. For example, suppose that we wish to define a content model for `<term>` which permits either a TEI `<ident>` or the `<ident>` defined by some other vocabulary. A suitable content model would be generated from the following `<content>` element:

```xml
<content autoPrefix="false">
  <rng:choice>
    <rng:ref name="TEI_ident"/>
    <rng:ref name="ident"/>
  </rng:choice>
</content>
```

### 22.5.2 Additional Constraints

In addition to the `<content>` element, a set of general `<constraintSpec>` elements can be used to express rules about the validity of an element. Like some other specification elements, they are identifiable (using the `ident` attribute) in order that a TEI customization may override, delete or change them individually. Each `<constraintSpec>` can be expressed in any notation which is found useful; the notation used must be recorded using the `scheme` attribute.

Schematron is an ISO standard ([ISO/IEC 19757-3:2006](http://www.iso.org/iso/iso_catalogue/catalogue_tc/catalogue_detail.htm?csnumber=30984) which defines a simple XML vocabulary for an ‘assertion language’, together with a RELAX NG schema to validate it. The Schematron assertion language provides a powerful way of expressing constraints on the content of any XML document in addition to those provided by other schema languages. Such constraints can be embedded within a TEI schema specification using the methods exemplified in this chapter. An ODD processor will typically process any `<constraintSpec>` elements in a TEI specification whose `scheme` attribute indicates that they are expressed in Schematron to create an ISO-conformant Schematron schema which may be used to validate document instances.

The TEI Guidelines include some additional constraints which are expressed using the ISO Schematron language. A conformant TEI document should respect these constraints, although automatic validation of them may not be possible for all processors. A TEI customization may likewise specify additional constraints using this mechanism. Some examples of what is possible using the Schematron language are given below.

Constraints are generally used to model local rules which may be outside the scope of the target schema language. For example, in earlier versions of these Guidelines several constraints on the usage of the attributes of the TEI element `<relation>` were expressed informally as follows: ‘only one of the attributes `active` and `mutual` may be supplied; the attribute `passive` may be supplied only if the attribute `active` is supplied.’ In the current version of the Guidelines, constraint specifications expressed as Schematron rules have been added, as follows:
The constraints in the preceding example all related to attributes in the empty namespace, and the Schematron rules did not therefore need to define a TEI namespace prefix. The Schematron language `<ns>` element should be used to do this when a constraint needs to refer to a TEI element, as in the following example, which models the constraint that a TEI `<div>` must contain either no subdivisions or at least two of them:

```
<constraintSpec ident="subclauses" scheme="schematron">
  <constraint>
    <s:ns prefix="tei" uri="http://www.tei-c.org/ns/1.0"/>
    <s:rule context="tei:div">
      <s:report test="count( tei:div ) eq 1">if it contains any subdivisions, a division must contain at least two of them</s:report>
    </s:rule>
  </constraint>
</constraintSpec>
```

Schematron rules are also useful where an application needs to enforce rules on attribute values, as in the following examples which check that various types of `<title>` are provided:

```
<constraintSpec ident="introtitle" scheme="schematron">
  <constraint>
    <s:assert test="tei:fileDesc/tei:titleStmt/tei:title[@type='introductory']"> an introductory component of the title is expected </s:assert>
  </constraint>
</constraintSpec>
<constraintSpec ident="maintitle" scheme="schematron">
  <constraint>
```
22.5 Element Specifications

As a further example, Schematron may be used to enforce rules applicable to a TEI document which is going to be rendered into accessible HTML, for example to check that some sort of content is available from which the *alt* attribute of an HTML `<img>` can be created:

```xml
<constraintSpec ident="alt"
scheme="schematron">
  <constraint>
    <s:ns prefix="tei" uri="http://www.tei-c.org/ns/1.0/>
    <s:pattern id="altTags">
      <s:rule context="tei:figure">
        <s:report test="not(tei:figDesc or tei:head)" style="error">You should provide information in a figure from which we can construct an alt attribute in HTML</s:report>
      </s:rule>
    </s:pattern>
  </constraint>
</constraintSpec>
```

Schematron rules can also be used to enforce other HTML accessibility rules about tables; note here the use of a report and an assertion within one pattern:

```xml
<constraintSpec ident="tables"
scheme="schematron">
  <constraint>
    <s:ns prefix="tei" uri="http://www.tei-c.org/ns/1.0/>
    <s:pattern id="Tables">
      <s:assert test="tei:head">A `<table>` should have a caption, using a `<head>` element</s:assert>
      <s:report test="parent::tei:body">Do not use tables to lay out the document body</s:report>
    </s:rule>
  </constraint>
</constraintSpec>
```

Constraints can be expressed using any convenient language. The following example uses a pattern matching language called SPITBOL to express the requirement that title and author should be different.

```xml
<constraintSpec ident="local"
scheme="SPITBOL">
  <constraint> (output = leq(title,author) "title and author cannot be the same")
</constraint>
</constraintSpec>
```
Note that the value of scheme is SPITBOL. In order to properly constrain and document the values of scheme used in their customization file, a project may wish to create a customization that (among other things) adds and explains this value for use in validating their customization file. Thus using schemes other than those provided for by the TEI (currently schematron and isoschematron) may require somewhat more effort when creating a customization file. Such private schemes will generally be even more problematic on implementation of the constraints themselves, as it may require significant programming work. The TEI only provides this capability for the suggested values.

22.5.3 Attribute List Specification

The <attList> element is used to document information about a collection of attributes, either within an <elementSpec>, or within a <classSpec>. An attribute list can be organized either as a group of attribute definitions, all of which are understood to be available, or as a choice of attribute definitions, of which only one is understood to be available. An attribute list may thus contain nested attribute lists.

The attribute org is used to indicate whether its child <attDef> elements are all to be made available, or whether only one of them may be used. For example, the attribute list for the element <moduleRef> contains a nested attribute list to indicate that either the include or the except attribute may be supplied, but not both:

```xml
<attList>
  <!-- other attribute definitions here -->
  <attList org="choice">
    <attDef ident="include">
      <!-- definition for the include attribute -->
      <attDef>
        <attDef ident="except">
          <!-- definition for the except attribute -->
        </attDef>
    </attList>
  </attList>
</attList>
```

The <attDef> element is used to document a single attribute, using an appropriate selection from the common elements already mentioned and the following:

- `<attDef>` (attribute definition) contains the definition of a single attribute.
  - `@usage` specifies the optionality of the attribute.

- `<datatype>` (datatype) specifies the declared value for an attribute, by referring to any datatype defined by the chosen schema language.
  - `@minOccurs` (minimum number of occurrences) indicates the minimum number of times this datatype may occur in an instance of the attribute being defined
  - `@maxOccurs` (maximum number of occurrences) indicates the maximum number of times this datatype may occur in an instance of the attribute being defined

- `<dataRef>` identifies the datatype of an attribute value, either by referencing an item in an externally defined datatype library, or by pointing to a TEI-defined data specification

- `<defaultValue>` (default value) specifies the default declared value for an attribute.

- `<valDesc>` (value description) specifies any semantic or syntactic constraint on the value that an attribute may take, additional to the information carried by the `<datatype>` element.

- `<valList>` (value list) contains one or more `<valItem>` elements defining possible values.

- `<valItem>` documents a single value in a predefined list of values.

The `<attList>` within an `<elementSpec>` is used to specify only the attributes which are specific to that particular element. Instances of the element may carry other attributes which are declared by the classes of which the element is a member. These extra attributes, which are shared by other elements, or by all elements, are specified by an `<attList>` contained within a `<classSpec>` element, as described in section 22.6. Class Specifications below.

22.5.3.1 Datatypes

The ‘datatype’ (i.e. the kind of value) for an attribute may be specified using the elements `<datatype>` and `<dataRef>`. A datatype may be defined in any of the following three ways:
• by reference to an existing TEI datatype definition;
• by use of its name in the widely used schema datatype library maintained by the W3C as part of the definition of its schema language;
• by referencing its URI within some other datatype library.

The TEI defines a number of datatypes, each with an identifier beginning `teidata.`, which are used in preference to the datatypes available natively from a target schema such as RELAX NG or W3C Schema since the facilities provided by different schema languages vary so widely. The TEI datatypes available are described in section 1.4.2, Datatype Specifications above. Note that each is, of necessity, mapped eventually to an externally defined datatype such as W3C Schema's `text` or `name`, possibly combined to give more expressivity, or constrained to a particular defined usage.

It is possible to reference a W3C schema datatype directly using `name`. In this case, the child `<dataFacet>` can be used instead of `restriction` to set W3C schema compliant restrictions on the datatype. A `<dataFacet>` is particularly useful for restrictions that can be difficult to impose and to read as a regular expression pattern.

```xml
<dataRef name="decimal">
  <dataFacet name="maxInclusive" value="360.0"/>
  <dataFacet name="minInclusive" value="-360.0"/>
</dataRef>
```

Note that restrictions are either expressed with `restriction` or `<dataFacet>`, never both.

Attributes `minOccurs` and `maxOccurs` are available for the case where an attribute may take more than one value of the type specified. For example, the `target` attribute provided by the `att.pointing` class has the following declaration:

```xml
<attDef ident="target">
  <desc versionDate="2010-05-02" xml:lang="en">specifies the destination of the reference by supplying one or more URI References</desc>
  <datatype minOccurs="1" maxOccurs="unbounded">
    <dataRef key="teidata.pointer"/>
  </datatype>
</attDef>
```

indicating that the `target` attribute may take any number of values, each being of the same datatype, namely the TEI data specification `teidata.pointer`. As is usual in XML, multiple values for a single attribute are separated by one or more white space characters. Hence, values such as `#a #b #c` or `http://example.org` `http://www.tei-c.org/index.xml` may be supplied.

22.5.3.2 Value Specification

The `<valDesc>` element may be used to describe constraints on data content in an informal way: for example

```xml
=valDesc>must point to another <gi>align</gi>
  element logically preceding this one.</valDesc>
```

```xml
=valDesc>Values should be Library of Congress
  subject headings.</valDesc>
```
<valDesc>A bookseller's surname, taken from the list in <title>Pollard and Redgrave</title>
</valDesc>

Constraints expressed in this way are purely documentary; to enforce them, the <constraintSpec> element described in section 22.5.2. Additional Constraints must be used. For example, to specify that an imaginary attribute ageAtDeath must take positive integer values less than 150, the datatype teidata.numeric might be used in combination with a <constraintSpec> such as the following:

```xml
<attDef ident="ageAtDeath">
  <desc>age in years at death</desc>
  <datatype>
    <dataRef key="teidata.count"/>
  </datatype>
  <constraintSpec ident="lessThan150" scheme="schematron">
    <constraint>
      <s:report test=". >= 150">age at death must be an integer less than 150</s:report>
    </constraint>
  </constraintSpec>
</attDef>
```

The elements <altIdent>, <equiv>, <gloss> and <desc> may all be used in the same way as they are elsewhere to describe fully the meaning of a coded value, as in the following example:

```xml
<valItem ident="dub">
  <altIdent xml:lang="fr">dou</altIdent>
  <equiv name="unknown"/>
  <gloss>dubious</gloss>
  <desc>used when the application of this element is doubtful or uncertain</desc>
</valItem>
```

Where all the possible values for an attribute can be enumerated, the datatype teidata.enumerated should be used, together with a <valList> element specifying the values and their significance, as in the following example:

```xml
<valList type="closed">
  <valItem ident="req">
    <gloss>required</gloss>
  </valItem>
  <valItem ident="rec">
    <gloss>recommended</gloss>
  </valItem>
  <valItem ident="opt">
    <gloss>optional</gloss>
  </valItem>
</valList>
```

Note the use of the <gloss> element here to explain the otherwise less than obvious meaning of the codes used for these values. Since this value list specifies that it is of type closed, only the values enumerated are legal, and an ODD processor will typically enforce these constraints in the schema fragment generated.

The <valList> element can also be used to provide illustrative examples of the kinds of values expected without listing all of them. In such cases the type attribute will have the value open, as in the following example:
The datatype will be `teidata.enumerated` in either case.

The `<valList>` or `<dataRef>` elements may also be used (as a child of the `<content>` element) to put constraints on the permitted content of an element, as noted at 22.5.1.2. Defining Content Models: RELAX NG. This use is not however supported by all schema languages, and is therefore not recommended if support for non-RELAX NG systems is a consideration.

### 22.5.4 Processing Models

As far as possible, the TEI defines elements and their attributes in a way which is entirely independent of their subsequent processing, since its intention is to maximize the reusability of encoded documents and their use in multiple contexts. Nevertheless, it can be very useful to specify one or more possible models for such processing, both to clarify the intentions of the encoder, and to provide default behaviours for a software engineer to implement when documents conforming to a particular TEI customization are processed. To that end, the following elements may be used to document one or more processing models for a given element.

- `<model>` describes the processing intended for a specified element.
- `<modelGrp>` any grouping of `<model>` or `<modelSequence>` elements with a common output method
- `<modelSequence>` any sequence of model or `<modelSequence>` elements which is to be processed as a single set of actions

One or more of these elements may appear directly within an element specification to define the processing anticipated for that element, more specifically how it should be processed to produce the kind of output indicated by the `output` attribute. Where multiple such elements appear directly within an `<elementSpec>`, they are understood to document mutually exclusive processing models, possibly for different outputs or applicable in different contexts. Alternatively, the `<modelGrp>` element may be used to group alternative `<model>` elements intended for a single kind of output. The `<modelSequence>` element is provided for the case where a sequence of models is to be processed, functioning as a single unit.
A processing model suggests how a given element may be transformed to produce one or more outputs. The model is expressed in terms of behaviours and parameters, using high-level formatting concepts familiar to software engineers and web designers, such as 'block' or 'inline'. As such, it has a different purpose from existing TEI mechanisms for documenting the appearance of source materials, such as the global attributes rend, rendition and style, described in sections 2.3.4.1. Rendition and 3.3.1. What Is Highlighting? It does not necessarily describe anything present in the original source, nor does it necessarily represent its original structure or semantics. A processing model is a template description, which may be used to simplify the task of producing or customizing the stylesheets needed by a formatting engine or any other form of processor.

22.5.4.1 The TEI processing model
The <model> element is used to document the processing model intended for a particular element in an abstract manner, independently of its implementation in whatever processing language is chosen. This is achieved by means of the following attributes and elements:

- The mandatory behaviour attribute defines in broad terms how an element should be processed, for example as a block or as an inline element. The optional predicate attribute may be used to specify a subset of contexts in which this model should be applicable: for example, an element might be treated as a block element in some contexts, but not in others. The output attribute supplies a name for the output for which this model is intended, for example for screen display, for a printed reading copy, for a scholarly publication, etc. The way in which an element should be rendered is declared independently of its behaviour, using either the attribute useSourceRendition or the element <outputRendition>. These Guidelines recommend that <outputRendition> be expressed using the W3C Cascading Style Sheet Language (CSS), but other possibilities are not excluded. The particular language used may be documented by means of the <styleDefDecl> element described in 2.3.5. The Default Style Definition Language Declaration.

22.5.4.2 Output Rendition
Here is a simple example of a processing model which might be included in the specification for an element such as <hi> or <foreign>. The intent is that these elements should be presented inline using an italic font.

```xml
<model behaviour="inline">
  <outputRendition>font-style: italic;</outputRendition>
</model>
```

If the <rendition> element, or the attributes style, rend, or rendition have already been used in the source document to indicate elements that were originally rendered in italic, and we wish simply to follow this in our processing, then there is no need to include an <outputRendition> element, and the attribute useSourceRendition could be used as follows:

```xml
<model behaviour="inline" useSourceRendition="true"/>
```
Any rendition information present in the source document will be ignored unless the useSourceRendition attribute has the value true. If that is the case, then such information will be combined with any rendition information supplied by the <outputRendition> element. For example, using CSS, an element which appears in the source as follows

```html
<hi style="font-weight:bold;">this is in bold</hi>
```

would appear in bold and italic if processed by the following model

```xml
<model behaviour="inline"
      useSourceRendition="true">
  <outputRendition>font-style: italic;</outputRendition>
</model>
```

### 22.5.4.3 CSS Class

In a typical workflow processing TEI documents for display on the web, a system designer will often wish to use an externally defined CSS stylesheet. The cssClass attribute simplifies the task of maintaining compatibility amongst the possibly many applications using such a stylesheet and also enables a TEI application to specify the names of classes to be used for particular processing models. For example, supposing that the associated CSS stylesheet includes a CSS class called `labeled-list`, the following processing model might be used to request it be used for `<list>` elements containing a child `<label>` element:

```xml
<elementSpec ident="list" mode="change">
  <model predicate="label" behaviour="list"
          cssClass="labeled-list"/>
</elementSpec>
```

In the following example, a table will be formatted using renditional information provided in the source if that is available, or by an external stylesheet, using one of the CSS classes specified, if it is not:

```xml
<elementSpec mode="change" ident="table">
  <!-- Preserve original rendition for tables which contain @rendition hints -->
  <model predicate=".//row/@rendition or .//cell/@rendition"
          behaviour="table" useSourceRendition="true"/>
  <!-- Use bootstrap for default table styling -->
  <model behaviour="table"
          useSourceRendition="true"
          cssClass="table table-hover table-bordered"/>
</elementSpec>
```

As discussed further below, the input data available to a processing model is by default the content of the element being processed, together with its child nodes.

### 22.5.4.4 Model Contexts and Outputs

Sometimes different processing models are required for the same element in different contexts. For example, we may wish to process the `<quote>` element as an inline italic element when it appears inside a `<p>` element, but as an indented block when it appears elsewhere. To achieve this, we need to change the specification for the `<quote>` element to include two `<model>` elements as follows:
As noted above, these two models are mutually exclusive. The first processing model will be used only for elements which match the XPath expression given as value for the *predicate* attribute. All other element occurrences will use the second processing model.

When, as here, multiple behaviours are required for the same element, it will often be the case that the appropriate processing will depend on the context. It may however be the case that the choice of an appropriate model will be made on the basis of the intended output. For example, we might wish to define quite different behaviours when a document is to be displayed on a mobile device and when it is to be displayed on a desktop screen. Different behaviours again might be specified for a print version intended for the general reader, and for a print version aimed at the technical specialist.

The `<modelGrp>` element can be used to group together all the processing models which have in common a particular intended output, as in the following example:

```
<modelGrp output="mobile">
  <model behaviour="inline" predicate="@rend='inline'">
    <outputRendition>font-size: 7pt;</outputRendition>
  </model>
  <model behaviour="block" predicate="@rend='block'">
    <outputRendition>text-color: red;</outputRendition>
  </model>
</modelGrp>

<modelGrp output="print">
  <model behaviour="inline" predicate="@rend='inline'">
    <outputRendition>font-size: 12pt;</outputRendition>
  </model>
  <model behaviour="block" useSourceRendition="true" predicate="@rend='block'">
    <outputRendition>text-align: center;</outputRendition>
  </model>
</modelGrp>
```

### 22.5.4.5 Behaviours and their parameters

In the examples above we have used without explanation or definition two simple *behaviours*: inline and block, but many other behaviours are possible. A list of recommended behaviour names forms part of the specification for the element `<model>`. A processing model can specify any named behaviour, some of which have additional parameters. The *parameters* of a *behaviour* resemble the arguments of a function in many programming languages: they provide names which can be used to distinguish particular parts of the input data available to the process used to implement the behaviour in question.

The following elements are used to represent and to define parameters:

- `<param>` provides a parameter for a model behaviour by supplying its name and an XPath expression identifying the location of its content.
  
  - `@name` a name for the parameter being supplied
22.5 Element Specifications

<paramList> list of parameter specifications
<paramSpec> supplies specification for one parameter of a model behaviour

By default, a processor implementing the TEI processing model for a particular element has available to it as input data the content of the element itself, and all of its children. One or more <param> elements may be supplied within a <model> element to specify parameters which modify this, either by selecting particular parts of the default input data, or by selecting data which would not otherwise be available. In either case, the value supplied for the parameter is given as an XPath expression, evaluated with respect to the element node being processed. An arbitrary name (defined in the corresponding <paramSpec>) is also supplied to a processor to identify each parameter.

For example, an element such as the TEI <ref> element will probably be associated with a processing model which treats it as a hyperlink. But a hyperlink (in most implementations) often has two associated pieces of information: the address indicated, and some textual content serving to label the link. In HTML, the former is provided as value of the href element, and the latter by the content of an <a> element. In the following processing model we define a behaviour called link, which will use whatever is indicated by the parameter called uri to provide the former, while the latter is provided by the content of the <ref> element itself:

```xml
<elementSpec ident="ref" mode="add">
  <model behaviour="link">
    <param name="uri" value="@target"/>
    <param name="content" value="."/>
  </model>
</elementSpec>
```

The value attribute of a <param> element supplies an XPath expression that indicates where the required value may be found. The context for this XPath is the element which is being processed; hence in this example, the uri parameter takes the value of the target attribute on the <ref> element being processed. The content parameter indicates that the content of that <ref> element should be provided as its value. (This parameter is not strictly necessary, since by default the whole content of the element being processed is always available to a processor, but supplying it in this way makes the procedure more explicit).

All the parameters available for a given behaviour are defined as a part of the definition of the behaviour itself, as further discussed in section 22.5.4.8. Defining a processing model below.

As a further example, the TEI <choice> element requires a different behaviour for which the name alternate is proposed as in the following example:

```xml
<elementSpec ident="choice" mode="change">
  <model predicate="sic and corr" behaviour="alternate">
    <param name="default" value="corr"/>
    <param name="alternate" value="sic"/>
  </model>
</elementSpec>
```

The processing model shown here will be selected for processing a <choice> element which has both <sic> and <corr> child elements. The names default and alternate here are provided for convenience. The default parameter provides the value of the child <corr> element, and the alternate parameter will provide that of the child <sic> elements. If neither <param> element was supplied, both elements would still be available to an application, but the application would need to distinguish them for itself.

A <choice> element might contain multiple corrections, each with differing values for their cert attribute. In the following processing model, we will accept as value of the default attribute only those child <corr> elements which have a value high for that attribute:

```xml
<elementSpec ident="choice" mode="change">
  <model predicate="sic and corr">
```

733
A `<choice>` element might contain several different pairs of alternate elements (`<abbr>` and `<expan>`, `<orig>` and `<reg>`, etc.) We might wish to group together a set of processing models for these, for example to determine which of the possible alternatives is displayed by default whenever a `<choice>` element is processed for output to the web:

```xml
<elementSpec ident="choice" mode="change">
  <modelGrp output="web">
    <model predicate="sic and corr" behaviour="alternate">
      <param name="default" value="corr[@cert='high']"/>
      <param name="alternate" value="sic"/>
    </model>
    <model predicate="abbr and expan" behaviour="alternate">
      <param name="default" value="expan[1]"/>
      <param name="alternate" value="abbr"/>
    </model>
    <model predicate="orig and reg" behaviour="alternate">
      <param name="default" value="reg"/>
      <param name="alternate" value="orig"/>
    </model>
  </modelGrp>
</elementSpec>
```

If nothing matches the XPath defining the value of a particular parameter (e.g. if in the above example there is no correction with `cert=high`) then the `default` parameter has no value. It is left to implementors to determine how null-valued parameters should be processed.

22.5.4.6 Outputs

As noted above, the `output` attribute is used to associate particular processing models with a specific type of output. The following example documents a range of processing intentions for the `<date>` element, intended to cope with at least the following three situations:

1. there is text inside the element, and the output is print;
2. there is no text inside the element but there is a `when` attribute, and the output is print;
3. there is a `when` attribute, there is text inside the element, and the output is web.

```xml
<elementSpec ident="date" mode="change">
  <modelGrp output="print">
    <model predicate="text()" behaviour="inline"/>
    <model predicate="@when and not(text())" behaviour="inline">
      <param name="content" value="@when"/>
    </model>
  </modelGrp>
</elementSpec>
```
For output to print we supply two processing models, one for the simplest case where the content of the `<date>` is to be treated as an inline element, and the other for the case where there is no content and the value of the `when` attribute is to be used in its place. This is specified by a parameter, called `content` in this example. For output to web, we use the `alternate` behaviour discussed in the previous section to indicate that by default the content of the element will be used, while retaining access to the value of the `when` attribute, this time via a parameter called `alternate`.

### 22.5.4.7 Model sequence

As well as being combined to form model groups, several models may be combined to form a *model sequence*. All of the individual components of a model sequence are understood to be applied, rather than considered to be mutually exclusive alternatives. For example, we might wish to define two different behaviours for a `<note>` element: the inline behaviour should be used to display the value of the note number (given by its `n` attribute), while a different behaviour (here called `footnote`) should be used to display the content of the element at a specified place, given by the parameter `place`. Because both of these actions are required, the two models are grouped by a `<modelSequence>` element:

```xml
elementSpec ident="note" mode="change">
  <modelSequence output="print">
    <model behaviour="inline">
      <param name="content" value="@n"/>
    </model>
    <model behaviour="footnote">
      <param name="place" value="'foot'"/>
    </model>
  </modelSequence>
</elementSpec>
```

The value of the parameter called `place` above is an XPath expression supplying an arbitrary string ('foot'), which is therefore quoted. It is left to implementors to validate or constrain the possible values for such expressions.

### 22.5.4.8 Defining a processing model

The processing model for an element is defined using some combination of `<model>`, `<modelSequence>`, or `<modelGrp>` elements within the `<elementSpec>` element containing its specification. The processing to be carried out is defined by means of the behaviour specified for each `<model>` element, possibly supplying specified values for a number of named parameters. The parameters available for a given behaviour are specified using a number of `<param>` elements grouped together in a `<paramList>` element. This `<paramList>` is supplied within the `<valItem>` used to document and name the behaviour. Here for example is the `<valItem>` which defines the `link` behaviour presented above:

```xml
class="valItem" ident="link">
  <desc>Create a hyperlink</desc>
  <paramList>
    <paramSpec ident="content">
      <desc>Supplies the location of some content describing the link</desc>
    </paramSpec>
  </paramList>
</valItem>
```
Similarly the `<valItem>` which defines the behaviour named alternate includes specifications for two parameters: one also called alternate and the other called default.

```xml
<valItem ident="alternate">
  <desc versionDate="2015-08-21" xml:lang="en">
    support display of alternative visualisations, for example by displaying the preferred content, by displaying both in parallel, or by toggling between the two.
  </desc>
  <paramList>
    <paramSpec ident="default">
      <desc versionDate="2015-08-21" xml:lang="en">
        supplies the location of the preferred content
      </desc>
    </paramSpec>
    <paramSpec ident="alternate">
      <desc versionDate="2015-08-21" xml:lang="en">
        supplies the location of the alternative content
      </desc>
    </paramSpec>
  </paramList>
</valItem>
```

The suggested behaviours provided by the `<model>` element are informally defined using commonly understood terminology, but specific details of how they should be implemented are left to the implementor. Such decisions may vary greatly depending on the kind of processing environment, the kind of output envisaged, etc. The intention is to reduce as far as possible any requirement for the implementor to be aware of TEI-specific rules, and to maximize the ability of the ODD to express processing intentions without fully specifying an implementation.

22.5.4.9 Implementation of Processing Models

As elsewhere in these Guidelines, the recommendations of this section are intended to be implementation-agnostic, not favouring any particular implementation method or technology. An implementor may choose, for example, whether to pre-process processing model specifications into a free standing ‘pipeline’, or to extract and process them dynamically during document processing. However, although implementors are generally free to interpret the processing model documentation according to their own requirements, some general assumptions underlie the recommendations made here:

- If a `<model>` element has no child `<param>` elements, the action specified by its behaviour should be applied to the whole element node concerned, including its child nodes of whatever type. If that behaviour requires distinguishing particular parts of the input, an implementation may choose either to make those distinctions itself, or to raise an error.

- If a `<model>` element has no predicate or output attribute then it is assumed to apply to all instances of the element defined in its parent `<elementSpec>` for all outputs. Otherwise its applicability depends on these attributes.

- Only one of the `<model>` is to be applied for a particular instance of the element, except when they appear within a `<modelSequence>`.

- A ‘matching’ model is one where the element to be processed satisfies the XPath in the predicate attribute of the `<model>` or `<modelSequence>` and the current output method matches the method specified in the output attribute of the `<model>`, `<modelSequence>`, or a containing `<modelGrp>`. A `<model>` or `<modelSequence>` without a
22.6 Class Specifications

A predicate always matches the element to be processed. A `<model>`, `<modelGrp>`, or `<modelSequence>` without an output attribute matches any output method.

- Processing Model implementations must execute only the first matching `<model>` or `<modelSequence>` in document order.
- If there are two or more `<model>` elements provided for an `<elementSpec>` but they have different output attributes then the implementation should choose the `<model>` appropriate to the desired output.
- If there are two or more `<model>` elements provided for an `<elementSpec>` but they have different predicate attributes then the implementation should choose the `<model>` whose predicate provides the most specific context (where specific is understood in the same way as in XSLT).

In the following example, which shows part of the element specification for the `<head>` element, there are two `<model>` elements, one with and one without a predicate attribute:

```xml
<model behaviour="inline"
      predicate="parent::list">
  <desc versionDate="2015-03-02"
      xml:lang="en">Model for list headings</desc>
</model>

<model behaviour="heading">
  <desc versionDate="2016-03-02"
      xml:lang="en">Default model for all headings.</desc>
</model>
```

In this example, an implementation should use the first processing model only for `<head>` elements with a `<list>` element as parent; for all other `<head>` elements, the second processing model should be used.

22.6 Class Specifications

The element `<classSpec>` is used to document either an attribute class or a 'model class', as defined in section 1.3, 'The TEI Class System'. A corresponding `<classRef>` element may be used to select a specific named class from those available.

- `<classSpec>` (class specification) contains reference information for a TEI element class; that is a group of elements which appear together in content models, or which share some common attribute, or both.
- `<attList>` (attribute list) contains documentation for all the attributes associated with this element, as a series of `<attDef>` elements.
- `<memberOf>` declares that the relevant element is a member of the class specified by the `key` attribute.
- `<classRef>` points to the specification for an attribute or model class which is to be included in a schema.

A model class specification does not list all of its members. Instead, its members declare that they belong to it by means of a `<memberOf>` element contained within the relevant `<elementSpec>`. This will contain a `<memberOf>` element for each class of which the relevant element is a member, supplying the name of the relevant class. For example, the `<elementSpec>` for the element `<hi>` contains the following:

```xml
<classes>
  <memberOf key="model.hiLike"/>
</classes>
```

This indicates that the `<hi>` element is a member of the class with identifier `model.hiLike`. The `<classSpec>` element that documents this class contains the following declarations:

- `<memberOf key="model.hiLike"/>` indicates that the `<hi>` element is a member of the class with identifier `model.hiLike`. The `<classSpec>` element that documents this class contains the following declarations:
which indicate that the class model.hiLike is actually a member (or subclass) of the class model.highlighted.

The function of a model class declaration is to provide another way of referring to a group of elements. It does not confer any other properties on the elements which constitute its membership.

The attribute type is used to distinguish between 'model' and 'attribute' classes. In the case of attribute classes, the attributes provided by membership in the class are documented by an <attList> element contained within the <classSpec>. In the case of model classes, no further information is needed to define the class beyond its description, its identifier, and optionally any classes of which it is a member.

When a model class is referenced in the content model of an element (i.e. by means of a <classRef> element within the <content> of an <elementSpec>, its meaning will depend on the value of its expand attribute.

If this attribute is not specified, the <classRef> is interpreted to mean an alternated list of all the current members of the class named. For example, suppose that the members of the class model.hiLike are elements <hi>, <it>, and <bo>. Then a content model such as

```xml
<content>
  <classRef key="model.hiLike"/>
</content>
```

would be equivalent to the explicit content model:

```xml
<content>
  <alternate>
    <elementRef key="hi"/>
    <elementRef key="it"/>
    <elementRef key="bo"/>
  </alternate>
</content>
```

(or, to use RELAX NG compact syntax, (hi|it|bo)*). However, a content model of <classRef expand="sequence"/> would be equivalent to the following explicit content model:

```xml
<content>
  <sequence>
    <elementRef key="hi"/>
    <elementRef key="it"/>
    <elementRef key="bo"/>
  </sequence>
</content>
```

(or, in RELAX NG compact syntax, (hi,it,bo)*).

An attribute class (a <classSpec> of type atts) contains an <attList> element which lists the attributes that all the members of that class inherit from it. For example, the class att.interpLike defines a small set of attributes common to all elements which are members of that class: those attributes are listed by the <attList> element.
contained by the `<classSpec>` for `att.interpLike`. When processing the documentation elements for elements which are members of that class, an ODD processor is required to extend the `<attList>` (or equivalent) for such elements to include any attributes defined by the `<classSpec>` elements concerned. There is a single global attribute class, `att.global`, to which some modules contribute additional attributes when they are included in a schema.

22.7 Macro Specifications

The `<macroSpec>` element is used to declare and document predefined strings or patterns not otherwise documented by the elements described in this section. A corresponding `<macroRef>` element may be used to select a specific named pattern from those available. Patterns are used as a shorthand chiefly to describe common content models and datatypes, but may be used for any purpose. The following elements are used to represent patterns:

- `<macroSpec>` (macro specification) documents the function and implementation of a pattern.
- `<macroRef>` points to the specification for some pattern which is to be included in a schema.

   @key the identifier used for the required pattern within the source indicated.

22.8 Building a TEI Schema

The specification elements, and some of their children, are all members of the `att.identified` class, from which they inherit the following attributes:

- `att.identified` provides identifying attributes for elements which can be subsequently referenced by means of a `key` attribute.
  - `@ident` supplies the identifier by which this element may be referenced.
  - `@predeclare` says whether this object should be predeclared in the `tei` infrastructure module.
  - `@module` supplies a name for the module in which this object is to be declared.

This attribute class is a subclass of the `att.combinable` class from which it (and some other elements) inherits the following attribute:

- `att.combinable` provides attributes indicating how multiple references to the same object in a schema should be combined.
  - `@mode` specifies the effect of this declaration on its parent object.

This attribute class, in turn, is a subclass of the `att.deprecated` class, from which it inherits the following attribute:

- `att.deprecated` provides attributes indicating how a deprecated feature will be treated in future releases.
  - `@validUntil` provides a date before which the construct being defined will not be removed.

The `validUntil` attribute may be used to signal an intent to remove a construct from future versions of the schema being specified.

The `<elementSpec>`, `<attDef>` and `<schemaSpec>` specification elements also have an attribute which determines which namespace to which the object being created will belong. In the case of `<schemaSpec>` this namespace is inherited by all the elements created in the schema, unless they have their own `ns`.

- `att.namespaceable` provides attributes indicating the target namespace for an object being created.

These attributes are used by an ODD processor to determine how declarations are to be combined to form a schema or DTD, as further discussed in this section.

22.8.1 TEI customizations

As noted above, a TEI schema is defined by a `<schemaSpec>` element containing an arbitrary mixture of explicit declarations for objects (i.e. elements, classes, patterns, or macro specifications) and references to other objects containing such declarations (i.e. references to specification groups, or to modules). A major purpose of this mechanism is to simplify the process of defining user customizations, by providing a formal method for the user to combine new declarations with existing ones, or to modify particular parts of existing declarations.

In the simplest case, a user-defined schema might just combine all the declarations from two nominated modules:

```xml
<schemaSpec ident="example">
  <moduleRef key="core"/>
</schemaSpec>
```
An ODD processor, given such a document, should combine the declarations which belong to the named modules, and deliver the result as a schema of the requested type. It may also generate documentation for the elements declared by those modules. No source is specified for the modules, and the schema will therefore combine the declarations found in the most recent release version of the TEI Guidelines known to the ODD processor in use.

The value specified for the source attribute, when it is supplied as a URL, specifies any convenient location from which the relevant ODD files may be obtained. For the current release of the TEI Guidelines, a URL in the form http://www.tei-c.org/Vault/P5/x.y.z/xml/tei/odd/p5subset.xml may be used, where x.y.z represents the P5 version number, e.g. 1.3.0. Alternatively, if the ODD files are locally installed, it may be more convenient to supply a value such as ../ODDs/p5subset.xml”.

The value for the source attribute may be any form of URI. A set of TEI-conformant specifications in a form directly usable by an ODD processor must be available at the location indicated. When no source value is supplied, an ODD processor may either raise an error or assume that the location of the current release of the TEI Guidelines is intended.

If the source is specified in the form of a private URI, the form recommended is aaa:x.y.z, where aaa is a prefix indicating the markup language in use, and x.y.z indicates the version number. For example, tei:1.2.1 should be used to reference release 1.2.1 of the current TEI Guidelines. When such a URI is used, it will usually be necessary to translate it before such a file can be used in blind interchange.

The effect of a <moduleRef> element is to include in the schema all declarations provided by that module. This may be modified by means of the attributes include and except which allow the encoder to supply an explicit lists of elements from the stated module which are to be included or excluded respectively. For example:

```
<schemaSpec ident="example">
  <moduleRef key="core" except="add del orig reg"/>
  <moduleRef key="linking" include="linkGroup link"/>
</schemaSpec>
```

The schema specified here will include all the elements supplied by the core module except for <add>, <del>, <orig>, and <reg>. It will also include only the <linkGroup> and <link> elements from the linking module.

Alternatively, the element <elementRef> may be used to indicate explicitly which elements are to be included in a schema. The same effect as the preceding example might thus be achieved by the following:

```
<schemaSpec ident="example">
  <moduleRef key="core" except="add del orig reg"/>
  <elementRef key="linkGroup"/>
  <elementRef key="link"/>
</schemaSpec>
```

Note that in this last case, there is no need to specify the name of the module from which the two element declarations are to be found; in the TEI scheme, element names are unique across all modules. The module is simply a convenient way of grouping together a number of related declarations.

In the same way, a schema may select a subset of the attributes available in a specific class, using the <classRef> element to point to an attribute class:
Here, only the `corresp` attribute is included; the other attributes in the class are not available. The same effect can be achieved using `except`:

```xml
<schemaSpec ident="example">
  <moduleRef key="tei"/>
  ... ...
  <classRef key="att.global.linking"
    include="corresp"/>
  ... ...
</schemaSpec>
```

A schema may also include declarations for new elements, as in the following example:

```xml
<schemaSpec ident="example">
  <moduleRef key="header"/>
  <moduleRef key="verse"/>
  <elementSpec ident="soundClip">
    <classes>
      <memberOf key="model.pPart.data"/>
    </classes>
  </elementSpec>
</schemaSpec>
```

A declaration for the element `<soundClip>`, which is not defined in the TEI scheme, will be added to the output schema. This element will also be added to the existing TEI class `model.pPart.data`, and will thus be available in TEI conformant documents. Attributes from existing TEI classes could be added to the new element using `<attRef>`:

```xml
<schemaSpec ident="example">
  <moduleRef key="header"/>
  <moduleRef key="verse"/>
  <elementSpec ident="soundClip">
    ... ...
    <attList>
      <attRef class="att.global.source"
        name="source"/>
    </attList>
  </elementSpec>
</schemaSpec>
```

This will provide the `source` attribute from the `att.global.source` class on the new `<soundClip>` element. A schema might also include re-declarations of existing elements, as in the following example:
The effect of this is to redefine the content model for the element `<head>` as plain text, by over-riding the `<content>` child of the selected `<elementSpec>`. The attribute specification `mode="change"` has the effect of over-riding only those children elements of the `<elementSpec>` which appear both in the original specification and in the new specification supplied above: `<content>` in this example. Note that if the value for `mode` were replace, the effect would be to replace all children elements of the original specification with the the children elements of the new specification, and thus (in this example) to delete all of them except `<content>`.

A schema may not contain more than two declarations for any given component. The value of the `mode` attribute is used to determine exactly how the second declaration (and its constituents) should be combined with the first. The following table summarizes how a processor should resolve duplicate declarations; the term identifiable refers to those elements which can have a `mode` attribute:

<table>
<thead>
<tr>
<th>mode value</th>
<th>existing declaration</th>
<th>effect</th>
</tr>
</thead>
<tbody>
<tr>
<td>add</td>
<td>no</td>
<td>add new declaration to schema; process its children in add mode</td>
</tr>
<tr>
<td>add</td>
<td>yes</td>
<td>raise error</td>
</tr>
<tr>
<td>replace</td>
<td>no</td>
<td>raise error</td>
</tr>
<tr>
<td>replace</td>
<td>yes</td>
<td>retain existing declaration; process new children in replace mode; ignore existing children</td>
</tr>
<tr>
<td>change</td>
<td>no</td>
<td>raise error</td>
</tr>
<tr>
<td>change</td>
<td>yes</td>
<td>process identifiable children according to their modes; process unidentifiable children in replace mode; retain existing children where no replacement or change is provided</td>
</tr>
<tr>
<td>delete</td>
<td>no</td>
<td>raise error</td>
</tr>
<tr>
<td>delete</td>
<td>yes</td>
<td>ignore existing declaration and its children</td>
</tr>
</tbody>
</table>

### 22.8.2 Combining TEI and Non-TEI Modules

In the simplest case, all that is needed to include a non-TEI module in a schema is to reference its RELAX NG source using the `url` attribute on `<moduleRef>`. The following specification, for example, creates a schema in which declarations from the non-TEI module `svg11.rng` (defining Standard Vector Graphics) are included. To avoid any risk of name clashes, the schema specifies that all TEI patterns generated should be prefixed by the string "TEI_".

```xml
<schemaSpec prefix="TEI_" ident="testsvg">
  <moduleRef key="header"/>
  <moduleRef key="core"/>
  <moduleRef key="tei"/>
  <moduleRef key="textstructure"/>
  <moduleRef url="svg11.rng"/>
</schemaSpec>
```

This specification generates a single schema which might be used to validate either a TEI document (with the root element `<TEI>`), or an SVG document (with a root element `<svg:svg>`), but would not validate a TEI document...
containing `<svg:svg>` or other elements from the SVG language. For that to be possible, the `<svg:svg>` element must become a member of a TEI model class ([1.3. The TEI Class System]). so that it may be referenced by other TEI elements. To achieve this, we modify the last `<moduleRef>` in the above example as follows:

```
<moduleRef url="svg11.rng">
  <content>
    <rng:define name="TEI_model.graphicLike" combine="choice">
      <rng:ref name="svg"/>
    </rng:define>
  </content>
</moduleRef>
```

This states that when the declarations from the `svg11.rng` module are combined with those from the other modules, the declaration for the model class `model.graphicLike` in the TEI module should be extended to include the element `<svg:svg>` as an alternative. This has the effect that elements in the TEI scheme which define their content model in terms of that element class (notably `<figure>`) can now include it. A RELAX NG schema generated from such a specification can be used to validate documents in which the TEI `<figure>` element contains any valid SVG representation of a graphic, embedded within an `<svg:svg>` element.

### 22.8.3 Linking Schemas to XML Documents

Schemas can be linked to XML documents by means of the `<?xml-model?>` processing instruction described in the W3C Working Group Note *Associating Schemas with XML documents* (http://www.w3.org/TR/xml-model/). `<?xml-model?>` can be used for any type of schema, and may be used for multiple schemas:

```
<?xml-model href="tei_tite.rng" type="application/xml" />
<?xml-model href="checkLinks.sch" type="application/xml" schematypens="http://purl.oclc.org/dsdl/schematron" />
<?xml-model href="tei_tite.odd" type="application/tei+xml" schematypens="http://www.tei-c.org/ns/1.0" />
```

This example includes a standard RELAX NG schema, a Schematron schema which might be used for checking that all pointing attributes point at existing targets, and also a link to the TEI ODD file from which the RELAX NG schema was generated. See also [2.3.10. The Schema Specification](#) for details of another method of linking an ODD specification into your file by including a `<schemaSpec>` element in `<encodingDesc>`.

### 22.9 Module for Documentation Elements

The module described in this chapter makes available the following components:

**Module tagdocs:** Documentation of TEI and other XML markup languages

- **Elements defined:** `altIdent` `alternate` `anyElement` `att` `attDef` `attList` `attRef` `classRef` `classSpec` `classes` `code` `constraint` `constraintSpec` `content` `dataFacet` `dataRef` `dataSpec` `datatype` `defaultVal` `eg` `egXML` `elementRef` `elementSpec` `empty` `equiv` `exemplum` `gi` `ident` `listRef` `macroRef` `macroSpec` `memberOf` `model` `modelGrp` `modelSequence` `moduleRef` `moduleSpec` `outputRendition` `param` `paramList` `paramSpec` `remarks` `schemaSpec` `sequence` `specDesc` `specGrp` `specGrpRef` `specList` `tag` `TextNode` `val` `valDesc` `valItem` `valList`

- **Classes defined:** `att.combinable` `att.deprecated` `att.identified` `att.namespaceable` `att.predicate` `att.repeatable` `att.translatable` `model.contentPart`

The selection and combination of modules to form a TEI schema is described in [1.2. Defining a TEI Schema](#). The elements described in this chapter are all members of one of three classes: `model.oddDecl`, `model.oddRef`, or `model.phrase.xml`, with the exceptions of `<schemaSpec>` (a member of
model.divPart) and both `<eg>` and `<egXML>` (members of model.common and model.egLike). All of these classes are declared along with the other general TEI classes, in the basic structure module documented in 1. The TEI Infrastructure.

In addition, some elements are members of the att.identified class, which is documented in 22.8.1. TEI customizations above.
23 Using the TEI

This section discusses some technical topics concerning the deployment of the TEI markup schema documented elsewhere in these Guidelines. In section 23.3, Customization we discuss the scope and variety of the TEI customization mechanisms. In 23.4, Conformance we define the notions of TEI Conformance and TEI Extension. Since the ODD markup description language defined in chapter 22, Documentation Elements is fundamental to the way conformance and customization are handled in the TEI system, these two definitional sections are followed by a section (23.5, Implementation of an ODD System) which describes the intended behaviour of an ODD processor.

23.1 Serving TEI files with the TEI Media Type

In February 2011, the media type application/tei+xml was registered with IANA for 'markup languages defined in accordance with the Text Encoding and Interchange guidelines' (RFC 6129). We recommend that any XML file whose root element is in the TEI namespace be served with the media type application/tei+xml to enable and encourage automated recognition and processing of TEI files by external applications.

23.2 Obtaining the TEI

As discussed in chapter 22, Documentation Elements, all components of the TEI schema are generated from a single set of TEI XML source files. Schemas can be generated in each of XML DTD language, W3C schema language, and RELAX NG schema language. Documentation can be generated in a variety of commonly-used document formats, including HTML, DOCX, or PDF.

TEI components are freely available over the Internet and elsewhere. The canonical home for the TEI source, the schema fragments generated from it, and example modifications, is the TEI repository at https://github.com/TEIC/TEI; versions are also available in other formats, along with copies of these Guidelines and related materials, from the TEI web site at http://www.tei-c.org/.

23.3 Customization

These Guidelines provide an encoding schema suitable for encoding a very wide range of texts, and capable of supporting a wide variety of applications. For this reason, the TEI schema supports a variety of different approaches to solving similar problems, and also defines a much richer set of elements than is likely to be necessary in any given project. Furthermore, the TEI schema may be extended in well-defined and documented ways for texts that cannot be conveniently or appropriately encoded using what is provided. For these reasons, it is almost impossible to use the TEI schema without customizing it in some way.

This section describes how the TEI encoding schema may be customized, and should be read in conjunction with chapter 22, Documentation Elements, which describes how a specific application of the TEI encoding schema should be documented. The documentation system described in that chapter is, like the rest of the TEI schema, independent of any particular schema or document type definition language.

Formally speaking, these Guidelines provide both syntactic rules about how elements and attributes may be used in valid documents and semantic recommendations about what interpretation should be attached to a given syntactic construct. In this sense, they provide both a document type definition and a document type declaration. More exactly, we may distinguish between the TEI Abstract Model, which defines a set of related concepts, and the TEI schema which defines a set of syntactic rules and constraints. Many (though not all) of the semantic recommendations are provided solely as informal descriptive prose, though some of them are also enforced by means of such constructs as datatypes (see 1.4.2, Datatype Specifications), or by schema constraints expressed using the Schematron language. Schematron constraints provide information about special kinds of validation errors dependent on conditional relationships, such as the invalidity of an attribute name or value on one element when another is present, or when, given a pair of attributes such as minOccurs and maxOccurs, the minimum value exceeds the maximum value. Schematron constraints also provide warnings when a particular element, attribute, or combination is to be deprecated in future releases of the TEI scheme, to alert users that the feature in question is no longer to be used after a certain date. Very rarely, TEI Schematron constraints offer warnings that do not explicitly break with the TEI but suggest a more efficient or less ambiguous encoding. Although the descriptions, validation errors, and warnings have been written with care, there will inevitably be cases where the intention of the contributors has not been conveyed with sufficient clarity to prevent users of these Guidelines from 'extending' them in the sense of attaching slightly variant semantics to them.
Beyond this unintentional semantic extension, some of the elements described can intentionally be used in a variety of ways; for example, the element `<note>` has an attribute `type` which can take on arbitrary string values, depending on how it is used in a document. A new type of `note`, therefore, requires no change in the existing model. On the other hand, for many applications, it may be desirable to constrain the possible values for the `type` attribute to a small set of possibilities. A schema modified in this way would no longer necessarily regard as valid the same set of documents as the corresponding unmodified TEI schema, but would remain faithful to the same conceptual model.

This section explains how the TEI schema can be customized by suppressing elements, modifying classes of elements, or adding elements. Documents which validate against an application of the TEI schema which has been customized in this way may or may not be considered 'TEI-conformant', as further discussed in section 23.4.

Conformance.

The TEI system is designed to support modification and customization in a documented way that can be validated by an XML processor. This is achieved by writing a small TEI-conformant document, known informally as an ODD (One Document Does it all), from which an appropriate processor can generate both human-readable documentation, and a schema expressed in a language such as RELAX NG or DTD. The mechanisms used to instantiate a TEI schema differ for different schema languages, and are therefore not defined here. In XML DTDs, for example, extensive use is made of parameter entities, while in RELAX NG schemas, extensive use is made of patterns. In either case, the names of elements and, wherever possible, their attributes and content models are defined indirectly. The syntax used to implement this indirection also varies with the schema language used, but the underlying constructs in the TEI Abstract Model are given the same names. This indirection makes it simpler to implement customization of the TEI system in an accessible and human-readable way.

As further discussed in section 1. The TEI Infrastructure, the TEI encoding schema comprises a set of class and macro declarations, and a number of modules. Each module is made up of element and attribute declarations, and a schema is made by combining a particular set of modules together. In the absence of any other kind of customization, when modules are combined together:

1. all the elements defined by the module (and described in the corresponding section of these Guidelines) are included in the schema;
2. each such element is identified by the canonical name given it in these Guidelines;
3. the content model of each such element is as defined by these Guidelines;
4. the names, datatypes, and permitted values declared for each attribute associated with each such element are as given in these Guidelines;
5. the elements comprising element classes and the meaning of macro declarations expressed in terms of element classes is determined by the particular combination of modules selected.

The TEI customization mechanisms allow the user to control this behaviour as follows:

1. particular elements may be suppressed, removing them from any classes in which they are members, and also from any generated schema;
2. new elements may be added to an existing class, thus making them available in macros or content models defined in terms of those classes;
3. additional attributes, or attribute values, may be specified for an individual element or for classes of elements;
4. within certain limits, attributes, or attribute values, may also be removed either from an individual element or for classes of elements;
5. the characteristics inherited by one class from another class may be modified by modifying its class membership: all members of the class then inherit the changed characteristics;
6. the set of values legal for an attribute or attribute class may be constrained or relaxed by supplying or modifying a value list, or by modifying its datatype.
7. within certain limits, the name (generic identifier) associated with an element may be changed, without changing the semantic or syntactic properties of the element;

The modification mechanisms presented in this section are quite general, and may be used to make all the types of changes just listed.

746
The recommended way of implementing and documenting all such modifications is by means of the ODD system described in chapter 22. *Documentation Elements*. In the remainder of this section we give specific examples to illustrate how that system may be applied. An ODD processor, such as the Roma application supported by the TEI, or any other comparable set of stylesheets will use the declarations provided by an ODD to generate appropriate sets of declarations in a specific schema language such as RELAX NG or the XML DTD language. We do not discuss in detail here how this should be done, since the details are schema language-specific; some background information about the methods used for XML DTD and RELAX NG schema generation is however provided in section 1.2. *Defining a TEI Schema*. Several example ODD files are also provided as part of the standard TEI release: see further section 23.3.4. *Examples of Modification* below.

### 23.3.1 Kinds of Modification

For ease of discussion, we distinguish the following different kinds of modification:

1. deletion of elements;
2. modification of content models;
3. modification of attribute and attribute-value lists;
4. modification of class membership;
5. addition of new elements;
6. renaming of elements;

Each of these is described in the following sections.

Each kind of modification changes the set of documents that will be considered valid according to the resulting schema. A schema derived from any combination of unmodified TEI declarations (an "unmodified schema") may be thought of as defining a certain set of documents. A schema deriving from a combination of modified TEI declarations (a "modified schema") will define a different set of documents. The set of documents valid according to the modified schema may or may not be properly contained by the set of documents considered to be valid according to the unmodified schema. The schema TEI-All is the special case of the unmodified schema which includes all currently available TEI modules. We use the term *clean modification* for cases where the set of documents defined by a modified schema is a proper subset of the set of documents defined by TEI-All. Where this is not the case, that is, where the modified schema considers valid some documents which TEI-All does not, we use the term *unclean modification*. Despite this terminology, unclean modifications are not particularly deprecated, and their use may often be vital to the success of a project. The concept is introduced solely to distinguish the effects of different kinds of modification.

#### 23.3.1.1 Deletion of Elements

The simplest way to modify the supplied modules is to suppress one or more of the supplied elements. This is simply done by setting the `mode` attribute to delete on an `<elementSpec>` for the element concerned.

For example, if the `<note>` element is not to be used in a particular application, but has been included via one of the supplied modules, then the schema specification concerned will contain a declaration like the following:

```
<elementSpec ident="note" mode="delete"/>
```

The `ident` attribute here supplies the canonical name of the element to be deleted and the `mode` attribute specifies what is to be done with it. There is no need to specify the module concerned, since element names are unique across all TEI modules. The full specification for a schema in which this modification is applied would thus be something like the following:

```
<schemaSpec ident="mySchema">
  <moduleRef key="core"/>
  <!-- other modules used by this customization -->
  <elementSpec ident="note" mode="delete"/>
</schemaSpec>
```
In most cases, deletion is a clean modification, since most elements are optional. Documents that are valid with respect to the modified schema are also valid according to TEI-All. To say this another way, the set of documents matching the new schema is contained by the set of documents matching the original schema.

There are however some elements in the TEI schema which have mandatory children; for example, the element `<listPerson>` must contain at least one element from the `model.personLike` class. If that class has no members because all of its member elements have been removed, then the content model cannot be satisfied. A modification which keeps `<listPerson>` but removes all of its possible children would therefore be regarded as unclean. So long as at least one member of the class remains available, however, deleting other members would not have this effect, and would therefore be regarded as a clean modification.

In general, whenever the element deleted by a modification is mandatory within the content model of some other (undeleted) element, the result is an unclean modification, and may also break the TEI Abstract Model (23.4.3, \textit{Conformance to the TEI Abstract Model}). However, the parent of a mandatory child can be safely removed if it is itself optional.

To determine whether or not an element is mandatory in a given context, the user must inspect the content model of the element concerned. In most cases, content models are expressed in terms of model classes rather than elements; hence, removing an element will generally be a clean modification, since there will generally be other members of the class available. If a class is completely depopulated by a modification, then the cleanliness of the modification will depend upon whether or not the class reference is mandatory or optional, in the same way as for an individual element.

23.3.1.2 Modification of Content Models

The content model for an element in the TEI schema is defined by means of a `<content>` element within the `<elementSpec>` which specifies it. For example, the specification for the element `<term>` provided by these Guidelines contains a `<content>` element like the following:

```xml
<content>
  <macroRef key="macro.phraseSeq"/>
</content>
```

This content model consists of a reference to a macro called `macro.phraseSeq`. Further examination shows that this macro in turn expands to an optional repeatable alternation of text (`<textNode>`) with references to three other classes (`model.gLike`, `model.phrase`, or `model.global`). For some particular application it might be preferable to insist that `<term>` elements should only contain plain text, excluding these other possibilities.\footnote{Excluding `model.gLike` is generally inadvisable however, since without it the resulting schema has no way of referencing non-Unicode characters.} This could be achieved simply by supplying a specification for `<term>` like the following:

```xml
<elementSpec ident="term" module="core"
mode="change">
  <content>
    <textNode/>
  </content>
</elementSpec>
```

This is a clean modification which does not change the meaning of a TEI element; there is therefore no need to assign the element to some other namespace than that of the TEI, though it may be considered good practice; see further 23.3.2, \textit{Modification and Namespaces} below.

A change of this kind, which simplifies the possible content of an element by reducing its model to one of its existing components, is always clean, because the set of documents matched by the resulting schema is a subset of the set of documents which would have been matched by TEI-All.

Note that content models are generally defined (as far as possible) in terms of references to model classes, rather than to explicit elements. This means that the need to modify content models is greatly reduced: if an element is deleted or modified, for example, then the deletion or modification will be available for every content model which
references that element via its class, as well as those which reference it explicitly. For this reason it is not (in general) good practice to replace class references by explicit element references, since this may have unintended side effects.

An unqualified reference to an element class within a content model generates a content model which is equivalent to an alternation of all the members of the class referenced. Thus, a content model which refers to the model class model.phrase will generate a content model in which any one of the members of that class is equally acceptable. The \(<\text{classRef}\>\) element used to reference a class has an \(<\text{expand}\>\) attribute which may be used to vary this behaviour, for example to require ‘an optional repeatable alternation of all members of a class’, ‘a sequence containing no more than one of each member of the class’, etc. as described further in 22.6. Class Specifications.

Content model changes which are not simple restrictions on an existing model should be undertaken with caution. The set of documents matching the schema which results from such changes is unlikely to be contained by the set of documents matching TEI-All, and such changes are therefore regarded as unclean. When content models are changed or extended, care should be taken to respect the existing semantics of the element concerned as stated in these Guidelines. For example, the element \(<\text{l}\>\) is defined as containing a line of verse. It would not therefore make sense to redefine its content model so that it could also include members of the class model.pLike such as \(<\text{p}\>\) or \(<\text{ab}\>\). Although syntactically feasible, such a modification would not be regarded as TEI-conformant because it breaks the TEI Abstract Model.

### 23.3.1.3 Modification of Attribute and Attribute Value Lists

The attributes applicable to a given element may be specified in two ways: they may be given explicitly, by means of an \(<\text{attList}\>\) element within the corresponding \(<\text{elementSpec}\>\), or they may be inherited from an attribute class, as specified in the \(<\text{classes}\>\) element. To add a new attribute to an element, the designer should therefore first check to see whether this attribute is already available from some existing attribute class. If it is, then the simplest method of adding it will be to make the element in question a member of that class, as further discussed below. If this is not possible, then a new \(<\text{attDef}\>\) element must be added to the existing \(<\text{attList}\>\) for the element in question.

Whichever method is adopted, the modification capabilities are the same as those available for elements. Attributes may be added or deleted from the list, using the \(<\text{mode}\>\) attribute on \(<\text{attDef}\>\) in the same way as on \(<\text{elementSpec}\>\). The ‘content’ of an attribute is defined by means of the \(<\text{datatype}\>\), \(<\text{valList}\>\), or \(<\text{valDesc}\>\) elements within the \(<\text{attDef}\>\) element. Any of these elements may be changed.

Suppose, for example, that we wish to add two attributes to the \(<\text{eg}\>\) element (used to indicate examples in a text), \(<\text{type}\>\) to characterize the example in some way, and \(<\text{valid}\>\) to indicate whether the example is considered valid or not.

A quick glance through the Guidelines indicates that the attribute class model.att.typed could be used to provide the \(<\text{type}\>\) attribute, but there is no comparable class which will provide a \(<\text{valid}\>\) attribute. The existing \(<\text{eg}\>\) element in fact has no local attributes defined for it at all: we will therefore need to add not only an \(<\text{attDef}\>\) element to define the new attribute, but also an \(<\text{attList}\>\) to hold it.

We begin by adding the new \(<\text{valid}\>\) attribute:

```xml
<elementSpec ident="eg" module="tagdocs"
mode="change">
  <attList>
    <attDef ident="valid" mode="add"
ns="http://www.example.com/ns/nonTEI">
      <desc>indicates whether or not the example is considered to be valid</desc>
      <datatype>
        <dataRef key="teidata.truthValue"/>
      </datatype>
    </attDef>
  </attList>
</elementSpec>
```

The value supplied for the \(<\text{mode}\>\) attribute on the \(<\text{attDef}\>\) element is add; if this attribute already existed on the element we are modifying this should generate an error, since a specification cannot have more than one attribute of the same name. If the attribute is already present, we can replace the whole of the existing declaration by supplying replace as the value for \(<\text{mode}\>\); alternatively, we can change some parts of an existing declaration only by supplying just the new parts, and setting change as the value for \(<\text{mode}\>\).
Because the new attribute is not defined by the TEI, it is good practice to specify a namespace for it on the `<attDef>`.

As noted above, adding the new `type` attribute involves changing this element’s class membership; we therefore discuss that in the next section (23.3.1.4. Class Modification).

The canonical name for the new attribute is `valid`, and is supplied on the `ident` attribute of the `<attDef>` element. In this simple example, we supply only a description and datatype for the new attribute; the former is given by the `<desc>` element, and the latter by the `<datatype>` element. (There are of course many other pieces of information which could be supplied, as documented in 22. Documentation Elements). The content of the `<datatype>` element is a `<dataRef>` element which references an existing TEI data specification.

It is often desirable to constrain the possible values for an attribute to a greater extent than is possible by simply supplying a TEI datatype for it. This facility is provided by the `<valList>` element, which can also appear as a child of the `<attDef>` element. Suppose for example that, rather than simply indicating whether or not the example is considered valid by means of the values true and false we wish to provide a more nuanced indication, using encoded values such as A, B, and C. A declaration like the following might be appropriate:

```xml
<elementSpec ident="eg" module="tagdocs"
mode="change">
  <attDef ident="valid"
    ns="http://www.example.com/ns/nonTEI" mode="add">
    <desc>indicates the validity of the example by supplying one of three predefined codes for it.</desc>
    <datatype>
      <dataRef key="teidata.enumerated"/>
    </datatype>
    <valList type="closed">
      <valItem ident="A">
        <desc>validity is of the highest class</desc>
      </valItem>
      <valItem ident="B">
        <desc>validity is of the second highest class</desc>
      </valItem>
      <valItem ident="C">
        <desc>validity is of the lowest class</desc>
      </valItem>
    </valList>
  </attDef>
</attList>
</elementSpec>
```

The same technique may be used to replace or extend the `<valList>` supplied as part of any attribute in the TEI schema.

23.3.1.4 Class Modification

The concept of element classes was introduced in 1.3.2. Model Classes, an understanding of it is fundamental to successful use of the TEI system. As noted there, we distinguish `model classes`, the members of which all have structural similarity, from `attribute classes`, the members of which simply share a set of attributes.

The part of an element specification which determines its class membership is an element called `<classes>`. All classes to which the element belongs must be specified within this, using a `<memberOf>` element for each.

To add an element to a class in which it is not already a member, all that is needed is to supply a new `<memberOf>` element within the `<classes>` element for the element concerned. For example, to add an element to the `att.typed` class, we include a declaration like the following:

```xml
<elementSpec ident="eg" module="tagdocs"
mode="change" ns="http://www.example.com/ns/nonTEI">
  <attDef ident="valid"
    ns="http://www.example.com/ns/nonTEI" mode="add">
    <desc>indicates the validity of the example by supplying one of three predefined codes for it.</desc>
    <datatype>
      <dataRef key="teidata.enumerated"/>
    </datatype>
    <valList type="closed">
      <valItem ident="A">
        <desc>validity is of the highest class</desc>
      </valItem>
      <valItem ident="B">
        <desc>validity is of the second highest class</desc>
      </valItem>
      <valItem ident="C">
        <desc>validity is of the lowest class</desc>
      </valItem>
    </valList>
  </attDef>
</attList>
</elementSpec>
```
Any existing class memberships for the element being changed are not affected because the `mode` attribute of the `<classes>` element is set to change (rather than its default value of replace). Consequently, in this case, the `<eg>` element retains its membership of the two classes (`model.common` and `model.graphicLike`) to which it already belongs.

Equally, to remove the attributes which an element inherits from its membership in some class, all that is needed is to remove the relevant `<memberOf>` element. For example, the element `<term>` defined in the core module is a member of two attribute classes, `att.typed` and `att.declaring`. It inherits the attributes `type` and `subtype` from the former, and the attribute `decls` from the latter. To remove the last of these attributes from this element, we need to remove it from that class:

```xml
<elementSpec ident="term" module="core"
    mode="change">
  <classes mode="change">
    <memberOf key="att.declaring"
             mode="delete"/>
  </classes>
</elementSpec>
```

If the intention is to change the class membership of an element completely, rather than simply add or remove it to or from one or more classes, the value of the `mode` attribute of `<classes>` can be set to `replace` (which is the default if no value is specified), indicating that the memberships indicated by its child `<memberOf>` elements are the only ones applicable. Thus the following declaration:

```xml
<elementSpec ident="term" module="core"
    mode="change" ns="http://www.example.com/ns/nonTEI">
  <classes mode="replace">
    <memberOf key="att.interpLike"/>
  </classes>
</elementSpec>
```

would have the effect of removing the element `<term>` from both its existing attribute classes, and adding it to the `att.interpLike` class.

If however the `mode` attribute is set to change, the implication is that the memberships indicated by its child `<memberOf>` elements are to be combined with the existing memberships for the element. To change or remove attributes inherited from an attribute class for all members of the class (as opposed to specific members of that class), it is also possible to modify the class specification itself. For example, the class `att.global.rendition` defines several attributes which are available for all elements, namely `rend`, `style`, and `rendition`. If we decide that we never wish to use the `rend` attribute, the simplest way of removing it is to supply a modified class specification for `att.global.rendition` as follows:

```xml
<classSpec ident="att.global.rendition"
            type="atts" mode="change">
  <attList>
    <attDef ident="rend" mode="delete"/>
  </attList>
</classSpec>
```
Because the mode attribute on the `<classSpec>` defining the attributes inherited through membership of this class has the value change, any of its existing identifiable components not specified in the modification above will remain unchanged. The only effect will therefore be to delete the rend attribute from the class, and hence from all elements which are members of the class.

The classes used in the TEI schema are further discussed in chapter 1. The TEI Infrastructure. Note in particular that classes are themselves classified: the attributes inherited by a member of attribute class A may come to it directly from that class, or from another class of which A is itself a member. For example, the class att.global is itself a member of the classes att.global.linking and att.global.analytic. By default, these two classes are predefined as empty. However, if (for example) the linking module is included in a schema, a number of attributes (corresp, sameAs, etc.) are defined as members of the att.global.linking class. All elements which are members of att.global will then inherit these new attributes (see further section 1.3.1. Attribute Classes). A new attribute may thus be added to the global class in two ways: either by adding it to the `<attList>` defined within the class specification for att.global; or by defining a new attribute class, and changing the class membership of the att.global class to reference it.

Such global changes should be undertaken with caution: in general removing existing non-mandatory attributes from a class will always be a clean modification, in the same way as removing non-mandatory elements. Adding a new attribute to a class however can be a clean modification only if the new attribute is labelled as belonging to some namespace other than the TEI.

The same mechanisms are available for modification of model classes. Care should be taken when modifying the model class membership of existing elements since model class membership is what determines the content model of most elements in the TEI schema, and a small change may have unintended consequences.

### 23.3.1.5 Addition of New Elements

To add a completely new element into a schema involves providing a complete element specification for it. It is recommended that the `<classes>` element of this new declaration should include a reference to at least one TEI model class. Without such a reference, the new element would not otherwise be referenced by the content model of any other TEI element, and would therefore be inaccessible within a TEI document. It is also possible to modify the content models of one or more existing elements to refer to the new element explicitly, as discussed in 23.3.1.2. Modification of Content Models but this will generally be less convenient.

For example, the three elements `<bibl>`, `<biblFull>` and `<biblStruct>` are all defined as members of the class model.biblLike. To add a fourth member (say `<myBibl>`) to this class, we need to include in the `<elementSpec>` defining our new element a `<memberOf>` element which nominates the intended class:

```xml
<elementSpec ident="myBibl" mode="add"
    ns="http://www.example.com/ns/nonTEI">
    <classes>
        <memberOf key="model.biblLike"/>
    </classes>
</elementSpec>
```

The other parts of this declaration will typically include a description for the new element and information about its content model, its attributes, etc., as further described in 22. Documentation Elements.

### 23.3.1.6 Renaming of Elements

Every element and other named markup construct in the TEI schema has a canonical name, usually composed of English language words or syllables: this name is supplied as the value of the ident attribute on the `<elementSpec>`, `<attDef>`, `<classSpec>`, or `<macroSpec>` used to define it. In some circumstances, it may be convenient for the element or attribute declaration used within a schema generated from that specification to take a different form, for example, permitting schemas to use generic identifiers from a different language, or in an abbreviated form. There may be many alternative identifiers for the same markup construct, and an ODD processor may choose which of them to use for a given purpose. Each such alternative name is supplied by means of an `<altIdent>` element within the specification element concerned.

For example, the following declaration converts `<note>` to `<nt>`:

```xml
<elementSpec ident="myBibl" mode="add"
    ns="http://www.example.com/ns/nonTEI">
    <classes>
        <memberOf key="model.biblLike"/>
    </classes>
</elementSpec>
```
Note that the `mode` attribute on the `<elementSpec>` now takes the value `change` to indicate that those parts of the element specification not supplied are to be inherited from the standard definition. The content of the `<altIdent>` element is now available for use in place of the canonical `ident` value in the schema generated.

Renaming in this way is an inherently unclean modification (because the set of documents matched by the resulting schema is not contained by the set matched by TEI-All), even though the process of converting any document in which elements have been renamed into an exactly equivalent document using canonical names is completely deterministic. Documents using such a schema should not claim to be in the TEI namespace, but either use a null namespace or some user-defined namespace, as further discussed in 23.3.2. Modification and Namespaces; this is necessary to avoid the risk of name collision between the new name and all existing TEI names as well as for reasons of conformance (see further 23.3. Customization).

### 23.3.2 Modification and Namespaces

All the elements defined by the TEI schema are labelled as belonging to a single `namespace`, maintained by the TEI and with the URI http://www.tei-c.org/ns/1.0 132 Only elements which are unmodified or which have undergone a clean modification may use this namespace. Note however that TEI-defined attributes are not associated with any namespace.

This implies that any other modification must either specify a different namespace or, equivalently, specify no namespace at all. The `ns` attribute is provided on elements `<schemaSpec>`, `<elementSpec>`, and `<attDef>` for this purpose.

Suppose, for example, that we wish to add a new attribute `topic` to the existing TEI element `<p>`. In the absence of namespace considerations, this would be an unclean modification, since `<p>` does not currently have such an attribute. The most appropriate action is to explicitly attach the new attribute to a new namespace by a declaration such as the following:

```xml
<elementSpec ident="p" mode="change">
  <attDef ident="topic" mode="add" ns="http://www.example.org/ns/nonTEI">
    <desc>indicates the topic of a TEI paragraph</desc>
    <datatype dataRef="teidata.word"/>
  </attDef>
</elementSpec>
```

Document instances using a schema derived from this ODD can now indicate clearly the status of this attribute:

```xml
<div xmlns:my="http://www.example.org/ns/nonTEI">
  <!-- ... -->
  <p n="12" my:topic="rabbits">Flopsy, Mopsy, Cottontail, and Peter...</p>
</div>
```

---

132This is not strictly the case, since the element `<egXML>` used to represent TEI examples has its own namespace, http://www.tei-c.org/ns/Examples; this is the only exception however.
Since topic is explicitly labelled as belonging to something other than the TEI namespace, we regard the modification which introduced it as clean. A namespace-aware processor will be able to validate those elements in the TEI namespace against the unmodified schema.  

Similar considerations apply when modification is made to the content model or some other aspect of an element, or when a new element is declared. All such changes should be explicitly labelled as belonging to some non-TEI namespace or to no namespace at all.  

If the ns attribute is supplied on a <schemaSpec> element, it identifies the namespace applicable to all components of the schema being specified. Even if such a schema includes unmodified modules from the TEI namespace, the elements contained by such modules will now be regarded as belonging to the namespace specified on the <schemaSpec>. This can be useful if it is desired simply to avoid namespace processing. For example, the following schema specification results in a schema called noName which has no namespace, even though it comprises declarations from the TEI header module:

```xml
<schemaSpec ns="" ident="noName">
  <moduleRef key="header"/>
</schemaSpec>
```

In addition to the TEI canonical namespace mentioned above, the TEI may also define namespaces for approved translations of the TEI schema into other languages. The namespace for such translations is the same as that for the canonical namespace, suffixed by the appropriate ISO language identifier (vi.1 Language Identification). A schema specification using the Chinese translation, for example, would use the namespace http://www.tei-c.org/ns/1.0/zh

23.3.3 Documenting the Modification  
The elements used to define a TEI customization (<schemaSpec>, <moduleRef>, <elementSpec>, etc.) will typically be used within a TEI document which supplies further information about the intended use of the new schema, the meaning and application of any new or modified elements within it, and so on. This document will typically conform to a schema which includes components from the module described in chapter 22. Documentation Elements.  

Where the customization to be documented simply consists in a selection of TEI modules, perhaps with some deletion of unwanted elements or attributes, the documentation need not specify anything further. Even here however it may be considered worthwhile to replace some of the semantic information provided by the unmodified TEI specification. For example, the <desc> element of an unmodified TEI <elementSpec> may describe an element in terms more general than appropriate to a particular project, or the <exemplum> elements within it may not illustrate the project’s actual intended usage of the element, or the <remarks> element may contain discussions of matters irrelevant to the project. These elements may therefore be replaced or deleted within an <elementSpec> as necessary.  

Radical revision is also possible. It is feasible to produce a modification in which the <teiHeader> or <text> elements are not required, or in which any other rule stated in these Guidelines is either not enforced or not enforceable. In fact, the mechanism, if used in an extreme way, permits replacement of all that the TEI has to say about every component of its schema. Such revisions would result in documents that are not TEI-conformant in even the broadest sense, and it is not intended that encoders use the mechanism in this way. We discuss exactly what is meant by the concept of TEI conformance in the next section, 23.4. Conformance.  

23.3.4 Examples of Modification  
Several examples of customizations of the TEI are provided as part of the standard release. They include the following:  

**tei_bare** The schema generated from this customization is the minimum needed for TEI Conformance. It provides only a handful of elements.
23.4 Conformance

The notion of TEI Conformance is intended to assist in the description of the format and contents of a particular XML document instance or set of documents. It may be found useful in such situations as:
- interchange or integration of documents amongst different researchers or users;
- software specifications for TEI-aware processing tools;
- agreements for the deposit of texts in, and distribution of texts from, archives;
- specifying the form of documents to be produced by or for a given project.

It is not intended to provide any other evaluation, for example of scholarly merit, intellectual integrity, or value for money. A document may be of major intellectual importance and yet not be TEI-conformant; a TEI-conformant document may be of no scholarly value whatsoever.

In this section we explore several aspects of conformance, and in particular attempt to define how the term TEI-conformant should be used. The terminology defined here should be considered normative: users and implementors of the TEI Guidelines should use the phrases ‘TEI-conformant’ and ‘TEI Extension’ only in the senses given and with the usages described.

A document is TEI-conformant if it:
- is a well-formed XML document (23.4.1. Well-formedness Criterion)
- can be validated against a TEI Schema, that is, a schema derived from the TEI Guidelines (23.4.2. Validation Constraint)
- conforms to the TEI Abstract Model (23.4.3. Conformance to the TEI Abstract Model)
- uses the TEI namespace (and other namespaces where relevant) correctly (23.4.4. Use of the TEI Namespace)
- is documented by means of a TEI-conformant ODD file (23.4.5. Documentation Constraint) which refers to the TEI Guidelines

Each of these criteria is discussed in more detail below.

A document is said to use a TEI Extension if it is a well-formed XML document which is valid against a TEI Schema which contains additional distinctions, representing concepts not present in the TEI Abstract Model, and therefore not documented in these Guidelines. Such a document cannot necessarily be transformed automatically to a TEI-conformant document without loss of information. However, since one of the goals of the TEI is to support extensions and modifications, it should not be assumed that no TEI document can include extensions: an extension
which is expressed by means of the recommended mechanisms is also a TEI-conformant document provided that those parts of it which are not extensions are TEI-conformant.

A TEI-conformant document is said to follow TEI Recommended Practice if, wherever these Guidelines prefer one encoding practice to another, the preferred practice is used.

23.4.1 Well-formedness Criterion

These Guidelines mandate the use of well-formed XML as representation format. Documents must conform to the World Wide Web Consortium recommendation of the Extensible Markup Language (XML) 1.0 (Fourth Edition) or successor editions found at http://www.w3.org/TR/xml/. Other ways of representing the concepts of the TEI Abstract Model are possible, and other representations may be considered appropriate for use in particular situations (for example, for data capture, or project-internal processing). But such alternative representations should not be considered in any way TEI-conformant.

Previous versions of these Guidelines used SGML as a representation format. With the release of P5, the only representation format supported by these Guidelines became valid XML; legacy documents in SGML format should therefore be converted using appropriate software.

A TEI-conformant document must use the TEI namespace, and therefore must also include an XML-conformant namespace declaration, as defined below (23.4.4. Use of the TEI Namespace).

The use of XML greatly reduces the need to consider hardware or software differences between processing environments when exchanging data. No special packing or interchange format is required for an XML document, beyond that defined by the W3C recommendations, and no special ‘interchange’ format is therefore proposed by these Guidelines. For discussion of encoding issues that may arise in the processing of special character sets or non-standard writing systems, see further chapter vi Languages and Character Sets.

In addition to the well-formedness criterion, the W3C defines the notion of a valid document, as being a well-formed document which matches a specific set of rules or syntactic constraints, defined by a schema. As noted above, TEI conformance implies that the schema used to determine validity of a given document should be derived from the present Guidelines, by means of an ODD which references and documents components which these Guidelines define.

23.4.2 Validation Constraint

All TEI-conformant documents must validate against a schema file that has been derived from the published TEI Guidelines, combined and documented in the manner described in section 23.3. Customization. We call the formal output of this process a TEI Schema.

The TEI does not mandate use of any particular schema language, only that this schema should have been generated from a TEI ODD file that references the TEI Guidelines. Currently available tools permit the expression of schemas in any or all of the XML DTD language, W3C XML Schema, and RELAX NG (both compact and XML formats). Some of what is syntactically possible using the ODD formalism cannot be represented by all schema languages; and there are some features of some schema languages which have no counterpart in ODD. No single schema language fully captures all the constraints implied by conformance to the TEI Abstract Model. A document which is valid according to a TEI schema represented using one schema language may not be valid against the same schema expressed in other languages; for example, the DTD language does not support namespaces.

As noted in section 23.3. Customization, many varieties of TEI schema are possible and not all of them are necessarily TEI-conformant; derivation from an ODD is a necessary but not a sufficient condition for TEI Conformance.

23.4.3 Conformance to the TEI Abstract Model

The TEI Abstract Model is the conceptual schema instantiated by the TEI Guidelines. These Guidelines define, both formally and informally, a set of abstract concepts such as ‘paragraph’ or ‘heading’, and their structural relationships, for example stating that ‘paragraph’s do not contain ‘heading’s. These Guidelines also define classes of elements, which have both semantic and structural properties in common. Those semantic and structural properties are also a part of the TEI Abstract Model; the class membership of an existing TEI element cannot therefore be changed without changing the model. Elements can however be removed from a class by deletion, and new non-TEI elements within their own namespaces can be added to existing TEI classes.

Here and elsewhere we use the word schema to refer to any formal document grammar language, irrespective of the formalism used to represent it.
23.4.3.1 Semantic Constraints

It is an important condition of TEI conformance that elements defined in the TEI Guidelines as having one specific meaning should not be used with another. For example, the element `<l>` is defined in the TEI Guidelines as containing a line of verse. A schema in which it is redefined to mean a typographic line, or an ordered queue of objects of some kind, cannot therefore be TEI-conformant, whatever its other properties.

The semantics of elements defined in the TEI Guidelines are conveyed in a number of ways, ranging from formally verifiable datatypes to informal descriptive prose. In addition, a mapping between TEI elements and concepts in other conceptual models may be provided by the `<equiv>` element where this is available.

A schema which shares equivalent concepts to those of the TEI conceptual model may be mappable to the TEI Schema by means of such a mechanism. For example, the concept of paragraph expressed in the TEI schema by the `<p>` element is probably the same concept as that expressed in the DocBook schema by the `<para>` element. Such areas of overlap facilitate interchange because elements from one namespace may be readily integrated with those from another, but do not affect the definition of conformance.

A document is said to conform to the TEI Abstract Model if features for which an encoding is proposed by the TEI Guidelines are encoded within it using the markup and other syntactic properties defined by means of a valid TEI-conformant schema. Hence, even though the names of elements or attributes may vary, a TEI-conformant document must respect the TEI Semantic Model, and be valid with respect to a TEI-conformant Schema. Although it may be possible to transform a document which follows the TEI Abstract Model into a TEI-conformant document, such a document is not itself conformant.

As noted above, the notion of semantic conformance cannot be completely enforced in a formal way. The TEI conceptual model is expressed by means of formal specification in a customization file, by means of descriptive prose in the body of these Guidelines, and implicitly by examples of usage. Any inconsistency between, for example, the text of these Guidelines and a part of a specification should be considered an error and reported to the TEI Council for correction.

23.4.3.2 Mandatory Components of a TEI Document

It is a long-standing requirement for any TEI-conformant document that it should contain a `<teiHeader>` element. To be more specific a TEI-conformant document must contain

- a single `<teiHeader>` element followed by one or more elements from the `model.resource` class; or
- in the case of a corpus or collection, a single overall `<teiHeader>` element followed by a series of `<TEI>` elements each with its own `<teiHeader>`

All `<teiHeader>` elements in a TEI-conformant document must include elements for:

**Title Statement** This should include the title of the TEI document expressed using a `<titleStmt>` element.

**Publication Statement** This should include the place and date of publication or distribution of the TEI document, expressed using the `<publicationStmt>` element.

**Source Statement** For a document derived from some previously existing document, this must include a bibliographic description of that source. For a document not so derived, this must include a brief statement that the document has no pre-existing source. In either case, this will be expressed using the `<sourceDesc>` element.

23.4.4 Use of the TEI Namespace

The Namespaces Recommendation of the W3C (Bray et al. (eds.) (2006)) provides a way for an XML document to combine markup from different vocabularies without risking name collision and consequent processing difficulties. While the scope of the TEI is large, there are many areas in which it makes no particular recommendation, or where it recommends that other defined markup schemas should be adopted, such as graphics or mathematics. It is also considered desirable that users of other markup schemas should be able to integrate documents using TEI markup with their own system. To meet these objectives without compromising the reliability of its encoding, a TEI-conformant document is required to make appropriate use of the TEI namespace.

Essentially all elements in a TEI Schema which represents concepts from the TEI Abstract Model belong to the TEI namespace, http://www.tei-c.org/ns/1.0, maintained by the TEI. A TEI-conformant document is required to declare the namespace for all the elements it contains whether these come from the TEI namespace or from other schemas.

A TEI Schema may be created which assigns TEI elements to some other namespace, or to no namespace at all. A document using such a schema cannot be considered TEI-conformant. A document which places non-TEI elements
or attributes within the TEI namespace cannot be considered TEI-conformant; such practices are strongly deprecated as they may lead to serious difficulties for processing or interchange.

23.4.5 Documentation Constraint

As noted in 23.4.2. Validation Constraint above, a TEI Schema can only be generated from a TEI ODD, which also serves to document the semantics of the elements defined by it. A TEI-conformant document should therefore always be accompanied by (or refer to) a valid TEI ODD file specifying which modules, elements, classes, etc. are in use together with any modifications applied, and from which a TEI Schema can be generated to validate the document. The TEI supplies a number of predefined TEI Customization exemplar ODD files and the schemas already generated from them (see 23.3.4. Examples of Modification), but most projects will typically need to customize the TEI beyond what these examples provide. It is assumed, for example, that most projects will customize the TEI schema by removing those elements that are not needed for the texts they are encoding, and by providing further constraints on the attribute values and element content models the TEI provides. All such customizations must be specified by means of a valid TEI ODD file.

As different sorts of customization have different implications for the interchange and interoperability of TEI documents, it cannot be assumed that every customization will necessarily result in a schema that validates only TEI-conformant documents. The ODD language permits modifications which conflict with the TEI Abstract Model, even though observing this model is a requirement for TEI Conformance. The ODD language can in fact be used to describe many kinds of markup schema, including schemas which have nothing to do with the TEI at all.

Equally, it is possible to construct a TEI Schema which is identical to that derived from a given TEI ODD file without using the ODD schema. A schema can constructed simply by combining the predefined schema language fragments corresponding with the required set of TEI modules and other statements in the relevant schema language. However, the status of such a schema with respect to the tei_all schema cannot in general be easily determined; it may therefore be impractical to determine whether such a schema represents a clean modification or an extension. This is one reason for making the presence of a TEI ODD file a requirement for conformance.

23.4.6 Varieties of TEI Conformance

The conformance status of a given document may be assessed by answering the following questions, in the order indicated:

1. Is it a valid XML document, for which a TEI Schema exists? If not, then the document cannot be considered TEI-conformant in any sense.
2. Is the document accompanied by a TEI-conformant ODD specification describing its markup schema and intended semantics? If not, then the document can only be considered TEI-conformant if it validates against a predefined TEI Schema and conforms to the TEI abstract model.
3. Does the markup in the document correctly represent the TEI abstract model? Though difficult to assess, this is essential to TEI conformance.
4. Does the document claim that all of its elements come from some namespace other than the TEI (or no namespace)? If so, the document cannot be TEI-conformant.
5. If the document claims to use the TEI namespace, in part or wholly, do the elements associated with that namespace in fact belong to it? If not, the document cannot be TEI-conformant; if so, and if all non-TEI elements and attributes are correctly associated with other namespaces, then the document may be TEI-conformant.
6. Is the document valid according to a schema made by combining all TEI modules as well as valid according to the schema derived from its associated ODD specification? If so, the document is TEI-conformant.
7. Is the document valid according to the schema derived from its associated ODD specification, but not according to tei_all? If so, the document uses a TEI extension.
8. Is it possible automatically to transform the document into a document which is valid according to tei_all, using only information supplied in the accompanying ODD and without loss of information? If so, the document is TEI-conformant.

In the following table, we examine more closely some specific, though imaginary, cases:
23.4 Conformance

</tbody>
</table>

We assume firstly that each sample document assessed here is a well-formed XML document, and that it is valid against some schema.

The document in column A is TEI-conformant. Its tagging follows the TEI Abstract Model, both as regards syntactic constraints (its <l> elements appear within <div> elements and not the reverse) and semantic constraints (its <l> elements appear to contain verse lines rather than typographic ones). It is accompanied by a valid ODD which documents exactly how it uses the TEI. All the TEI-defined elements and attributes in the document are placed in the TEI namespace. The schema against which it is valid is a 'clean' subset of the tei_all schema.

The document in column B is not a TEI document. Although it is accompanied by a valid TEI ODD, the resulting schema includes some 'unclean' modifications, and represents some concepts from the TEI Abstract Model using non-TEI elements; for example, it re-defines the content model of <p> to permit <div> within it, and it includes an element <pageTrimming> which appears to have the same meaning as the existing TEI <fw> element, but the equivalence is not made explicit in the ODD. It uses the TEI namespace correctly to identify the TEI elements it contains, but the ODD does not contain enough information automatically to convert its non-TEI elements into TEI equivalents.

The document in column C is TEI conformant. It is almost the same as the document in column A, except that the names of the elements used are not those specified for the TEI namespace. Because the ODD accompanying it contains an exact mapping for each element name (using the <altIdent> element) and there are no name conflicts, it is possible to make an automatic conversion of this document.

The document in column D is a TEI Extension. It combines elements from its own namespace with unmodified TEI elements in the TEI namespace. Its usage of TEI elements conforms to the TEI Abstract Model. Its ODD defines a new <blort> element which has no exact TEI equivalent, but which is assigned to an existing TEI class; consequently its schema is not a clean subset of tei_all. If the associated ODD provided a way of mapping this element to an existing TEI element, then this would be TEI-conformant.

The document in column E is superficially similar to document D, but because it does not use any namespace declarations (or, equivalently, it assigns unmodified TEI elements to its own namespace), it may contain name collisions; there is no way of knowing whether a <p> within it is the same as the TEI's <p> or has some other meaning. The accompanying ODD file may be used to provide the human reader with information about equivalently named elements in the TEI namespace, and hence to determine whether the document is valid with respect to the TEI Abstract Model but this is not an automatable process. In particular, cases of apparent conflict (for example use of an element <p> to represent a concept not in the TEI Abstract Model but in the abstract model of some other system, whose namespace has been removed as well) cannot be reliably resolved. By our current definition therefore, this is not a TEI document.

The document in column F is TEI-conformant. The difference between it and that in column D is that the new element <blort> which is used in this document is a specialization of an existing TEI element, and the ODD in which it is defined specifies the mapping (a <my:blort> may be automatically converted to a <tei:seg type="blort">, for example). For this to work, however, the <blort> must observe the same syntactic constraints as the <seg> if it does not, this would also be a case of TEI Extension.

The document in column G is not a TEI document. Its structure is fully documented by a valid TEI ODD, but it does not claim to represent the TEI Abstract Model, does not use the TEI namespace, and is not intended to validate against any TEI schema.

The document in column H is very like that in column A, but it lacks an accompanying ODD. Instead, the schema used to validate it is produced simply by combining TEI schema fragments in the same way as an ODD processor would, given the ODD. If the resulting schema is a clean subset of tei_all, such a document is indistinguishable
from a TEI-conformant one, but there is no way of determining (without inspection) whether this is the case if any 
modification or extension has been applied. Its status is therefore, like that of Text E, impossible to determine.

23.5 Implementation of an ODD System

This section specifies how a processing system may take advantage of the markup specification elements documented 
in chapter 22. Documentation Elements of these Guidelines in order to produce project specific user documentation, 
schemas in one or more schema languages, and validation tools for other processors.

The specifications in this section are illustrative but not normative. Its function is to further illustrate the intended 
scope and application of the elements documented in chapter 22. Documentation Elements, since it is believed that 
these may have application beyond the areas directly addressed by the TEI.

An ODD processing system has to accomplish two main tasks. A set of selections, deletions, changes, and additions 
supplied by an ODD customization (as described in 23.3. Customization) must first be merged with the published TEI 
P5 ODD specifications. Next, the resulting unified ODD must be processed to produce the desired outputs.

An ODD processor is not required to do these two stages in sequence, but that may well be the simplest approach; 
the ODD processing tools currently provided by the TEI Consortium, which are also used to process the source of 
these Guidelines, adopt this approach.

23.5.1 Making a Unified ODD

An ODD customization must contain a single <schemaSpec> element, which defines the schema to be constructed. 

<schemaSpec> (schema specification) generates a TEI-conformant schema and documentation for it.

@start specifies entry points to the schema, i.e. which patterns may be used as the root of 
documents conforming to it.
@prefix specifies a default prefix which will be prepended to all patterns relating to TEI elements, 
unless otherwise stated.
@targetLang (target language) specifies which language to use when creating the objects in a 
schema if names for elements or attributes are available in more than one language 
@docLang (documentation language) specifies which languages to use when creating 
documentation if the description for an element, attribute, class or macro is available in more 
than one language

Amongst other attributes inherited from the att.identified class, this element also carries a required ident 
attribute. This provides a name for the generated schema, which other components of the processing system may 
use to refer to the schema being generated, e.g. in issuing error messages or as part of the generated output schema 
file or files. The ns attribute may be used to specify the default namespace within which elements valid against the 
resulting schema belong, as discussed in 23.3.2. Modification and Namespaces.

The <schemaSpec> element contains an unordered series of specialized elements, each of which is of one of the 
following four types:

specifications elements from the class model.oddDecl (by default <elementSpec>, <classSpec>, <moduleSpec>, 
and <macroSpec>; these must have a mode attribute which determines how they will be processed. If the 
value of mode is add, then the object is simply copied to the output, but if it is change, delete, or replace, then 
it will be looked at by other parts of the process.

references to specifications <specGrpRef> elements refer to <specGrp> elements that occur elsewhere in this, or 
another, document. A <specGrp> element, in turn, groups together a set of ODD specifications (among other 
things, including further <specGrpRef> elements). The use of <specGrp> and <specGrpRef> permits the ODD 
markuptooccuratthepointsindocumentationwherethyarediscussed,ratherthanallinside<schemaSpec>

The target attribute of any <specGrpRef> should be followed, and the <elementSpec>, <classSpec> and 
<macroSpec>, elements in the corresponding <specGrp> should be processed as described in the previous 
item; <specGrpRef> elements should be processed as described here.

references to TEI Modules <moduleRef> elements with key attributes refer to components of the TEI. The value 
of the key attribute matches the ident attribute of the <moduleSpec> element defining a TEI module. The key

---

136 An ODD processor should recognize as erroneous such obvious inconsistencies as an attempt to include an <elementSpec> in add mode for 
an element which is already present in an imported module.
must be dereferenced by some means, such as reading an XML file with the TEI ODD specification (either from the local hard drive or off the Web), or looking up the reference in an XML database (again, locally or remotely); whatever means is used, it should return a stream of XML containing the element, class, and macro specifications collected together in the specified module. These specification elements are then processed in the same way as if they had been supplied directly within the <schemaSpec> being processed.

**References to external modules** a <moduleRef> element may also refer to a compatible external module by means of its url attribute; the content of such modules, which must be available in the RELAX NG XML syntax, are passed directly and without modification to the output schema when that is created.

Each object obtained from the TEI ODD specification using <moduleRef> by means of the key attribute must be checked against objects in the customization <schemaSpec> according to the following rules:

1. if there is an object in the ODD customization with the same value for the ident attribute, and a mode value of delete, then the object from the module is ignored;
2. if there is an object in the ODD customization with the same value for the ident attribute, and a mode value of replace, then the object from the module is ignored, and the one from the ODD customization is used in its place;
3. if there is an object in the ODD customization with the same value for the ident attribute, and a mode value of change, then the two objects must be merged, as described below;
4. if there is an object in the ODD customization with the same value for the ident attribute, and a mode value of add, then an error condition should be raised;
5. otherwise, the object from the module is copied to the result.

To merge two objects with the same ident, their component attributes and child elements must be looked at recursively. Each component may fall into one of the following four categories:

1. Some components may occur only once within the merged object (for example attributes, and <altIdent>, <content>, or <classes> elements). If such a component is found in the ODD customization, it will be copied to the output; if it is not found there, but is present in the TEI ODD specification, then that will be copied to the output.
2. Some components are grouping objects (<attList>, <valList>, for example); these are always copied to the output, and their children are then processed following the rules given in this list.
3. Some components are ‘identifiable’: this means that they are members of the att_identified class from which they inherit the ident attribute; examples include <attDef> and <valItem>. A component of this type will be processed according to its mode attribute, following the rules given above.
4. Some components may occur multiple times, but are neither grouped nor identifiable. Examples include the members of model.glossLike such as <equiv>, <desc>, <gloss>, the <exemplum>, <remarks>, <listRef>, <datatype> or <defaultValue> elements. These should be copied from both the TEI ODD specification and the ODD customization, and all occurrences included in the output.

A special problem arises with elements which are members of attribute classes, as they are permitted to override attributes inherited from a class. For example, consider this simple modification:

```xml
<elementSpec ident="p">
  <classes>
    <memberOf key="att.typed"/>
  </classes>
</elementSpec>
```

The effect of its membership in the att.typed class is to provide <p> with a type attribute and a subtype attribute. If we wish <p> to not have subtype, we could extend the customization in our schema as follows:
This means that when `<memberOf key="att.typed"/>` is processed, that class is looked up, each attribute which it defines is examined in turn, and the customization is searched for an override. If the modification is of the attribute class itself, work proceeds as usual; if, however, the modification is at the element level, the class reference is deleted and a series of `<attRef>` elements is added to the element, one for each attribute inherited from the class. Since attribute classes can themselves be members of other attribute classes, membership must be followed recursively.

The effect of the concatenation of unidentifiable components should be considered carefully. An original may have

```xml
<elementSpec ident="p">
  <desc>marks paragraphs in prose.</desc>
</elementSpec>
```

which would usefully be extended with this:

```xml
<elementSpec ident="p" mode="change">
  <desc xml:lang="es">marca párrafos en prosa.</desc>
</elementSpec>
```

to provide an alternate description in another language. Nothing prevents the user from supplying `<desc>` several times in the same language, and subsequent applications will have to decide what that may mean.

Similar considerations apply to multiple example elements, though these are less likely to cause problems in documentation. Note that existing examples can only be deleted by supplying a completely new `<elementSpec>` in replace mode, since the `<exemplum>` element is not identifiable.

In the processing of the content models of elements and the content of macros, deleted elements may require special attention. A content model like this:

```xml
<elementSpec ident="person">
  <!... ... -->
  <content>
    <alternate>
      <classRef key="model.pLike" minOccurs="1" maxOccurs="unbounded"/>
      <alternate minOccurs="0" maxOccurs="unbounded">
        <classRef key="model.personPart"/>
        <classRef key="model.global"/>
      </alternate>
    </alternate>
  </content>
</elementSpec>
```

137 The cartago program behind the Pizza Chef application, written by Michael Sperberg-McQueen for TEI P3 and P4, went to very great efforts to get this right. The XSLT transformations used by the P5 Roma application are not as sophisticated, partly because the RELAX NG language is more forgiving than DTDs.
requires no special treatment because everything is expressed in terms of model classes; if the class `model.personPart` is deleted explicitly, or removed because all of its members have been deleted, then `model.global` is left as the only child of the inner `<alternate>`. An ODD processor may or may not elect to simplify the resulting choice between nothing and `model.global` by removing the wrapper `<alternate>` element. However, such simplification may be considerably more complex in the general case and an ODD processor is therefore likely to be more successful in carrying out such simplification as a distinct stage during processing of ODD sources.

If an element refers directly to an element child, like this:

```
<elementSpec ident="figure">
  ... ...
</elementSpec>
```

and `<figDesc>` has been deleted, it will be necessary to remove that reference, or the resulting schema will be invalid.

The result of the work carried out should be a new `<schemaSpec>` which contains a complete and internally consistent set of element, class, and macro specifications, possibly also including `<moduleRef>` elements with `url` attributes identifying external modules.

### 23.5.2 Generating Schemas

Assuming that any modifications have been resolved, as outlined in the previous section, making a schema is now a four stage process:

1. all datatype and other macro specifications must be collected together and declared at the start of the output schema;
2. all classes must be declared in the right order (order is significant because since some classes reference others);
3. all elements are declared;
4. any `<moduleRef>` elements with a `url` attribute identifying an external schema must be processed.

Working in this order gives the best chance of successfully supporting all the schema languages. However, there are a number of obstacles to overcome along the way.

An ODD processor may choose to use any desired schema language or languages for its schema output, since ODD specifications are expressed as far as possible in a form independent of any schema language. The current TEI ODD processing system produces schema output in the three main schema languages as follows:

---

138 Note that deletion of required elements will cause the schema specification to accept as valid documents which cannot be TEI-conformant, since they no longer conform to the TEI Abstract Model; conformance topics are addressed in more detail in 23.4. Conformance.
• A RELAX NG (XML) schema is generated by converting content models, datatypes, and macro specifications provided within the ODD specification; a version re-expressed in the RELAX NG compact syntax is generated using James Clark’s trang application.

• A DTD schema is generated by converting the RELAX NG content models to DTD language, often simplifying it to allow for the less-sophisticated output language.

• A W3C Schema schema is created by generating a RELAX NG schema and then using James Clark’s trang application.

Note that the method used to generate W3C Schema means that a processor must ensure that the RELAX NG it generates follows the subset which trang is able to translate properly (see further below)—this may involve simple trial and error.

Other projects may decide to follow a different route, perhaps implementing a direct ODD to W3C Schema translator.

Secondly, it is possible to create two rather different styles of schema. On the one hand, the schema can try to maintain all the flexibility of ODD by using the facilities of the schema language for parameterization; on the other, it can remove all customization features and produce a flat result which is not suitable for further manipulation. The TEI project currently generates both styles of schema; the first as a set of schema fragments in DTD and RELAX NG languages, which can be included as modules in other schemas, and customized further; the second as the output from a processor such as Roma, in which many of the parameterization features have been removed.

The difference between the schema styles may be illustrated by considering this ODD specification:

```xml
<elementSpec module="drama"
  ident="performance">
  <!-- ... -->
  <classes>
    <memberOf key="model.frontPart.drama"/>
  </classes>
  <content>
    <sequence>
      <alternate minOccurs="0"
        maxOccurs="unbounded">
        <classRef key="model.divTop"/>
        <classRef key="model.global"/>
      </alternate>
      <sequence minOccurs="1"
        maxOccurs="unbounded">
        <classRef key="model.common"/>
        <classRef key="model.global"
          minOccurs="0"
          maxOccurs="unbounded"/>
      </sequence>
      <sequence minOccurs="0"
        maxOccurs="unbounded">
        <classRef key="model.divBottom"/>
        <classRef key="model.global"
          minOccurs="0"
          maxOccurs="unbounded"/>
      </sequence>
    </sequence>
  </content>
  <!-- ... -->
</elementSpec>
```

A simple rendering to RELAX NG produces this:
23.5 Implementation of an ODD System

performance =
  element performance {
  (model.divTop | model.global)*,
  (model.common, model.global*)+,
  (model.divBottom, model.global*)*
  att.global.attribute.xmlspace,
  att.global.attribute.xmlid,
  att.global.attribute.n,
  att.global.attribute.xmllang,
  att.global.attribute.rend,
  att.global.attribute.xmlbase,
  att.global.linking.attribute.corresp,
  att.global.linking.attribute.synch,
  att.global.linking.attribute.sameAs,
  att.global.linking.attribute.copyOf,
  att.global.linking.attribute.next,
  att.global.linking.attribute.prev,
  att.global.linking.attribute.exclude,
  att.global.linking.attribute.select
}

In the above, a subsequent redefinition of the attribute class (such as att.global) would have no effect, since references to such classes have been expanded to reference their constituent attributes.

The equivalent parameterized version might look like this:

performance =
  element performance { performance.content, performance.attributes }
  performance.content =
  (model.divTop | model.global)*,
  (model.common, model.global*)+,
  (model.divBottom, model.global*)*
  performance.attributes = att.global.attributes, empty

Here, the attribute class att.global is provided via an explicit reference (att.global.attributes), and can therefore be redefined. Moreover, the attributes are separated from the content model, allowing either to be overridden.

In the remainder of this section, the terms simple schema and parameterized schema are used to distinguish the two schema types. An ODD processor is not required to support both, though the simple schema output is generally preferable for most applications.

Thirdly, the problem of missing components must be resolved. For example, consider this (fictitious) model for <sp>:

```
<elementSpec ident="sp">
  <!-- ... -->
  <content>
    <classRef key="model.global" minOccurs="0" maxOccurs="unbounded"/>
    <sequence minOccurs="0" maxOccurs="1">
      <elementRef key="speaker"/>
      <classRef key="model.global" minOccurs="0" maxOccurs="unbounded"/>
    </sequence>
  </content>
</elementSpec>
```
This proposes anything from the class `model.global`, followed optionally by a `<speaker>` element followed by anything from the `model.global` class. What happens if `<speaker>` is removed from the schema? The following would result:

```xml
<elementSpec ident="sp">
  <!-- ... -->
  <content>
    <classRef key="model.global" minOccurs="0" maxOccurs="unbounded"/>
    <classRef key="model.global" minOccurs="0" maxOccurs="unbounded"/>
  </content>
  <!-- ... -->
</elementSpec>
```

which is illegal in DTD and W3C schema languages, since for a given member of `model.global` it is impossible to be sure which rule is being used. This situation is not detected when RELAX NG is used, since the language is able to cope with non-deterministic content models of this kind and does not require that only a single rule be used.

Finally, an application will need to have some method of associating the schema with document instances that use it. The TEI does not mandate any particular method of doing this, since different schema languages and processors vary considerably in their requirements. ODD processors may wish to build in support for some of the methods for associating a document instance with a schema. The TEI does not mandate any particular method, but does suggest that those which are already part of XML (the `DOCTYPE` declaration for DTDs) and W3C Schema (the `xmlns:schemaLocation` attribute) be supported where possible.

In order for the `xmlns:schemaLocation` attribute to be valid when a document is validated against either a DTD or a RELAX NG schema, ODD processors may wish to add declarations for this attribute and its namespace to the root element, even though these are not part of the TEI per se. For DTDs this means adding

```xml
<xsi:schemaLocation CDATA #IMPLIED xmlns:xsi CDATA #FIXED 'http://www.w3.org/2001/XMLSchema-instance'>
  <list { teidata.namespace, teidata.pointer }+ }
```

Note that declaration of the `xmlns:schemaLocation` attribute in a W3C Schema schema is not permitted. Therefore, if W3C Schemas are being generated by converting the RELAX NG schema (for example, with `trang`), it may be necessary to perform that conversion prior to adding the `xmlns:schemaLocation` declaration to the RELAX NG.
It is recognized that this is an unsatisfactory solution, but it permits users to take advantage of the W3C Schema facility for indicating a schema, while still permitting documents to be validated using DTD and RELAX NG processors without any conflict.

### 23.5.3 Names and Documentation in Generated Schemas

When processing class, element, or macro specifications, there are three general rules:

1. If a RELAX NG pattern or DTD parameter entity is being created, its name is the value of the corresponding `ident` attribute, prefixed by the value of any `prefix` attribute on `<schemaSpec>`. This allows for elements from an external schema to be mixed in without risk of name clashes, since all TEI elements can be given a distinctive prefix such as `tei_`. Thus:

   ```xml
   <schemaSpec ident="test" prefix="tei_">
     <elementSpec ident="sp">
       <!--...-->
     </elementSpec>
   </schemaSpec>
   ```

   may generate a RELAX NG (compact syntax) pattern like this:

   ```xml
   tei_ sp = element sp { ... }
   ```

   References to these patterns (or, in DTDs, parameter entities) also need to be prefixed with the same value.

2. If an element or attribute is being created, its default name is the value of the `ident` attribute, but if there is an `<altIdent>` child, its content is used instead.

3. Where appropriate, the documentation strings in `<gloss>` and `<desc>` should be copied into the generated schema. If there is only one occurrence of either of these elements, it should be used regardless, but if there are several, local processing rules will need to be applied. For example, if there are several with different values of `xml:lang`, a locale indication in the processing environment might be used to decide which to use. For example,

   ```xml
   <elementSpec module="core" ident="head">
     <equiv/>
     <gloss>heading</gloss>
     <gloss xml:lang="fr">en-tête</gloss>
     <gloss xml:lang="es">encabezamiento</gloss>
     <gloss xml:lang="it">titolo</gloss>
     <!-- ... -->
   </elementSpec>
   ```

   might generate a RELAX NG schema fragment like the following, if the locale is determined to be French:

   ```xml
   head =
     ## en-tête
     element head { head.content, head.attributes }
   ```

   Alternatively, a selection might be made on the basis of the value of the `version` attribute which these elements carry as members of the `att.translatable` class.

   In addition, there are three conventions about naming patterns relating to classes; ODD processors need not follow them, but those reading the schemas generated by the TEI project will find it necessary to understand them:
1. when a pattern for an attribute class is created, it is named after the attribute class identifier (as above) suffixed by `.attributes` (e.g. `att.editLike.attributes`);

2. when a pattern for an attribute is created, it is named after the attribute class identifier (as above) suffixed by `.attribute. and then the identifier of the attribute (e.g. `att.editLike.attribute.resp`);

3. when a parameterized schema is created, each element generates patterns for its attributes and its contents separately, suffixing respectively `.attributes` and `.contents` to the element name.

### 23.5.4 Making a RELAX NG Schema

To create a RELAX NG schema, the processor processes every `<macroSpec>`, `<classSpec>`, and `<elementSpec>` in turn, creating a RELAX NG pattern for each, using the naming conventions listed above. The order of declaration is not important, and a processor may well sort them into alphabetical order of identifier.

A complete RELAX NG schema must have an `<rng:start>` element defining which elements can occur as the root of a document. The ODD `<schemaSpec>` has an optional `start` attribute, containing one or more patterns, which can be used to construct the `<rng:start>`. A pattern normally corresponds to an element name, but if a prefix (see above, 23.5.3 Names and Documentation in Generated Schemas) is supplied for an element, the pattern consists of the prefix name with the element name.

#### 23.5.4.1 Macros

An ODD macro generates a corresponding RELAX NG pattern by processing the body of the `<content>` element in the same way as elsewhere. Thus

```xml
<macroSpec module="tei" ident="macro.phraseSeq">
  <content>
    <alternate minOccurs="0" maxOccurs="unbounded">
      <textNode/>
      <classRef key="model.gLike"/>
      <classRef key="model.phrase"/>
      <classRef key="model.global"/>
    </alternate>
  </content>
</macroSpec>
```

produces the following

```xml
<rng:define name="macro.phraseSeq">
  <rng:zeroOrMore>
    <rng:choice>
      <rng:text/>
      <rng:ref name="model.gLike"/>
      <rng:ref name="model.phrase"/>
      <rng:ref name="model.global"/>
    </rng:choice>
  </rng:zeroOrMore>
</rng:define>
```

#### 23.5.4.2 Classes

An ODD model class always generates a RELAX NG pattern definition listing all the members of the class in alternation. For example
will produce something like the following:

```
<rng:define name="model.measureLike">
  <rng:choice>
    <rng:ref name="num"/>
    <rng:ref name="measure"/>
    <rng:ref name="measureGrp"/>
  </rng:choice>
</rng:define>
```

assuming that the elements `<num>`, `<measure>`, and `<measureGrp>` are all defined in the schema concerned as members of that class. A model declaration may also generate a number of other patterns corresponding with sequences or alternations of the class members:

```
<rng:define name="model.measureLike_sequence">
  <rng:ref name="num"/>
  <rng:ref name="measure"/>
  <rng:ref name="measureGrp"/>
</rng:define>

<rng:define name="model.measureLike_sequenceOptional">
  <rng:optional>
    <rng:ref name="num"/>
  </rng:optional>
  <rng:optional>
    <rng:ref name="measure"/>
  </rng:optional>
  <rng:optional>
    <rng:ref name="measureGrp"/>
  </rng:optional>
</rng:define>

<rng:define name="model.measureLike_sequenceOptionalRepeatable">
  <rng:zeroOrMore>
    <rng:ref name="num"/>
  </rng:zeroOrMore>
  <rng:zeroOrMore>
    <rng:ref name="measure"/>
  </rng:zeroOrMore>
  <rng:zeroOrMore>
    <rng:ref name="measureGrp"/>
  </rng:zeroOrMore>
</rng:define>

<rng:define name="model.measureLike_sequenceRepeatable">
  <rng:oneOrMore>
    <rng:ref name="num"/>
  </rng:oneOrMore>
  <rng:oneOrMore>
    <rng:ref name="measure"/>
  </rng:oneOrMore>
  <rng:oneOrMore>
    <rng:ref name="measureGrp"/>
  </rng:oneOrMore>
</rng:define>
```
where the pattern name is created by appending an underscore and the name of the generation type to the class name.

When classes are referenced using the `<classRef>` element, it is possible to indicate which of the available patterns is required by means of the `expand` attribute.

Attribute classes work by producing a pattern containing definitions of the appropriate attributes. So

```
<classSpec module="verse" type="atts"
ident="att.enjamb">
<attList>
  <attDef ident="enjamb" usage="opt">
    <equiv/>
    <desc>indicates whether the end of a verse line is marked by enjambement.</desc>
    <datatype>
      <dataRef key="teidata.enumerated"/>
    </datatype>
  </attDef>
</attList>
</classSpec>
```

produces

```
<rng:define name="att.enjamb.attributes">
  <rng:ref name="att.enjamb.attribute.enjamb"/>
</rng:define>
```

```
<rng:define name="att.enjamb.attribute.enjamb">
  <rng:optional>
    <rng:attribute name="enjamb">
      <a:documentation>(enjambement) indicates whether the end of a verse line is marked by enjambement. Sample values include: 1] no; 2] yes; 3] weak; 4] strong</a:documentation>
    </rng:attribute>
  </rng:optional>
</rng:define>
```
Since the processor may have expanded the attribute classes already, separate patterns are generated for each attribute in the class as well as one for the class itself. This allows an element to refer directly to a member of a class. Notice that the `<desc>` element is used to add an `<a:documentation>` element to the schema, which some editors use to provide help during composition. The `<desc>` elements in the `<valList>` are used to create the human-readable sentence 'Sample values include: 1] no; 2] yes; 3] weak; 4] strong' Naturally, this behaviour is not mandatory; and other ODD processors may create documentation in other ways, or ignore those parts of the ODD specifications when creating schemas.

An individual attribute consists of an `<rng:attribute>` with a `name` attribute derived according to the naming rules described above (23.5.3, Names and Documentation in Generated Schemas). In addition, the ODD model supports a `<defaultVal>`, which is transformed to a `defaultValue` attribute in the namespace `http://relaxng.org/ns/compatibility/annotations/1.0` on the `<rng:attribute>`. The body of the attribute is taken from the `<datatype>` child, unless there is a supporting `<valList>` with a `type` value of closed. In that case an `<rng:choice>` is created, listing the allowed values. Thus the following attribute definition

```xml
<attDef ident="full" usage="opt">
  <defaultVal>yes</defaultVal>
  <valList type="closed">
    <valItem ident="yes">
      <desc>the name component is spelled out in full.</desc>
    </valItem>
    <valItem ident="abb">
      <gloss>abbreviated</gloss>
      <desc>the name component is given in an abbreviated form.</desc>
    </valItem>
    <valItem ident="init">
      <gloss>initial letter</gloss>
      <desc>the name component is indicated only by one initial.</desc>
    </valItem>
  </valList>
</attDef>
```

may generate this RELAX NG code:

```xml
<rng:define name="att.full">
  <rng:optional>
    <rng:attribute name="full" a:defaultValue="yes">
      <rng:choice>
        <rng:value>yes</rng:value>
        <a:documentation>the name component is spelled out in full.</a:documentation>
        <rng:value>abb</rng:value>
        <a:documentation>the name component is given in an abbreviated form.</a:documentation>
        <rng:value>init</rng:value>
        <a:documentation>the name component is indicated only by one initial.</a:documentation>
      </rng:choice>
    </rng:attribute>
  </rng:optional>
</rng:define>
```
Note the use of the http://relaxng.org/ns/compatibility/annotations/1.0 namespace to provide default values and documentation.

23.5.4.3 Elements
An <elementSpec> produces a RELAX NG specification in two parts; firstly, it must generate an <rng:define> pattern by which other elements can refer to it, and then it must generate an <rng:element> with the content model and attributes. It may be convenient to make two separate patterns, one for the element’s attributes and one for its content model.

The content model is created by processing the TEI declarations found within the <content> element; the attributes are processed in the same way as those from attribute classes, described above.

23.5.5 Making a DTD
Generation of DTDs largely follows the same pattern as RELAX NG generation, with one important exception—the order of declaration matters. A DTD may not refer to an entity which has not yet been declared. Since both macros and classes generate DTD parameter entities, the TEI Guidelines are constructed so that they can be declared in the right order. A processor must therefore work in the following order:

1. declare all model classes which have a predeclare value of true
2. declare all macros which have a predeclare value of true
3. declare all other classes
4. declare the modules (if DTD fragments are being constructed)
5. declare any remaining macros
6. declare the elements and their attributes

Let us consider a complete example, a simple element with no attributes of its own:

```
<elementSpec module="namesdates" ident="faith">
  <desc>specifies the faith, religion, or belief set of a person.</desc>
  <classes>
    <memberOf key="model.persStateLike"/>
    <memberOf key="att.editLike"/>
    <memberOf key="att.datable"/>
  </classes>
  <content>
    <macroRef key="macro.phraseSeq"/>
  </content>
</elementSpec>
```

If DTD fragments are being generated (for use as described in 23.5.7. Using TEI Parameterized Schema Fragments), this will result in the following:

```
<!ENTITY % faith 'INCLUDE'>
<![ %faith; ]>
<!doc:specifies the faith, religion, or belief set of a person. -->
<!ELEMENT %n.faith; %om.RR; %macro.phraseSeq;>
```
23.5 Implementation of an ODD System

Here the whole stanza is contained in a marked section (for use as described in 23.5.7.2, Inclusion and Exclusion of Elements), the element name is parameterized (see 23.5.7.3, Changing the Names of Generic Identifiers), and the class attributes are entity references derived from the <memberOf> records in <classes>. Note the additional attribute which provides a default xmlns declaration for the element; the effect of this is that if the document is processed by a DTD-aware XML processor, the namespace declaration will be present automatically without the document author even being aware of it.

A simpler rendition for a flattened DTD generated from a customization will result in the following, with no containing marked section, and no parameterized name:

Here the attributes from classes have been expanded into individual entity references.

23.5.6 Generating Documentation

In Donald Knuth’s literate programming terminology (Knuth (1992)), the previous sections have dealt with the tangle process; to generate documentation, we now turn to the weave process.

An ODD customization may consist largely of general documentation and examples, requiring no ODD-specific processing. It will normally however also contain a <schemaSpec> element and possibly some <specGrp> fragments.

The generated documentation may be of two forms. On the one hand, we may document the customization itself, that is, only those elements (etc.) which differ in their specification from that provided by the TEI reference documentation. Alternatively, we may generate reference documentation for the complete subset of the TEI which
results from applying the customization. The TEI Roma tools take the latter approach, and operate on the result of
the first stage processing described in 23.5.1. Making a Unified ODD.

Generating reference documentation for `<elementSpec>`, `<classSpec>`, and `<macroSpec>` elements is largely
dependent on the design of the preferred output. Some applications may, for example, want to turn all names
of objects into hyperlinks, show lists of class members, or present lists of attributes as tables, lists, or inline prose.
Another technique implemented in these Guidelines is to show lists of potential ‘parents’ for each element, by tracing
which other elements have them as possible members of their content models.

One model of display on a web page is shown in 35, corresponding to the `<faith>` element shown in section 23.5.5.

Making a DTD.

```xml
<faith>
  <module> specifies the faith, religion, or belief set of a person.
  <attributes> 
    <att.editable att.datablue />
  </attributes>
  <declaration>
    <element faith
        att.global.attributes,
        att.entry.head.attributes,
        att.entry.rsc.attributes,
        att.datablue.iso.attributes,
        macro.phraseSeq
    }
  </declaration>
  <example>
    <faith>protestant</faith>
  </example>
  <contained by> 
    model.per TraitInfo
  </contained by>
</faith>
```

Figure 35: Example reference documentation for `<faith>`

23.5.7 Using TEI Parameterized Schema Fragments

The TEI parameterized DTD and RELAX NG fragments make use of parameter entities and patterns for several
purposes. In this section we describe their interface for the user. In general we recommend use of ODD instead of
this technique, which has been retained only for compatibility reasons.

23.5.7.1 Selection of Modules

Special-purpose parameter entities are used to specify which modules are to be combined into a TEI DTD. They take
the form TEI.xxxxx where XXXX is the name of the module as given in table the table on p. 2 in 1.1. TEI Modules. For
example, the parameter entity TEI.linking is used to define whether or not to include the module linking. All such parameter entities are declared by default with the value IGNORE: to select a module, therefore, the encoder declares the appropriate parameter entities with the value INCLUDE.

For XML DTD fragments, note that some modules generate two DTD fragments: for example the analysis
module generates fragments called `analysis-decl` and `analysis`. This is because the declarations they contain
are needed at different points in the creation of an XML DTD.

The parameter entity named for the module is used as the keyword controlling a conditional marked section in
the DTD fragment generated by the tei module. The declarations for each DTD fragment constituting the module
are contained within such marked sections. For example, the parameter entity TEI.linking appears twice in
`tei.dtd`, once for the `linking-decl` schema fragment.
23.5 Implementation of an ODD System

If TEI.linking has its default value of IGNORE, neither declaration has any effect. If however it has the value INCLUDE, then the content of each marked section is acted upon: the parameter entities file.linking and file.linking-decl are referenced, which has the effect of embedding the content of the files they represent at the appropriate point in the DTD.

The RELAX NG schema fragments can be combined in a wrapper schema using the standard mechanism of `<rng:include>` in that language.

23.5.7.2 Inclusion and Exclusion of Elements

The TEI DTD fragments also use marked sections and parameter entity references to allow users to exclude the definitions of individual elements, in order either to make the elements illegal in a document or to allow the element to be redefined. The parameter entities used for this purpose have exactly the same name as the generic identifier of the element concerned. The default definition for these parameter entities is INCLUDE but they may be changed to IGNORE in order to exclude the standard element and attribute definition list declarations from the DTD.

The declarations for the element `<p>` for example, are preceded by a definition for a parameter entity with the name `p` and contained within a marked section whose keyword is given as `%p;`:

```xml
<!ENTITY % p 'INCLUDE' >
<![(%p; [ <!-- element and attribute list declaration for p here --> ])
```

These parameter entities are defined immediately preceding the element whose declarations they control; because their names are completely regular, they are not documented further.

To define a DTD in which the element `<p>` is excluded therefore, the entity `p` needs to be redefined as IGNORE by ensuring that a declaration such as

```xml
<!ENTITY % p 'IGNORE' >
```

is added earlier in the DTD than the default (see further 23.5.7.4. Embedding Local Modifications (DTD only)).

Similarly, in the parameterized RELAX NG schemas, every element is defined by a pattern named after the element. To undefine an element therefore all that is necessary is to add a declaration like the following:
23.5.7.3 Changing the Names of Generic Identifiers

In the TEI DTD fragments, elements are not referred to directly by their generic identifiers; instead, the DTD fragments refer to parameter entities which expand to the standard generic identifiers. This allows users to rename elements by redefining the appropriate parameter entity. Parameter entities used for this purpose are formed by taking the standard generic identifier of the element and attaching the string n. as a prefix. Thus the standard generic identifiers for paragraphs, notes, and quotations, `<p>`, `<note>`, and `<persName>` are defined by declarations of the following form:

```
<!ENTITY % n.p "p">
<!ENTITY % n.note "note">
<!ENTITY % n.persName "persName">
```

Note that since all names are case-sensitive, the specific mix of uppercase and lowercase letters in the standard generic identifier must be preserved in the entity name.

These declarations are generated by an ODD processor when TEI DTD fragments are created.

In the RELAX NG schemas, all elements are normally defined using a pattern with the same name as the element (as described in 23.5.3. Names and Documentation in Generated Schemas): for example

```
abbr = element abbr { abbr.content, abbr.attributes }
```

The easiest way of renaming the element is thus simply to rewrite the pattern with a different element name; any references use the pattern, not the element, name.

```
abbr = element abbrev { abbr.content, abbr.attributes }
```

More complex revisions, such as redefining the content of the element (defined by the pattern `abbr.content`) or its attributes (defined by the pattern `abbr.attributes`) can be accomplished in a similar way, using the features of the RELAX NG language. The recommended method of carrying out such modifications is however to use the ODD language as further described in section 22. Documentation Elements.

23.5.7.4 Embedding Local Modifications (DTD only)

Any local modifications to a DTD (i.e. changes to a schema other than simple inclusion or exclusion of modules) are made by declarations stored in one of two local extension files, one containing modifications to the TEI parameter entities, and the other new or changed declarations of elements and their attributes. Entity declarations must be made which associate the names of these two files with the appropriate parameter entity so that the declarations they contain can be embedded within the TEI DTD at an appropriate point.

The following entities are referred to by the main `tei.dtd` file to embed portions of the TEI DTD fragments or locally developed extensions.

**TEI.extensions.ent** identifies a local file containing extensions to the TEI parameter entities

**TEI.extensions.dtd** identifies a local file containing extensions to the TEI module

For example, if the relevant files are called `project.ent` and `project.dtd`, then declarations like the following would be appropriate:
When an entity is declared more than once, the first declaration is binding and the others are ignored. The local modifications to parameter entities should therefore be handled before the standard parameter entities themselves are declared in tei.dtd. The entity TEI.extensions.ent is referred to before any TEI declarations are handled, to allow the user’s declarations to take priority. If the user does not provide a TEI.extensions.ent entity, the entity will be expanded to the empty string.

For example the encoder might wish to add two phrase-level elements <it> and <bd>, perhaps as synonyms for <hi rend='italics'> and <hi rend='bold'>. As described in chapter 23.3. Customization, this involves two distinct steps: one to define the new elements, and the other to ensure that they are placed into the TEI document structure at the right place.

Creating the new declarations is done in the same way for user-defined elements as for any other; the same parameter entities need to be defined so that they may be referenced by other elements. The content models of these new elements may also reference other parameter entities, which is why they need to be declared after other declarations.

The second step involves modifying the element class to which the new elements should be attached. This requires that the parameter entity macro.phraseSeq should be modified to include the generic identifiers for the new elements we wish to create. The declaration for each modifiable parameter entity in the DTD includes a reference to an additional parameter entity with the same name prefixed by an x.; these entities are declared by default as the null string. However, in the file containing local declarations they may be redeclared to include references to the new class members:

```
<!ENTITY % x.macro.phraseSeq 'it | bd |'>
```

and this declaration will take precedence over the default when the declaration for macro.phraseSeq is evaluated.
A Model Classes

A.1 About the Model Classes Appendix

This appendix gives you a list of model classes and links to the reference pages for them. There are 124 distinctly-named model classes in revision b4f72b1ff of TEI P5 Version 4.3.0 of the TEI Guidelines.

---

**model.addressLike** groups elements used to represent a postal or email address. [i. The TEI Infrastructure]

*Module* tei — The TEI Infrastructure

*Used by* location model.correspActionPart model.pPart.data

Members entry entryFree superEntry

model.entryPart groups non-morphological elements appearing within a dictionary entry. [9.1. Dictionary Body and Overall Structure]
model.entryPart.top groups high level elements within a structured dictionary entry. [9.2. The Structure of Dictionary Entries]

Module tei — The TEI Infrastructure
Used by ct dictScrap entryFree nym
Members colloc def etym form gramGrp hom hyph lbl orth pos pron re sense subc superEntry syll usg xr

Note Members of this class typically contain related parts of a dictionary entry which form a coherent subdivision, for example a particular sense, homonym, etc.

model.eventLike groups elements which describe events.

Module tei — The TEI Infrastructure
Used by listEvent model.orgPart model.personPart place
Members event listEvent

model.featureVal groups elements which represent feature values in feature structures.

Module tei — The TEI Infrastructure
Used by f vAlt vDefault vLabel vMerge vNot vRange
Members model.featureVal.complex[fs vColl vMerge vNot] model.featureVal.single[binary|default numeric string symbol vAlt vLabel]

model.featureVal.complex groups elements which express complex feature values in feature structures.

Module tei — The TEI Infrastructure
Used by model.featureVal
Members fs vColl vMerge vNot

model.featureVal.single group elements used to represent atomic feature values in feature structures.

Module tei — The TEI Infrastructure
Used by model.featureVal vColl
Members binary|default numeric string symbol vAlt vLabel

model.formPart groups elements allowed within a <form> element in a dictionary. [9.3.1. Information on Written and Spoken Forms]

Module dictionaries — Dictionaries
Used by form

786
model.frontPart groups elements which appear at the level of divisions within front or back matter. [7.1 Front and Back Matter]

Module tei — The TEI Infrastructure

Used by back front

Members model.frontPart.drama[castList epilogue performance prologue set] divGen listBibl schemaSpec titlePage

model.frontPart.drama groups elements which appear at the level of divisions within front or back matter of performance texts only. [7.1 Front and Back Matter]

Module tei — The TEI Infrastructure

Used by model.frontPart

Members castList epilogue performance prologue set

model.fsdDeclPart groups elements which can occur as direct children of `<fsdDecl>`. [18.11 Feature System Declaration]

Module iso-fs — Feature Structures

Used by fsdDecl

Members fLib fsDecl fsdLink fvLib

model.gLike groups elements used to represent individual non-Unicode characters or glyphs.

Module tei — The TEI Infrastructure

model.global.edit groups globally available elements which perform a specifically editorial function. [1.3. The TEI Class System]

Module: tei — The TEI Infrastructure
Used by: model.global
Members: addSpan, app, damageSpan, delSpan, ellipsis, gap, space, witDetail

model.global.meta groups globally available elements which describe the status of other elements. [1.3. The TEI Class System]

Module: tei — The TEI Infrastructure
Used by: model.global, model.standOffPart
Members: alt, altGrp, certainty, fLib, fs, fLib, interp, interpGrp, join, joinGrp, link, linkGrp, listTranspose, precision, respons, span, spanGrp, substJoin, timeline

Note: Elements in this class are typically used to hold groups of links or of abstract interpretations, or by provide indications of certainty etc. It may find be convenient to localize all metadata elements, for example to contain them within the same divison as the elements that they relate to; or to locate them all to a division of their own. They may however appear at any point in a TEI text.

model.global.spoken groups elements which may appear globally within spoken texts. [8.1. General Considerations and Overview]

Module: spoken — Transcriptions of Speech
Used by: annotationBlock, model.global
Members: incident, kinesic, pause, shift, vocal, writing

Note: This class groups elements which can appear anywhere within transcribed speech.

model.glossLike groups elements which provide an alternative name, explanation, or description for any markup construct.

Module: tei — The TEI Infrastructure
Used by: attDef, classSpec, constraintSpec, dataSpec, elementSpec, macroSpec, model, modelGrp, modelSequence, moduleSpec, paramSpec, schemaSpec, valItem
Members: altIdent, equiv, gloss

model.gramPart groups elements allowed within a <gramGrp> element in a dictionary. [9.3.2. Grammatical Information]

Module: dictionaries — Dictionaries
Used by: gramGrp, model.formPart
Members: model.lexicalRefinement, colloc, gramGrp, lbl, pos, subc, useg, model.morphLike, case, gen, gram, iType, mood, number, per, tns

model.graphicLike groups elements containing images, formulae, and similar objects. [3.10. Graphics and Other Non-textual Components]

788
model.headLike groups elements used to provide a title or heading at the start of a text division. 

Module tei — The TEI Infrastructure

Used by char cit facsimile figure formula glyph model.phrase sourceDoc surface table zone

Members binaryObject formula graphic media

B Attribute Classes

B.1 About the Attribute Classes Appendix

This appendix gives you a list of attribute classes and links to the reference pages for them. There are 81 distinctly-named attribute classes in revision 4f72b1ff of TEI P5 Version 4.3.0 of the TEI Guidelines.

att.anchoring (anchoring) provides attributes for use on annotations, e.g. notes and groups of notes describing the existence and position of an anchor for annotations.

Module tei — The TEI Infrastructure

Attributes

@anchored (anchored) indicates whether the copy text shows the exact place of reference for the note.

Status Optional

Datatype teidata.truthValue

Default true

Note In modern texts, notes are usually anchored by means of explicit footnote or endnote symbols. An explicit indication of the phrase or line annotated may however be used instead (e.g. 'page 218, lines 3–4'). The anchored attribute indicates whether any explicit location is given, whether by symbol or by prose cross-reference. The value true indicates that such an explicit location is indicated in the copy text; the value false indicates that the copy text does not indicate a specific place of attachment for the note. If the specific symbols used in the copy text at the location the note is anchored are to be recorded, use the n attribute.

@targetEnd (target end) points to the end of the span to which the note is attached, if the note is not embedded in the text at that point.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Note This attribute is retained for backwards compatibility; it may be removed at a subsequent release of the Guidelines. The recommended way of pointing to a span of elements is by means of the range function of XPointer, as further described in 16.2.4.6. range().

Example

```
<p>(...) tamen reuerendos dominos archiepiscopum et canonicos Leopolientes necnon episcopum in duplicibus Quatuortemporibus<anchor xml:id="A55234"/> totaliter expediiu...</p>
<!-- elsewhere in the document -->
<noteGrp targetEnd="#A55234">
  <note xml:lang="en"> Quatuor Tempora, so called dry fast days. </note>
  <note xml:lang="pl"> Quatuor Tempora, tzw. Suche dni postne. </note>
</noteGrp>
```

att.ascribed provides attributes for elements representing speech or action that can be ascribed to a specific individual. [3.3.3. Quotation 8.3. Elements Unique to Spoken Texts]

Module tei — The TEI Infrastructure

Attributes
@key provides an externally-defined means of identifying the entity (or entities) being named, using a coded value of some kind.
The value may be a unique identifier from a database, or any other externally-defined string identifying the referent. No particular syntax is proposed for the values of the key attribute, since its form will depend entirely on practice within a given project. For the same reason, this attribute is not recommended in data interchange, since there is no way of ensuring that the values used by one project are distinct from those used by another. In such a situation, a preferable approach for magic tokens which follows standard practice on the Web is to use a ref attribute whose value is a tag URI as defined in RFC 4151.

@ref (reference) provides an explicit means of locating a full definition or identity for the entity being named by means of one or more URIs.

att.citeStructurePart provides attributes for selecting particular elements within a document.

att.citing provides attributes for specifying the specific part of a bibliographic item being cited.
**att.combinable** provides attributes indicating how multiple references to the same object in a schema should be combined.

*Module* tagdocs — Documentation Elements

*Members* att.combinable, att.deprecated

*Attributes* @mode

**att.coordinated** provides attributes that can be used to position their parent element within a two-dimensional coordinate system.
Module transcr — Representation of Primary Sources
Members line path surface zone
Attributes Attributes
@start indicates the element within a transcription of the text containing at least the start of the writing represented by this zone or surface.
Status Optional
Datatype teidata.pointer
@ulx gives the x coordinate value for the upper left corner of a rectangular space.
Status Optional
Datatype teidata.numeric
@uly gives the y coordinate value for the upper left corner of a rectangular space.
Status Optional
Datatype teidata.numeric
@lrx gives the x coordinate value for the lower right corner of a rectangular space.
Status Optional
Datatype teidata.numeric
@lry gives the y coordinate value for the lower right corner of a rectangular space.
Status Optional
Datatype teidata.numeric
@points identifies a two dimensional area by means of a series of pairs of numbers, each of which gives the x,y coordinates of a point on a line enclosing the area.
Status Optional
Datatype 3–∞ occurrences of teidata.point separated by whitespace

att.cReferencing provides attributes that may be used to supply a canonical reference as a means of identifying the target of a pointer.
Module tei — The TEI Infrastructure
Members gloss ptr ref term
Attributes Attributes
@cRef (canonical reference) specifies the destination of the pointer by supplying a canonical reference expressed using the scheme defined in a <refsDecl> element in the TEI header
Status Optional
Datatype teidata.text
Note The value of cRef should be constructed so that when the algorithm for the resolution of canonical references (described in section 16.2.5. Canonical References) is applied to it the result is a valid URI reference to the intended target.
The <refsDecl> to use may be indicated with the decls attribute.
Currently these Guidelines only provide for a single canonical reference to be encoded on any given <ptr> element.

att.damaged provides attributes describing the nature of any physical damage affecting a reading. [11.3.3.1. Damage, Illegibility, and Supplied Text [1.3.1. Attribute Classes]]
Module tei — The TEI Infrastructure
Members damage damageSpan
Attributes att.dimensions (@unit, @quantity, @extent, @precision, @scope) (att.ranging (@atLeast, @atMost, @min, @max, @confidence)) att.written (@hand)
@agent categorizes the cause of the damage, if it can be identified.

Status Optional

Datatype teidata.enumerated

Sample values include:
- rubbing damage results from rubbing of the leaf edges
- mildew damage results from mildew on the leaf surface
- smoke damage results from smoke

@degree provides a coded representation of the degree of damage, either as a number between 0 (undamaged) and 1 (very extensively damaged), or as one of the codes high, medium, low, or unknown. The <damage> element with the degree attribute should only be used where the text may be read with some confidence; text supplied from other sources should be tagged as <supplied>.

Status Optional

Datatype teidata.probCert

Note The <damage> element is appropriate where it is desired to record the fact of damage although this has not affected the readability of the text, for example a weathered inscription. Where the damage has rendered the text more or less illegible either the <unclear> tag (for partial illegibility) or the <gap> tag (for complete illegibility, with no text supplied) should be used, with the information concerning the damage given in the attribute values of these tags. See section 11.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination for discussion of the use of these tags in particular circumstances.

@group assigns an arbitrary number to each stretch of damage regarded as forming part of the same physical phenomenon.

Status Optional

Datatype teidata.count

att.datable provides attributes for normalization of elements that contain dates, times, or datable events. [3.6.4. Dates and Times 13.4. Dates]

Module tei — The TEI Infrastructure

Members acquisition affiliation age altIdentifier application author binding birth bloc change climate conversion country creation custEvent date death district editor education event faith floruit funder geogFeat geogName idno langKnowledge langKnown licence location meeting name nationality objectName occupation offset orgName origDate origPlace origin persName persPronouns placeName population precision principal provenance region relation residence resp seal settlement sex socsecStatus sponsor stamp state terrain time title trait unitDecl unitDef

Attributes att.datable.w3c (@when, @notBefore, @notAfter, @from, @to) att.datable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso) att.datable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @DatingPoint, @DatingMethod)

@calendar indicates one or more systems or calendars to which the date represented by the content of this element belongs.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Schematron <sch:rule context="tei:[@calendar]"> <sch:assert test="string-length(.) gt 0" > @calendar indicates one or more systems or calendars to which the date represented by the content of this element belongs, but this <sch:name/> element has no textual content.</sch:assert> </sch:rule>

He was born on <date calendar="#gregorian">Feb. 22, 1732</date> (with "1732-02-22") Feb. 11, 1731/32,
He was born on `<date calendar="#gregorian #julian" when="1732-02-22"">Feb. 22, 1732 (Feb. 11, 1731/32, O.S.)</date>`.

Note Note that the `calendar` attribute (unlike `datingMethod` defined in `att.datable.custom`) defines the calendar system of the date in the original material defined by the parent element, not the calendar to which the date is normalized.

@period supplies pointers to one or more definitions of named periods of time (typically `<category>`s or `<calendar>`s) within which the datable item is understood to have occurred.

Status Optional

Datatype 1–∞ occurrences of `teidata.pointer` separated by whitespace

This ‘superclass’ provides attributes that can be used to provide normalized values of temporal information. By default, the attributes from the `att.datable.w3c` class are provided. If the module for names & dates is loaded, this class also provides attributes from the `att.datable.iso` and `att.datable.custom` classes. In general, the possible values of attributes restricted to the W3C datatypes form a subset of those values available via the ISO 8601 standard. However, the greater expressiveness of the ISO datatypes may not be needed, and there exists much greater software support for the W3C datatypes.

`att.datable.custom` provides attributes for normalization of elements that contain datable events to a custom dating system (i.e. other than the Gregorian used by W3 and ISO). [[13.4. Dates]

Module `namesdates` — Names, Dates, People, and Places

Members `att.datable[acquisition] affiliation age altIDentifier application author binding birth bloc change climate conversion country creator custEvent date death district editor education event faith floruit funder geogFeat geogName idno langKnowledge langKnown licence location meeting name nationality objectName occupation offset orgName origDate origPlace origin persName persPronouns placeName population precision principal provenance region relation residence resp seal settlement sex socsecStatus sponsor stamp state terrain time title trait unitDecl unitDef`

Attributes

@when-custom supplies the value of a date or time in some custom standard form.

Status Optional

Datatype 1–∞ occurrences of `teidata.word` separated by whitespace

The following are examples of custom date or time formats that are not valid ISO or W3C format normalizations, normalized to a different dating system `<p>Alhazen died in Cairo on the `<date when="1040-03-06" when-custom="431-06-12">12th day of Jumada t-Tania, 430 AH</date>`.</p>`

`<p>The current world will end at the `<date when="2012-12-21" when-custom="13.0.0.0.0">end of B’ak’tun 13</date>`.</p>`

`<p>The Battle of Meggido `<date when-custom="Thutmose_III:23">23rd year of reign of Thutmose III</date>`.</p>`

`<p>Esidorus bixit in pace annos LXX plus minus sub `<date when-custom="Ind:4-10-11">die XI mensis Octobris indictione IIII</date>`.</p>`

`<p>Not all custom date formulations will have Gregorian equivalents. The when-custom attribute and other custom dating

808
are not constrained to a datatype by the TEI, but individual projects are recommended to regularize and document their dating formats.

@notBefore-custom specifies the earliest possible date for the event in some custom standard form.

Status Optional
Datatype 1–∞ occurrences of leidata.word separated by whitespace

@notAfter-custom specifies the latest possible date for the event in some custom standard form.

Status Optional
Datatype 1–∞ occurrences of leidata.word separated by whitespace

@from-custom indicates the starting point of the period in some custom standard form.

Status Optional
Datatype 1–∞ occurrences of leidata.word separated by whitespace

@to-custom indicates the ending point of the period in some custom standard form.

Status Optional
Datatype 1–∞ occurrences of leidata.word separated by whitespace

@from datingMethod supplies a pointer to some location defining a named point in time with reference to which the datable item is understood to have occurred

Status Optional
Datatype leidata.pointer

@to datingMethod supplies a pointer to a <calendar> element or other means of interpreting the values of the custom dating attributes.

Status Optional
Datatype leidata.pointer

Contayning the Originall, Antiquity, Increafe, Moderne eftate, and description of that Citie, written in the yeare

<date when-custom="1598"
    calendar="#julian"
    datingMethod="#julian">
    1598</date>. by Iohn Stow Citizen of London. In this example, the calendar attribute points to a <calendar> element for the Julian calendar, specifying that the text content of the <date> element is a Julian date, and the datingMethod attribute also points to the Julian calendar to indicate that the content of the when-custom attribute value is Julian too.

<date when="1382-06-28"
    when-custom="6890-06-20"
    datingMethod="#creationOfWorld">
    μηνὶ Ἰουνίου εἰς <num>κ</num> <num>ςωϞ</num>
</date>. In this example, a date is given in a Mediaeval text measured "from the creation of the world", which is normalised (in when) to the Gregorian date, but is also normalized (in when-custom) to a machine-actionable, numeric version of the date from the Creation.

Note Note that the datingMethod attribute (unlike calendar defined in att.datable) defines the calendar or dating system to which
the date described by the parent element is normalized (i.e. in the `when-custom` or other `X-custom` attributes), not the calendar of the original date in the element.

`att.datable.iso` provides attributes for normalization of elements that contain datable events using the ISO 8601 standard. [3.6.4. Dates and Times | 3.4. Dates]

Attributes

- `@when-iso` supplies the value of a date or time in a standard form.
  
  Status: Optional
  
  Datatype: `teidata.temporal.iso`

  The following are examples of ISO date, time, and date & time formats that are not valid W3C format normalizations.

  ```xml
  <date when-iso="1996-09-24T07:25+00">Sept. 24th, 1996 at 3:25 in the morning</date>
  <time when-iso="1999-01-04T20:42-05">4 Jan 1999 at 8:42 pm</time>
  <time when-iso="1999-W01-1T20:42:05">4 Jan 1999 at 8:42 pm</time>
  <date when-iso="2006-05-18T10:03">a few minutes after ten in the morning on Thu 18 May</date>
  <time when-iso="03:00">3 A.M.</time>
  <time when-iso="14">around two</time>
  <time when-iso="15,5">half past three</time>
  All of the examples of the `when` attribute in the `att.datable.w3c` class are also valid with respect to this attribute.

  He likes to be punctual. I said `<q>`
  `<time when-iso="12">around noon</time>`
  `<q>`, and he showed up at `<time when-iso="12:00:00">12 0'clock</time>` on the dot. The second occurrence of `<time>` could have been encoded with the `when` attribute, as 12:00:00 is a valid time with respect to the W3C XML Schema Part 2: Datatypes Second Edition specification. The first occurrence could not.

- `@notBefore-iso` specifies the earliest possible date for the event in standard form, e.g. `yyyy-mm-dd`.
  
  Status: Optional
  
  Datatype: `teidata.temporal.iso`

- `@notAfter-iso` specifies the latest possible date for the event in standard form, e.g. `yyyy-mm-dd`.
  
  Status: Optional
  
  Datatype: `teidata.temporal.iso`

- `@from-iso` indicates the starting point of the period in standard form.
  
  Status: Optional
  
  Datatype: `teidata.temporal.iso`
@to-iso indicates the ending point of the period in standard form.

Status Optional

Datatype [teidata.temporal.iso]

The value of these attributes should be a normalized representation of the date, time, or combined date & time intended, in any of the standard formats specified by ISO 8601, using the Gregorian calendar.

If both when-iso and dur-iso are specified, the values should be interpreted as indicating a span of time by its starting time (or date) and duration. That is,

```
<date when-iso="2007-06-01" dur-iso="P8D"/>
```

indicates the same time period as

```
<date when-iso="2007-06-01/P8D"/>
```

In providing a 'regularized' form, no claim is made that the form in the source text is incorrect; the regularized form is simply that chosen as the main form for purposes of unifying variant forms under a single heading.

---

Schematron <sch:rule context="tei:[@to]"> <sch:report test="@notAfter" role="nonfatal">The @to and @notAfter attributes cannot be used together.</sch:report> </sch:rule>

Example

<date from="1863-05-28" to="1863-06-01">28 May through 1 June 1863</date>

Note The value of these attributes should be a normalized representation of the date, time, or combined date & time intended, in any of the standard formats specified by XML Schema Part 2: Datatypes Second Edition, using the Gregorian calendar.

The most commonly-encountered format for the date portion of a temporal attribute is yyyy-mm-dd, but yyyy, - - - mm, - - dd, yyyy-mm, or - - mm-dd may also be used. For the time part, the form hh:mm:ss is used.

Note that this format does not currently permit use of the value 0000 to represent the year 1 BCE; instead the value -0001 should be used.

att.datcat provides attributes that are used to align XML elements or attributes with the appropriate Data Categories (DCs) defined by the ISO 12620:2009 standard and stored in the Web repository called ISOCat at [http://www.isocat.org/](http://www.isocat.org/)[9.5.2. Lexical View 18.3. Other Atomic Feature Values]

Module tei — The TEI Infrastructure

Members att.lexicographic|case|colloc|def|entryFree|etym|form|gen|gram|gramGrp|hom|hyph|iType|lang|lbl|mood|number|oRef|orth|pRef|per|pos|pron|re|sense|subc|syll|ins|iusg|xt|att.segLike|cl|m|pc|phr|s|seg|w|binary|f|is|numeric|string|symbol

Attributes Attributes

812
@datcat contains a PID (persistent identifier) that aligns the given element with the appropriate Data Category (or categories) in ISOcat.

Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

@valueDatcat contains a PID (persistent identifier) that aligns the content of the given element or the value of the given attribute with the appropriate simple Data Category (or categories) in ISOcat.

Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Example In this example dcr:datcat relates the feature name to the data category "partOfSpeech" and dcr:valueDatcat the feature value to the data category "commonNoun". Both these data categories reside in the ISOcat DCR at www.isocat.org, which is the DCR used by ISO TC37 and hosted by its registration authority, the MPI for Psycholinguistics in Nijmegen.

```xml
<fs
   xmlns:dcr="http://www.isocat.org/ns/dcr">
   <f
      name="POS"
      dcr:datcat="http://www.isocat.org/datcat/DC-1345"
      fVal="#commonNoun"
      dcr:valueDatcat="http://www.isocat.org/datcat/DC-1256"/>
</fs>
```

Note ISO 12620:2009 is a standard describing the data model and procedures for a Data Category Registry (DCR). Data categories are defined as elementary descriptors in a linguistic structure. In the DCR data model each data category gets assigned a unique Persistent IDentifier (PID), i.e., an URL. Linguistic resources or preferably their schemas that make use of data categories from a DCR should refer to them using this PID. For XML-based resources, like TEI documents, ISO 12620:2009 normative Annex A gives a small Data Category Reference XML vocabulary (also available online at http://www.isocat.org/12620/), which provides two attributes, dcr:datcat and dcr:valueDatcat.

**att.declarable** provides attributes for those elements in the TEI header which may be independently selected by means of the special purpose decls attribute. [[15.3. Associating Contextual Information with a Text]]

**Module** tei — The TEI Infrastructure

**Attributes**

@default indicates whether or not this element is selected by default when its parent is selected.

Status Optional
Datatype teidata.truthValue

Legal values are: true This element is selected if its parent is selected
false This element can only be selected explicitly, unless it is the only one of its kind, in which case it is selected if its parent is selected.[Default]

The rules governing the association of declarable elements with individual parts of a TEI text are fully defined in chapter [15.3. Associating Contextual Information with a Text]. Only one element of a particular type may have a default attribute with a value of true.
att.declaring provides attributes for elements which may be independently associated with a particular
declarable element within the header, thus overriding the inherited default for that element. [15.3,
Associating Contextual Information with a Text]

Attributes

@decls identifies one or more declarable elements within the header, which are understood to
apply to the element bearing this attribute and its content.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

The rules governing the association of declarable elements with individual parts of a TEI text are fully
defined in chapter [15.3. Associating Contextual Information with a Text].

att.deprecated provides attributes indicating how a deprecated feature will be treated in future releases.

Module tagdocs — Documentation Elements

Attributes

@validUntil provides a date before which the construct being defined will not be removed.

Status Optional

Datatype date

Schematron <sch:rule context="tei:[@validUntil]">
    <sch:let name="advance_warning_period" value="current-date() +
        xs:dayTimeDuration('P60D')"/>

            longer supported' )"/>
    </sch:assert>  
    <sch:assert role="nonfatal" test="@validUntil
        cast as xs:date ge $advance_warning_period">  
        <sch:value-of select="concat( $me_phrase, ' construct becomes outdated on ', @validUntil )"/>
    </sch:assert>
</sch:rule>

Schematron <sch:rule context="tei:[@validUntil] not( self::valDesc | self::valList |
    self::defaultVal )"> <sch:assert test="child::tei:desc[ @type eq 'deprecationInfo' ]"> A
deprecated construct should include, whenever possible, an explanation, but this
<sch:value-of select="name(.)"/> does not have a child <desc
type="deprecationInfo"/></sch:assert> </sch:rule>

Note The value of this attribute should represent a date (in standard yyyy-mm-dd
format) which is later than the date on which the attribute is added to an ODD.

Technically, this attribute asserts only the intent to leave a construct in future
releases of the markup language being defined up to at least the specified date, and
makes no assertion about what happens past that date. In practice, the expectation is
that the construct will be removed from future releases of the markup language being
defined sometime shortly after the validUntil date.

An ODD processor will typically not process a specification element which has a
validUntil date that is in the past. An ODD processor will typically warn users about
constructs which have a validUntil date that is in the future. E.g., the documentation
for such a construct might include the phrase warning: deprecated in red.
att.dimensions provides attributes for describing the size of physical objects.

**Module**  
*tei — The TEI Infrastructure*

**Members**  
att.dimensions[att.damaged][addSpan][age][birth][death][del][damage][delSpan][depth][dim][dimensions][ellipsis][ex][floruit][gap][geogFeats][height][offset][origDate][population][redo][retrieve][restore][retrace][secl][space][state][subst][substJoin][supplied][surplus][time][trait][unclear][undo][width]

**Attributes**  
att.ranging[@atLeast, @atMost, @min, @max, @confidence]

@unit names the unit used for the measurement  
**Status** Optional  
**Datatype** leidata.enumerated  
**Suggested values include:** cm (centimetres)  
m (millimetres)  
in (inches)  
line lines of text  
char (characters) characters of text

@quantity specifies the length in the units specified  
**Status** Optional  
**Datatype** leidata.numeric

@extent indicates the size of the object concerned using a project-specific vocabulary combining quantity and units in a single string of words.  
**Status** Optional  
**Datatype** leidata.text

<gap extent="5 words"/>

<height extent="half the page"/>

@precision characterizes the precision of the values specified by the other attributes.  
**Status** Optional  
**Datatype** leidata.certainty

@scope where the measurement summarizes more than one observation, specifies the applicability of this measurement.  
**Status** Optional  
**Datatype** leidata.enumerated  
**Sample values include:** all measurement applies to all instances.  
mmost measurement applies to most of the instances inspected.  
range measurement applies to only the specified range of instances.

---

att.divLike provides attributes common to all elements which behave in the same way as divisions.  

**Module**  
*tei — The TEI Infrastructure*

**Members**  
div div1 div2 div3 div4 div5 div6 div7[lg]

**Attributes**  
att.metrical[@met, @real, @rhyme] att.fragmentable[@part]

@org (organization) specifies how the content of the division is organized.  
**Status** Optional  
**Datatype** leidata.enumerated  
**Legal values are:** composite no claim is made about the sequence in which the immediate contents of this division are to be processed, or their inter-relationships.
The immediate contents of this element are regarded as forming a logical unit, to be processed in sequence. [Default]

@sample indicates whether this division is a sample of the original source and if so, from which part.

Status Optional

Datatype teidata.enumerated

Legal values are:

initial division lacks material present at end in source.
medial division lacks material at start and end.
final division lacks material at start.
unknown position of sampled material within original unknown.
complete division is not a sample. [Default]

att.docStatus provides attributes for use on metadata elements describing the status of a document.

Module tei — The TEI Infrastructure

Members bibl biblFull biblStruct change msDesc object revisionDesc schemaSpec

Attributes

@status describes the status of a document either currently or, when associated with a dated element, at the time indicated.

Status Optional

Datatype teidata.enumerated

Sample values include: approved candidate cleared deprecated draft [Default] embargoed expired frozen galley proposed published recommendation submitted unfinished withdrawn

Example

<revisionDesc status="published">
  <change when="2010-10-21" status="published"/>
  <change when="2010-10-02" status="cleared"/>
  <change when="2010-08-02" status="embargoed"/>
  <change when="2010-05-01" status="frozen" who="#MSM"/>
  <change when="2010-03-01" status="draft"/>
**att.duration** provides attributes for normalization of elements that contain datable events.

**Module** spoken — Transcriptions of Speech

**Members**

- att.timed
- annotationBlock
- binaryObject
- ellipsis
- gap
- incident
- kinesic
- media
- pause
- u
- vocal
- writing
- date
- recording
- time

**Attributes**

- att.duration.w3c (@dur)
- att.duration.iso (@dur-iso)

**Note** This 'superclass' provides attributes that can be used to provide normalized values of temporal information. By default, the attributes from the **att.duration.w3c** class are provided. If the module for names & dates is loaded, this class also provides attributes from the **att.duration.iso** class. In general, the possible values of attributes restricted to the W3C datatypes form a subset of those values available via the ISO 8601 standard. However, the greater expressiveness of the ISO datatypes is rarely needed, and there exists much greater software support for the W3C datatypes.

**att.duration.iso** provides attributes for recording normalized temporal durations.

**Module** tei — The TEI Infrastructure

**Members**

- att.duration
- att.timed
- annotationBlock
- binaryObject
- ellipsis
- gap
- incident
- kinesic
- media
- pause
- u
- vocal
- writing
- date
- recording
- time

**Attributes**

- @dur-iso (duration) indicates the length of this element in time.

  **Status** Optional

  **Datatype** teidata.duration.iso

  If both **when** and **dur** or **dur-iso** are specified, the values should be interpreted as indicating a span of time by its starting time (or date) and duration. In order to represent a time range by a duration and its ending time the **when-iso** attribute must be used.

  In providing a 'regularized' form, no claim is made that the form in the source text is incorrect; the regularized form is simply that chosen as the main form for purposes of unifying variant forms under a single heading.

**att.duration.w3c** provides attributes for recording normalized temporal durations.

**Module** tei — The TEI Infrastructure

**Members**

- att.duration
- att.timed
- annotationBlock
- binaryObject
- ellipsis
- gap
- incident
- kinesic
- media
- pause
- u
- vocal
- writing
- date
- recording
- time

**Attributes**

- @dur (duration) indicates the length of this element in time.

  **Status** Optional

  **Datatype** teidata.duration.w3c

  If both **when** and **dur** are specified, the values should be interpreted as indicating a span of time by its starting time (or date) and duration. In order to represent a time range by a duration and its ending time the **when-iso** attribute must be used.
In providing a ‘regularized’ form, no claim is made that the form in the source text is incorrect; the regularized form is simply that chosen as the main form for purposes of unifying variant forms under a single heading.

`att.edition` provides attributes identifying the source edition from which some encoded feature derives.

*Module* tei — [The TEI Infrastructure]

*Members* cb gb lb milestone pb refState

*Attributes*

- **@ed** (edition) supplies a sigil or other arbitrary identifier for the source edition in which the associated feature (for example, a page, column, or line break) occurs at this point in the text.
  - **Status** Optional
  - **Datatype** 1–∞ occurrences of `teidata.word` separated by whitespace

- **@edRef** (edition reference) provides a pointer to the source edition in which the associated feature (for example, a page, column, or line break) occurs at this point in the text.
  - **Status** Optional
  - **Datatype** 1–∞ occurrences of `teidata.pointer` separated by whitespace

*Example*

```xml
<l>Of Mans First Disobedience, <lb ed="1674"/> and <lb ed="1667"/> the Fruit</l>
<l>Of that Forbidden Tree, whose <lb ed="1667 1674"/> mortal tast </l>
<l>Brought Death into the World, <lb ed="1667"/> and all <lb ed="1674"/> our woe, </l>
```

*Example*

```xml
<listBibl>
  <bibl xml:id="stapledon1937">
    <author>Olaf Stapledon</author>, <title>Starmaker</title>, <publisher>Methuen</publisher>, <date>1937</date>
  </bibl>
  <bibl xml:id="stapledon1968">
    <author>Olaf Stapledon</author>, <title>Starmaker</title>, <publisher>Dover</publisher>, <date>1968</date>
  </bibl>
</listBibl>
```

*att.editLike* provides attributes describing the nature of an encoded scholarly intervention or interpretation of any kind. [3.5. Simple Editorial Changes | 10.3.1. Origination | 13.3.2. The Person Element | 11.3.1. Core Elements for Transcriptional Work]

*Module* tei — [The TEI Infrastructure]
att.enjamb

Module verse — Verse
Members

Attributes

@enjamb (enjambement) indicates that the end of a verse line is marked by enjambement.

Status Optional

Datatype teidata.enumerated

Sample values include: no the line is end-stopped

yes the line in question runs on into the next

weak the line is weakly enjambed

strong the line is strongly enjambed

Note The usual practice will be to give the value ‘yes’ to this attribute when enjambement is being marked, or the values ‘weak’ and ‘strong’ if degrees of enjambement are of interest; if no value is given, however, the attribute does not default to a value of ‘no’; this allows the attribute to be omitted entirely when enjambement is not of particular interest.

att.entryLike provides attributes used to distinguish different styles of dictionary entries. [9.1. Dictionary Body and Overall Structure, 9.2. The Structure of Dictionary Entries]

Module dictionaries — Dictionaries
Members entry entryFree superEntry
The TEI Guidelines

Attributes

@type indicates type of entry, in dictionaries with multiple types.

Status Optional

Datatype teidata.enumerated

Suggested values include: main a main entry (default). [Default]

hom (homograph) groups information relating to one homograph within an entry.

xref (cross reference) a reduced entry whose only function is to point to another main entry (e.g. for forms of an irregular verb or for variant spellings: was pointing to be, or esthete to aesthete).

affix an entry for a prefix, infix, or suffix.

abbr (abbreviation) an entry for an abbreviation.

supplemental a supplemental entry (for use in dictionaries which issue supplements to their main work in which they include updated information about entries).

foreign an entry for a foreign word in a monolingual dictionary.

The global n attribute may be used to encode the homograph numbers attached to entries for homographs.

att.formula provides attributes for defining a mathematical formula. [2.3.9. The Unit Declaration]

Module tei – The TEI Infrastructure

Members conversion

Attributes

@formula A formula is provided to describe a mathematical calculation such as a conversion between measurement systems.

Status Optional

Datatype teidata.xpath

Example

```xml
<encodingDesc>
  <unitDecl>
    <unitDef xml:id="stadium" type="linear">
      <label>stadium</label>
      <placeName ref="#rome"/>
      <conversion fromUnit="#pes" toUnit="#stadium" formula="$/fromUnit * 625"/>
      <desc>The stadium was a Roman unit of linear measurement equivalent to 625 pedes, or Roman feet.</desc>
    </unitDef>
  </unitDecl>
</encodingDesc>
```

Example

```xml
<encodingDesc>
  <unitDecl>
    <unitDef xml:id="wmw" type="power">
      <label>whatmeworry</label>
      <conversion fromUnit="#hpk" toUnit="#wmw" formula="$/fromUnit * 1"/>
      <desc>In the Potrzebie system of measures as introduced by Donald Knuth, the whatmeworry unit of power is equivalent to one hah per kovac.</desc>
    </unitDef>
  </unitDecl>
</encodingDesc>
```
<unitDef xml:id="kwmw" type="power">
  <label>kiilowhatmeworry</label>
  <conversion fromUnit="#kwmw" toUnit="#kwmw" formula="$fromUnit div 1000"/>
  <desc>The kilowhatmeworry is equivalent to 1000 whatmeworries.</desc>
</unitDef>

<unitDef xml:id="ap" type="power">
  <label>kiilowhatmeworry</label>
  <conversion fromUnit="#kwmw" toUnit="#ap" formula="$fromUnit div 100"/>
  <desc>One unit of aeolipower (A.P.) is equivalent to 100 kilowhatmeworries.</desc>
</unitDef>
</unitDecl>

Example

<conversion fromUnit="#furlongsPerFortnight" toUnit="#milesPerHour" formula="$fromUnit cast as xs:decimal * 0.000372"/>

Example

<conversion fromUnit="#deciday" toUnit="#hour" formula="$fromUnit cast as xs:decimal * 144 div 60"/>

Note This attribute class provides formula for use in defining a value used in mathematical calculation. It can be used to store a mathematical operation needed to convert from one system of measurement to another. We use the teidata.xpath datatype to express this value in order to communicate mathematical operations on an XML node or nodes. The $fromUnit variable notation referencing of the fromUnit attribute on the parent <conversion> element. Note that 'div' is required to express the division operator in XPath.

att.fragmentable provides attributes for representing fragmentation of a structural element, typically as a consequence of some overlapping hierarchy.

Module tei — The TEI Infrastructure

Attributes

@part specifies whether or not its parent element is fragmented in some way, typically by some other overlapping structure: for example a speech which is divided between two or more verse stanzas, a paragraph which is split across a page division, a verse line which is divided between two speakers.

Status Optional

Datatype teidata.enumerated

Legal values are: Y (yes) the element is fragmented in some (unspecified) respect

N (no) the element is not fragmented, or no claim is made as to its completeness[Default]

I (initial) this is the initial part of a fragmented element

M (medial) this is a medial part of a fragmented element

F (final) this is the final part of a fragmented element

821
Note: The values I, M, or F should be used only where it is clear how the element may be reconstituted.

att.gaijiProp provides attributes for defining the properties of non-standard characters or glyphs. [5]

Characters, Glyphs, and Writing Modes

Module: gaiji — Characters, Glyphs, and Writing Modes

Members: localProp, unicodeProp, unihanProp

Attributes: Attributes

@name provides the name of the character or glyph property being defined.

  Status: Required
  Datatype: teidata.xmlName

@value provides the value of the character or glyph property being defined.

  Status: Required
  Datatype: teidata.text

@version specifies the version number of the Unicode Standard in which this property name is defined.

  Status: Optional
  Datatype: teidata.enumerated

  Suggested values include: 1.0.1

  1.1
  2.0
  2.1
  3.0
  3.1
  3.2
  4.0
  4.1
  5.0
  5.1
  5.2
  6.0
  6.1
  6.2
  6.3
  7.0
  8.0
  9.0
  10.0
  11.0
  12.0
  12.1
  unassigned

Example: In this example a definition for the Unicode property Decomposition Mapping is provided.

  <unicodeProp name="Decomposition_Mapping" value="circle"/>
Note  All name-only attributes need an xs:boolean attribute value inside value.
Attributes

- att.global.rendition (@rend, @style, @rendition)
- att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)
- att.global.analytic (@ana)
- att.global.facs (@facs)
- att.global.change (@change)
- att.global.responsibility (@cert, @resp)
- att.global.source (@source)

@xml:id (identifier) provides a unique identifier for the element bearing the attribute.

- Status: Optional
- Datatype: ID

Note: The xml:id attribute may be used to specify a canonical reference for an element; see section 3.11. Reference Systems.

@n (number) gives a number (or other label) for an element, which is not necessarily unique within the document.

- Status: Optional
- Datatype: leidata.text

Note: The value of this attribute is always understood to be a single token, even if it contains space or other punctuation characters, and need not be composed of numbers only. It is typically used to specify the numbering of chapters, sections, list items, etc.; it may also be used in the specification of a standard reference system for the text.

@xml:lang (language) indicates the language of the element content using a 'tag' generated according to BCP 47.

- Status: Optional
- Datatype: leidata.language

Note: The xml:lang value will be inherited from the immediately enclosing element, or from its parent, and so on up the document hierarchy. It is generally good practice to specify xml:lang at the highest appropriate level, noticing that a different default may be needed for the <teiHeader> from that needed for the associated resource element or elements, and that a single TEI document may contain texts in many languages.

Only attributes with free text values (rare in these guidelines) will be in the scope of xml:lang.

The authoritative list of registered language subtags is maintained by IANA and is available at http://www.iana.org/assignments/language-subtag-registry. For a good general overview of the construction of language tags, see http://www.w3.org/International/articles/language-tags/, and for a practical step-by-step guide, see https://www.w3.org/International/questions/qa-choosing-language-tags.en.php.

The value used must conform with BCP 47. If the value is a private use code (i.e., starts with x- or contains -x-), a <language> element with a matching value for its ident attribute should be supplied in the TEI header to document this value. Such documentation may also optionally be supplied for non-private-use codes, though these must remain consistent with their (IETF) Internet Engineering Task Force definitions.

@xml:base provides a base URI reference with which applications can resolve relative URI references into absolute URI references.

- Status: Optional
- Datatype: leidata.pointer

Note: The consequences of this rapid depopulation were the loss of the last ariki or chief (Routledge 1920:205,210) and their connections to ancestral territorial organization.

The value used must conform with BCP 47. If the value is a private use code (i.e., starts with x- or contains -x-), a <language> element with a matching value for its ident attribute should be supplied in the TEI header to document this value. Such documentation may also optionally be supplied for non-private-use codes, though these must remain consistent with their (IETF) Internet Engineering Task Force definitions.
att.global.analytic provides additional global attributes for associating specific analyses or interpretations with appropriate portions of a text. [17.2. Global Attributes for Simple Analyses | 17.3. Spans and Interpretations]

Module analysis — Simple Analytic Mechanisms

Members att.global[AB] ab abbr abstract accMat acquisition activity actor add addName addSpan additional additions addrLine address adminInfo affiliation age alt altGrp altIdent altIdentifier alternate am analytic anchor annotation annotationBlock anyElement app appInfo application arc argument att attDef attList attRef author authority availability back bib bibFull biblScope biblStruct bicond binary binaryObject binding bindingDesc birth bloc body broadcast byline c cRefPattern caesura calendar calendarDesc camera caption case castGroup castItem castList catDesc catRef catchwords category ch cell certainty change channel char charDecl charName charProp choice cite citeData citeStructure citedRange classCode classDec classRef classSpec classes climate closer code collation collection colloc colophon cond condition constitution constraint constraintSpec content conversion corr correction correspAction correspContext correspDesc country creation custEvent custodialHist damage damageSpan data dataRef dataSpec datatype date dateline death decoDesc decoNote def default defaultVal del delSpan depth derivation desc dictScrap dim dimensions distinct distributor district div div1 div2 div3 div4 div5
The TEI Guidelines

Attributes

@ana (analysis) indicates one or more elements containing interpretations of the element on which the ana attribute appears.

Status
Optional

Datatype
1–∞ occurrences of teidata.pointer separated by whitespace

Note
When multiple values are given, they may reflect either multiple divergent interpretations of an ambiguous text, or multiple mutually consistent interpretations of the same passage in different contexts.

att.global.change provides attributes allowing its member elements to specify one or more states or revision campaigns with which they are associated.

Module
transcr — Representation of Primary Sources

Members

**Attributes**

**Attributes**

828
@fac$\text{ (facsimile) points to one or more images, portions of an image, or surfaces which correspond to the current element.}$

\text{Status Optional}

\text{Datatype 1–∞ occurrences of teidata.pointer separated by whitespace}

\text{att.global.linking} provides a set of attributes for hypertextual linking. [16. Linking, Segmentation, and Alignment]
In this example a <group> contains two <text>s, each containing the same document in a different language. The correspondence is indicated using corresp. The language is indicated using xml:lang, whose value is inherited; both the tag with the corresp and the tag pointed to by the corresp inherit the value from their immediate parent.

<!-- In a placeography called "places.xml" -->
<place xml:id="LOND1"
corresp="people.xml#LOND2 people.xml#GENI1">
  <placeName>London</placeName>
  <desc>The city of London...</desc>
</place>

<!-- In a literary personography called "people.xml" -->
<person xml:id="LOND2"
corresp="places.xml#LOND1 #GENI1">
  <persName type="lit">London</persName>
  <note>
    <p>Allegorical character representing the city of London</p>
  </note>
</person>

<person xml:id="GENI1"
corresp="places.xml#LOND1 #LOND2">
  <persName type="lit">London’s Genius</persName>
  <note>
  </note>
</person>
Personification of London’s genius. Appears as an allegorical character in mayoral shows.

In this example, a `<place>` element containing information about the city of London is linked with two `<person>` elements in a literary personography. This correspondence represents a slightly looser relationship than the one in the preceding example; there is no sense in which an allegorical character could be substituted for the physical city, or vice versa, but there is obviously a correspondence between them.

@synch (synchronous) points to elements that are synchronous with the current element.

@sameAs points to an element that is the same as the current element.

@copyOf points to an element of which the current element is a copy.

@next points to the next element of a virtual aggregate of which the current element is part.

@prev (previous) points to the previous element of a virtual aggregate of which the current element is part.

@exclude points to elements that are in exclusive alternation with the current element.

@select selects one or more alternants; if one alternant is selected, the ambiguity or uncertainty is marked as resolved. If more than one alternant is selected, the degree of ambiguity or uncertainty is marked as reduced by the number of alternants not selected.

`att.global.rendition` provides rendering attributes common to all elements in the TEI encoding scheme.

[1.3.1.1.3. Rendition Indicators]

Module `tei` – The TEI Infrastructure

Members `att.global`, `abbr`, `abstract`, `accMat`, `acquisition`, `activity`, `actor`, `add`, `addName`, `addSpan`, `additional`, `additions`, `addrLine`, `address`, `adminInfo`, `affiliation`, `age`, `altGrp`, `altIdent`, `altIdentifier`, `alternate`, `am`, `analytic`
Attributes

@rend (rendition) indicates how the element in question was rendered or presented in the source text.

Status Optional

Datatype 1–∞ occurrences of leidata.word separated by whitespace

Attributes

@rend (rendition) indicates how the element in question was rendered or presented in the source text.
Note These Guidelines make no binding recommendations for the values of the \textit{rend} attribute; the characteristics of visual presentation vary too much from text to text and the decision to record or ignore individual characteristics varies too much from project to project. Some potentially useful conventions are noted from time to time at appropriate points in the Guidelines. The values of the \textit{rend} attribute are a set of sequence-indeterminate individual tokens separated by whitespace.

\textit{@style} contains an expression in some formal style definition language which defines the rendering or presentation used for this element in the source text

\textbf{Status} Optional

\textbf{Datatype}\teidata.text

\begin{verbatim}
<hi rend="case(mixed)">New Blazing-World</hi>.
</head>

Note Unlike the attribute values of \textit{rend}, which uses whitespace as a separator, the \textit{style} attribute may contain whitespace. This attribute is intended for recording inline stylistic information concerning the source, not any particular output. The formal language in which values for this attribute are expressed may be specified using the \texttt{<styleDefDecl>} element in the TEI header.

If \textit{style} and \textit{rendition} are both present on an element, then \textit{style} overrides or complements \textit{rendition}. \textit{style} should not be used in conjunction with \textit{rend}, because the latter does not employ a formal style definition language.

\textit{@rendition} points to a description of the rendering or presentation used for this element in the source text.

\textbf{Status} Optional

\textbf{Datatype}\ 1–∞ occurrences of \teidata.pointer\ separated by whitespace

\begin{verbatim}
<hi rendition="#ac #sc">New Blazing-World</hi>.
</head>

Note The \textit{rendition} attribute is used in a very similar way to the \textit{class} attribute defined for XHTML but with the important distinction that its function is to describe the appearance of the source text, not necessarily to determine how that text should be presented on screen or paper.

If \textit{rendition} is used to refer to a style definition in a formal language like CSS, it is recommended that it not be used in conjunction with \textit{rend}. Where both \textit{rendition} and \textit{rend} are

833
att.global.responsibility provides attributes indicating the agent responsible for some aspect of the text, the markup or something asserted by the markup, and the degree of certainty associated with it.

each URI provided should indicate a `<rendition>` element defining the intended rendition in terms of some appropriate style language, as indicated by the `scheme` attribute.
Attributes

@cert (certainty) signifies the degree of certainty associated with the intervention or interpretation.
- Status: Optional
- Datatype: `teidata.probCert`

@resp (responsible party) indicates the agency responsible for the intervention or interpretation, for example an editor or transcriber.
- Status: Optional
- Datatype: 1–∞ occurrences of `teidata.pointer` separated by whitespace

Note: To reduce the ambiguity of a `resp` pointing directly to a person or organization, we recommend that `resp` be used to point not to an agent (<person> or <org>) but to a <respStmt>, <author>, <editor> or similar element which clarifies the exact role played by the agent. Pointing to multiple <respStmt>s allows the encoder to specify clearly each of the roles played in part of a TEI file (creating, transcribing, encoding, editing, proofing etc.).

Example

Blessed are the

```xml
<choice>
   <sic>cheesemakers</sic>
   <corr resp="#editor" cert="high">peacemakers</corr>
</choice>: for they shall be called the children of God.
```

Example

```xml
<!-- in the <text> ... --><lg>
<!-- ... -->
<l>Punkes, Panders, bafe extortionizing sla</l>
   <sic>n</sic>
   <corr resp="#JENS1_transcriber">u</corr>
</choice>
es,<l/>
<!-- ... -->
</lg>
<!-- in the <teiHeader> ... -->
<!-- ... -->
<respStmt xml:id="JENS1_transcriber">
   <resp when="2014">Transcriber</resp>
   <name>Janelle Jenstad</name>
</respStmt>
```

`att.global.source` provides attributes used by elements to point to an external source. [1.3.1.1.4. Sources, certainty, and responsibility 3.3.3. Quotation 8.3.4. Writing]

Module tei – The TEI Infrastructure
The TEI Guidelines

### Attributes

**Attributes** specify the source from which some aspect of this element is drawn.

**Status** Optional

**Datatype** 1–∞ occurrences of `teidata.pointer` separated by whitespace

**Note** The `source` attribute points to an external source. When used on elements describing
schema components such as `<schemaSpec>` or `<moduleRef>` it identifies the source from which declarations for the components of the object being defined may be obtained.

On other elements it provides a pointer to the bibliographical source from which a quotation or citation is drawn.

In either case, the location may be provided using any form of URI, for example an absolute URI, a relative URI, or private scheme URI that is expanded to an absolute URI as documented in a `<prefixDef>`.

If more than one location is specified, the default assumption is that the required source should be obtained by combining the resources indicated.

**Example**

```xml
<p>
  <!-- ... --> As Willard McCarty (<bibl xml:id="mcc_2012">2012, p.2</bibl>) tells us, <quote source="#mcc_2012">‘Collaboration’ is a problematic and should be a contested term.</quote>
  <!-- ... -->
</p>
```

**Example**

```xml
<p>
  <!-- ... -->
  <quote source="#chicago_15_ed">Grammatical theories are in flux, and the more we learn, the less we seem to know.</quote>
  <!-- ... -->
</p>

<bibl xml:id="chicago_15_ed">
</bibl>
```

**Example**

```xml
<elementRef key="p" source="tei:2.0.1"/>
```

Include in the schema an element named `<p>` available from the TEI P5 2.0.1 release.

**Example**

```xml
<schemaSpec ident="myODD" source="mycompiledODD.xml">
  <!-- further declarations specifying the components required -->
</schemaSpec>
```

Create a schema using components taken from the file `mycompiledODD.xml`. 
**att.handFeatures** provides attributes describing aspects of the hand in which a manuscript is written.

### [11.3.2.1. Document Hands](#)

**Module** tei — The TEI Infrastructure

**Members** handNote handShift scriptNote typeNote

**Attributes**

- **@scribe** gives a name or other identifier for the scribe believed to be responsible for this hand.
  - **Status** Optional
  - **Datatype** teidata.name

- **@scribeRef** points to a full description of the scribe concerned, typically supplied by a `<person>` element elsewhere in the description.
  - **Status** Optional
  - **Datatype** 1–∞ occurrences of teidata.pointer separated by whitespace

- **@script** characterizes the particular script or writing style used by this hand, for example *secretary*, *copperplate*, *Chancery*, *Italian*, etc.
  - **Status** Optional
  - **Datatype** 1–∞ occurrences of teidata.name separated by whitespace

- **@scriptRef** points to a full description of the script or writing style used by this hand, typically supplied by a `<scriptNote>` element elsewhere in the description.
  - **Status** Optional
  - **Datatype** 1–∞ occurrences of teidata.pointer separated by whitespace

- **@medium** describes the tint or type of ink, e.g. *brown*, or other writing medium, e.g. *pencil*
  - **Status** Optional
  - **Datatype** 1–∞ occurrences of teidata.enumerated separated by whitespace

- **@scope** specifies how widely this hand is used in the manuscript.
  - **Status** Optional
  - **Datatype** teidata.enumerated
  - **Legal values are:**
    - **sole** only this hand is used throughout the manuscript
    - **major** this hand is used through most of the manuscript
    - **minor** this hand is used occasionally in the manuscript

  Usually either script or scriptRef, and similarly, either scribe or scribeRef, will be supplied.

---

**attidentified** provides identifying attributes for elements which can be subsequently referenced by means of a key attribute.

**Module** tagdocs — Documentation Elements

**Members** attDef classSpec constraintSpec dataSpec elementSpec macroSpec moduleSpec paramSpec schemaSpec

**Attributes**

- **@ident** supplies the identifier by which this element may be referenced.
  - **Status** Required
  - **Datatype** teidata.name

- **@predeclare** says whether this object should be predeclared in the tei infrastructure module.
  - **Status** Optional
  - **Datatype** teidata.truthValue
  - **Default** false

- **@module** supplies a name for the module in which this object is to be declared.
  - **Status** Optional
  - **Datatype** teidata.xmlName
att.internetMedia provides attributes for specifying the type of a computer resource using a standard taxonomy.

**Module**  
**tei** — The TEI Infrastructure

**Members**  
att.media|binaryObject|graphic|media|equiv|ptr|ref

**Attributes**

* @mimeType (MIME media type) specifies the applicable multimedia internet mail extension  
**Status** Optional

**Datatype**  
1–∞ occurrences of teidata.word separated by whitespace

**Example**  
In this example `mimeType` is used to indicate that the URL points to a TEI XML file encoded in UTF-8.

```xml
<ref mimeType="application/tei+xml; charset=UTF-8" target="http://sourceforge.net/p/tei/code/HEAD/tree/trunk/P5/Source/guidelines-en.xml"/>
```

**Note**  
This attribute class provides an attribute for describing a computer resource, typically available over the internet, using a value taken from a standard taxonomy. At present only a single taxonomy is supported, the Multipurpose Internet Mail Extensions (MIME) Media Type system. This typology of media types is defined by the Internet Engineering Task Force in RFC 2046. The list of types is maintained by the Internet Assigned Numbers Authority (IANA). The `mimeType` attribute must have a value taken from this list.

att.lexicographic provides a set of attributes for specifying standard and normalized values, grammatical functions, alternate or equivalent forms, and information about composite parts. [9.2. The Structure of Dictionary Entries]

**Module** dictionaries — Dictionaries

**Members**  
att.dataCat|case|colloc|def|entryFree|etym|form|gen|gram|gramGrp|hom|hyph|iType|lang|lbl|mood|number|oRef|orth|pRef|per|pos|pron|re|sense|subc|syll|tns|usg|xr

**Attributes**  
att.dataCat (@dataCat, @valueDataCat) att.lexicographic.normalized (@norm, @orig)

* @expand (expand) gives an expanded form of information presented more concisely in the dictionary  
**Status** Optional

**Datatype** teidata.text

```xml
<gramGrp>
  <pos expand="noun">n</pos>
</gramGrp>
```

* @split (split) gives the list of split values for a merged form  
**Status** Optional

**Datatype** teidata.text

* @value (value) gives a value which lacks any realization in the printed source text.  
**Status** Optional

**Datatype** teidata.text
@location (location) indicates an <anchor> element typically elsewhere in the document, but possibly in another document, which is the original location of this component.
   Status Optional
   Datatype teidata.pointer

@mergedIn (merged into) gives a reference to another element, where the original appears as a merged form.
   Status Optional
   Datatype teidata.pointer

@opt (optional) indicates whether the element is optional or not
   Status Optional
   Datatype teidata.truthValue
   Default false

att.lexicographic.normalized provides attributes for usage within word-level elements in the analysis module and within lexicographic microstructure in the dictionaries module.
   Module analysis — Simple Analytic Mechanisms
   Members att.lexicographic[c|ase|colloc|def|entry|Free|etym|form|gen|gram|gramGrp|hom|hyph|iType|lang|lbr|mood|number|oRef|orth|pRef|per|pos|pron|re|sense|subc|syll|tms|usg|xr] att.linguistic[pc|w]
   Attributes Attributes

@norm (normalized) provides the normalized/standardized form of information present in the source text in a non-normalized form
   Status Optional
   Datatype teidata.text

Example of normalization from Aviso. Relation oder Zeitung. Wolfenbüttel, 1609. In: Deutsches Textarchiv, <s>
   <w norm="freiwillig">freywillig</w>
   <pc norm=",">
       join="left"/>
   <w norm="unbedrängt">vnbedräht</w>
   <w norm="und">vnd</w>
   <w norm="unverhindert">vnverhindert</w>
   </s>
   <w norm="Teil">Theyll</w>
   <w norm="Freude">Frewde</w>

@orig (original) gives the original string or is the empty string when the element does not appear in the source text.
   Status Optional
Example from a language documentation project of the Mixtepec-Mixtec language (ISO 639-3: 'mix'). This is a use case where speakers spell something incorrectly but we would like to preserve it for any number of reasons, the use of orig is essential and could have uses for both the speaker to see past mistakes, researchers to get insight into how untrained speakers write their language instinctually (in contrast to prescribed convention), etc.: `<w orig="nts sia'1">ntsasia'1</w>`

Example from the EarlyPrint project. Fragment of text where obvious errors have been corrected but the original forms remain recorded: `<w lemma="he" pos="pns" xml:id="blafj-003-a-0950">he</w>`
`<w lemma="have" pos="vvz" xml:id="blafj-003-a-0960">hath</w>`
`<w lemma="bring" pos="vvn" xml:id="blafj-003-a-0970">brought</w>`
`<w lemma="forth" pos="av" xml:id="blafj-003-a-0980" orig="sorth">forth</w>`

An example from the EarlyPrint project showing the use of both norm and orig. The orig attribute preserves the original version (sometimes with spelling errors, often with printer abbreviations), the element content resolves printer abbreviations but retains the original orthography, and the norm attribute holds normalized values: `<w lemma="commandment" pos="n1" norm="commandment" xml:id="b9avr-018-a-7720" orig="commandemēt">commandement</w>`

It needs to be stressed that the two attributes in this class are meant for strictly lexicographic and linguistic uses, and not for editorial interventions. For the latter, the mechanism based on `<choice>`, `<orig>`, and `<reg>` needs to be employed.

---

**att.linguistic** provides a set of attributes concerning linguistic features of tokens, for usage within token-level elements, specifically `<w>` and `<pc>` in the analysis module. ([17.4.2. Lightweight Linguistic Annotation](#))

**Module** analysis — Simple Analytic Mechanisms

**Members** pc

**Attributes** att.lexicographic.normalized (@norm, @orig)

@**lemma** provides a lemma (base form) for the word, typically uninflected and serving both as an identifier (e.g. in dictionary contexts, as a headword), and as a basis for potential inflections.

Status Optional

Datatype teidata.text

`<w lemma="wife">wives</w>`
`<w lemma="Arznei">Artzeneyen</w>`

@**lemmaRef** provides a pointer to a definition of the lemma for the word, for example in an online lexicon.

Status Optional

Datatype teidata.pointer

`<w type="verb" lemma="hit"`
@pos (part of speech) indicates the part of speech assigned to a token (i.e. information on whether it is a noun, adjective, or verb), usually according to some official reference vocabulary (e.g. for German: STTS, for English: CLAWS, for Polish: NKJP, etc.).

Status Optional

Datatype [teidata.text]

The German sentence 'Wir fahren in den Urlaub.' tagged with the Stuttgart-Tuebingen-Tagset (STTS).

<s>
  <w pos="PPER">Wir</w>
  <w pos="VVFIN">fahren</w>
  <w pos="APPR">in</w>
  <w pos="ART">den</w>
  <w pos="NN">Urlaub</w>
  <w pos="$.">.</w>
</s>

The English sentence 'We're going to Brazil.' tagged with the CLAWS-5 tagset, arranged inline (with significant whitespace).

<p>
  <w pos="PNP">We</w><w pos="VBB">'re</w><w pos="VVG">going</w><w pos="PRP">to</w>
</p>

The English sentence 'We're going on vacation to Brazil for a month!' tagged with the CLAWS-7 tagset and arranged sequentially.

<p>
  <w pos="PPIS2">We</w><w pos="VBR">'re</w><w pos="VVG">going</w>
  <w pos="II">on</w>
  <w pos="NN1">vacation</w>
  <w pos="II">to</w>
  <w pos="NPI">Brazil</w>
  <w pos="IF">for</w>
  <w pos="ATI">a</w>
  <w pos="NNT1">month</w>
</p>

@msd (morphosyntactic description) supplies morphosyntactic information for a token, usually according to some official reference vocabulary (e.g. for German: STTS-large tagset; for a feature description system designed as (pragmatically) universal, see Universal Features).

Status Optional

Datatype [teidata.text]

<ab>
  <w pos="PPER" msd="1.Pl_.Nom">Wir</w>
  <w pos="VVFIN" msd="1.Pl.Pres.Ind">fahren</w>
  <w pos="APPR" msd="--">in</w>
  <w pos="ART" msd="Def.Masc.Akk.Sg">den</w>
  <w pos="NN" msd="Masc.Akk.Sg">Urlaub</w>
  <pc pos="$." msd="--">.</pc>
</ab>

@join when present, it provides information on whether the token in question is adjacent to
another, and if so, on which side. The definition of this attribute is adapted from ISO MAF (Morpho-syntactic Annotation Framework), ISO 24611:2012.

**Status** Optional

**Datatype** `teidata.text`

**Legal values are:**
- `no` (the token is not adjacent to another)
- `left` (there is no whitespace on the left side of the token)
- `right` (there is no whitespace on the right side of the token)
- `both` (there is no whitespace on either side of the token)
- `overlap` (the token overlaps with another; other devices (specifying the extent and the area of overlap) are needed to more precisely locate this token in the character stream)

The example below assumes that the lack of whitespace is marked redundantly, by using the appropriate values of `join`. `<s>`

```
<pc join="right">"</pc>
<w join="left">Friends</w>
<w>will</w>
<w>be</w>
<w join="right">friends</w>
<pc join="both">
<pc join="left">"</pc>
```

Note that a project may make a decision to only indicate lack of whitespace in one direction, or do that non-redundantly. The existing proposal is the broadest possible, on the assumption that we adopt the "streamable view", where all the information on the current element needs to be represented locally.

The English sentence ‘We’re going on vacation.’ tagged with the CLAWS-5 tagset, arranged sequentially, tagged on the assumption that only the lack of the preceding whitespace is indicated. `<p>`

```
<w pos="PNP">We</w>
<w pos="VBB">’re</w>
<w pos="VVG">going</w>
<w pos="PRP">on</w>
<w pos="NN1">vacation</w>
<pc pos="PUN" join="left">."</pc>
```

These attributes make it possible to encode simple language corpora and to add a layer of linguistic information to any tokenized resource. See section [17.4.2. Lightweight Linguistic Annotation](#) for discussion.

---

**att.locatable** provides attributes for referencing locations by pointing to entries in a canonical list of places.

[2.3.9. The Unit Declaration](#) | [3.3.4.3. States, Traits, and Events](#)
---

**Module** `tei` — [The TEI Infrastructure](#)

**Members** `conversion` `event`

**Attributes** `Attributes`

- `@where` indicates one or more locations by pointing to a `<place>` element or other canonical description.

**Status** Optional

**Datatype** `1–∞ occurrences of teidata.pointer` separated by whitespace
att.measurement provides attributes to represent a regularized or normalized measurement.

Module tei — The TEI Infrastructure

Members measure measureGrp unit

Attributes Attributes

@unit (unit) indicates the units used for the measurement, usually using the standard symbol for the desired units.

Status Optional

Datatype teidata.enumerated

Suggested values include: m (metre) SI base unit of length

kg (kilogram) SI base unit of mass

s (second) SI base unit of time

Hz (hertz) SI unit of frequency

Pa (pascal) SI unit of pressure or stress

Ω (ohm) SI unit of electric resistance

L (litre) 1 dm³

t (tonne) 10³ kg

ha (hectare) 1 hm²

Å (ångström) 10⁻¹⁰ m

mL (millilitre)

cm (centimetre)

dB (decibel) see remarks, below

kbit (kilobit) 10³ or 1000 bits

Kibit (kibibit) 2¹⁰ or 1024 bits

kB (kilobyte) 10³ or 1000 bytes

KiB (kibibyte) 2¹⁰ or 1024 bytes

MB (megabyte) 10⁶ or 1000 000 bytes

MiB (mebibyte) 2²⁰ or 1048 576 bytes

Note If the measurement being represented is not expressed in a particular unit, but rather is a number of discrete items, the unit count should be used, or the unit attribute may be left unspecified.

Wherever appropriate, a recognized SI unit name should be used (see further http://www.bipm.org/en/publications/si-brochure/; http://physics.nist.gov/cuu/Units/). The list above is indicative rather than exhaustive.

@unitRef points to a unique identifier stored in the xml:id of a <unitDef> element that defines a unit of measure.

Status Optional

Datatype teidata.pointer

@quantity (quantity) specifies the number of the specified units that comprise the measurement

Status Optional

Datatype teidata.numeric

@commodity (commodity) indicates the substance that is being measured

Status Optional

Datatype 1–∞ occurrences of teidata.word separated by whitespace

Note In general, when the commodity is made of discrete entities, the plural form should be used, even when the measurement is of only one of them.
Schematron  <sch:rule context="tei:[@unitRef]"> <sch:report test="@unit" role="info">The @unit attribute may be unnecessary when @unitRef is present.</sch:report> </sch:rule>

Note This attribute class provides a triplet of attributes that may be used either to regularize the values of the measurement being encoded, or to normalize them with respect to a standard measurement system.

<lt>
<!-- regularization: -->
So weren't you gonna buy <measure quantity="0.5" unit="gal"
  commodity="ice cream">half a gallon</measure>, baby
</lt>

<lt>
<!-- normalization: -->
So won't you go and buy <measure quantity="1.893" unit="L"
  commodity="ice cream">half a gallon</measure>, baby?
</lt>

The unit should normally be named using the standard symbol for an SI unit (see further http://www.bipm.org/en/publications/si-brochure/; http://physics.nist.gov/cuu/Units/). However, encoders may also specify measurements using informally defined units such as lines or characters.

---

att.media provides attributes for specifying display and related properties of external media.

Module tei – The TEI Infrastructure

Members binaryObject graphic media

Attributes

- @width Where the media are displayed, indicates the display width
  Status Optional
  Datatype teidata.outputMeasurement

- @height Where the media are displayed, indicates the display height
  Status Optional
  Datatype teidata.outputMeasurement

- @scale Where the media are displayed, indicates a scale factor to be applied when generating the desired display size
  Status Optional
  Datatype teidata.numeric

---

att.metrical defines a set of attributes that certain elements may use to represent metrical information. [6.4 Rhyme and Metrical Analysis]

Module verse – Verse

Members att.divLike[div1 div2 div3 div4 div5 div6 div7 lg] att.segLike[c cl m pc phr seg w sl]

Attributes

- @met (metrical structure, conventional) contains a user-specified encoding for the conventional metrical structure of the element.
  Status Recommended
  Datatype token

Note The pattern may be specified by means of either a standard term for the kind of metrical unit (e.g. hexameter) or an encoded representation for the metrical pattern
The TEI Guidelines

(e.g. +–+-+-+-+). In either case, the notation used should be documented by a `<metDecl>` element within the `<encodingDesc>` of the associated header.

Where this attribute is not specified, the metrical pattern for the element concerned is understood to be inherited from its parent.

@real (metrical structure, realized) contains a user-specified encoding for the actual realization of the conventional metrical structure applicable to the element.

Status Optional
Datatype token

Note The pattern may be specified by means of either a standard term for the kind of metrical unit (e.g. hexameter) or an encoded representation for the metrical pattern (e.g. +–+-+-+-+). In either case, the notation used should be documented by a `<metDecl>` element within the `<encodingDesc>` of the associated header.

Where this attribute is not specified, the metrical realization for the element concerned is understood to be identical to that specified or implied for the `met` attribute.

@rhyme (rhyme scheme) specifies the rhyme scheme applicable to a group of verse lines.

Status Recommended
Datatype token

Note By default, the rhyme scheme is expressed as a string of alphabetic characters each corresponding with a rhyming line. Any non-rhyming lines should be represented by a hyphen or an X. Alternative notations may be defined as for `met` by use of the `<metDecl>` element in the TEI header.

When the default notation is used, it does not make sense to specify this attribute on any unit smaller than a line. Nor does the default notation provide any way to record internal rhyme, or to specify non-conventional rhyming practice. These extensions would require user-defined alternative notations.

att.milestoneUnit provides attributes to indicate the type of section which is changing at a specific milestone. [3.11.3. Milestone Elements | 2.3.6.3. Milestone Method | 2.3.6. The Reference System Declaration]

Module core — Elements Available in All TEI Documents

Members milestone refState

Attributes Attributes

@unit provides a conventional name for the kind of section changing at this milestone.

Status Required
Datatype leidata.enumerated

Suggested values include: page physical page breaks (synonymous with the `<pb>` element).

column column breaks.
line line breaks (synonymous with the `<lb>` element).
book any units termed book, liber, etc.
poem individual poems in a collection.
canto cantos or other major sections of a poem.
speaker changes of speaker or narrator.
stanza stanzas within a poem, book, or canto.
act acts within a play.
scene scenes within a play or act.
section sections of any kind.
absent passages not present in the reference edition.
unnumbered passages present in the text, but not to be included as part of the reference.

\[\texttt{<milestone n="23"
    ed="La"
    unit="Dreissiger"/>}
\] ...

\[\texttt{<milestone n="24"
    ed="AV"
    unit="verse"/>} ...\]

**Note** If the milestone marks the beginning of a piece of text not present in the reference edition, the special value **absent** may be used as the value of **unit**. The normal interpretation is that the reference edition does not contain the text which follows, until the next <milestone> tag for the edition in question is encountered.

In addition to the values suggested, other terms may be appropriate (e.g. Stephanus for the Stephanus numbers in Plato).

The **type** attribute may be used to characterize the unit boundary in any respect other than simply identifying the type of unit, for example as word-breaking or not.

---

**att.msClass** provides attributes to indicate text type or classification. ([10.6. Intellectual Content][10.6.1. The msItem and msItemStruct Elements])

**Module** msdescription — Manuscript Description

**Members** msContents msItem msItemStruct

**Attributes**

@class identifies the text types or classifications applicable to this item by pointing to other elements or resources defining the classification concerned.

**Status** Optional

**Datatype** 1–∞ occurrences of teidata.pointer separated by whitespace

---

**att.msExcerpt** (manuscript excerpt) provides attributes used to describe excerpts from a manuscript placed in a description thereof. ([10.6. Intellectual Content])

**Module** msdescription — Manuscript Description

**Members** colophon explicit finalRubric incipit msContents msItem msItemStruct quote rubric

**Attributes**

@defective indicates whether the passage being quoted is defective, i.e. incomplete through loss or damage.

**Status** Optional

**Datatype** teidata.xTruthValue

In the case of an incipit, indicates whether the incipit as given is defective, i.e. the first words of the text as preserved, as opposed to the first words of the work itself. In the case of an explicit, indicates whether the explicit as given is defective, i.e. the final words of the text as preserved, as opposed to what the closing words would have been had the text of the work been whole.

---

**att.namespaceable** provides attributes indicating the target namespace for an object being created

**Module** tagdocs — Documentation Elements

**Members** elementSpec schemaSpec

---

847
Attributes

@ns (namespace) specifies the namespace to which this element belongs

<table>
<thead>
<tr>
<th>Status</th>
<th>Datatype</th>
<th>Default</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>leidata.namespace</td>
<td><a href="http://www.tei-c.org/ns/1.0">http://www.tei-c.org/ns/1.0</a></td>
</tr>
</tbody>
</table>

**att.naming** provides attributes common to elements which refer to named persons, places, organizations etc.

[3.6.1. Referring Strings][13.3.6. Names and Nyms]

**Module** tei — The TEI Infrastructure

**Members**

- att.personal
- addName
- forename
- genName
- name
- orgName
- persName
- placeName
- roleName
- surname
- affiliation
- author
- birth

- nationality
- occupation
- offset
- origPlace
- population
- pubPlace
- region
- repository
- residence
- rs
- settlement
- socecStatus
- state
- terrain
- trait

**Attributes**

@role may be used to specify further information about the entity referenced by this name in the form of a set of whitespace-separated values, for example the occupation of a person, or the status of a place.

<table>
<thead>
<tr>
<th>Status</th>
<th>Datatype</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>teidata.enumerated separated by whitespace</td>
</tr>
</tbody>
</table>

@nymRef (reference to the canonical name) provides a means of locating the canonical form (nym) of the names associated with the object named by the element bearing it.

<table>
<thead>
<tr>
<th>Status</th>
<th>Datatype</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optional</td>
<td>teidata.pointer separated by whitespace</td>
</tr>
</tbody>
</table>

**Note** The value must point directly to one or more XML elements by means of one or more URLs, separated by whitespace. If more than one is supplied, the implication is that the name is associated with several distinct canonical names.

**att.notated** provides attributes to indicate any specialised notation used for element content.

**Module** tei — The TEI Infrastructure

**Members**

- pref (prefix)
- suff (suffix)
att.patternReplacement provides attributes for regular-expression matching and replacement. [16.2.3. Using Abbreviated Pointers | 2.3.6.3. Milestone Method | 2.3.6. The Reference System Declaration | 2.3.6.2. Search-and-Replace Method]

Module header — The TEI Header
Members

Attributes

@matchPattern specifies a regular expression against which the values of other attributes can be matched.
Status Required
Datatype teidata.pattern
Note The syntax used should follow that defined by W3C XPath syntax. Note that parenthesized groups are used not only for establishing order of precedence and atoms for quantification, but also for creating subpatterns to be referenced by the replacementPattern attribute.

@replacementPattern specifies a ‘replacement pattern’, that is, the skeleton of a relative or absolute URI containing references to groups in the matchPattern which, once subpattern substitution has been performed, complete the URI.
Status Required
Datatype teidata.replacement
Note The strings $1, $2 etc. are references to the corresponding group in the regular expression specified by matchPattern (counting open parenthesis, left to right). Processors are expected to replace them with whatever matched the corresponding group in the regular expression.
If a digit preceded by a dollar sign is needed in the actual replacement pattern (as opposed to being used as a back reference), the dollar sign must be written as %24.

att.personal (attributes for components of names usually, but not necessarily, personal names) common attributes for those elements which form part of a name usually, but not necessarily, a personal name.

Module tei — The TEI Infrastructure
Members

Attributes att.naming (@role, @nymRef) (att.canonical (@key, @ref))

@full indicates whether the name component is given in full, as an abbreviation or simply as an initial.
Status Optional
Datatype teidata.enumerated
Legal values are: yes (yes) the name component is spelled out in full.[Default]
   abb (abbreviated) the name component is given in an abbreviated form.
   init (initial letter) the name component is indicated only by one initial.

@sort (sort) specifies the sort order of the name component in relation to others within the name.
Status Optional

849
att.placement provides attributes for describing where on the source page or object a textual element appears.

Datatype  `teidata.count`

Attributes

@place  specifies where this item is placed.

Status  Recommended

Datatype  1–∞ occurrences of `teidata.enumerated` separated by whitespace

Suggested values include:

- top  at the top of the page
- bottom  at the foot of the page
- margin  in the margin (left, right, or both)
- opposite  on the opposite, i.e. facing, page
- overleaf  on the other side of the leaf
- above  above the line
- right  to the right, e.g. to the right of a vertical line of text, or to the right of a figure
- below  below the line
- left  to the left, e.g. to the left of a vertical line of text, or to the left of a figure
- end  at the end of e.g. chapter or volume.
- inline  within the body of the text.
- inspace  in a predefined space, for example left by an earlier scribe.

```
<add place="margin">[An addition written in the margin]</add>
<add place="bottom opposite">[An addition written at the foot of the current page and also on the facing page]</add>
<note place="bottom">Ibid, p.7</note>
```

att.pointing provides a set of attributes used by all elements which point to other elements by means of one or more URI references.

Datatype  `teidata.language`

Attributes

@targetLang  specifies the language of the content to be found at the destination referenced by target, using a ‘language tag’ generated according to BCP 47.

Status  Optional

```
<linkGrp xml:id="pol-swh_aln_2.1-linkGrp">
  <ptr xml:id="pol-swh_aln_2.1.1-ptr"
    target="pol/UDHR/text.xml#pol_txt_1-head"
    type="tuv"
    targetLang="pl"/>
</linkGrp>

<linkGrp xml:id="pol-swh_aln_2.1.2-linkGrp">
  <ptr xml:id="pol-swh_aln_2.1.2-ptr"
    target="swh/UDHR/text.xml#swh_txt_1-head"
    type="tuv"
    targetLang="pl"/>
</linkGrp>
```
In the example above, the `<linkGrp>` combines pointers at parallel fragments of the *Universal Declaration of Human Rights*: one of them is in Polish, the other in Swahili.

*Note* The value must conform to BCP 47. If the value is a private use code (i.e., starts with x- or contains -x-), a `<language>` element with a matching value for its `ident` attribute should be supplied in the TEI header to document this value. Such documentation may also optionally be supplied for non-private-use codes, though these must remain consistent with their (IETF) Internet Engineering Task Force definitions.

@target specifies the destination of the reference by supplying one or more URI References

**Status** Optional

**Datatype** 1–∞ occurrences of `teidata.pointer` separated by whitespace

*Note* One or more syntactically valid URI references, separated by whitespace. Because whitespace is used to separate URIs, no whitespace is permitted inside a single URI. If a whitespace character is required in a URI, it should be escaped with the normal mechanism, e.g. TEI%20Consortium.

@evaluate (evaluate) specifies the intended meaning when the target of a pointer is itself a pointer.

**Status** Optional

**Datatype** `teidata.enumerated`

*Legal values are:*  
- `all` if the element pointed to is itself a pointer, then the target of that pointer will be taken, and so on, until an element is found which is not a pointer.  
- `one` if the element pointed to is itself a pointer, then its target (whether a pointer or not) is taken as the target of this pointer.  
- `none` no further evaluation of targets is carried out beyond that needed to find the element specified in the pointer’s target.

*Note* If no value is given, the application program is responsible for deciding (possibly on the basis of user input) how far to trace a chain of pointers.

---

**att.pointing.group** provides a set of attributes common to all elements which enclose groups of pointer elements. [16. Linking, Segmentation, and Alignment]

**Module** tei – The TEI Infrastructure

**Members** `altGrp` `joinGrp` `linkGrp`

**Attributes** `att.pointing ( @targetLang, @target, @evaluate)` `att.typed ( @type, @subtype)

- @domains optionally specifies the identifiers of the elements within which all elements indicated by the contents of this element lie.

  **Status** Optional

  **Datatype** 2–∞ occurrences of `teidata.pointer` separated by whitespace

  *Note* If this attribute is supplied every element specified as a target must be contained within the element or elements named by it. An application may choose whether or not to report failures to satisfy this constraint as errors, but may not access an element of the right identifier but in the wrong context. If this attribute is not supplied, then target elements may appear anywhere within the target document.

- @targFunc (target function) describes the function of each of the values of the `target` attribute of the enclosed `<link>`, `<join>`, or `<alt>` tags.

  **Status** Optional

  **Datatype** 2–∞ occurrences of `teidata.word` separated by whitespace
The number of separate values must match the number of values in the target attribute in the enclosed `<link>`, `<join>` or `<alt>` tags (an intermediate `<ptr>` element may be needed to accomplish this). It should also match the number of values in the domains attribute, of the current element, if one has been specified.

**att.predicate** provides attributes for filtering by an XPath predicate expression. [22.4. Common Elements](#)

<table>
<thead>
<tr>
<th>Module</th>
<th>tagdocs — Documentation Elements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Members</td>
<td>equiv model</td>
</tr>
<tr>
<td>Attributes</td>
<td></td>
</tr>
<tr>
<td>@predicate</td>
<td>the condition under which the element bearing this attribute applies, given as an XPath predicate expression.</td>
</tr>
<tr>
<td>Status</td>
<td>Optional</td>
</tr>
<tr>
<td>Datatype</td>
<td>teidata.xpath</td>
</tr>
</tbody>
</table>

*Note* The XPath predicate expression given as the value of the `predicate` attribute has to be provided without wrapping square brackets.

**Example**

```xml
<model predicate="parent::person"
    behaviour="inline">
  <desc versionDate="2015-08-21"
    xml:lang="en">If it is a child of a person element, treat as inline</desc>
</model>
```

**Example** The following example declares that the `<name>` element can be mapped to, or is equivalent to, the external concepts of 'PERSON' and 'PLACE' depending on the 'XPath' expression given in `predicate`

```xml
<elementSpec ident="name" mode="change">
  <equiv name="PERSON"
    predicate="@type eq 'person'"
    uri="http://www.example.com/entities/person"/>
  <equiv name="PLACE"
    predicate="@type eq 'place'"
    uri="http://www.example.com/entities/place"/>
</elementSpec>
```

**att.ranging** provides attributes for describing numerical ranges.

<table>
<thead>
<tr>
<th>Module</th>
<th>tei — The TEI Infrastructure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Members</td>
<td>att.dimensions</td>
</tr>
<tr>
<td>Attributes</td>
<td>@atLeast</td>
</tr>
<tr>
<td>Status</td>
<td>Optional</td>
</tr>
<tr>
<td>Datatype</td>
<td>teidata.numeric</td>
</tr>
<tr>
<td>@atMost</td>
<td>gives a maximum estimated value for the approximate measurement.</td>
</tr>
<tr>
<td>Status</td>
<td>Optional</td>
</tr>
<tr>
<td>Datatype</td>
<td>teidata.numeric</td>
</tr>
</tbody>
</table>
where the measurement summarizes more than one observation or a range, supplies the
minimum value observed.

Status Optional
Datatype teidata.numeric

@max where the measurement summarizes more than one observation or a range, supplies the
maximum value observed.

Status Optional
Datatype teidata.numeric

@confidence specifies the degree of statistical confidence (between zero and one) that a value
falls within the range specified by min and max, or the proportion of observed values that fall
within that range.

Status Optional
Datatype teidata.probability

Example

The MS. was lost in transmission by mail from <del rend="overstrike">
<gap reason="illegible"
extent="one or two letters" atLeast="1" atMost="2" unit="chars"/>
</del> Philadelphia to the Graphic office, New York.

att.rdgPart provides attributes to mark the beginning or ending of a fragmentary manuscript or other witness.

[12.1.5. Fragmentary Witnesses]

Module textcrit — Critical Apparatus
Members lacunaEnd|lacunaStart|wit|witEnd|witStart
Attributes @wit (witness or witnesses) contains a space-delimited list of one or more sigla indicating the
witnesses to this reading beginning or ending at this point.

Status Optional
Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

These elements may appear anywhere within the elements <lem> and <rdg>, and also within any of
their constituent elements.

att.repeatable provides attributes for the elements which define component parts of a content model.

Module tagdocs — Documentation Elements
Members alternate|anyElement|classRef|datatype|elementRef|sequence
Attributes @minOccurs (minimum number of occurrences) indicates the smallest number of times this
component may occur.

Status Optional
Datatype teidata.count
Default 1

@maxOccurs (maximum number of occurrences) indicates the largest number of times this
component may occur.

Status Optional
Datatype teidata.unboundedInt
Default 1
The TEI Guidelines

Schematron

```
<sch:rule context="*[ @minOccurs and @maxOccurs ]">
  <sch:let name="min" value="@minOccurs cast as xs:integer"/>
  <sch:let name="max" value="if ( normalize-space(@maxOccurs) eq "unbounded" ) then -1 else @maxOccurs cast as xs:integer"/>
  <sch:assert test="$max eq -1 or $max ge $min">@maxOccurs should be greater than or equal to @minOccurs</sch:assert>
</sch:rule>
```

```
<sch:rule context="*[ @minOccurs and not( @maxOccurs ) ]">
  <sch:assert test="@minOccurs cast as xs:integer lt 2">When @maxOccurs is not specified, @minOccurs must be 0 or 1</sch:assert>
</sch:rule>
```

Note The value of minOccurs must always be less than or equal to that of maxOccurs. Since the default value of maxOccurs is 1, when maxOccurs is not specified minOccurs must always be less than or equal to 1. The default value of minOccurs is also 1, and therefore, when minOccurs is not specified the value of maxOccurs must always be greater than or equal to 1. An ODD processor should raise an error if either of these conditions is not met.

---

**att.resourced** provides attributes by which a resource (such as an externally held media file) may be located.

**Module** tei — The TEI Infrastructure

**Members** graphic media schemaRef

**Attributes**

- **@url** (uniform resource locator) specifies the URL from which the media concerned may be obtained.
  - **Status** Required
  - **Datatype** leidata.pointer

**att.scoping** provides attributes for selecting particular elements within a document.

**Module** tei — The TEI Infrastructure

**Members** certainty precision respons

**Attributes**

- **@target** points at one or more sets of zero or more elements each.
  - **Status** Optional
  - **Datatype** 1–∞ occurrences of leidata.pointer separated by whitespace

  Elizabeth went to `<persName xml:id="ESSEX">Essex</persName>`
  `<certainty target="#ESSEX" locus="name" degree="0.6"/>

- **@match** supplies an XPath selection pattern using the syntax defined in Kay (ed.) (2017) which identifies a set of nodes, selected within the context identified by the target attribute if this is supplied, or within the context of the parent element if it is not.
  - **Status** Optional
  - **Datatype** leidata.xpath

  `<gap reason="cancelled">
   <certainty match="@reason" locus="value" cert="low"/>
  </gap>`

The semantics of this element apply to the nodeset identified by the value of the target attribute, possibly modified by the value of the match attribute. If more than one identifier is given, the implication is that all elements (or nodesets) are intended. The match attribute may also be used as a means of identifying groups of elements.

854
If *target* and *match* are present, *target* selects an element and the XPath expression in *match* is evaluated in the context of that element. If neither attribute is present, the expression applies to its parent element. If only *target* is given, the expression refers to the selected element or nodeselement. If only *match* is given, the XPath expression is evaluated in the context of the parent element of the bearing element.

Note that the value of the *target* attribute may include an XPointer expression including an XPath expression (see 16.2.4. TEI XPointer Schemes).

---

**att.segLike** provides attributes for elements used for arbitrary segmentation. [16.3. Blocks, Segments, and Anchors] [17.1. Linguistic Segment Categories]

*Module* tei — The TEI Infrastructure

*Members* cl m pc phr seg w

*Attributes* 

@att.segLike@metmetrical (met, real, rhyme) @att.segLike@datcat (datcat, valueDatcat) @att.segLike@fragmentable (part)

`@function` (function) characterizes the function of the segment.

<table>
<thead>
<tr>
<th>Status</th>
<th>Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datatype</td>
<td>teidata.enumerated</td>
</tr>
</tbody>
</table>

*Note* Attribute values will often vary depending on the type of element to which they are attached. For example, a `<cl>` may take values such as coordinate, subject, adverbial etc. For a `<phr>` such values as subject, predicate etc. may be more appropriate. Such constraints will typically be implemented by a project-defined customization.

---

**att.sortable** provides attributes for elements in lists or groups that are sortable, but whose sorting key cannot be derived mechanically from the element content. [9.1. Dictionary Body and Overall Structure]

*Module* tei — The TEI Infrastructure

*Members* bibl biblFull biblStruct correspAction entry entryFree event idno item list listApp listBibl listChange listEvent listNym listObject listPerson listPlace listRelation listWit msDesc nym object org person personGrp persona place relation superEntry term witness

*Attributes* 

@att.sortable@sortKey supplies the sort key for this element in an index, list or group which contains it.

<table>
<thead>
<tr>
<th>Status</th>
<th>Optional</th>
</tr>
</thead>
<tbody>
<tr>
<td>Datatype</td>
<td>teidata.word</td>
</tr>
</tbody>
</table>

David's other principal backer, Josiah ha-Kohen

`<index indexName="NAMES">`

`<term sortKey="Azarya_Josiah_Kohen">Josiah ha-Kohen b. Azarya</term>`

`</index>` b. Azarya, son of one of the last gaons of Sura was David's own first cousin.

*Note* The sort key is used to determine the sequence and grouping of entries in an index. It provides a sequence of characters which, when sorted with the other values, will produce the desired order; specifics of sort key construction are application-dependent

Dictionary order often differs from the collation sequence of machine-readable character sets; in English-language dictionaries, an entry for `4-H` will often appear alphabetized under `fourh`, and `McCoy` may be alphabetized under `maccoy`, while `A1`, `A4`, and `A5` may all appear in numeric order `alphabetized` between `a-` and `AA`. The sort key is required
if the orthography of the dictionary entry does not suffice to
determine its location.

att.spanning provides attributes for elements which delimit a span of text by pointing mechanisms rather than
by enclosing it. [11.3.1.4. Additions and Deletions 1.3.1. Attribute Classes]

Module  tei — The TEI Infrastructure
Members addSpan cb damageSpan delSpan gb index lb metamark milestone mod pb redo retrace undo
Attributes  
@spanTo indicates the end of a span initiated by the element bearing this attribute.

Status  Optional
Datatype  leidata.pointer
Schematron  The @spanTo attribute must point to an element following the current
element <sch:rule context="tei:[@spanTo]"> <sch:assert test="id(substring(@spanTo,2)) and
following::*[@xml:id=substring(current()/@spanTo,2)]">The element indicated by
@spanTo (<sch:value-of select="@spanTo"/>) must follow the current element
 <sch:name/> </sch:assert> </sch:rule>

The span is defined as running in document order from the start of the content of the pointing element
to the end of the content of the element pointed to by the spanTo attribute (if any). If no value is supplied
for the attribute, the assumption is that the span is coextensive with the pointing element. If no content is
present, the assumption is that the starting point of the span is immediately following the element itself.

att.styleDef provides attributes to specify the name of a formal definition language used to provide formatting
or rendition information.

Module  tei — The TEI Infrastructure
Members  rendition styleDefDecl
Attributes  
@scheme identifies the language used to describe the rendition.

Status  Optional
Datatype  leidata.enumerated
Legal values are: css  Cascading Stylesheet Language
            xslfo  Extensible Stylesheet Language Formatting Objects
            free  Informal free text description
            other  A user-defined rendition description language

Note  If no value for the @scheme attribute is provided, then the default assumption
should be that CSS is in use.

@schemeVersion supplies a version number for the style language provided in scheme.

Status  Optional
Datatype  leidata.versionNumber
Schematron  <sch:rule context="tei:[@schemeVersion]"> <sch:assert test="@scheme and
not(@scheme = 'free')"> @schemeVersion can only be used if @scheme is specified.
 </sch:assert> </sch:rule>

Note  If schemeVersion is used, then scheme should also appear, with a value other than free.
**att.tableDecoration** provides attributes used to decorate rows or cells of a table.  

**Module** figures — Tables, Formulæ, Graphics, and Notated Music  
**Members** cell row  
**Attributes**  
*role* (role) indicates the kind of information held in this cell or in each cell of this row.  
**Status** Optional  
**Datatype** leidata.enumerated  
**Suggested values include:** label labelling or descriptive information only.  
**data** data values [Default]  
**Note** When this attribute is specified on a row, its value is the default for all cells in this row. When specified on a cell, its value overrides any default specified by the role attribute of the parent <row> element.  
*rows* (rows) indicates the number of rows occupied by this cell or row.  
**Status** Optional  
**Datatype** leidata.count  
**Default** 1  
**Note** A value greater than one indicates that this cell spans several rows. Where several cells span multiple rows, it may be more convenient to use nested tables.  
*cols* (columns) indicates the number of columns occupied by this cell or row.  
**Status** Optional  
**Datatype** leidata.count  
**Default** 1  
**Note** A value greater than one indicates that this cell or row spans several columns. Where an initial cell spans an entire row, it may be better treated as a heading.  

---  

**att.textCritical** defines a set of attributes common to all elements representing variant readings in text critical work.  

**Module** textcrit — Critical Apparatus  
**Members** lem rdg rdgGrp  
**Attributes**  
*written* (@hand) **att.typed** (@subtype)  
*type* classifies the reading according to some useful typology.  
**Status** Optional  
**Datatype** leidata.enumerated  
**Sample values include:** substantive (substantive) the reading offers a substantive variant.  
orthographic (orthographic) the reading differs only orthographically, not in substance, from other readings.  
*cause* classifies the cause for the variant reading, according to any appropriate typology of possible origins.  
**Status** Optional  
**Datatype** leidata.enumerated  
**Sample values include:** homeoteleuton homeoarchy paleographicConfusion haplography ditography falseEmendation
`@varSeq` (variant sequence) provides a number indicating the position of this reading in a sequence, when there is reason to presume a sequence to the variants.

**Status** Optional

**Datatype** `teidata.count`

**Note** Different variant sequences could be coded with distinct number trails: 1-2-3 for one sequence, 5-6-7 for another. More complex variant sequences, with (for example) multiple branchings from single readings, may be expressed through the `<join>` element.

`@require` points to other readings that are required when adopting the current reading or lemma.

**Status** Optional

**Datatype** `1–∞ occurrences of teidata.pointer` separated by whitespace

This element class defines attributes inherited by `<rdg>`, `<lem>`, and `<rdgGrp>`.

---

**att.timed** provides attributes common to those elements which have a duration in time, expressed either absolutely or by reference to an alignment map. ([8.3.5. Temporal Information](#))

**Module** `tei — The TEI Infrastructure`

**Members** `annotationBlock binaryObject ellipsis gap incident kinesic media pause vocal writing`

**Attributes**

- `@start` indicates the location within a temporal alignment at which this element begins.
  
  **Status** Optional

  **Datatype** `teidata.pointer`

  **Note** If no value is supplied, the element is assumed to follow the immediately preceding element at the same hierarchic level.

- `@end` indicates the location within a temporal alignment at which this element ends.
  
  **Status** Optional

  **Datatype** `teidata.pointer`

  **Note** If no value is supplied, the element is assumed to precede the immediately following element at the same hierarchic level.

---

**att.transcriptional** provides attributes specific to elements encoding authorial or scribal intervention in a text when transcribing manuscript or similar sources. ([11.3.1.4. Additions and Deletions](#))

**Module** `tei — The TEI Infrastructure`

**Members** `add addSpan del delSpan mod redo restore retrace rt subst substJoin undo`

**Attributes**

- `@status` indicates the effect of the intervention, for example in the case of a deletion, strikeouts which include too much or too little text, or in the case of an addition, an insertion which duplicates some of the text already present.
  
  **Status** Optional

  **Datatype** `teidata.enumerated`

  **Sample values include:**

  - `duplicate` all of the text indicated as an addition duplicates some text that is in the original, whether the duplication is word-for-word or less exact.
  - `duplicate-partial` part of the text indicated as an addition duplicates some text that is in the original
  - `excessStart` some text at the beginning of the deletion is marked as deleted even though it clearly should not be deleted.
excessEnd some text at the end of the deletion is marked as deleted even though it clearly should not be deleted.

shortStart some text at the beginning of the deletion is not marked as deleted even though it clearly should be.

shortEnd some text at the end of the deletion is not marked as deleted even though it clearly should be.

partial some text in the deletion is not marked as deleted even though it clearly should be.

unremarkable the deletion is not faulty.

Note Status information on each deletion is needed rather rarely except in critical editions from authorial manuscripts; status information on additions is even less common. Marking a deletion or addition as faulty is inescapably an interpretive act; the usual test applied in practice is the linguistic acceptability of the text with and without the letters or words in question.

@cause documents the presumed cause for the intervention.

@seq (sequence) assigns a sequence number related to the order in which the encoded features carrying this attribute are believed to have occurred.

att.translatable provides attributes used to indicate the status of a translatable portion of an ODD document.

att.typed provides attributes that can be used to classify or subclassify elements in any way.
The TEI Guidelines

Attributes

@type characterizes the element in some sense, using any convenient classification scheme or typology.

Status Optional

Datatype teidata.enumerated

Note The type attribute is present on a number of elements, not all of which are members of att.typed, usually because these elements restrict the possible values for the attribute in a specific way.

@subtype (subtype) provides a sub-categorization of the element, if needed

Status Optional

Datatype teidata.enumerated

Note The subtype attribute may be used to provide any sub-classification for the element additional to that provided by its type attribute.

Schematron <sch:rule context="tei:[@subtype]"> <sch:assert test="@type">The <sch:name/> element should not be categorized in detail with @subtype unless also categorized in general with @type</sch:assert> </sch:rule>

Note When appropriate, values from an established typology should be used. Alternatively a typology may be defined in the associated TEI header. If values are to be taken from a project-specific list, this should be defined using the <valList> element in the project-specific schema description, as described in 23.3.1.3 Modification of Attribute and Attribute Value Lists.

att.witnessed provides attributes used to identify the witnesses supporting a particular reading in a critical apparatus. [12.1. The Apparatus Entry, Readings, and Witnesses]

Module textcrit — Critical Apparatus

Members lem rdg
Attributes Attributes

@wit (witness or witnesses) contains a space-delimited list of one or more pointers indicating the
witnesses which attest to a given reading.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Note If the apparatus contains readings only for a single witness, this attribute may be
consistently omitted.

This attribute may occur both within an apparatus gathering variant readings in the
transcription of an individual witness and within an apparatus gathering readings
from different witnesses.

Additional descriptions or alternative versions of the sigla referenced may be
supplied as the content of a child <wit> element.

att.written provides attributes to indicate the hand in which the content of an element was written in the
source being transcribed. [1.3.1. Attribute Classes]

Module tei — The TEI Infrastructure

Members att.damaged[damage damageSpan] att.textCritical[lem rdg rdGrp] att.transcriptional[add addSpan
del delSpan] mod redo restore retrace rt subst substJoin undo] ab closer div figure fw head hi label line
note noteGrp opener p path postscript[quote salut] seg signed text trailer zone

Attributes Attributes

@hand points to a <handNote> element describing the hand considered responsible for the content
of the element concerned.

Status Optional

Datatype teidata.pointer
C Elements

C.1 About the Elements Appendix

This appendix gives you links to reference pages for all elements in the TEI Guidelines. There are 590 TEI elements in revision b4f72b1ff of TEI P5 Version 4.3.0 of the TEI Guidelines.

The elements listed here are in the TEI Namespace: http://www.tei-c.org/ns/1.0 unless otherwise noted on that element’s reference page.

<ab> (anonymous block) contains any arbitrary component-level unit of text, acting as an anonymous container for phrase or inter level elements analogous to, but without the semantic baggage of, a paragraph. [16.3. Blocks, Segments, and Anchors]

Module linking — Linking, Segmentation, and Alignment

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp))
(att.global.source (@source))

att.typed (@type, @subtype)

att.declaring (@decls)

att.fragmentable (@part)

att.written (@hand)

The <ab> element may be used at the encoder’s discretion to mark any component-level elements in a text for which no other more specific appropriate markup is defined.

Example

```xml
<div type="book" n="Genesis">
  <div type="chapter" n="1">
    <ab>In the beginning God created the heaven and the earth.\</ab>
    <ab>And the earth was without form, and void; and darkness was upon the face of the deep. And the spirit of God moved upon the face of the waters.\</ab>
    <ab>And God said, Let there be light: and there was light.\</ab>
  </div>
</div>
```

Schematron

```xml
  Abstract model violation: ab may not occur inside paragraphs or other ab elements.
</report>
```

Schematron

```xml
<report test="'(ancestor::tei or ancestor::tei:q) and not(ancestor::tei:figure or parent::tei:note or ancestor::tei:floatingText)'">
  Abstract model violation: Lines may not contain higher-level divisions such as p or ab, unless ab is a child of figure or note, or is a descendant of floatingText.
</report>
```

Content model

```xml
<content>
  <macroRef key="macro.paraContent"/>
</content>
```

Schema Declaration

```xml
element ab { }
```

Note: The <ab> element may be used at the encoder's discretion to mark any component-level elements in a text for which no other more specific appropriate markup is defined.
The TEI Guidelines

att.global.attributes,
att.global.rendition.attributes,
att.global.linking.attributes,
att.global.analytic.attributes,
att.global.facs.attributes,
att.global.change.attributes,

873
In a diplomatic edition attempting to represent an original source, the `<add>` element should not be used for additions to the current TEI electronic edition made by editors or encoders. In these cases, either the `<corr>` or `<supplied>` element are recommended.

Example

The story I am
going to relate is true as to its main facts, and as to the
consequences `<add place="above">`of these facts`</add>` from which
this tale takes its title.

Note

In a diplomatic edition attempting to represent an original source, the `<add>` element should not be used for additions to the current TEI electronic edition made by editors or encoders. In these cases, either the `<corr>` or `<supplied>` element are recommended.

In a TEI edition of a historical text with previous editorial emendations in which such additions or reconstructions are considered part of the source text, the use of `<add>` may be appropriate, dependent on the editorial philosophy of the project.

Example

The story I am
going to relate is true as to its main facts, and as to the
consequences `<add place="above">`of these facts`</add>` from which
this tale takes its title.

Note This element should be used for postal addresses only. Within it, the generic element <addrLine> may be used as an alternative to any of the more specialized elements available from the model.addrPart class, such as <street>, <postCode>, etc.

Example Using just the elements defined by the core module, an address could be represented as follows:

```xml
<address>
  <street>via Marsala 24</street>
  <postCode>40126</postCode>
  <name>Bologna</name>
  <name>Italy</name>
</address>
```

Example When a schema includes the names and dates module more specific elements such as country or settlement would be preferable over generic <name>:

```xml
<address>
  <street>via Marsala 24</street>
  <postCode>40126</postCode>
  <settlement>Bologna</settlement>
  <country>Italy</country>
</address>
```

Example

```xml
<address>
  <addrLine>Computing Center, MC 135</addrLine>
  <addrLine>P.O. Box 6998</addrLine>
  <addrLine>Chicago, IL 60680</addrLine>
  <addrLine>USA</addrLine>
</address>
```

Example

```xml
<address>
  <country key="FR"/>
  <settlement type="city">Lyon</settlement>
  <postCode>69002</postCode>
  <district type="arrondissement">IIème</district>
  <district type="quartier">Perrache</district>
  <street>
    <num>30</num>, Cours de Verdun
  </street>
</address>
```

Content model

```
<content>
  <sequence>
    <classRef key="model.global"
               minOccurs="0" maxOccurs="unbounded"/>
    <sequence minOccurs="1"
```
The TEI Guidelines

maxOccurs="unbounded">
  <classRef key="model.addrPart"/>
  <classRef key="model.global"
    minOccurs="0" maxOccurs="unbounded"/>
</sequence>
</sequence>
</content>

Addresses may be encoded either as a sequence of lines, or using any sequence of component elements from the model.addrPart class. Other non-postal forms of address, such as telephone numbers or email, should not be included within an address element directly but may be wrapped within an addrLine if they form part of the printed address in some source text.

Example

```xml
<address>
  <addrLine>Computing Center, MC 135</addrLine>
  <addrLine>P.O. Box 6998</addrLine>
  <addrLine>Chicago, IL</addrLine>
  <addrLine>60680 USA</addrLine>
</address>
```

Example

```xml
<addrLine>
  <ref target="tel:+1-201-555-0123">(201) 555 0123</ref>
</addrLine>
```

Content model

```xml
<content>
  <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```xml
element addrLine
{
  att.global.attributes,

The TEI Guidelines

If included, the name of an organization may be tagged using either the `<name>` element as above, or the more specific `<orgName>` element.

**Example**

```xml
<affiliation>
  Junior project officer for the US <name type="org">National Endowment for the Humanities</name>
</affiliation>
```

**Example** This example indicates that the person was affiliated with the Australian Journalists Association at some point between the dates listed.

```xml
<affiliation notAfter="1960-01-01" notBefore="1957-02-28">Paid up member of the <orgName>Australian Journalists Association</orgName>
</affiliation>
```
Example: This example indicates that the person was affiliated with Mount Holyoke College throughout the entire span of the date range listed.

```
<affiliation from="1902-01-01" to="1906-01-01">Was an assistant professor at Mount Holyoke College.</affiliation>
```

Content model

```
<content>
  <macroRef key="macro.phraseSeq"/>

(character data)

Note As with other culturally-constructed traits such as sex, the way in which this concept is described in different cultural contexts may vary. The normalizing attributes are provided as a means of simplifying that variety to Western European norms and should not be used where that is inappropriate. The content of the element may be used to describe the intended concept in more detail, using plain text.

Example

<age value="2" notAfter="1986">under 20 in the early eighties</age>

Content model

<content>

<alt> (alternation) identifies an alternation or a set of choices among elements or passages. [16.8. Alternation]

Module linking — Linking, Segmentation, and Alignment

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype) att.pointing

@target specifies the destination of the reference by supplying one or more URI References

Derived from att.pointing

Status Optional

Datatype 2–∞ occurrences of teidata.pointer separated by whitespace

@mode states whether the alternations gathered in this collection are exclusive or inclusive.

Status Recommended

Datatype teidata.enumerated

Legal values are: excl (exclusive) indicates that the alternation is exclusive, i.e. that at most one of the alternatives occurs.

incl (inclusive) indicates that the alternation is not exclusive, i.e. that one or more of the alternatives occur.

@weights If mode is excl, each weight states the probability that the corresponding alternative occurs. If mode is incl each weight states the probability that the corresponding alternative occurs given that at least one of the other alternatives occurs.

Status Optional

Datatype 2–∞ occurrences of teidata.probability separated by whitespace

891
Note  If mode is excl, the sum of weights must be 1. If mode is incl, the sum of weights must be in the range from 0 to the number of alternants.

}
<altIdent> (alternate identifier) supplies the recommended XML name for an element, class, attribute, etc. in some language. [3.4.1. Terms and Glosses][22.4.1. Description of Components]

Module  tagdocs — Documentation Elements

Attributes  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) (att.typed (@type, @subtype))

Member of  model.glossLike

Contained by  tagdocs  attDef  classSpec  constraintSpec  dataSpec  elementSpec  macroSpec  model  modelGrp  modelSequence  moduleSpec  paramSpec  schemaSpec  valItem

May contain  Character data only

Note  All documentation elements in ODD have a canonical name, supplied as the value for their ident attribute. The <altIdent> element is used to supply an alternative name for the corresponding XML object, perhaps in a different language.

Example

<altIdent xml:lang="fr">balisageDoc</altIdent>

Content model  <content> <textNode/></content>

Schema Declaration

```xml
element altIdent
{
    att.global.attributes,
    att.global.rendition.attributes,
    att.global.linking.attributes,
    att.global.analytic.attributes,
    att.global.facs.attributes,
    att.global.change.attributes,
    att.global.responsibility.attributes,
    att.global.source.attributes,
    att.typed.attributes,
    text
}
```

<altIdentifier> (alternative identifier) contains an alternative or former structured identifier used for a manuscript or other object, such as a former catalogue number. [10.4. The Manuscript Identifier]
Module msdescription — Manuscript Description

Schema Declaration
The <analytic> element (analytic level) contains bibliographic elements describing an item (e.g., an article or poem) published within a monograph or journal and not as an independent publication. [3.12.2.1. Analytic, Monographic, and Series Levels]

Module: core — Elements Available in All TEI Documents

Attributes:
- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by:
core: biblStruct

May contain:
core: author date editor ptr ref respStmt textLang title
header: availability idno

Note:
- May contain titles and statements of responsibility (author, editor, or other), in any order.
- The <analytic> element may only occur within a <biblStruct>, where its use is mandatory for the description of an analytic level bibliographic item.

Example:

```xml
<biblStruct>
  <analytic>
    <author>Chesnutt, David</author>
    <title>Historical Editions in the States</title>
  </analytic>
  <title level="j">Computers and the Humanities</title>
  <imprint>
    <date when="1991-12">(December, 1991)</date>
  </imprint>
  <biblScope>25.6</biblScope>
  <biblScope>377–380</biblScope>
</biblStruct>
```

Content model:

```xml
<content>
  <alternate minOccurs="0"
```
anchor: (anchor point) attaches an identifier to a point within a text, whether or not it corresponds with a
textual element. [§4.2. Synchronization and Overlap] [16.5. Correspondence and Alignment]

empty
}
```

<annotation> represents an annotation following the Web Annotation Data Model. [16.10. The standOff Container]

Module linking — Linking, Segmentation, and Alignment

902
Attributes: Attributes \texttt{att.global} \((\texttt{xml:id}, \texttt{@n}, \texttt{@xml:lang}, \texttt{@xml:base}, \texttt{@xml:space})\) \texttt{att.global.rendition} \((\texttt{@rend}, \texttt{@style}, \texttt{@rendition})\) \texttt{att.global.linking} \((\texttt{@corresp}, \texttt{@synchrony}, \texttt{@sameAs}, \texttt{@copyOf}, \texttt{@next}, \texttt{@prev}, \texttt{@exclude}, \texttt{@select})\) \texttt{att.global.analytic} \((\texttt{@ana})\) \texttt{att.global.facs} \((\texttt{@facs})\) \texttt{att.global.change} \((\texttt{@change})\) \texttt{att.global.responsibility} \((\texttt{@cert}, \texttt{@resp})\) \texttt{att.global.source} \((\texttt{@source})\) \texttt{att.pointing} \((\texttt{target}, \texttt{@targetLang}, \texttt{@evaluate})\)

\texttt{@xml:id} (identifier) provides a unique identifier for the element bearing the attribute.

\textit{Derived from} \texttt{att.global}

\textit{Status} Required

\textit{Datatype} \texttt{ID}

\texttt{@target} specifies the destination of the reference by supplying one or more URI References

\textit{Derived from} \texttt{att.pointing}

\textit{Status} Required

\textit{Datatype} \(1\sim\infty\) occurrences of \texttt{teidata.pointer} separated by whitespace

\texttt{@motivation} \(1\sim\infty\) occurrences of \texttt{teidata.enumerated} separated by whitespace

\textit{Legal values are:}

- assessing: intent is to assess the target resource in some way, rather than simply make a comment about it
- bookmarking: intent is to create a bookmark to the target or part thereof
- classifying: intent is to classify the target in some way
- commenting: intent is to comment about the target
- describing: intent is to describe the target, rather than (for example) comment on it
- editing: intent is to request an edit or a change to the target resource
- highlighting: intent is to highlight the target resource or a segment thereof
- identifying: intent is to assign an identity to the target
- linking: intent is to link to a resource related to the target
- moderating: intent is to assign some value or quality to the target
- questioning: intent is to ask a question about the target
- replying: intent is to reply to a previous statement, either an annotation or another resource
- tagging: intent is to associate a tag with the target

\textit{Note} For further detailed explanation of the suggested values, see the Web Annotation Vocabulary (WAV). The motivations described here map to URIs defined by the WAV and when exported to RDF or JSON-LD must have the URI \texttt{http://www.w3.org/ns/oa#} prepended.

As an RDF vocabulary, WADM permits the definition of new motivations (see Appendix C of the WAV). In TEI, new motivations may be defined in a custom ODD (see section 23.3.1.3). New motivations must also map to URIs defined by an RDF ontology extending the WAV.

```

Schema Declaration

```xml
element annotationBlock
{
  att.ascribed.attributes,
  att.timed.attributes,
  att.duration.w3c.attributes,
}
```
<anyElement> indicates the presence of any elements in a content model [22. Documentation Elements] 

Module tagdocs — Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) 

@require supplies a list of namespaces to one of which the permitted elements must belong.
Status Optional
Datatype 1–∞ occurrences of teidata.namespace separated by whitespace

@except supplies a list of namespaces or prefixed element names which are not permitted.
Status Optional
Datatype 1–∞ occurrences of teidata.namespaceOrName separated by whitespace

Note When RELAX NG DTD Compatibility Mode is turned on, validation requires that any elements which may take an xml:id be excluded from the content of anyName name classes. For normal TEI purposes, this includes anything in the TEI namespace and the <egXML> element. Default elements and namespaces to be excluded are set on the defaultExceptions attribute of the <schemaSpec> element. except may be used when the exceptions need to be locally specified. Element prefixes must be declared using a namespace declaration on the parent or an ancestor element.

Member of model.contentPart
Contained by tagdocs: alternate content sequence
May contain Empty element
Example

    <content>
      <anyElement except="http://www.tei-c.org/ns/1.0"/>
    </content>

    This <content> element permits one occurrence of any element which does not belong to the TEI namespace.

Example

    <content>
      <anyElement minOccurs="1"
        maxOccurs="unbounded"
        require="http://www.w3.org/1998/Math/MathML"
This `<content>` element permits one or more elements which belong either to the MathML namespace or to the TEI examples namespace.

**Example**

```xml
<content>
  <alternate minOccurs="1"
    maxOccurs="unbounded">
    <textNode/>
    <anyElement require="http://www.tei-c.org/ns/Examples/1.0"/>
  </alternate>
</content>
```

This `<content>` element permits one or more children which are either text nodes or elements from the TEI examples namespace. It is the equivalent of the content model `ANY` in an XML DTD using the TEI All schema.

**Content model**

```
<content> <empty/> </content>
```

**Schema Declaration**

```xml
element anyElement
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.repeatable.attributes,
  attribute require { list { + } }?,
  attribute except { list { + } }?,
  empty
}
```

**<app>** (apparatus entry) contains one entry in a critical apparatus, with an optional lemma and usually one or more readings or notes on the relevant passage. [12.1.1. The Apparatus Entry]

**Module** textcrit — Critical Apparatus

**Attributes**

- `att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
- `att.global.analytic (@ana) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (<-<, @subtype)`

**@type** classifies the variation contained in this element according to some convenient typology.

- `Derived from att.typed`
- `Status Optional`
- `Datatype teidata.enumerated`

**@from** identifies the beginning of the lemma in the base text.

- `Status Optional`
- `Datatype teidata.pointer`
This attribute should be used when either the double-end point method of apparatus markup, or the location-referenced method with a URL rather than canonical reference, are used.

@to identifies the endpoint of the lemma in the base text.

Status: Optional
Datatype: leidata-pointer

@loc (location) indicates the location of the variation, when the location-referenced method of apparatus markup is used.

Status: Optional
Datatype: 1–∞ occurrences of leidata.word separated by whitespace

Note: This attribute is only used when the double-end point method of apparatus markup is used, when the encoded apparatus is not embedded in-line in the base-text.

Note: This attribute is used only when the location-referenced encoding method is used. It supplies a string containing a canonical reference for the passage to which the variation applies.

```

(application information) records information about an application which has edited the TEI file.

### [2.3.11. The Application Information Element]

**Module** header — The TEI Header

Attributes att.global(@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

**Member of** model.encodingDescPart

**Contained by** header: encodingDesc

**May contain** header: application

**Example**

```xml
<appInfo>
  <application version="1.24" ident="Xaira">
    <label>XAIRA Indexer</label>
    <ptr target="#P1"/>
  </application>
</appInfo>
```

**Content model**
Schema Declaration

```xml
<application>

<appInfo
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  model.applicationLike+
}
```

**<application>** provides information about an application which has acted upon the document. [2.3.11. The Application Information Element]

**Module header — The TEI Header**

**Attributes**
- `@id` (xml:id, @n, @xml:lang, @xml:base, @xml:space)
- `@rend` (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))
- `@type` (att.typed) (att.global.responsibility)
- `@calendar` (att.datable.w3c (@when, @notBefore, @notAfter, @from, @to))
- `@when-iso` (att.datable.iso)
- `@when-custom` (att.datable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod))
- `@ident` supplies an identifier for the application, independent of its version number or display name.
- `@version` supplies a version number for the application, independent of its identifier or display name.

**Datatypes**
- `teidata.name`
- `teidata.versionNumber`

**Member of**
- model.applicationLike

**Contained by**
- header: appInfo

**May contain**
- core: desc label ptr ref

**linking:** ab

**Example**

```xml
<appInfo>
  <application version="1.5"
```
This example shows an appInfo element documenting the fact that version 1.5 of the Image Markup Tool1 application has an interest in two parts of a document which was last saved on June 6 2006. The parts concerned are accessible at the URLs given as target for the two <ptr> elements.

Content model

```
<content>
  <sequence>
    <classRef key="model.labelLike" minOccurs="1" maxOccurs="unbounded"/>
  </sequence>
  <alternate>
    <classRef key="model.ptrLike" minOccurs="0" maxOccurs="unbounded"/>
    <classRef key="model.pLike" minOccurs="0" maxOccurs="unbounded"/>
  </alternate>
</content>
```

Schema Declaration

```xml
<element application
  { att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.Typed.attributes,
  att.datable.attributes,
  att.datable.w3c.attributes,
  att.datable.iso.attributes,
  att.datable.custom.attributes,
  attribute ident { text },
  attribute version { text },
  ( model.labelLike+, ( model.ptrLike* | model.pLike* ) ) }
```

<arc> (arc) encodes an arc, the connection from one node to another in a graph. [19.1. Graphs and Digraphs]
@from gives the identifier of the node which is adjacent from this arc.
   Status Required
   Datatype teidata.pointer
@to gives the identifier of the node which is adjacent to this arc.
   Status Required
   Datatype teidata.pointer

Contained by graph

May contain
   core: label

Note The <arc> element must be used if the arcs are labeled. Otherwise, arcs can be encoded using the adj, adjTo and adjFrom attributes on the <node> tags in the graph. Both <arc> tags and adjacency attributes can be used, but the resulting encoding would be highly redundant.

Zero, one, or two children <label> elements may be present. The first occurrence of <label> provides a label for the arc; the second provides a second label for the arc, and should be used if a transducer is being encoded.

Example

   <arc from="#T3" to="#T3">
      <label>OLD</label>
      <label>VIEUX</label>
   </arc>

Content model

   <content>
      <sequence minOccurs="0">
         <elementRef key="label"/>
         <elementRef key="label" minOccurs="0"/>
      </sequence>
   </content>

Schema Declaration

   element arc
   {
      att.global.attributes,
      att.global.rendition.attributes,
      att.global.linking.attributes,
      att.global.analytic.attributes,
      att.global.facs.attributes,
      att.global.change.attributes,
      att.global.responsibility.attributes,
      att.global.source.attributes,
      attribute from { text },
      attribute to { text },
      ( label, label? )?
   }

<argument> (argument) contains a formal list or prose description of the topics addressed by a subdivision of a text. [4.2. Elements Common to All Divisions 4.6. Title Pages]
Module textstructure — Default Text Structure

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synchronized, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@certified, @responsibility)) (att.global.source (@source))

}
```

<att> (attribute) contains the name of an attribute appearing within running text. [[22. Documentation Elements]]

**Module** tagdocs — Documentation Elements

**Attributes**

- `att.global` (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.renditioni (@rend, @style, @rendition)) (att.global.linkingi (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

**@scheme** (scheme) supplies an identifier for the scheme in which this name is defined.

**Status** Optional

**Datatype** teidata.enumerated

**Sample values include:**

- **TEI** (Text Encoding Initiative) this attribute is part of the TEI scheme. [Default]
- **DBK** (Docbook) this attribute is part of the Docbook scheme.
- **XX** (unknown) this attribute is part of an unknown scheme.
- **imaginary** (imaginary) the attribute is from a non-existent scheme, for illustrative purposes only
- **XHTML** (XHTML) the attribute is part of the XHTML language
- **XML** (XML) the attribute is part of the XML language
- **XI** (XI) the attribute is defined in the xInclude schema

**Member of** model.phrase.xml

**Contained by**

- `cl`, `phr`, `span`

**Core:**

- `abbr`, `add`, `addrLine`, `author`, `biblScope`, `citedRange`, `corr`, `date`, `del`, `desc`, `distinct`, `editor`, `email`, `emph`, `expansion`
- `foreign`, `gloss`, `head`, `headItem`, `headLabel`, `hi`, `item`, `label`, `measure`, `meeting`, `mentioned`, `name`, `note`, `num`, `orig`, `p`
<att>

The TEI defines several <soCalled>global</soCalled> attributes; their names include
<att>xml:id</att>, <att>rend</att>, <att>xml:lang</att>, <att>n</att>,
<att>xml:space</att>, and <att>xml:base</att>; <att>scheme="XX"</att>type</att> is not amongst them.</p>

Content model <content> <dataRef key="teidata.name"/></content>

Particularly where cataloguing is likely to be based on the content of the header, it is advisable to use a generally recognized name authority file to supply the content for this element. The attributes key or ref may also be used to reference canonical information about the author(s) intended from any appropriate authority, such as a library catalogue or online resource.

In the case of a broadcast, use this element for the name of the company or network responsible for making the broadcast.

Where an author is unknown or unspecified, this element may contain text such as Unknown or Anonymous. When the appropriate TEI modules are in use, it may also contain detailed tagging of the names used for people, organizations or places, in particular where multiple names are given.

Example

```xml
<author>British Broadcasting Corporation</author>
<author>La Fayette, Marie Madeleine Pioche de la Vergne, comtesse de (1634–1693)</author>
<author>Anonymous</author>
<author>Bill and Melinda Gates Foundation</author>
<author><persName>Beaumont, Francis</persName> and <persName>John Fletcher</persName></author>
<author><orgName key="BBC">British Broadcasting Corporation</orgName>: Radio 3 Network</author>
```

Content model

Content model

<content>

macro.phraseSeq.limited”/>
<availability>

<availability> (availability) supplies information about the availability of a text, for example any restrictions on its use or distribution, its copyright status, any licence applying to it, etc. [2.2.4. Publication, Distribution, Licensing, etc.]

Module header — The TEI Header

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.declarable (@default)

@status (status) supplies a code identifying the current availability of the text.

Status Optional

Datatype teidata.enumerated

Legal values are: free (free) the text is freely available.

unknown (unknown) the status of the text is unknown.

restricted (restricted) the text is not freely available.

Member of model.biblPart model.publicationStmtPart.detail

Contained by

core: analytic bibl monogr series

Note Because cultural conventions differ as to which elements are grouped as back matter and which as front matter, the content models for the <back> and <front> elements are identical.

Example

```xml
<back>
  <head type="appendix">The Golden Dream or, the Ingenuous Confession</head>
  <p>TO shew the Depravity of human Nature, and how apt the Mind is to be misled by Trinkets and false Appearances, Mrs. Two-Shoes does acknowledge, that after she became rich, she had like to have been, too fond of Money</p>
</back>
```

A letter from the Printer, which he desires may be inserted

Sir,

I have done with your Copy, so you may return it to the Vatican, if you please;

The Books usually read by the Scholars of Mrs Two-Shoes are these and are sold at Mr Newbery's at the Bible and Sun in St Paul's Church-yard.

The Christmas Box, Price 1d.

The History of Giles Gingerbread, 1d.

A Curious Collection of Travels, selected from the Writers of all Nations, 10 Vol, Pr. bound 1l.

By the KING's Royal Patent, Are sold by J. NEWBERY, at the Bible and Sun in St. Paul's Church-Yard.

Dr. James's Powders for Fevers, the Small-Pox, Measles, Colds, &c. 2s. 6d

Dr. Hooper's Female Pills, 1s.

The TEI Guidelines

<bicond> (bi-conditional feature-structure constraint) defines a biconditional feature-structure constraint; both consequent and antecedent are specified as feature structures or groups of feature structures; the constraint is satisfied if both subsume a given feature structure, or if both do not. [i8.11. Feature System Declaration]

Module iso-fs — Feature Structures
Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@una)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by iso-fs: fsConstraints
May contain iso-fs: iff

Example

```xml
<bicond>
  <fs>
      <f name="FOO">
          <symbol value="42"/>
      </f>
   </fs>
  <iff/>
  <fs>
      <f name="BAR">
          <binary value="true"/>
      </f>
   </fs>
</bicond>
```

Content model

```xml
<content>
  <sequence>
  <alternate>
      <elementRef key="fs"/>
      <elementRef key="f"/>
  </alternate>
  <elementRef key="iff"/>
  <alternate>
      <elementRef key="fs"/>
      <elementRef key="f"/>
  </alternate>
  </sequence>
</content>
```

Schema Declaration

```xml
element bicond
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
}
```

938
<binary> (binary value) represents the value part of a feature-value specification which can contain either of exactly two possible values. [18.2. Elementary Feature Structures and the Binary Feature Value]

Module iso-fs — Feature Structures

Attributes

\[
\text{att.global (\texttt{@xml:id}, \texttt{@n}, \texttt{@xml:lang}, \texttt{@xml:base}, \texttt{@xml:space}) (att.global.rendition (\texttt{@rend}, \texttt{@style}, \texttt{@rendition})) (att.global.linking (\texttt{@corresp}, \texttt{@synch}, \texttt{@sameAs}, \texttt{@copyOf}, \texttt{@next}, \texttt{@prev}, \texttt{@exclude}, \texttt{@select})) (att.global.analytic (\texttt{@ana})) (att.global.facs (\texttt{@facs})) (att.global.change (\texttt{@change})) (att.global.responsibility (\texttt{@cert}, \texttt{@resp})) (att.global.source (\texttt{@source})) \text{att.datcat (\texttt{@datcat}, \texttt{@valueDatcat})}
\]

@value supplies a binary value.

Status Required

Datatype teidata.truthValue

Note This attribute has a datatype of \texttt{teidata.truthValue}, which may be represented by the values 1 or true, or 0 or false.

Member of model.featureVal.single

Contained by iso-fs: \texttt{fvLib|vAlt|vColl|vDefault|vLabel|vMerge|vNot|vRange}

May contain Empty element

Note The value attribute may take any value permitted for attributes of the W3C datatype Boolean: this includes for example the strings \texttt{true} or \texttt{1} which are equivalent.

Example

\[
\begin{align*}
&<f \text{name}="strident">
&\quad <\text{binary} \text{value}="true"/>
&\quad \text{/f}>
&<f \text{name}="exclusive">
&\quad <\text{binary} \text{value}="false"/>
&\quad \text{/f}>
\end{align*}
\]

Content model \texttt{<content> <empty/></content>}

Schema Declaration

\[
\text{element binary}
\
\{
\quad \text{att.global.attributes},
\quad \text{att.global.rendition.attributes},
\quad \text{att.global.linking.attributes},
\quad \text{att.global.analytic.attributes},
\quad \text{att.global.facs.attributes},
\quad \text{att.global.change.attributes},
\quad \text{att.global.responsibility.attributes},
\quad \text{att.global.source.attributes},
\quad \text{att.datcat.attributes},
\quad \text{attribute value \{ text \}, empty}
\}
\]

939
<binaryObject> provides encoded binary data representing an inline graphic, audio, video or other object.

Module core – Elements Available in All TEI Documents

Attributes

- @encoding The encoding used to encode the binary data. If not specified, this is assumed to be Base64.
- @status Optional

Datatype 1–∞ occurrences of teidata.word separated by whitespace

Member of model.graphicLike model.titlePagePart

Contained by

- analysis:
- core:
- dictionaries:
- drama:
- figures:
- gaiji:
- header:
- linking:
- msdescription:
- namesdates:
- spoken:
- textcrit:
- textstructure:
- transcr:
- verse:

May contain Character data only

Example

<binaryObject mimeType="image/gif">
R6Lg0dMhMAwAPAAAAPAAP///ywAAAAAMwAAAC8IyPqcvt3wCcDkiLc7C0qwyGhHWpjQ0u5ymCYSapyvUULv0Nm02tfzgFzBYTB100gxOR0TqBoeJhR2Nv0fKVJ+5YiUr XF5Y5LKh/DeUcPc5yLWGSebotliOSpa/TPg7JpJHxeyendzWTBFxOcxOnK
PjgBzi4diinWjdF8kjdmficQZXZeYGejmJlZeGl9i1cVqaNVailT6F51J90m6
</binaryObject>
<binding> (binding) contains a description of one binding, i.e. type of covering, boards, etc. applied to a manuscript or other object. [10.7.3.1. Binding Descriptions]

Module mdescription — Manuscript Description

Attributes
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.datable (@calendar, @period) (att.datable.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.datable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.datable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod))

@contemporary (contemporary) specifies whether or not the binding is contemporary with the majority of its contents

Status Optional

Datatype teidata.xTruthValue

Note The value true indicates that the binding is contemporaneous with its contents; the value false that it is not. The value unknown should be used when the date of either binding or manuscript is unknown

Contained by mdescription: bindingDesc

May contain
core: P
linking: ab
msdescription: condition decoNote

Example
Contemporary blind stamped leather over wooden boards with evidence of a fore edge clasp closing to the back cover.

Example

Quarter bound by the Phillipps' binder, Bretherton, with his sticker on the front pastedown.

Rebound by an unknown 19th c. company; edges cropped and gilt.

(binding description) describes the present and former bindings of a manuscript or other object, either as a series of paragraphs or as a series of distinct <binding> elements, one for each binding of the manuscript. [10.7.3.1. Binding Descriptions]
Module msdirection — Manuscript Description

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Member of model.physDescPart

Contained by msdirection: physDesc

May contain core: p

linking: ab

msdescription: binding condition decoNote

Example

<bindingDesc>
  <p>Sewing not visible; tightly rebound over 19th-cent. pasteboards, reusing panels of 16th-cent. brown leather with gilt tooing à la fanfare, Paris c. 1588-90, the centre of each cover inlaid with a 17th-cent. oval medallion of red morocco tooled in gilt (perhaps replacing the identifying mark of a previous owner); the spine similarly tooled, without raised bands or title-piece; coloured endbands; the edges of the leaves and boards gilt.Boxed.</p>
</bindingDesc>

Content model

<content>
  <alternate>
    <alternate minOccurs="1" maxOccurs="unbounded">

<byline> (byline) contains the primary statement of responsibility given for a work on its title page or at the head or end of the work. [4.2.2. Openers and Closers | 4.5. Front Matter]

 Module  textstructure — Default Text Structure

 Attributes  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))

951
The byline on a title page may include either the name or a description for the document’s author. Where the name is included, it may optionally be tagged using the `<docAuthor>` element.

Example

```xml
<byline>Written by a CITIZEN who continued all the while in London. Never made publick before.</byline>
```

Example

```xml
<byline>Written from her own MEMORANDUMS</byline>
```
Example

By George Jones, Political Editor, in Washington

By THOMAS PHILIPOTT,
Master of Arts,
(Sometimes)
Of Clare-Hall in Cambridge.

Note The rend attribute may be used, as here, to indicate whether the grouping is indicated by a brace, whitespace, font change, etc.

Note that in this example the role description 'friends of Mathias' is understood to apply to both roles equally.

Example

```xml
<castGroup rend="braced">
  <castItem>
    <role>Walter</role>
    <actor>Mr Frank Hall</actor>
  </castItem>
  <castItem>
    <role>Hans</role>
    <actor>Mr F.W. Irish</actor>
  </castItem>
  <roleDesc>friends of Mathias</roleDesc>
</castGroup>
```

Content model

```xml
<content>
  <sequence>
    <alternate minOccurs="0" maxOccurs="unbounded">
      <classRef key="model.global"/>
      <classRef key="model.headLike"/>
    </alternate>
    <sequence minOccurs="1" maxOccurs="unbounded">

      <elementRef key="castGroup"/>
      <elementRef key="roleDesc"/>
    </sequence>
    <classRef key="model.global" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
  <sequence minOccurs="0">
    <elementRef key="trailer"/>
    <classRef key="model.global" minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
</content>
```
Schema Declaration

```xml
<castItem>
  (cast list item) contains a single entry within a cast list, describing either a single role or a list of non-speaking roles. [7.1.4. Cast Lists]
</castItem>
```

Attributes

```xml
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global rendition (@rend, @style, @rendition)) (att.global linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global analytic (@ana)) (att.global facs (@facs)) (att.global change (@change)) (att.global responsibility (@cert, @resp)) (att.global source (@source)) att.typed (@type, @subtype)
```

- **@type** characterizes the cast item.
  - Derived from **att.typed**
  - Status Optional
  - Datatype teidata.enumerated

Legal values are:

- role the item describes a single role.[Default]
- list the item describes a list of non-speaking roles.

**Containddings**: castGroup castList

**May contain**

- analysis: cl cl interp interpGrp m pc phr s span spanGrp w

May contain Empty element

Note On this element, the global n attribute indicates the number or other value associated with the column which follows the point of insertion of this <cb> element. Encoders should adopt a clear and consistent policy as to whether the numbers associated with column breaks relate to the physical sequence number of the column in the whole text, or whether columns are numbered within the page. The <cb> element is placed at the head of the column to which it refers.

Example Markup of an early English dictionary printed in two columns:

```xml
<pb/>
<cb n="1"/>
<form>Well</form>, <sense>a Pit to hold Spring-Water</sense>:
<form>Well</form>, <sense>In the Art of <hi rend="italic">War</hi>, a Depth the Miner sinks into the Ground, to find out and disappoint the Enemies Mines, or to prepare one</sense>.
</entryFree>
<entryFree>To <form>Welter</form>, <sense>to wallow</sense>, or <sense>lie groveling</sense>.</entryFree>
<!-- remainder of column -->
<cb n="2"/>
<entryFree>
<form>Wey</form>, <sense>The greatest Measure for dry Things, containing five Chaldron</sense>.
</entryFree>
<entryFree>
<form>Whale</form>, <sense>The greatest of Sea-Fishes</sense>.
</entryFree>
```

Content model

<macroRef key="macro.specialPara"/>

Example

<certainty> indicates the degree of certainty associated with some aspect of the text markup. 

Module certainty — Certainty, Precision, and Responsibility

Attributes
att.scoping (@target, @match) att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)
att.global.attributes
att.global.rendition.attributes
att.global.linking.attributes
att.global.analytic.attributes
att.global.facs.attributes
att.global.change.attributes
att.global.responsibility.attributes
att.global.source.attributes
att.tableDecoration.attributes
macro.specialPara

@cert (certainty) signifies the degree of certainty associated with the object pointed to by the <certainty> element.

Derived from att.global.responsibility

Status Optional

Datatype teidata.certainty
@type characterizes the element in some sense, using any convenient classification scheme or typology; sample categorization of annotations of uncertainty might use following values:

- Derived from att.typed
- Status Optional
- Datatype teidata.enumerated

Sample values include:
- ignorance
- incompleteness
- credibility
- imprecision

@locus indicates more exactly the aspect concerning which certainty is being expressed:

- specifically, whether the markup is correctly located, whether the correct element or attribute name has been used, or whether the content of the element or attribute is correct, etc.
- Status Required
- Datatype teidata.enumerated

Legal values are:
- name uncertainty concerns whether the name of the element or attribute used is correctly applied.
- start uncertainty concerns whether the start of the element is correctly identified.
- end uncertainty concerns whether the end of the element is correctly identified.
- location uncertainty concerns both the start and the end of the element.
- value uncertainty concerns the content (for an element) or the value (for an attribute)

@assertedValue provides an alternative value for the aspect of the markup in question—an alternative generic identifier, transcription, or attribute value, or the identifier of an element (to indicate an alternative starting or ending location). If an assertedValue is given, the confidence level specified by degree applies to the alternative markup specified by assertedValue; if none is given, it applies to the markup in the text.

Status Recommended

Datatype teidata.word

```xml
<certainty target="#ESX" locus="name" assertedValue="placeName" cert="low">
  <desc>It is unlikely, but possible, that this refers to the place rather than the person.</desc>
</certainty>
```

Note: This attribute makes it possible to indicate the degree of confidence in a specific alternative to some aspect of the markup. In the first example above the encoder is expressing the likelihood (.2) that the generic identifier should be <placeName> rather than <persName>, which is the coded element.

@given indicates one or more element(s) characterizing the conditions which are assumed in the assignment of a degree of confidence.

Status Recommended

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Note: The envisioned typical value of this attribute would be the identifier of another <certainty> element or a list of such identifiers. It may thus be possible to construct probability networks by chaining <certainty> elements together. Such networks would ultimately be grounded in unconditional <certainty> elements (with no value for given). The semantics of this chaining would be understood in this way: if a <certainty> element is specified, via a reference, as the assumption, then it is not the attribution of uncertainty that is the assumption, but rather the assertion itself. For
instance, in the example above, the first `<certainty>` element indicates that the confidence in the identification of the new scribe as *msm*. The second indicates the degree of confidence that *Essex* is a personal name, given that the new scribe is *msm*. Note that the given in the second `<certainty>` element is not the assertion that the likelihood that *msm* is the new scribe is 0.6, but simply the assertion that *msm* is the new scribe; this is a recommended convention to facilitate building networks.

The ambitious encoder may wish to attempt complex networks or probability assertions, experimenting with references to other elements or prose assertions, and deploying feature structure connectives such as `<alt>`, `<join>`, and `<note>`. However, we do not believe that the `<certainty>` element gives, at this time, a comprehensive ambiguity-free system for indicating certainty.

@degree indicates the degree of confidence assigned to the aspect of the markup named by the `locus` attribute.

  att.global.responsibility.attributes,
  att.global.source.attributes,
  ( desc?, ( char | glyph )+ )
}
```

<charName> (character name) contains the name of a character, expressed following Unicode conventions.

[5.2. Markup Constructs for Representation of Characters and Glyphs]

**Deprecated** will be removed on 2022-02-15

Module gaiji – Characters, Glyphs, and Writing Modes

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))
May contain  Character data only

Note  The name must follow Unicode conventions for character naming. Projects working in similar fields are recommended to coordinate and publish their list of `<charName>`s to facilitate data exchange.

Example

```
<charName>CIRCLED IDEOGRAPH 4EBA</charName>
```

Content model `<content> <textNode/> </content>`

Schema Declaration

```
element charName
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  text
}
```

`<charProp>` (character property) provides a name and value for some property of the parent character or glyph.

[5.2. Markup Constructs for Representation of Characters and Glyphs]

Deprecated  will be removed on 2022-02-15

Module  gaiji — Characters, Glyphs, and Writing Modes

Attributes  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype)

Contained by  gaiji: char glyph

May contain  gaiji: localName unicodeName value

Note  If the property is a Unicode Normative Property, then its `<unicodeName>` must be supplied. Otherwise, its name must be specied by means of a `<localName>`.

Example

```
<charProp>
  <unicodeName>Decomposition_Mapping</unicodeName>
  <value>circle</value>
</charProp>
<charProp>
  <localName>daikanwa</localName>
  <value>36</value>

991
Note Because the children of a `<choice>` element all represent alternative ways of encoding the same sequence, it is natural to think of them as mutually exclusive. However, there may be cases where a full representation of a text requires the alternative encodings to be considered as parallel.

Note also that `<choice>` elements may self-nest.

Where the purpose of an encoding is to record multiple witnesses of a single work, rather than to identify multiple possible encoding decisions at a given point, the `<app>` element and associated elements discussed in section 12.1. The Apparatus Entry, Readings, and Witnesses should be preferred.

Example An American encoding of *Gulliver's Travels* which retains the British spelling but also provides a version regularized to American spelling might be encoded as follows.

```xml
<p>Lastly, That, upon his solemn oath to observe all the above articles, the said man-mountain shall have a daily allowance of meat and drink sufficient for the support of <choice>
   <sic>1724</sic>
   <corr>1728</corr>
</choice>
with free access to our royal person, and other marks of our</p>
```

Content model

```xml
<content>
   <alternate minOccurs="2" maxOccurs="unbounded">
      <classRef key="model.choicePart"/>
      <elementRef key="choice"/>
   </alternate>
</content>
```

Schema Declaration

```xml
element choice
{
   att.global.attributes,
   att.global.rendition.attributes,
   att.global.linking.attributes,
   att.global.analytic.attributes,
}
```
<cit>

(cited quotation) contains a quotation from some other document, together with a bibliographic reference to its source. In a dictionary it may contain an example text with at least one occurrence of the word form, used in the sense being described, or a translation of the headword, or an example. [3.3.3. Quotation 4.3.1. Grouped Texts 9.3.5.1. Examples]

Note When a single page is being cited, use the from and to attributes with an identical value. When no clear endpoint is provided, the from attribute may be used without to; for example a citation such as ‘p. 3ff’ might be encoded &lt;citedRange from="3">p. 3ff&lt;/citedRange&gt;.

Example

&lt;citedRange&gt;pp 12–13&lt;/citedRange&gt;
&lt;citedRange&gt; unit="page" from="12" to="13"/&gt
&lt;citedRange&gt unit="volume">II&lt;/citedRange&gt;
&lt;citedRange&gt unit="page">12&lt;/citedRange&gt;

Example

&lt;bibl&gt;
 &lt;ptr target="#mueller01"/&gt,
 &lt;p unit="page">4–5&lt;/citedRange&gt;
 &lt;/bibl&gt;

Content model

&lt;content&gt;
 &lt;macroRef key="macro.phraseSeq"/&gt;
 &lt;/content&gt;

Schema Declaration

element citedRange
 { att.global.attributes,
   att.global.rendition.attributes,
   att.global.linking.attributes,
   att.global.analytic.attributes,
   att.global.facs.attributes,
   att.global.change.attributes,
   att.global.responsibility.attributes,
   att.global.source.attributes,
   att.pointing.attributes,
   att.citing.attributes,
   macro.phraseSeq
 }

&lt;citeStructure&gt; (citation structure) declares a structure and method for citing the current document. [3.11.4. Declaring Reference Systems | 16.2.5.4. Citation Structures]

Module header – The TEI Header
Attributes | att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev), @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.citeStructurePart (@use)
@delim (delimiter) supplies a delimiting string preceding the structural component.

**Status** Optional

**Datatype** string

**Schematron**

```xml
<s:rule context="tei:citeStructure[parent::tei:citeStructure]">
  <s:assert test="@delim">A <s:name/> with a parent <s:name/> must have a @delim attribute.</s:assert> </s:rule>
```

**Note** delim must contain at least one character.

@match (match) supplies an XPath selection pattern using the syntax defined in Kay (ed.) (2017) which identifies a set of nodes which are citable structural components. The expression may be absolute (beginning with '/') or relative. match on a <citeStructure> without a <citeStructure> parent must be an absolute XPath. If it is relative, its context is set by the match of the parent <citeStructure>.

**Status** Required

**Datatype** teidata.xpath

**Schematron**

```xml
<s:rule context="tei:citeStructure[not(parent::tei:citeStructure)]">
  <s:assert test="starts-with(@match,'/')">An XPath in @match on the outer <s:name/> must start with '/</s:assert> </s:rule>
```

```xml
<s:rule context="tei:citeStructure[parent::tei:citeStructure]">
  <s:assert test="not(starts-with(@match,'/'))">An XPath in @match must not start with '/' except on the outer <s:name/>.</s:assert> </s:rule>
```

@unit (unit) describes the structural unit indicated by the <citeStructure>.

**Status** Optional

**Datatype** teidata.enumerated

**Sample values include:** book, chapter, entry, poem, letter, line, section, verse, volume

**Contained by:** citeStructure, refsDecl

**May contain:** core: desc

**header:** citeData, citeStructure

**Example**

```xml
<citeStructure unit="book"
  match="//body/div" use="@n">
  <citeStructure unit="chapter" match="div"
    use="position()" delim=" ">
    <citeStructure unit="verse" match="div"
      use="position()" delim=":">
    </citeStructure>
  </citeStructure>
</citeStructure>
```

**Content model**

```xml
<content>

998
```
<sequence>
  <elementRef key="citeData" minOccurs="0" maxOccurs="unbounded"/>
  <elementRef key="citeStructure" minOccurs="0" maxOccurs="unbounded"/>
  <classRef key="model.descLike" minOccurs="0" maxOccurs="unbounded"/>
</sequence>

Schema Declaration

```xml
<element citeStructure
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.citeStructurePart.attributes,
  attribute delim { text }?,
  attribute match { text },
  attribute unit { text }?,
  ( citeData*, citeStructure*, model.descLike* )
}
```

 `<cl>` (clause) represents a grammatical clause. [17.1. Linguistic Segment Categories]

**Module** analysis — Simple Analytic Mechanisms

**Attributes** att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.segLike (@function) (att.metrical (@met, @real, @rhyme)) (att.datcat (@datcat, @valueDatcat)) (att.fragmentable (@part)) att.typed (@type, @subtype) att.notated (@notation)

element classDecl
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  taxonomy+
}

<classes> (classes) specifies all the classes of which the documented element or class is a member or subclass.

Module tagdocs -- Documentation Elements
Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@mode specifies the effect of this declaration on its parent module.

Status Optional

Datatype teidata.enumerated

Legal values are: change this declaration changes the declaration of the same name in the current definition
replace this declaration replaces the declaration of the same name in the current definition[Default]

1003
The TEI Guidelines

**Tagdoc Descriptions**

- **classSpec**
- **elementSpec**

**May contain**

- **memberOf**

**Note** An empty `<classes>` element indicates that the element documented is not a member of any class. This should not generally happen.

**Example**

```xml
<classes>
  <memberOf key="model.attributable"/>
  <memberOf key="att.declarable"/>
</classes>
```

This `<classes>` element indicates that the element documented (which may be an element or a class) is a member of two distinct classes: `model.attributable` and `att.declarable`.

**Content Model**

```xml
<content>
  <elementRef key="memberOf" minOccurs="0" maxOccurs="unbounded"/>
</content>
```

**Schema Declaration**

```xml
element classes
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute mode { "change" | "replace" },
  memberOf*,
}
```

**<classRef>** points to the specification for an attribute or model class which is to be included in a schema [22.6: Class Specifications]

**Module tagdocs — Documentation Elements**

**Attributes**

- `att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)`
- `att.global.rendition (@rend, @style, @rendition)`
- `att.global.linking (@corresp, @synchrony, @sameAs, @copyOf, @next, @prev, @exclude, @select)`
- `att.global.analytic (@ana)`
- `att.global.facs (@facs)`
- `att.global.change (@change)`
- `att.global.responsibility (@cert, @resp)`
- `att.global.source (@source)`
- `att.repeatable (@minOccurs, @maxOccurs)`

**@key** the identifier used for the required class within the source indicated.

**Status** Required

**Datatype** teidata.xmlName

**@expand** indicates how references to this class within a content model should be interpreted.

**Status** Optional

**Legal values are:**

- **alternation** any one member of the class may appear
- **sequence** a single occurrence of all members of the class may appear in sequence
sequenceOptional a single occurrence of one or more members of the class may appear in sequence.

sequenceOptionalRepeatable one or more occurrences of one or more members of the class may appear in sequence.

sequenceRepeatable one or more occurrences of all members of the class may appear in sequence.

Note If the members of the class are a, b and c, then a reference to the class within a content model is understood as being a reference to a|b|c when expand is omitted or has the value alternation; to a,b,c when it has the value sequence; to (a?,b?,c?) when it has the value sequenceOptional; to (a*,b*,c*) when it has the value sequenceOptionalRepeatable; or to (a+,b+,c+) when it has the value sequenceRepeatable.

@include supplies a list of class members which are to be included in the schema being defined.

Status Optional

Datatype 0–∞ occurrences of teidata.xmlName separated by whitespace

@except supplies a list of class members which are to be excluded from the schema being defined.

Status Optional

Datatype 0–∞ occurrences of teidata.xmlName separated by whitespace

Member of model.contentPart

Contained by
tagdocs: alternate content schemaSpec sequence specGrp

May contain Empty element

Note Attribute and model classes are identified by the name supplied as value for the ident attribute on the <classSpec> element in which they are declared. All TEI class names are unique; attribute class names conventionally begin with the letters att.

Example

```
<schemaSpec ident="myTEIe" start="TEI">

  </moduleRef>
  <classRef key="att.global.facs"/>
</schemaSpec>
```

Content model <content> <empty/> </content>

Schema Declaration

```xml
<element classRef
{
   att.global.attributes,
```

1005
<classSpec> (class specification) contains reference information for a TEI element class; that is a group of elements which appear together in content models, or which share some common attribute, or both.

[22.3. Specification Elements][22.6. Class Specifications]

**Module** — Documentation Elements

**Attributes**
- `att.global` (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.identified (@ident, @predeclare, @module) (att.combinable (@mode) (att.deprecated (@validUntil))) att.typed (@type)

@type indicates whether this is a model class or an attribute class

**Derived from** `att.typed`

**Status** Required

**Datatype** `teidata.enumerated`

**Legal values are:**
- `model` (content model) members of this class appear in the same content models
- `atts` (attributes) members of this class share common attributes

@generate indicates which alternation and sequence instantiations of a model class may be referenced. By default, all variations are permitted.

**Status** Optional

**Datatype** `1–5 occurrences of teidata.enumerated` separated by whitespace

**Legal values are:**
- `alternation` members of the class are alternatives
- `sequence` members of the class are to be provided in sequence
- `sequenceOptional` members of the class may be provided, in sequence, but are optional
- `sequenceOptionalRepeatable` members of the class may be provided one or more times, in sequence, but are optional.
- `sequenceRepeatable` members of the class may be provided one or more times, in sequence

Member of `model.oddDecl`
<classSpec module="tei" type="model" ident="model.segLike">
  <desc>groups elements used for arbitrary segmentation.</desc>
  <classes>
    <memberOf key="model.phrase"/>
  </classes>
  <remarks>
    <p>The principles on which segmentation is carried out, and any special codes or attribute values used, should be defined explicitly in the <gi>segmentation</gi> element of the <gi>encodingDesc</gi> within the associated TEI header.</p>
  </remarks>
</classSpec>

character data

1022
There are lacunae in three places in this manuscript. After 14v two leaves has been cut out and narrow strips leaves remains in the spine. After 68v one gathering is missing and after 101v at least one gathering of 8 leaves has been lost. 

Several leaves are damaged with tears or holes or have a irregular shape. Some of the damages do not allow the lines to be of full length and they are apparently older than the script. There are tears on fol. 2r-v, 9r-v, 10r-v, 15r-18v, 19r-v, 20r-22v, 23r-v, 24r-28v, 30r-v, 32r-35v, 37r-v, 38r-v, 40r-43v, 45r-47v, 49r-v, 51r-v, 53r-60v, 67r-v, 68r-v, 70r-v, 74r-80v, 82r-v, 86r-v, 88r-v, 89r-v, 95r-v, 97r-98v 99r-v, 100r-v. On fol. 98 the corner has been torn off. Several leaves are in a bad condition due to moist and wear, and have become dark, bleached or wrinkled.

The script has been touched up in the 17th century with black ink. The touching up on the following fols. was done by Bishop Brynjólf Sveinsson: 1v, 3r, 4r, 5r, 6v, 8v, 9r, 10r, 14r, 14v, 22r, 30v, 36r-52v, 72v, 77r, 78r, 103r, 104r,. An AM-note says according to the lawman Sigurður Björnsson that the rest of the touching up was done by himself and another lawman Sigurður Jónsson. Sigurður Björnsson did the touching up on the following fols.: 46v, 47r, 48r, 49r-v, 50r, 52r-v. Sigurður Jónsson did the rest of the touching up in the section 36r-59r containing Bretasögur.

The script has been touched up in the 17th century with black ink. Note The function of this element seems to overlap with both the org attribute on <div> and the <samplingDecl> in the <encodingDesc>.

Example

1024
<constraint> (constraint rules) the formal rules of a constraint [22.5. Element Specifications]

Module  tagdocs — Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by tagdocs: constraintSpec
May contain ANY

Example

<constraintSpec ident="isoconstraint" scheme="schematron">
  <constraint>
    <s:assert test="tei:fileDesc/tei:titleStmt/tei:title[@type='main']"> a main title must be supplied </s:assert>
  </constraint>
</constraintSpec>

Example

<constraintSpec ident="local" scheme="private">
  <constraint>
    (output = (ident(title) ident(author) "You must supply a title or an author"))
  </constraint>
</constraintSpec>
<constraintSpec> (constraint on schema) contains a formal constraint, typically expressed in a rule-based schema language, to which a construct must conform in order to be considered valid [22.5. Element Specifications]

Module tagdocs — Documentation Elements
Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.identified (@ident, @predeclare, @module) (att.combinable (@mode)) (att.deprecated (@validUntil)) att.typed (@mode) (att.deprecated (@validUntil))

@type characterizes the <constraintSpec> element in some sense; used to indicate when a <constraintSpec> warns about a deprecated construct.

Status Optional

Datatype teidata.enumerated

Suggested values include: depreciationWarning Indicates that this constraint specification warns that some other construct in the schema is deprecated.

@scheme supplies the name of the language in which the constraints are defined

Status Required

Datatype teidata.enumerated

Suggested values include: schematron (ISO Schematron)

Note These Guidelines no longer recommend, and the available TEI stylesheets no longer support, the use of Schematron 1.x within <constraintSpec>. Thus the value schematron is used to indicate that ISO Schematron is used within the <constraintSpec>.
Example This constraint uses Schematron to enforce the presence of the \textit{spanTo} attribute (which comes from an attribute class) on the `<addSpan>` element:

```xml
<constraintSpec ident="demo-c1" scheme="schematron"
xmlns:sch="http://purl.oclc.org/dsdl/schematron">
  <desc>Enforce the presence of the `<att>spanTo</att>` attribute</desc>
  <constraint>
    <sch:assert test="@spanTo">The `spanTo` attribute of `<sch:name/>` is required.</sch:assert>
  </constraint>
</constraintSpec>
```

Example This constraint uses SPITBOL (a language which is not expressed in XML) to check whether the title and author are identical:
The TEI Guidelines

```
<constraintSpec ident="local"
scheme="SPITBOL">
  <constraint>
    (output = leq(title,author) "title and author cannot be the same")
  </constraint>
</constraintSpec>
```

**Schematron** Relationship between scheme attribute and contents: Schematron 1.x

```
<sch:ns prefix="s" uri="http://www.ascc.net/xml/schematron"/>
<sch:report test="tei:constraint/s:* and @scheme = ('isoschematron','schematron')">Rules in the Schematron 1.* language must be inside a constraintSpec with a value other than 'schematron' or 'isoschematron' on the scheme attribute</sch:report>
```

**Schematron** Relationship between scheme attribute and contents: ISO Schematron

```
<sch:ns prefix="sch" uri="http://purl.oclc.org/dsdl/schematron"/>
<sch:report test="tei:constraint/sch:* and not( @scheme eq 'schematron')">Rules in the ISO Schematron language must be inside a constraintSpec with the value 'schematron' on the scheme attribute</sch:report>
```

**Content model**

```
<content>
  <sequence>
    <alternate minOccurs="0" maxOccurs="unbounded">
      <classRef key="model.glossLike"/>
      <classRef key="model.descLike"/>
    </alternate>
    <elementRef key="constraint" minOccurs="0"/>
  </sequence>
</content>
```

**Schema Declaration**

```
element constraintSpec
{*
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.identified.attributes,
  att.combinable.attributes,
  att.deprecated.attributes,
  att.typed.attribute.subtype,
  attribute type { "deprecationWarning" }?,
  attribute scheme { "schematron" },
  ( ( model.glossLike | model.descLike )* , constraint? )
}
```
**Module** tagdocs — Documentation Elements

**Attributes**

- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@autoPrefix controls whether or not pattern names generated in the corresponding RELAX NG schema source are automatically prefixed to avoid potential nameclashes.

**Status** Optional

**Datatype** teidata.truthValue

**Legal values are**

- **true** Each name referenced in e.g. an `<rng:ref>` element within a content model is automatically prefixed by the value of the prefix attribute on the current `<schemaSpec>`. (Default)

- **false** No prefixes are added: any prefix required by the value of the prefix attribute on the current `<schemaSpec>` must therefore be supplied explicitly, as appropriate.

**Contained by**

dataSpec, elementSpec, macroSpec, moduleRef

**May contain** ANY

**Example** This sample `<content>` element indicates that the element being specified has no content:

```xml
<content>
  <empty/>
</content>
```

**Example** This `<content>` element defines a content model, expressed directly in the TEI ODD language, that allows either a sequence of paragraphs or a series of msItem elements optionally preceded by a summary:

```xml
<content>
  <alternate>
    <classRef key="model.pLike" maxOccurs="unbounded"/>
  </alternate>
  <sequence>
    <elementRef key="summary" minOccurs="0" maxOccurs="1"/>
    <elementRef key="msItem" maxOccurs="unbounded"/>
  </sequence>
</content>
```

**Example** This sample `<content>` element defines a content model, expressed in the RELAX NG schema language, that allows either a sequence of paragraphs or a series of msItem elements optionally preceded by a summary:

```xml
<content>
  <rng:choice>
    <rng:oneOrMore>
      <rng:ref name="model.pLike"/>
    </rng:oneOrMore>
    <rng:group>
      <rng:optional>
        <rng:ref name="summary"/>
      </rng:optional>
    </rng:group>
  </rng:choice>
</content>
```
<content>
<alternate>
<elementRef key="valList" minOccurs="1" maxOccurs="1"/>
<classRef key="model.contentPart" minOccurs="1" maxOccurs="unbounded"/>
<anyElement minOccurs="1" maxOccurs="unbounded" require="http://relaxng.org/ns/compatibility/annotations/1.0 http://relaxng.org/ns/structure/1.0"/>
</alternate>
</content>

Schema Declaration

```
<conversion>
defines how to calculate one unit of measure in terms of another. [2.3.9. The Unit Declaration]
```

<Module
header — The TEI Header

Attributes

```
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.matching (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.datetime (@calendar, @period) (att.datetime.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.datetime.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.datetime.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod)) att.formula (@formula) att.locatable (@where)
```

@fromUnit indicates a source unit of measure that is to be converted into another unit indicated in toUnit.

Status Required

Datatype teidata.pointer
@toUnit the target unit of measurement for a conversion from a source unit referenced in fromUnit.

Status Required

Datatype leidata.pointer

Containable: unitDef

May contain Empty element

Note The conversion element is designed to store information about converting from one unit of measurement to another. The formula attribute holds an XPath expression that indicates how the measurement system in fromUnit is converted to the system in toUnit. Do not confuse the usage of the dating attributes (from and to) in the examples with the attributes (fromUnit and toUnit) designed to reference units of measure.

Example

```xml
<conversion fromUnit="#shilling" toUnit="#pence" formula="$fromUnit * 12" from="1707" to="1971"/>
```

Example

```xml
<conversion fromUnit="#pound" toUnit="#shilling" formula="$fromUnit * 20" from="1701" to="1971"/>
```

Content model `<content> <empty/></content>`

Schema Declaration

```xml
element conversion
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.databindable.attributes,
  att.databindable.w3c.attributes,
  att.databindable.iso.attributes,
  att.databindable.custom.attributes,
  att.formula.attributes,
  att.locatable.attributes,
  attribute fromUnit { text },
  attribute toUnit { text },
  empty
}
```

<corr> (correction) contains the correct form of a passage apparently erroneous in the copy text. [3.5.1. Apparent Errors]

Module core — Elements Available in All TEI Documents

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility
Example If all that is desired is to call attention to the fact that the copy text has been corrected, `<corr>` may be used alone:

I don’t know, Juan. It’s so far in the past now – how `<corr>`can we</corr> prove or disprove anyone’s theories?

Example It is also possible, using the `<choice>` and `<sic>` elements, to provide an uncorrected reading:

I don’t know, Juan. It’s so far in the past now – how `<choice>`

`<sic>`we can</sic>

`<corr>`can we</corr>

`</choice>` prove or disprove anyone’s theories?

Content model

```
<content>
  <macroRef key="macro.paraContent"/>
</content>
```

Schema Declaration

```xml
<element corr
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.editLike.attributes,
  att.typed.attributes,
  macro.paraContent}
```

`<corr>` (correction principles) states how and under what circumstances corrections have been made in the text. [2.3.3. The Editorial Practices Declaration 15.3.2. Declarable Elements]
(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.declarable (@default)

@status indicates the degree of correction applied to the text.

Status Optional

Datatype teidata.enumerated

Legal values are: high the text has been thoroughly checked and proofread.
medium the text has been checked at least once.
low the text has not been checked.
unknown the correction status of the text is unknown.

@method indicates the method adopted to indicate corrections within the text.

Status Optional

Datatype teidata.enumerated

Legal values are: silent corrections have been made silently [Default]
markup corrections have been represented using markup.

Member of model.editorialDeclPart

Contained by header: editorialDecl

May contain core: p

linking: ab

Note May be used to note the results of proof reading the text against its original, indicating (for example) whether discrepancies have been silently rectified, or recorded using the editorial tags described in section 3.5. Simple Editorial Changes.

Example

```
<correction>
  <p>Errors in transcription controlled by using the WordPerfect spelling checker, with a user defined dictionary of 500 extra words taken from Chambers Twentieth Century Dictionary.</p>
</correction>
```

Content model

```
<content>
  <classRef key="model.pLike" minOccurs="1" maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```
element correction {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.declarable.attributes,
  ...
} 1034
```
<correspAction> (correspondence action) contains a structured description of the place, the name of a person/organization and the date related to the sending/receiving of a message or any other action related to the correspondence. [2.4.6. Correspondence Description]

Module header — The TEI Header

Attributes
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.sortable (@sortKey) att.typed (@type, @subtype)

@type describes the nature of the action.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Suggested values include:

sent information concerning the sending or dispatch of a message.

received information concerning the receipt of a message.

transmitted information concerning the transmission of a message, i.e. between the dispatch and the next receipt, redirect or forwarding.

redirected information concerning the redirection of an unread message.

forwarded information concerning the forwarding of a message.

character data

Note The <creation> element may be used to record details of a text’s creation, e.g. the date and place it was composed, if these are of interest.

It may also contain a more structured account of the various stages or revisions associated with the evolution of a text; this should be encoded using the <listChange> element. It should not be confused with the <publicationStmt> element, which records date and place of publication.

Example

<creation>
  <date>Before 1987</date>
</creation>

Example

<creation>
  <date when="1988-07-10">10 July 1988</date>
</creation>

Content model

<content>

    <textNode/>
    <classRef key="model.limitedPhrase"/>
    <elementRef key="listChange"/>
  </alternate>
</content>
The TEI Guidelines

```
</content>
```

**Schema Declaration**

```python
element creation
{
    att.global.attributes,
    att.global.rendition.attributes,
    att.global.linking.attributes,
    att.global.analytic.attributes,
    att.global.facs.attributes,
    att.global.change.attributes,
    att.global.responsibility.attributes,
    att.global.source.attributes,
    att.datable.attributes,
    att.datable.w3c.attributes,
    att.datable.iso.attributes,
    att.datable.custom.attributes,
    ( text | model.limitedPhrase | listChange )*
}
```

**<cRefPattern>** (canonical reference pattern) specifies an expression and replacement pattern for transforming a canonical reference into a URI. [2.3.6.3. Milestone Method][2.3.6. The Reference System Declaration][2.3.6.2. Search-and-Replace Method]

Module **header** – The TEI Header

Attributes `att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)` (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) `att.patternReplacement (@matchPattern, @replacementPattern)`

Contained by
- header: `refsDecl`

May contain
- core: `p`
- linking: `ab`

**Note** The result of the substitution may be either an absolute or a relative URI reference. In the latter case it is combined with the value of `xml:base` in force at the place where the `cRef` attribute occurs to form an absolute URI in the usual manner as prescribed by **XML Base**.

**Example**

```
<RefPattern matchPattern="([1-9A-Za-z]+)\s+([0-9]+):([0-9]+)"
replacementPattern="#xpath(//div[@type='book'][@n='$1']//div[@type='chap'][@n='$2'])"/>
```

**Content model**

```
<content>
    <classRef key="model.pLike" minOccurs="0"
        maxOccurs="unbounded"/>

<damage> (damage) contains an area of damage to the text witness. [11.3.3.1, Damage, Illegibility, and Supplied Text] Module transcr – Representation of Primary Sources Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype) att.damaged (@agent, @degree, @group) (att.dimensions (@unit, @quantity, @extent, @precision, @scope) (att.ranging (@atLeast, @atMost, @min, @max, @confidence)) ) (att.written (@hand))

Member of model.linePart model.pPart.transcriptional

1045
Since damage to text witnesses frequently makes them harder to read, the `<damage>` element will often contain an `<unclear>` element. If the damaged area is not continuous (e.g. a stain affecting several strings of text), the `group` attribute may be used to group together several related `<damage>` elements; Alternatively the `<join>` element may be used to indicate which `<damage>` and `<unclear>` elements are part of the same physical phenomenon. The `<damage>`, `<gap>`, `<del>`, `<unclear>`, and `<supplied>` elements may be closely allied in use. See section 11.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination for discussion of which element is appropriate for which circumstance.

**Example**

```xml
<l>The Moving Finger writes; and</l>
having writ,&lt;l&gt;
Moves &lt;damage agent="water" group="1">having writ,</l&gt;
&lt;supplied>on: nor all your&lt;/supplied&gt;
</l>PIETY nor WIT&lt;/l&gt;
```

**Content model**

```xml
&lt;content&gt;
 &lt;macroRef key="macro.paraContent"/&gt;
&lt;/content&gt;
```

**Schema Declaration**

```xml
element damage
 {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.typed.attributes,
  att.damaged.attributes,
  att.dimensions.attributes,
  att.ranging.attributes,
  att.written.attributes,
  macro.paraContent}
```
The damaged text must be at least partially legible, in order for the encoder to be able to transcribe it. If it is not legible at all, the <damageSpan> element should not be used. Rather, the <gap> or <unclear> element should be employed, with the value of the reason attribute giving the cause. See further sections [11.3.3.1. Damage, Illegibility, and Supplied Text] and [11.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination].
<p>Paragraph partially damaged. This is the undamaged portion <code><span damageSpan xml:id="a34"/></span>and this the damaged portion of the paragraph.</p>

<p>This paragraph is entirely damaged.</p>

<p>Paragraph partially damaged; in the middle of this paragraph the damage ends and the anchor point marks the start of the <code><span anchor xml:id="a34"/></span> undamaged part of the text. ...</code></p>

Schematron  <code>&lt;s:assert test="@spanTo">The @spanTo attribute of <s:name/> is required.</s:assert&gt;</code>

Schematron  <code>&lt;s:assert test="@spanTo">L’attribut spanTo est requis.</s:assert&gt;</code>

Content model  <code>&lt;content&gt; &lt;empty/&gt;&lt;/content&gt;</code>

Schema Declaration

```xml
<element damageSpan
{
  att.global.attributes, 
  att.global.rendition.attributes, 
  att.global.linking.attributes, 
  att.global.analytic.attributes, 
  att.global.facs.attributes, 
  att.global.change.attributes, 
  att.global.responsibility.attributes, 
  att.global.source.attributes, 
  att.damaged.attributes, 
  att.dimensions.attributes, 
  att.ranging.attributes, 
  att.written.attributes, 
  att.typed.attributes, 
  att.spanning.attributes, 
  empty
}
```

<code>&lt;dataFacet&gt;</code>  Restricts the value of the strings used to represent values of a datatype, according to XML Schemas: Part 2: Datatypes. [22.5.3.1. Datatypes]

Module  tagdocs – Documentation Elements

Attributes  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@name the name of the facet.

Status  Required

Datatype  teidata.word

Legal values are:  length

  minLength
  maxLength
  pattern
  enumeration
  whiteSpace
  maxInclusive
  minInclusive
maxExclusive
minExclusive
totalDigits
fractionDigits
@value the facet value.
    Status  Required
    Datatype  string

Contents: dataRef
May contain Empty element

Note This element is only allowed when the parent <dataRef> refers with name to a datatype from the specification XML Schemas: Part 2: Datatypes.

Example

```xml
<datatype>
  <dataRef name="decimal">
    <dataFacet name="maxInclusive" value="360.0"/>
    <dataFacet name="minInclusive" value="-360.0"/>
  </dataRef>
</datatype>
```

Example

```xml
<dataSpec ident="data.integerExample">
  <desc>datatype used for attributes taking an integer value between 0 and 99</desc>
  <content>
    <dataRef name="nonNegativeInteger">
      <dataFacet name="maxInclusive" value="99"/>
      <dataFacet name="minInclusive" value="0"/>
    </dataRef>
  </content>
</dataSpec>
```

Content model <content> <empty/></content>

Schema Declaration

```xml
<element dataFacet {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global/linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global/change.attributes,
  att.global/responsibility.attributes,
  att.global/source.attributes,
  attribute name
  {
    "length"
    | "minLength"
    | "maxLength"
```
<dataRef> identifies the datatype of an attribute value, either by referencing an item in an externally defined datatype library, or by pointing to a TEI-defined data specification [22.5.3.1. Datatypes].

Module tagdocs - Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml-base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@key the identifier used for this datatype specification
   Status Optional
   Datatype teidata.xmlName

@name the name of a datatype in the list provided by XML Schemas: Part 2: Datatypes
   Status Optional
   Datatype teidata.xmlName

@ref a pointer to a datatype defined in some datatype library
   Status Optional
   Datatype teidata.pointer

@restriction supplies a string representing a regular expression providing additional constraints on the strings used to represent values of this datatype
   Status Optional
   Datatype teidata.pattern

Member of model.contentPart | model.oddRef

Contained by
tagdocs: alternate | content | datatype | schemaSpec | sequence | specGrp

May contain
tagdocs: [dataFacet]

Note Only one of the attributes key, name, and ref may be used.
   <dataFacet> children are only allowed when <dataRef> refers with name to a datatype from the specification XML Schemas: Part 2: Datatypes.
   restriction is only permitted when <dataRef> uses the name attribute.

Example

```xml
<schemaSpec ident="myTEI"
   source="http://www.tei-c.org/Vault/P5/current/xml/tei/odd/p5subset.xml">
</!-- ... -->
<dataRef key="teidata.enumerated"/>
```
Example

```
<schemaSpec ident="myTEI"
    source="http://www.tei-c.org/Vault/P5/current/xml/tei/odd/p5subset.xml">
    <!-- ... -->
    <dataRef name="float"/>
    <!-- ... -->
</schemaSpec>
```

Example

```
<dataSpec ident="data.integerExample">
    <desc>datatype used for attributes taking an integer value between 0 and 99</desc>
    <content>
        <dataRef name="nonNegativeInteger"
            restriction="[0-9]*"/>
    </content>
</dataSpec>
```

Schematron

```
<sch:rule context="tei:dataRef[tei:dataFacet]">
    <sch:assert test="@name" role="nonfatal">
        Data facets can only be specified for references to datatypes specified by XML Schemas: Part 2: Datatypes</sch:assert>
</sch:rule>
```

```
<sch:rule context="tei:dataRef[tei:dataFacet]">
    <sch:report test="@restriction">
        The attribute restriction cannot be used when dataFacet elements are present.</sch:report>
</sch:rule>
```

```
<sch:rule context="tei:dataRef">
    <sch:report test="@restriction and not(@name)" role="fatal">
        The attribute restriction can only be used with a name attribute.</sch:report>
</sch:rule>

  )
}
```

<datatype> (datatype) specifies the declared value for an attribute, by referring to any datatype defined by the chosen schema language. [1.4.2. Datatype Specifications | 22.5.3. Attribute List Specification]

Module tagdocs — Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
<datatype>

(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@minOccurs (minimum number of occurences) indicates the minimum number of times this
datatype may occur in an instance of the attribute being defined
Derived from att.repeatable
Status Optional
Datatype teidata.count
Default 1

@maxOccurs (maximum number of occurences) indicates the maximum number of times this
datatype may occur in an instance of the attribute being defined
Derived from att.repeatable
Status Optional
Datatype teidata.unboundedInt
Default 1

Contents: attDef
May contain ANY

Note In the TEI scheme, most datatypes are expressed using pre-defined TEI macros, which map a name in the
form teidata.xxxx to a datatype defined by RELAX NG or the W3C Schema Language.

Example

<datatype>
  <dataRef name="token"/>
</datatype>

Example

<datatype>
  <dataRef key="teidata.enumerated"/>
</datatype>

Example The encoding in the following example requires that the attribute being defined contain at least two
URIs in its value, as is the case for the target attribute of <join>.

<datatype minOccurs="2"
maxOccurs="unbounded">
  <dataRef key="teidata.pointer"/>
</datatype>

Content model

<content>
  <alternate>
    <elementRef key="dataRef"/>
    <anyElement require="http://relaxng.org/ns/structure/1.0"/>
  </alternate>
</content>

1067
Note This element should be used for deletion of shorter sequences of text, typically single words or phrases. The <delSpan> element should be used for longer sequences of text, for those containing structural subdivisions, and for those containing overlapping additions and deletions.

The text deleted must be at least partially legible in order for the encoder to be able to transcribe it (unless it is restored in a <supplied> tag). Illegible or lost text within a deletion may be marked using the <gap> tag to signal that text is present but has not been transcribed, or is no longer visible. Attributes on the <gap> element may be used to indicate how much text is omitted, the reason for omitting it, etc. If text is not fully legible, the <unclear> element (available when using the additional tagset for transcription of primary sources) should be used to signal the areas of text which cannot be read with confidence in a similar way.

Degrees of uncertainty over what can still be read, or whether a deletion was intended may be indicated by use of the <certainty> element (see 21. Certainty, Precision, and Responsibility).

There is a clear distinction in the TEI between <del> and <surplus> on the one hand and <gap> or <unclear> on the other. <del> indicates a deletion present in the source being transcribed, which states the author’s or a later scribe’s intent to cancel or remove text. <surplus> indicates material present in the source being transcribed which should have been so deleted, but which is not in fact. <gap> or <unclear>, by contrast, signal an editor’s or encoder’s decision to omit something or their inability to read the source text. See sections 11.3.1.7. Text Omitted from or Supplied in the Transcription and 11.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination for the relationship between these and other related elements used in detailed transcription.

Example

```xml
<l>
  <del rend="overtyped">Mein</del> Frisch
  <del rend="overstrike" type="primary">schwebt</del>
  weht der Wind
</l>
```

Example

```xml
<del rend="overstrike">
  <gap reason="illegible" quantity="5"
  unit="character"/>
</del>
```

Content model

```xml
<content>
  <macroRef key="macro.paraContent"/>
</content>
```

Schema Declaration

```xml
element del {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.transcriptional.attributes,
}
```
May contain Empty element

Note  Both the beginning and ending of the deleted sequence must be marked: the beginning by the `<delSpan>` element, the ending by the target of the `spanTo` attribute.

The text deleted must be at least partially legible, in order for the encoder to be able to transcribe it. If it is not legible at all, the `<delSpan>` tag should not be used. Rather, the `<gap>` tag should be employed to signal that text cannot be transcribed, with the value of the `reason` attribute giving the cause for the omission from the transcription as deletion. If it is not fully legible, the `<unclear>` element should be used to signal the areas of text which cannot be read with confidence. See further sections 11.3.1.7. Text Omitted from or Supplied in the Transcription and, for the close association of the `<delSpan>` tag with the `<gap>`, `<damage>`, `<unclear>` and `<supplied>` elements, 11.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination.

The `<delSpan>` tag should not be used for deletions made by editors or encoders. In these cases, either the `<corr>` tag or the `<gap>` tag should be used.

Example

<p>Paragraph partially deleted. This is the undeleted portion `<delSpan> spanTo="#a23"/>` and this the deleted portion of the paragraph.</p>

<p>Paragraph deleted together with adjacent material.</p>

<p>Second fully deleted paragraph.</p>

<p>Paragraph partially deleted; in the middle of this paragraph the deletion ends and the anchor point marks the resumption `<anchor xml:id="a23"/>` of the text. ...</p>

Schematron `<s:assert test="@spanTo">The @spanTo attribute of `<s:name/>` is required.</s:assert>`

Schematron `<s:assert test="@spanTo">L’attribut spanTo est requis.</s:assert>`

Content model `<content> <empty/></content>`

character data

Note When used in a specification element such as <elementSpec>, TEI convention requires that this be expressed as a finite clause, beginning with an active verb.

Example Example of a <desc> element inside a documentation element.

```xml
<dataSpec module="tei"
  ident="teidata.point">
  <desc versionDate="2010-10-17"
    xml:lang="en">defines the data type used to express a point in cartesian space.</desc>
  <content>
    <dataRef name="token"
  </content>
</dataSpec>
```

Example Example of a <desc> element in a non-documentation element.

```xml
<place xml:id="KERG2">
  <placeName>Kerguelen Islands</placeName>
  <!-- ... -->
  <terrain>
    <desc>antarctic tundra</desc>
  </terrain>
  <!-- ... -->
</place>
```

Schematron A <desc> with a type of deprecationInfo should only occur when its parent element is being deprecated. Furthermore, it should always occur in an element that is being deprecated when <desc> is a
valid child of that element. 

```
<sch:rule context="tei:desc[@type eq 'deprecationInfo']">  
  <sch:assert test="../@validUntil">Information about a deprecation should only be present in a 
  specification element that is being deprecated: that is, only an element that has a @validUntil attribute 
  should have a child <desc type="deprecationInfo">.</sch:assert> </sch:rule>
```

- att.global.source (@source)
- att.dimensions (@unit, @quantity, @extent, @precision, @scope)
- att.ranging (@atLeast, @atMost, @min, @max, @confidence)
- att.typed (@type, @subtype)

@type indicates which aspect of the object is being measured.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Sample values include:

- **leaves** dimensions relate to one or more leaves (e.g. a single leaf, a gathering, or a separately bound part)
- **ruled** dimensions relate to the area of a leaf which has been ruled in preparation for writing.
- **pricked** dimensions relate to the area of a leaf which has been pricked out in preparation for ruling (used where this differs significantly from the ruled area, or where the ruling is not measurable).
- **written** dimensions relate to the area of a leaf which has been written, with the height measured from the top of the minims on the top line of writing, to the bottom of the minims on the bottom line of writing.
- **miniatures** dimensions relate to the miniatures within the manuscript
binding dimensions relate to the binding in which the codex or manuscript is contained.

box dimensions relate to the box or other container in which the manuscript is stored.

transcr: damage fw metamark mark restore retrace secl supplied surplus
verse: metSym rhyme

May contain

msdescription: depth dim height width

Note Contains no more than one of each of the specialized elements used to express a three-dimensional object's height, width, and depth, combined with any number of other kinds of dimensional specification.

Example

```xml
<dimensions type="leaves">
  <height scope="range">157-160</height>
  <width>105</width>
</dimensions>
<dimensions type="ruled">
  <height scope="most">90</height>
  <width scope="most">48</width>
</dimensions>
<dimensions unit="in">
  <height>12</height>
```
Example  This element may be used to record the dimensions of any text-bearing object, not necessarily a codex. For example:

```xml
<dimensions type="panels">
  <height scope="all">7004</height>
  <width scope="all">1803</width>
  <dim type="relief" unit="mm">345</dim>
</dimensions>
```

This might be used to show that the inscribed panels on some (imaginary) monument are all the same size (7004 by 1803 cm) and stand out from the rest of the monument by 345 mm.

Example  When simple numeric quantities are involved, they may be expressed on the `quantity` attribute of any or all of the child elements, as in the following example:

```xml
<dimensions type="leaves">
  <height scope="range">157-160</height>
  <width quantity="105"/>
</dimensions>
<dimensions type="ruled">
  <height unit="cm" scope="most" quantity="90"/>
  <width unit="cm" scope="most" quantity="48"/>
</dimensions>
<dimensions unit="in">
  <height quantity="12"/>
  <width quantity="10"/>
</dimensions>
```

Schematron  `<s:report test="count(tei:width) > 1">The element `<s:name/>` may appear once only </s:report>`

```xml
<s:report test="count(tei:height) > 1">The element `<s:name/>` may appear once only </s:report>
<s:report test="count(tei:depth) > 1">The element `<s:name/>` may appear once only </s:report>
```

**Content model**

```xml
<content>
  <alternate minOccurs="0" maxOccurs="unbounded">
    <elementRef key="dim"/>
    <classRef key="model.dimLike"/>
  </alternate>
</content>
```

**Schema Declaration**

```xml
element dimensions
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global/linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global/responsibility.attributes,
  att.global/source.attributes,
```
att.dimensions.attributes,
att.ranging.attributes,
att.typed.attribute.subtype,
attribute type { text },{ dim | model.dimLike }*

identifies any word or phrase which is regarded as linguistically distinct, for example as archaic, technical, dialectal, non-preferred, etc., or as forming part of a sublanguage. [3.3.2.3. Other Linguistically Distinct Material]

Module core — Elements Available in All TEI Documents

</div5>
<div5>
<head>Sufficient</head>
<p>for 10 persons</p>
</div5>
</div5>
</div2>
```
This useful fruit is mentioned in Holy Writ; and Homer describes it as valuable in his time. As a food, the apple cannot be considered to rank high, as more than the half of it consists of water, and the rest of its properties are not the most nourishing. It is however a useful adjunct to other kinds of food, and, when cooked, is esteemed as slightly laxative.
<div6> (level-6 text division) contains a sixth-level subdivision of the front, body, or back of a text. [4.1.2]

    att.global.source.attributes,
    att.divLike.attributes,
    att.metrical.attributes,
    att.fragmentable.attributes,
    att.typed.attributes,
    att.declaring.attributes,
    {
        ( model.divTop | model.global )*,
        ( ( model.common, model.global* )+,
        ( model.divBottom, model.global* )* )?
    }
}
<divGen> (automatically generated text division) indicates the location at which a textual division generated automatically by a text-processing application is to appear. [3.9.2. Index Entries]

Module core — Elements Available in All TEI Documents

Attributes att.global (@xml:id, @n, @xml:lang, @xml-base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (type, @subtype)

@type specifies what type of generated text division (e.g. index, table of contents, etc.) is to appear. Derived from att.typed

Status Optional

Datatype teidata.enumerated

Sample values include: index an index is to be generated and inserted at this point. toc a table of contents figlist a list of figures tablist a list of tables

Note Valid values are application-dependent; those shown are of obvious utility in document production, but are by no means exhaustive.

Member of model.divGenLike model.frontPart

Contained by textstructure: back body div div1 div2 div3 div4 div5 div6 front

May contain core: head

Note This element is intended primarily for use in document production or manipulation, rather than in the transcription of pre-existing materials; it makes it easier to specify the location of indices, tables of contents, etc., to be generated by text preparation or word processing software.

Example One use for this element is to allow document preparation software to generate an index and insert it in the appropriate place in the output. The example below assumes that the indexName attribute on <index> elements in the text has been used to specify index entries for the two generated indexes, named NAMES and THINGS:

Example Another use for <divGen> is to specify the location of an automatically produced table of contents:
Content model

```xml
<content>
  <classRef key="model.headLike" minOccurs="0" maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```xml
element divGen
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.typed.attribute.subtype,
  attribute type { text }?,
  model.headLike*
}
```

<docAuthor> (document author) contains the name of the author of the document, as given on the title page (often but not always contained in a byline). [4.6. Title Pages]

Module textstructure — Default Text Structure

Attributes

- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
- att.global.analytic (@ana)
- att.global.facs (@facs)
- att.global.change (@change)
- att.global.responsibility (@cert, @resp)
- att.global.source (@source)
- att.canonical (@key, @ref)

Member of model.divWrapper, model.pLike.front, model.titlepagePart

May contain

analysis: c, cl, interp, interpGrp, m, pc, phr, s, span, spanGrp, w

certainty: certainty, precision, respons

core: abbr, add, address, binaryObject, cb, choice, cit, corr, date, del, distinct, ellipsis, email, emph, expan, foreign, gap, gb, gloss, graphic, hi, index, it, measure, measureGrp, media, mentioned, milestone, name, note, noteGrp, num, orig, pb, ptr, q, quote, ref, reg, rb, ruby, said, sic, soCalled, term, time, title, unclear, unit

dictionaries: lang, oRef, pRef
Note: The document author’s name often occurs within a byline, but the `<docAuthor>` element may be used whether the `<byline>` element is used or not. It should be used only for the author(s) of the entire document, not for author(s) of any subset or part of it. (Attributions of authorship of a subset or part of the document, for example of a chapter in a textbook or an article in a newspaper, may be encoded with `<byline>` without `<docAuthor>`.)

Example:

```
<titlePage>
  <docTitle>
    <titlePart>Travels into Several Remote Nations of the World, in Four Parts.</titlePart>
  </docTitle>
  <byline>By <docAuthor>Lemuel Gulliver</docAuthor>, First a Surgeon, and then a Captain of several Ships</byline>
</titlePage>
```

Content model

```
<content>
  <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
}
<docDate> (document date) contains the date of a document, as given on a title page or in a dateline. [4.6. Title]

Module textstructure — Default Text Structure

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.response (@cert, @resp)) (att.global.source (@source))

@when (when) gives the value of the date in standard form, i.e. YYYY-MM-DD.

Status Optional

Datatype teidata.temporal.w3c

Note For simple dates, the when attribute should give the Gregorian or proleptic Gregorian date in one of the formats specified in XML Schema Part 2: Datatypes Second Edition.

character data

Note If the example contains material in XML markup, either it must be enclosed within a CDATA marked section, or character entity references must be used to represent the markup delimiters. If the example contains well-formed XML, it should be marked using the more specific <egXML> element.

Example

<p>The <gi>term</gi> element is declared using the following syntax: </p>

```xml
<eg><![CDATA[<!ELEMENT term (%phrase.content;)>]]></eg>
</p>
```

Content model

```xml
<content>
 <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```xml
element eg {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  macro.phraseSeq
}
```
<egXML> (example of XML) a single XML fragment demonstrating the use of some XML, such as elements, attributes, or processing instructions, etc., in which the <egXML> element functions as the root element.

[22.1.1. Phrase Level Terms]

Namespace http://www.tei-c.org/ns/Examples

Module tagdocs — Documentation Elements

Attributes
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global rend) (@rend, @style, @rendition) (att.global linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global source (@source))

@valid indicates the intended validity of the example with respect to a schema.

Status Optional

Datatype teidata.enumerated

Legal values are: true the example is intended to be fully valid, assuming that its root element, or a provided root element, could have been used as a possible root element in the schema concerned. [Default]

feasible the example could be transformed into a valid document by inserting any number of valid attributes and child elements anywhere within it; or it is valid against a version of the schema concerned in which the provision of character data, list, element, or attribute values has been made optional.

false the example is not intended to be valid, and contains deliberate errors.

May contain ANY

Note In the source of the TEI Guidelines, this element declares itself and its content as belonging to the namespace http://www.tei-c.org/ns/Examples. This enables the content of the element to be validated independently against the TEI scheme. Where this element is used outside this context, a different namespace or none at all may be preferable. The content must however be a well-formed XML fragment or document: where this is not the case, the more general <eg> element should be used in preference.

Example
A slide about egXML

egXML can be used to give XML examples in the TEI Examples namespace.

Attributes values for valid:

- true: intended to be fully valid
- feasible: valid if missing nodes provided
- false: not intended to be valid

The rend attribute in the TEI namespace can be used for recording how parts of the example was rendered.

Example

<egXML valid="feasible" source="#UND" xmlns="http://www.tei-c.org/ns/Examples"><text>
<!-- front matter for the whole group -->
</text>
<!-- first text -->
</text>
<!-- second text -->
</text>
<!-- This example is not valid TEI, but could be made so by adding missing components -->
</egXML>

Example

<egXML xmlns="http://www.tei-c.org/ns/Examples" valid="false">
<para xml:lang="en">Doubloons are a pirate's best friend</para>
</egXML>

Content model

<content>
<alternate minOccurs="0" maxOccurs="unbounded">
<textNode/>
</content>
<eLeaf>
(leaf or terminal node of an embedding tree) provides explicitly for a leaf of an embedding tree, which
may also be encoded with the <eTree> element. [19.3. Another Tree Notation]

Module  nets — Graphs, Networks, and Trees

Attributes  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rrendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype)

@value indicates the value of an embedding leaf, which is a feature structure or other analytic element.

Status  Optional

Datatype  teidata.pointer

Containedby  eTree|triangle

May contain  label|ptr|ref

Note  The <eTree> tag may be used if the encoder does not wish to distinguish by name between nonleaf and leaf nodes in embedding trees; they are distinguished by their arrangement.

Example

```xml
<eLeaf value="http://an.fsurl.tei/#FSWITH">
  <label>with</label>
</eLeaf>
```

Content model

```xml
<content>
  <sequence>
    <elementRef key="label" minOccurs="0"/>
    <classRef key="model.ptrLike"
      minOccurs="0"/>
  </sequence>
</content>
```
The TEI Guidelines

Schema Declaration

```xml
<elementRef>
    points to the specification for some element which is to be included in a schema 
    22.2. Modules and Schemas

Module tagdocs — Documentation Elements
Attributes
    @xml:id, @n, @xml:lang, @xml:base, @xml:space
    @rend, @style, @rendition
    @corresp, @synchrony, @sameAs, @copyOf, @next, @prev, @exclude, @select
    @analytic, @facs, @change, @responsibility
    @cert, @resp
    @minOccurs, @maxOccurs
@key the identifier used for the required element within the source indicated.
Status Required
Datatype teidata.xmlName
Member of model.contentPart|model.oddRef
Contained by tagdocs: alternate|content|schemaSpec|sequence|specGrp
May contain Empty element
Note Elements are identified by the name supplied as value for the ident attribute on the <elementSpec> element in which they are declared. TEI element names are unique.
Example

    <elementRef key="p"/>

Include in the schema an element named <p> available from the current default source.
Example

    <elementRef key="p" source="tei:1.2.1"/>

Include in the schema an element named <p> available from the TEI P5 1.2.1 release.

Content model
    <content> <empty/></content>
Schema Declaration

```
att.global.attributes,
att.global.rendition.attributes,
att.global.linking.attributes,
att.global.analytic.attributes,
att.global.facs.attributes,
att.global.change.attributes,
att.global.responsibility.attributes,
att.global.source.attributes,
att.repeatable.attributes,
attribute key { text },
empty

[elementSpec] (element specification) documents the structure, content, and purpose of a single element type. [22.5. Element Specifications 22. Documentation Elements]

Module tagdocs — Documentation Elements
Attributes att.global (xmlns:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.identified (@ident, @predeclare, @module) att.combinable (@mode) (att.deprecated (@validUntil)) att.namespaceable (@ns)
@example
@prefix specifies a default prefix which will be prepended to all patterns relating to the element, unless otherwise stated.
Status Optional
Datatype 0–1 occurrences of teidata.xmlName separated by whitespace
Note Colons, although permitted inside the value, will cause an invalid schema to be generated.

May contain

Note Unlike <gap>, which indicates content that the encoder cannot or chooses not to represent, <ellipsis> indicates a passage explicitly signalled in the source document as absent. The <ellipsis> element is not appropriate for every use of ellipsis points, such as when they indicate that a speaker is pausing.

Example

```xml
<lg>
  <l>What projects men make—what queer turns they take,</l>
  <l>Since <emph>steam</emph> has improved our condition;</l>
  <l>They never are still, but must cure or must kill</l>
  <l>With steam physic or steam ammunition.</l>
  <l>But a short time ago, to a quack you would go,</l>
  <l>Now changed from all that, if you wish to get <emph>fat</emph>, come to Barton's and eat a <emph>steam dinner</emph>!</l>
  <l>Oh dear! think of a scheme, odd though it seem—</l>
  <l>I'm sure 'twill succeed if you make it by steam.</l>
</lg>
```

```xml
<lg>
  You may sleep, you may dream, you may travel by steam,
  For the outcry is still to go faster;
  And what does it reck, should you 'e'en break your neck,
  If 'tis <emph>steam</emph> that brings on the disaster?
</lg>
```
The printer omits four lines here, skipping the second half of the second octave, before the refrain."

---

Example

```xml
<lg xml:id="chorus">
  <label>[Refrain]</label>
  <l>She says she loves you</l>
  <l>And you know that can't be bad</l>
  <l>Yes, she loves you</l>
  <l>And you know you should be glad</l>
</lg>

<lg>
  <l>She said you hurt her so</l>
  <l>She almost lost her mind</l>
  <l>But now she said she knows</l>
  <l>You're not the hurting kind</l>
</lg>

<ellipsis>******</ellipsis>
```

---

Content model

  ( model.encodingDescPart | model.pLike )+
}
```

---

**<entry>** *(entry)* contains a single structured entry in any kind of lexical resource, such as a dictionary or lexicon.

**Module** dictionaries — Dictionaries

*Attributes*  
att.global (xml:id, @n, @xml:lang, @xml:base, @xml:space)  
(att.global.rendition (rend, @style, @rendition))  
(att.global.linking (corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))  
(att.global.analytic (@ana))  
(att.global.facs (@facs))  
(att.global.change (@change))  
(att.global.responsibility (@cert, @resp))  
(att.global.source (@source))  
(att.entryLike (@type))  
(att.sortable (@sortKey))

**Member of** model.entryLike | model.entryPart.top

**Contained by**  
entry, hom, re, sense, superEntry

---

1143
Like all elements, <entry> inherits an xml:id attribute from the class global. No restrictions are placed on the method used to construct xml:ids; one convenient method is to use the orthographic form of the headword, appending a disambiguating number where necessary. Identification codes are sometimes included on machine-readable tapes of dictionaries for in-house use.

It is recommended to use the <sense> element even for an entry that has only one sense to group together all parts of the definition relating to the word sense since this leads to more consistent encoding across entries.

Example

```xml
<entry>
  <form>
    <orth>disproof</orth>
    <pron>dIs"pru:f</pron>
  </form>
  <gramGrp>
    <pos>n</pos>
  </gramGrp>
  <sense n="1">
    <def>facts that disprove something.</def>
  </sense>
  <sense n="2">
    <def>the act of disproving.</def>
  </sense>
</entry>
```

Content model

```xml
<alternate minOccurs="1" maxOccurs="unbounded">
  <elementRef key="hom"/>
  <elementRef key="sense"/>
  <elementRef key="pc"/>
  <classRef key="model.entryPart.top"/>
  <classRef key="model.global"/>
  <classRef key="model.ptrLike"/>
</alternate>
```
<entryFree>

(unstructured entry) contains a single unstructured entry in any kind of lexical resource, such as a dictionary or lexicon. [9.1. Dictionary Body and Overall Structure | 9.2. The Structure of Dictionary Entries]

Module  dictionaries — Dictionaries
Attributes  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.entryLike (@type) att.lexicographic (@expand, @split, @value, @location, @mergedIn, @opt) att.datcat (@datcat, @valueDatcat) att.lexicographic.normalized (@norm, @orig) att.sortable (@sortKey)

<equipment> (equipment) provides technical details of the equipment and media used for an audio or video recording used as the source for a spoken text. [8.2. Documenting the Source of Transcribed Speech 15.3.2 Declarable Elements]

Module spoken — Transcriptions of Speech

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.response (@cert, @resp)) (att.global.source (@source)) att.declarable (@default)

Member of model.recordingPart

Contained by

spoken: recording

May contain

core: p

linking: ab

Example

1150
"Hi-8" 8 mm NTSC camcorder with integral directional microphone and windshield and stereo digital sound recording channel.

Example

8-track analogue transfer mixed down to 19 cm/sec audio tape for cassette mastering

}
```

<equiv> (equivalent) specifies a component which is considered equivalent to the parent element, either by co-reference, or by external link. [3.4.1. Terms and Glosses: 22.4.1. Description of Components]

Module tagdocs — Documentation Elements

Attributes

- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyof, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) @internetMedia (@mimeType) @predicate (@predicate)
- @name a single word which follows the rules defining a legal XML name (see http://www.w3.org/TR/REC-xml/#dt-name), naming the underlying concept of which the parent is a representation.
- @uri (uniform resource identifier) references the underlying concept of which the parent is a representation by means of some external identifier.

Status Optional

Datatype teidata.name

1151
The TEI Guidelines

Datatype teidata.pointer

@filter references an external script which contains a method to transform instances of this
element to canonical TEI

Status Optional

Datatype teidata.pointer

Member of model.glossLike

Contained by

header: category|taxonomy|

linking: joinGrp

tagdocs: attDef classSpec classSpec classSpec classSpec classSpec classSpec model modelGrp modelSequence

moduleSpec paramspec|moduleSpec|moduleSpec|moduleSpec|moduleSpec|moduleSpec

May contain Empty element

Note The mimeType attribute should be used to supply the MIME media type of the filter script specified by the
filter attribute.

Example The following example declares that the <bo> element is conceptually equivalent to the markup
construct <hi rend='bold'>, and that an external definition of this concept is available from the URI indicated

```xml
<elementSpec ident="hi" mode="change">
  <equiv name="BOLD"/>
  <desc>bold typography</desc>
  <attList>
    <attDef ident="rend" mode="change">
      <valList>
        <valItem ident="bold"/>
      </valList>
    </attDef>
  </attList>
</elementSpec>

<elementSpec ident="bo" mode="add">
  <equiv name="BOLD" uri="http://www.example.com/typesetting/bold"/>
</elementSpec>
```

Content model <content> <empty/> </content>

Schema Declaration

```
<content> <empty/> </content>
```

element equiv

```java
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.internetMedia.attributes,
  att.predicate.attributes,
  attribute name { text }?,
  attribute uri { text }?,
  attribute filter { text }?,
  empty
}
```
<eTree> (embedding tree) provides an alternative to the <tree> element for representing ordered rooted tree structures. [19.3. Another Tree Notation]

Module nets — Graphs, Networks, and Trees

Attributes

- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
- att.global.analytic (@ana)
- att.global.facs (@facs)
- att.global.change (@change)
- att.global.responsibility (@cert, @resp)
- att.global.source (@source)
- att.typed (@type, @subtype)

@value provides the value of an embedding tree, which is a feature structure or other analytic element.

Status Optional

  attribute value { text }?,
  ( label?, ( eTree | triangle | eLeaf | model.ptrLike )* )
}
```

<etym> (etymology) encloses the etymological information in a dictionary entry. [9.3.4. Etymological Information]
May contain character data mixed with any other elements defined in the dictionary tag set.

There is no consensus on the internal structure of etymologies, or even on whether such a structure is appropriate. The `<etym>` element accordingly simply contains prose, within which names of languages, cited words, or parts of words, glosses, and examples will typically be prominent. The tagging of such internal objects is optional.

**Example**

```xml
<entry>
  <form>
    <orth>publish</orth> ... </form>
  <etym>
    <lang>ME.</lang>
    <mentioned> publishshen </mentioned>,
    <lang>F.</lang>
    <mentioned> publier </mentioned>, <lang>L. </lang>
    <mentioned> publicare, publicatum </mentioned>. <xr>See <ref>public</ref>; cf. 2d</xr>
  </etym>
</entry> (From: Webster's Second International)```
Example

```xml
<entry>
  <form>Handschuh</form> ... </form>
  <etym type="compounding">
    <orRef>Hand</orRef> (<pRef notation="ipa">ˈhant</pRef>): <gloss>hand</gloss>,
    <etym type="metaphor">
      <orRef>Schuh</orRef> (<pRef notation="ipa">ʃuː</pRef>): <gloss>shoe</gloss>
  </etym>
</entry>
```

Content model

```xml
<content>
  <alternate minOccurs="0" maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.gLike"/>
    <classRef key="model.global"/>

The TEI Guidelines

The content of this element should be the expanded abbreviation, usually (but not always) a complete word or phrase. The `<ex>` element provided by the `transcr` module may be used to mark up sequences of letters supplied within such an expansion.

If abbreviations are expanded silently, this practice should be documented in the `<editorialDecl>`, either with a `<normalization>` element or a `<p>.

Example

```
The address is Southmoor
  <choice>
    <expan>Road</expan>
    <abbr>Rd</abbr>
  </choice>
```

Example

```
<choice xml:lang="la">
  <abbr>Imp</abbr>
  <expan>Imp<ex>erator</ex>
</expan>
</choice>
```

Content model

```
<content>
  <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```

\texttt{1165}
<f> (feature) represents a feature value specification, that is, the association of a name with a value of any of several different types. [18.2. Elementary Feature Structures and the Binary Feature Value]

Module iso-fs — Feature Structures

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) att.global.rendition (@rend, @style, @rendition) att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) att.global.analytic (@ana) att.global.facs (@facs) att.global.change (@change) att.global.responsibility (@cert, @resp) att.global.source (@source) att.datcat (@datcat, @valueDatcat)

@name a single word which follows the rules defining a legal XML name (see http://www.w3.org/TR/REC-xml/#dt-name), providing a name for the feature.

Status Required

Datatype teidata.name

@fVal (feature value) references any element which can be used to represent the value of a feature.

Status Optional

Datatype teidata.pointer

Note If this attribute is supplied as well as content, the value referenced is to be unified with that contained.

Contained by iso-fs: bicond cond fLib fs if

May contain iso-fs: binary default fs numeric string symbol vAlt vColl vLabel vMerge vNot character data

Note The content of <f> may be textual, with the assumption that the data type of the feature value is determined by the schema—this is the approach used in many language-technology-oriented projects and recommendations.

Example

```xml
<f name="gender">
    <symbol value="feminine"/>
</f>
```

Example

```xml
<fs>
    <f name="voice">active</f>
    <f name="tense">SimPre</f>
</fs>
```

Content model

```xml
<content>
    <alternate minOccurs="1" maxOccurs="1">
        <textNode/>
        <classRef key="model.featureVal"/>
    </alternate>
</content>
```

Schema Declaration

```xml

**<factuality>** (factuality) describes the extent to which the text may be regarded as imaginative or non-imaginative, that is, as describing a fictional or a non-fictional world. [15.2.1. The Text Description]

**Module** corpus — Language Corpora

**Attributes**
- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (—, @subtype)

**@type** categorizes the factuality of the text.

- **Derived from** att.typed
- **Status** Optional
- **Datatype** teidata.enumerated
- **Legal values are:**
  - **fiction** the text is to be regarded as entirely imaginative
  - **fact** the text is to be regarded as entirely informative or factual
  - **mixed** the text contains a mixture of fact and fiction
  - **inapplicable** the fiction/fact distinction is not regarded as helpful or appropriate to this text

**Member of** model.textDescPart

1168
<factuality>

Note: Usually empty, unless some further clarification of the type attribute is needed, in which case it may contain running prose.

For many literary texts, a simple binary opposition between 'fiction' and 'fact' is naïve in the extreme; this parameter is not intended for purposes of subtle literary analysis, but as a simple means of characterizing the claimed fictiveness of a given text. No claim is made that works characterized as 'fact' are in any sense 'true'.

Example

<factuality type="fiction"/>

Example

<factuality type="mixed">contains a mixture of gossip and speculation about real people and events</factuality>

Content model

<content>
  <macroRef key="macro.phraseSeq.limited"/>
</content>

Schema Declaration

element factuality

}
```

(feature declaration) declares a single feature, specifying its name, organization, range of allowed values, and optionally its default value. [[18.11. Feature System Declaration]]

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@name  a single word which follows the rules defining a legal XML name (see http://www.w3.org/TR/REC-xml/#dt-name), indicating the name of the feature being declared; matches the name attribute of <f> elements in the text.
  Status Required
  Datatype teidata.name

@optional  indicates whether or not the value of this feature may be present.
  Status Optional
  Datatype teidata.truthValue
  Default true
Note: If a feature is marked as optional, it is possible for it to be omitted from a feature structure. If an obligatory feature is omitted, then it is understood to have a default value, either explicitly declared, or, if no default is supplied, the special value any. If an optional feature is omitted, then it is understood to be missing and any possible value (including the default) is ignored.

Example

```xml
<fDecl name="INV">
  <fDescr>inverted sentence</fDescr>
  <vRange>
    <vAlt>
      <binary value="true"/>
      <binary value="false"/>
    </vAlt>
  </vRange>
  <vDefault>
    <binary value="false"/>
  </vDefault>
</fDecl>
```

Content model

```
<content>
  <sequence>
    <elementRef key="fDescr" minOccurs="0"/>
    <elementRef key="vRange"/>
    <elementRef key="vDefault" minOccurs="0"/>
  </sequence>
</content>
```

Schema Declaration

```xml
element fDecl
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,

```
<fileDesc>

(file description) contains a full bibliographic description of an electronic file. [2.2. The File Description 2.1.1. The TEI Header and Its Components]

Module header – The TEI Header

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by header: biblFull teiHeader

May contain header: editionStmt extentNotesStmt publicationStmt seriesStmt sourceStmt titleStmt

Note The major source of information for those seeking to create a catalogue entry or bibliographic citation for an electronic file. As such, it provides a title and statements of responsibility together with details of the publication or distribution of the file, of any series to which it belongs, and detailed bibliographic notes

1177
for matters not addressed elsewhere in the header. It also contains a full bibliographic description for the
source or sources from which the electronic text was derived.

Example

```
<fileDesc>
  <titleStmt>
    <title>The shortest possible TEI document</title>
  </titleStmt>
  <publicationStmt>
    <p>Distributed as part of TEI P5</p>
  </publicationStmt>
  <sourceDesc>
    <p>No print source exists: this is an original digital text</p>
  </sourceDesc>
</fileDesc>
```

Content model

```
<content>
  <sequence>
    <elementRef key="titleStmt"/>
    <elementRef key="editionStmt" minOccurs="0"/>
    <elementRef key="extent" minOccurs="0"/>

Example
In this example, the reference to 'Dujchev N17' includes a link to some other manuscript description which has the identifier DN17.

Example

The "Guan-ben" was widely current among mathematicians in the Qing dynasty, and "Zhao Qimei version" was also read. It is therefore difficult to know the correct filiation path to follow. The study of this era is much indebted to Li Di. We explain the outline of his conclusion here. Kong Guangsen (1752-1786) was from the same town as Dai Zhen, so he obtained "Guan-ben" from him and studied it (18). Li Huang (d. 1811) took part in editing Si Ku Quan Shu, so he must have had "Guan-ben". Then Zhang Dunren (1754-1834) obtained this version, and studied "Da Yan Zong Shu Shu" (The General Dayan Computation). He wrote Jiu Yi Suan Shu (Mathematics Searching for One, 1803) based on this version of Shu Xue Jiu Zhang (20).

One of the most important persons in restoring our knowledge concerning the filiation of these books was Li Rui (1768-1817) (see his biography). .... only two volumes remain of this manuscript, as far as chapter 6 (chapter 3 part 2) p.13, that is, question 2 of "Huan Tian San Ji" (square of three loops), which later has been lost.

The global `xml:lang` attribute should be supplied for this element to identify the language of the word or phrase marked. As elsewhere, its value should be a language tag as defined in vi.1 Language Identification.

This element is intended for use only where no other element is available to mark the phrase or words concerned. The global `xml:lang` attribute should be used in preference to this element where it is intended to mark the language of the whole of some text element.

The `<distinct>` element may be used to identify phrases belonging to sublanguages or registers not generally regarded as true languages.

Example

This is heathen Greek to you still? Your `<foreign xml:lang="la">lapis philosophicus</foreign>`?

(form information group) groups all the information on the written and spoken forms of one headword.

**9.3.1. Information on Written and Spoken Forms**

**Module** dictionaries — Dictionaries

**Attributes**
- \texttt{att.global} (\texttt{xmlns}, \texttt{@n}, \texttt{xml:lang}, \texttt{xml:base}, \texttt{xml:space}) \texttt{(att.global.rendition \texttt{(rend, @style, @rendition)}) att.global.linking \texttt{(@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select}) att.global.analytic \texttt{(@ana)}) att.global.facs \texttt{(@facs)}) att.global.change \texttt{(change}) att.global.responsibility \texttt{(cert, @resp}) att.global.source \texttt{(source)}) \texttt{att.lexicographic} \texttt{(expand, @split, @value, @location, @mergedIn, @opt}) \texttt{att.typed} \texttt{(type, @subtype)}

**@type** classifies form as simple, compound, etc.

**Derived from** \texttt{att.typed}

**Status** Optional

**Datatype** teidata.enumerated

**Suggested values include:** simple single free lexical item

- lemma the headword itself
- variant a variant form
- compound word formed from simple lexical items
- derivative word derived from headword
- inflected word in other than usual dictionary form
- phrase multiple-word lexical item

**Member of** model.entryPart | model.entryPart.top | model.formPart

**Contained by**

}

<front> (front matter) contains any prefatory matter (headers, abstracts, title page, prefaces, dedications, etc.) found at the start of a document, before the main body. [4.6. Title Pages | 4. Default Text Structure]

Module textstructure — Default Text Structure

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition) (@rend, @style, @rendition) (att.global.linking) (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)
Because cultural conventions differ as to which elements are grouped as front matter and which as back matter, the content models for the `<front>` and `<back>` elements are identical.

Example

```xml
<front>
  <epigraph>
    <quote>Nam Sibyllam quidem Cumis ego ipse oculis meis vidi in ampulla pendere, et cum illi pueri dicerent: <q xml:lang="grc">Σίβυλλα τί θέλεις</q>; respondebat illa: <q xml:lang="grc">ἀποθανεῖν θέλω.</q>
  </quote>
</epigraph>
  <div type="dedication">
    <p>For Ezra Pound <q xml:lang="it">il miglior fabbro.</q></p>
  </div>
</front>
```

Example

```xml
<front>
  <div type="dedication">
    <p>To our three selves</p>
  </div>
</front>
```

Example

```xml
<front>
  <div type="dedication">
    <p>All the characters in this book are purely imaginary, and if the author has used names that may suggest a reference to living persons she has done so inadvertently. ...</p>
  </div>
</front>
```
Food insecurity can put children at greater risk of obesity because of altered food choices and nonuniform consumption patterns.

We examined the association between obesity and both child-level food insecurity and personal food insecurity in US children.

Data from 9,701 participants in the National Health and Nutrition Examination Survey, 2001-2010, aged 2 to 11 years were analyzed. Child-level food insecurity was assessed with the US Department of Agriculture's Food Security Survey Module based on eight child-specific questions. Personal food insecurity was assessed with five additional questions. Obesity was defined, using physical measurements, as body mass index (calculated as kg/m^2) greater than or equal to the age- and sex-specific 95th percentile of the Centers for Disease Control and Prevention growth charts. Logistic regressions adjusted for sex, race/ethnic group, poverty level, and survey year were conducted to describe associations between obesity and food insecurity.

Obesity was significantly associated with personal food insecurity for children aged 6 to 11 years (odds ratio=1.81; 95% CI 1.33 to 2.48), but not in children aged 2 to 5 years (odds ratio=0.88; 95% CI 0.51 to 1.51). Child-level food insecurity was not associated with obesity among 2- to 5-year-olds or 6- to 11-year-olds.

Personal food insecurity is associated with an increased risk of obesity only in children aged 6 to 11 years. Personal food-insecurity measures may give different results than aggregate food-insecurity measures in children.

<fs> (feature structure) represents a feature structure, that is, a collection of feature-value pairs organized as a structural unit. [18.2. Elementary Feature Structures and the Binary Feature Value]

Module iso-fs — Feature Structures

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global rendition (@rend, @style, @rendition)) (att.global linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global analytic (@ana)) (att.global facs (@facs)) (att.global change (@change)) (att.global responsibility (@cert, @resp)) (att.global source (@source)) att.datcat (@datcat, @valueDatcat)

@type specifies the type of the feature structure.

Status Optional

Datatype teidata.enumerated

@feats (features) references the feature-value specifications making up this feature structure.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Note May be used either instead of having features as content, or in addition. In the latter case, the features referenced and contained are unified.

The TEI Guidelines

**Contained by**
iso-fs: fsDecl

**May contain**
iso-fs: bicond cond

**Note**  May contain a series of conditional or biconditional elements.

**Example**

```xml
<fsConstraints>
  <cond>
    <fs>
      <!-- ... -->
    </fs>
    <then/>
    <fs>
      <!-- ... -->
    </fs>
  </cond>
</fsConstraints>
```

**Content model**

```xml
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <elementRef key="cond"/>
    <elementRef key="bicond"/>
  </alternate>
</content>
```

**Schema Declaration**

```xml
element fsConstraints
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  ( cond | bicond )*  
}
```

**<fsdDecl>**  (feature system declaration) provides a feature system declaration comprising one or more feature structure declarations or feature structure declaration links. [18.11. Feature System Declaration]

**Module**  iso-fs — Feature Structures

**Attributes**  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

**Member of**  model.encodingDescPart | model.resource

1204
<fsDecl>

**Example**

```xml
<fsDecl type="GPSG">
  <fDecl xml:id="GPSG-1" name="GPSG_feat1">
    <vRange>
      <symbol value="red"/>
      <symbol value="blue"/>
      <symbol value="green"/>
    </vRange>
  </fDecl>
  <!--other feature declarations for GPSG here ... -->
</fsDecl>
```

**Content model**

```xml
<content>
  <classRef key="model.fsdDeclPart" minOccurs="1" maxOccurs="unbounded"/>
</content>
```

**Schema Declaration**

```xml
element fsdDecl {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  model.fsdDeclPart+
}
```

<fsDecl> (feature structure declaration) declares one type of feature structure. [[18.11. Feature System Declaration]]

**Module** iso-fs — Feature Structures

**Attributes**

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))
@type gives a name for the type of feature structure being declared.

*Status* Required

*Datatype* teidata.enumerated

@baseTypes gives the name of one or more typed feature structures from which this type inherits feature specifications and constraints; if this type includes a feature specification with the same name as that of any of those specified by this attribute, or if more than one specification of the same name is inherited, then the set of possible values is defined by unification. Similarly, the set of constraints applicable is derived by combining those specified explicitly within this element with those implied by the baseTypes attribute. When no baseTypes attribute is specified, no feature specification or constraint is inherited.

*Status* Optional

*Datatype* 1–∞ occurrences of teidata.name separated by whitespace

*Note* Inheritance is defined here as a monotonous relation.

The process of combining constraints may result in a contradiction, for example if two specifications for the same feature specify disjoint ranges of values, and at least one such specification is mandatory. In such a case, there is no valid representative for the type being defined.

**Member of** model.fsdDeclPart

**Contained by**

iso-fs: fsdDecl

**May contain**

iso-fs: fDecl fsConstraints fsDescr

**Example**

```xml
<fsDecl type="SomeName">
  <fsDescr>Describes what this type of fs represents</fsDescr>
  <fDecl name="featureOne">
    <!-- The declaration for featureOne -->
    <vRange>
      <!-- the range of possible values for this feature -->
    </vRange>
  </fDecl>
  <fDecl name="featureTwo">
    <!-- The declaration for featureTwo -->
    <vRange>
      <!-- the range of possible values for this feature -->
    </vRange>
  </fDecl>
  <fsConstraints>
    <!-- Any additional constraints for the feature structure -->
  </fsConstraints>
</fsDecl>
```

**Content model**

```xml
<content>
  <sequence>
    <elementRef key="fsDescr" minOccurs="0"/>
    <elementRef key="fDecl" minOccurs="1" maxOccurs="unbounded"/>
    <elementRef key="fsConstraints" minOccurs="0"/>
  </sequence>
</content>
```
**Schema Declaration**

```xml
<fsDecl
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute type { text },
  attribute baseTypes { list { + } },
  ( fsDecl?, fDecl+, fsConstraints? )
}
```

**<fsDescr>** (feature system description (in FSD)) describes in prose what is represented by the type of feature structure declared in the enclosing fsDecl. [18.11. Feature System Declaration]

**Module** iso-fs — Feature Structures

**Attributes**

- `att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)`

  att.global.responsibility.attributes,
  att.global.source.attributes,
  macro.limitedContent}
```

<fsdLink> (feature structure declaration link) associates the name of a typed feature structure with a feature structure declaration for it. [18.11. Feature System Declaration]
@type identifies the type of feature structure to be documented; this will be the value of the type attribute on at least one feature structure.

Status Required
Datatype @idata.enumerated

@target supplies a pointer to a feature structure declaration (<fsDecl>) element within the current document or elsewhere.

Status Required
Datatype @idata.pointer

Member of model.fsdDeclPart
Contained by iso-fs: fsdDecl

May contain Empty element

Example

```xml
<fsdLink type="subentry" target="http://www.example.com/fsdLib.xml#L1234"/>
```

Content model `<content> <empty/></content>`

Schema Declaration

```xml
element fsdLink
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute type { text },
  attribute target { text },
  empty
}
```

<funder> (funding body) specifies the name of an individual, institution, or organization responsible for the funding of a project or text. [2.2.1. The Title Statement]

Module header — The TEI Header

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.canonical (@key, @ref) att.datable (@calendar, @period) (att.datable.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.datable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.datable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @to-custom, @datingPoint, @datingMethod))

1211
A feature value library may include any number of values of any kind, including multiple occurrences of identical values such as `<binary value="true"/>` or `default`. The only thing guaranteed unique in a feature value library is the set of labels used to identify the values.

Example

```xml
<fvLib n="symbolic values">
  <symbol xml:id="sfirst" value="first"/>
  <symbol xml:id="ssecond" value="second"/>
  <!-- ... -->
  <symbol xml:id="ssing" value="singular"/>
  <symbol xml:id="splur" value="plural"/>
  <!-- ... -->
</fvLib>
```

Content model

```xml
<content>
  <classRef key="model.featureVal"
    minOccurs="0" maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```xml
element fvLib
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  model.featureVal*
}
```

<fw> (forme work) contains a running head (e.g. a header, footer), catchword, or similar material appearing on the current page. [11.6. Headers, Footers, and Similar Matter]

Module transcr — Representation of Primary Sources

Attributes `att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.placement (@place) att.written (@hand) att.typed (@type, @subtype)

`@type` classifies the material encoded according to some useful typology.

Derived from `att.typed`

Status Recommended

Datatype `teidata.enumerated`

Sample values include: header a running title at the top of the page footer a running title at the bottom of the page pageNum (page number) a page number or foliation symbol lineNum (line number) a line number, either of prose or poetry
sig (signature) a signature or gathering symbol

catch (catchword) a catch-word

Note Where running heads are consistent throughout a chapter or section, it is usually more convenient to relate them to the chapter or section, e.g. by use of the \textit{rend} attribute. The \texttt{<fw>} element is intended for cases where the running head changes from page to page, or where details of page layout and the internal structure of the running heads are of paramount importance.

Example

\begin{verbatim}
<fw type="sig" place="bottom">C3</fw>
\end{verbatim}

Content model

\begin{verbatim}
<content>
<macroRef key="macro.phraseSeq"/>
</content>
\end{verbatim}

\textbf{Schema Declaration}

May contain Character data only

Note The name g is short for gaiji, which is the Japanese term for a non-standardized character or glyph.

Example

```xml
@g ref="#ctlig">ct</g>
```

This example points to a `<glyph>` element with the identifier ctlig like the following:

```xml
<glyph xml:id="ctlig">
<!-- here we describe the particular ct-ligature intended -->
</glyph>
```

Example

```xml
@g ref="#per-glyph">per</g>
```

The medieval brevigraph per could similarly be considered as an individual glyph, defined in a `<glyph>` element with the identifier per-glyph as follows:
<glyph xml:id="per-glyph">
</glyph>

Content model: `<content> <textNode/></content>`

Schema Declaration:

```xml
element g {
    att.global.attributes,
    att.global.rendition.attributes,
    att.global.linking.attributes,
    att.global.analytic.attributes,
    att.global.facs.attributes,
    att.global.change.attributes,
    att.global.responsibility.attributes,
    att.global.source.attributes,
    att.typed.attributes,
    attribute ref { text }?,
    text
}
```

<gap> (gap) indicates a point where material has been omitted in a transcription, whether for editorial reasons described in the TEI header, as part of sampling practice, or because the material is illegible, invisible, or inaudible. [3.5.3. Additions, Deletions, and Omissions]

Module: core — Elements Available in All TEI Documents

Attributes: att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) att.global.rendition (@rend, @style, @rendition) att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) att.global.analytic (@ana) att.global.facs (@facs) att.global.change (@change) att.global.responsibility (@cert, @resp) att.global.source (@source) att.timed (@start, @end) att.duration (att.duration.w3c (@dur) att.duration.iso (@dur-iso)) att.editLike (@evidence, @instant) att.dimensions (@unit, @quantity, @extent, @precision, @scope) att.ranging (@atLeast, @atMost, @min, @max, @confidence) att.reason (reason) gives the reason for omission

Status: Optional

Datatype: 1–∞ occurrences of teidata.enumerated separated by whitespace

Suggested values include: cancelled (cancelled)

deleted (deleted)

editorial (editorial) for features omitted from transcription due to editorial policy

illegible (illegible)

inaudible (inaudible)

irrelevant (irrelevant)

sampling (sampling)

@agent (agent) in the case of text omitted because of damage, categorizes the cause of the damage, if it can be identified.

Status: Optional

Datatype: teidata.enumerated

Sample values include: rubbing (rubbing) damage results from rubbing of the leaf edges

mildew (mildew) damage results from mildew on the leaf surface

smoke (smoke) damage results from smoke
May contain:

core:

Note: The `<gap>`, `<unclear>`, and `<del>` core tag elements may be closely allied in use with the `<damage>` and `<supplied>` elements, available when using the additional tagset for transcription of primary sources. See section 11.3.3.2. *Use of the gap, del, damage, unclear, and supplied Elements in Combination* for discussion of which element is appropriate for which circumstance.

The `<gap>` tag simply signals the editors decision to omit or inability to transcribe a span of text. Other information, such as the interpretation that text was deliberately erased or covered, should be indicated using the relevant tags, such as `<del>` in the case of deliberate deletion.

Example

```xml
<gap quantity="4" unit="chars" reason="illegible"/>
```
<gap quantity="1" unit="essay"
    reason="sampling"/>

Example

<del>
    <gap atLeast="4" atMost="8" unit="chars"
        reason="illegible"/>
</del>

Example

<gap extent="several lines" reason="lost"/>

Content model

Member of model.measureLike

May contain Character data only

Note Uses of <geo> can be associated with a coordinate system, defined by a <geoDecl> element supplied in the TEI header, using the decls attribute. If no such link is made, the assumption is that the content of
<geoDecl>

Each <geo> element will be a pair of numbers separated by whitespace, to be interpreted as latitude followed by longitude according to the World Geodetic System.

Example

```xml
<geoDecl xml:id="WGS" datum="WGS84">World Geodetic System</geoDecl>
<geoDecl xml:id="OS" datum="OSGB36">Ordnance Survey</geoDecl>
</geoDecl>

<location>
<desc>A tombstone plus six lines of Anglo-Saxon text, built into the west tower (on the south side of the archway, at 8 ft. above the ground) of the Church of St. Mary-le-Wigford in Lincoln.</desc>
<geo decls="#WGS">53.226658 -0.541254</geo>
<geo decls="#OS">SK 97481 70947</geo>
</location>
```

Example

```xml
<geo>41.687142 -74.870109</geo>
```

Content model  

```xml
<content> <textNode/></content>
```

Schema Declaration

```xml
element geo {
    att.global.attributes,
    att.global.rendition.attributes,
    att.global.linking.attributes,
    att.global.analytic.attributes,
    att.global.facs.attributes,
    att.global.change.attributes,
    att.global.responsibility.attributes,
    att.global.source.attributes,
    att.declaring.attributes,
    text
}
```

<geoDecl> (geographic coordinates declaration) documents the notation and the datum used for geographic coordinates expressed as content of the <geo> element elsewhere within the document. [2.3.8. The Geographic Coordinates Declaration]

Module header - The TEI Header

Attributes  
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.declarable (@default)

@datum supplies a commonly used code name for the datum employed.

Status Optional

Datatype teidata.enumerated

Suggested values include:  
WGS84 (World Geodetic System) a pair of numbers to be interpreted as latitude followed by longitude according to the World Geodetic System.[Default]

MGRS (Military Grid Reference System) the values supplied are geospatial entity object codes, based on
OSGB36 (Ordnance Survey Great Britain) the value supplied is to be interpreted as a British National Grid Reference.

ED50 (European Datum coordinate system) the value supplied is to be interpreted as latitude followed by longitude according to the European Datum coordinate system.

**Example**

```
<geoDecl datum="OSGB36"/>
```

**Content model**

```
<content>
  <macroRef key="macro.phraseSeq"/>
</content>
```

**Schema Declaration**

```
element geoDecl
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
}
```
<geogFeat> (geographical feature name) contains a common noun identifying some geographical feature contained within a geographic name, such as valley, mount, etc. [13.2.3. Place Names]

Module: namesdates — Names, Dates, People, and Places

Attributes:
- att.global.analytic.attributes
- att.global.facs.attributes
- att.global.change.attributes
- att.global.responsibility.attributes
- att.global.source.attributes
- att.declarable.attributes

attribute datum { "WGS84" | "MGRS" | "OSGB36" | "ED50" }?

Macro: phraseSeq

```

<glyph> (character glyph) provides descriptive information about a character glyph. [5.2. Markup Constructs for Representation of Characters and Glyphs]

Module gaiji — Characters, Glyphs, and Writing Modes

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by gaiji: charDecl

May contain core: binaryObject desc graphic media note noteGrp

figures: figure formula
<glyphName>

**gaiji:** charProp glyphName localProp mapping unicodeProp unihanProp

**Example**

```xml
<glyph xml:id="rstroke">
  <localProp name="Name" value="LATIN SMALL LETTER R WITH A FUNNY STROKE"/>
  <localProp name="entity" value="rstroke"/>
  <figure>
    <graphic url="glyph-rstroke.png"/>
  </figure>
</glyph>
```

**Content model**

```xml
<content>
  <alternate minOccurs="0" maxOccurs="unbounded">
    <elementRef key="glyphName"/>
    <elementRef key="charProp"/>
    <elementRef key="unicodeProp"/>
    <elementRef key="unihanProp"/>
    <elementRef key="localProp"/>
    <elementRef key="mapping"/>
    <elementRef key="figure"/>
    <classRef key="model.graphicLike"/>
    <classRef key="model.noteLike"/>
    <classRef key="model.descLike"/>
  </alternate>
</content>
```

**Schema Declaration**

```xml
element glyph {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  {
    glyphName | charProp | unicodeProp | unihanProp | localProp | mapping
  }
}
```

**<glyphName>** (character glyph name) contains the name of a glyph, expressed following Unicode conventions for character names. [5.2. Markup Constructs for Representation of Characters and Glyphs]

**Deprecated** will be removed on 2022-02-15

**Module** gaiji — Characters, Glyphs, and Writing Modes

**Attributes** att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))
Note: For characters of non-ideographic scripts, a name following the conventions for Unicode names should be chosen. For ideographic scripts, an Ideographic Description Sequence (IDS) as described in Chapter 10.1 of the Unicode Standard is recommended where possible. Projects working in similar fields are recommended to coordinate and publish their list of `<glyphName>`s to facilitate data exchange.

Example

```xml
<glyphName>CIRCLED IDEOGRAPH 4EBA</glyphName>
```

Content model `<content> <textNode/></content>`

Schema Declaration

```
element glyphName
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  text
}
```

<gram> (grammatical information) within an entry in a dictionary or a terminological data file, contains grammatical information relating to a term, word, or form. [9.3.2. Grammatical Information]

Module dictionaries — Dictionaries

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) (att.lexicographic (@expand, @split, @value, @location, @mergedIn, @opt)) (att.dataCat (@DatCat, @valueDatCat)) (att.lexicographic.normalized (@norm, @orig)) att.typed (type, @subtype)

@type classifies the grammatical information given according to some convenient typology—in the case of terminological information, preferably the dictionary of data element types specified in ISO 12620.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Sample values include: pos (part of speech) any of the word classes to which a word may be assigned in a given language, based on form, meaning, or a combination of features, e.g. noun, verb, adjective, etc.

gen (gender) formal classification by which nouns and pronouns, and often accompanying modifiers, are grouped and inflected, or changed in form, so as to control certain syntactic relationships

num (number) grammatical number, e.g. singular, plural, dual, ...

animate animate or inanimate
**proper**  proper noun or common noun

*Note* A much fuller list of values for the *type* attribute may be generated from the data category registry accessible from [http://www.isoCat.org/](http://www.isoCat.org/) and maintained by ISO technical committee 37.

<graph> (graph) encodes a graph, which is a collection of nodes, and arcs which connect the nodes. ![19.1. Graphs and Digraphs]

Module nets — Graphs, Networks, and Trees

Attributes
- `att.global` (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (-----, @subtype)

@type describes the type of graph.
- Derived from att.typed
- Status Recommended
- Datatype teidata.enumerated
- Suggested values include: undirected undirected graph
  - directed directed graph
  - transitionNetwork a directed graph with distinguished initial and final nodes
  - transducer a transition network with up to two labels on each arc

Note If `type` is specified as undirected, then the distinction between the `to` and `from` attributes of the `<arc>` tag is neutralized. Also, the `adj` attribute, rather than the `adjFrom` and `adjTo` attributes, should be used to encode pointers to the ends of the arcs. If `type` is specified as directed (or any other value which implies directionality), then the `adjFrom` and `adjTo` attributes should be used, instead of the `adj` attribute.

@order states the order of the graph, i.e., the number of its nodes.
- Status Optional
- Datatype teidata.count

@size states the size of the graph, i.e., the number of its arcs.
- Status Optional
- Datatype teidata.count

Note The mimeType attribute should be used to supply the MIME media type of the image specified by the url attribute.

Within the body of a text, a <graphic> element indicates the presence of a graphic component in the source itself. Within the context of a <facsimile> or <sourceDoc> element, however, a <graphic> element provides an additional digital representation of some part of the source being encoded.

Example

<figure>
<graphic url="fig1.png"/>
<head>Figure One: The View from the Bridge</head>
<figDesc>A Whisteresque view showing four or five sailing boats in the foreground, and a
series of buoys strung out between them.</figure>

Example

<facsimile>
  <surfaceGrp n="leaf1">
    <surface>
      <graphic url="page1.png"/>
    </surface>
    <surface>
      <graphic url="page2-highRes.png"/>
      <graphic url="page2-lowRes.png"/>
    </surface>
  </surfaceGrp>
</facsimile>

<handDesc> (description of hands) contains a description of all the different hands used in a manuscript or other object. [10.7.2. Writing, Decoration, and Other Notations]

**Module** msdescription — Manuscript Description

**Attributes**

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@hands (hands) specifies the number of distinct hands identified within the manuscript

**Status** Optional

**Datatype** teidata.count

**Member of** model.physDescPart

**Contained by**

msdescription: physDesc

**May contain**

core: P

header: handNote

linking: ab

msdescription: summary

**Example**

```
<handDesc>
  <handNote scope="major">Written throughout in <term>angelicana formata</term>.</handNote>
</handDesc>
```

Example

1246
The manuscript is written in two contemporary hands, otherwise unknown, but clearly those of practised scribes. Hand I writes ff. 1r-22v and hand II ff. 23 and 24. Some scholars, notably Verner Dahlerup and Hreinn Benediktsson, have argued for a third hand on ff. 24, but the evidence for this is insubstantial.
Example

```xml
<handNote scope="sole">
  <p>Written in insular phase II half-uncial with interlinear Old English gloss in an Anglo-Saxon pointed minuscule.</p>
</handNote>
```

Content model

```xml
<content>

May contain Empty element

Note The <handShift> element may be used either to denote a shift in the document hand (as from one scribe to another, on one writing style to another). Or, it may indicate a shift within a document hand, as a change of writing style, character or ink. Like other milestone elements, it should appear at the point of transition from some other state to the state which it describes.

Example
When wolde the cat dwelle in his ynne

And if the cattes skynne be slyk and gaye.

class data

Note The <head> element is used for headings at all levels; software which treats (e.g.) chapter headings, section headings, and list titles differently must determine the proper processing of a <head> element based on its structural position. A <head> occurring as the first element of a list is the title of that list; one occurring as the first element of a <div1> is the title of that chapter or section.

Example The most common use for the <head> element is to mark the headings of sections. In older writings, the headings or incipits may be rather longer than usual in modern works. If a section has an explicit ending as well as a heading, it should be marked as a <trailer>, as in this example:

```xml
<div1 n="I" type="book">
  <head>In the name of Christ here begins the first book of the ecclesiastical history of Georgius Florentinus, known as Gregory, Bishop of Tours.</head>
</div1>

<div2 type="section">
  <head>In the name of Christ here begins Book I of the history.</head>
  <p>Proposing as I do . . .  </p>
  <p>From the Passion of our Lord until the death of Saint Martin four hundred and twelve years passed.</p>
  <trailer>Here ends the first Book, which covers five thousand, five hundred and ninety-six years from the beginning of the world down to the death of Saint Martin.</trailer>
</div2>
```

Example When headings are not inline with the running text (see e.g. the heading "Secunda conclusio") they might however be encoded as if. The actual placement in the source document can be captured with the place attribute.
<head>
  <head place="margin">Secunda conclusio</head>
  <p>
    <lb n="1251"/>
    <hi rend="large">Potencia: habitus: et actus: recipiunt speciem ab
    objectis</supplied>::</supplied>
  </p>
  <lb n="1252">Probatur sic. Omne importans necessariam habitudinem ad
  proprium
  [...]
  </p>
</head>

Example The <head> element is also used to mark headings of other units, such as lists:

With a few exceptions, connectives are equally useful in all kinds of discourse: description, narration, exposition, argument.

<list rend="bulleted">
  <head>Connectives</head>
  <item>above</item>
  <item>accordingly</item>
  <item>across from</item>
  <item>adjacent to</item>
  <item>again</item>
</list>

  att.lexicographic.normalized.attributes,
  att.notated.attributes,
  macro.paraContent}

<hyphenation> (hyphenation) summarizes the way in which hyphenation in a source text has been treated in an encoded version of it. [2.3.3. The Editorial Practices Declaration | 15.3.2. Declarable Elements]

Module header — The TEI Header

Attributes  
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.declarable (@default)

@eol (end-of-line) indicates whether or not end-of-line hyphenation has been retained in a text.

  Status   Optional
  Datatype  teidata.enumerated

Legal values are:  
  all all end-of-line hyphenation has been retained, even though the lineation of the original may not have been.
  some end-of-line hyphenation has been retained in some cases. [Default]
  hard all soft end-of-line hyphenation has been removed: any remaining end-of-line hyphenation should be retained.
  none all end-of-line hyphenation has been removed: any remaining hyphenation occurred within the line.

Member of  | model.editorialDeclPart

( text | model.gLike | idno )*

<if> defines a conditional default value for a feature; the condition is specified as a feature structure, and is met if it subsumes the feature structure in the text for which a default value is sought. [18.11. Feature System Declaration]

Module iso-fs — Feature Structures
Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by
iso-fs: vDefault

May contain
iso-fs: binary|default|fs|numeric|string|symbol|then|vAlt|vColl|vLabel|vMerge|vNot

Note May contain a feature structure, followed by a feature value; the two are separated by a <then> element.

Example

```
<vDefault>
  <if>
    <fs>
      <symbol value="INF"/>
    </fs>
    <f name="SUBJ">
      <binary value="true"/>
    </f>
  </then/>
  <symbol value="for"/>
</if>
```

Content model

```
<content>
  <sequence>
    <alternate>
      <elementRef key="fs"/>
      <elementRef key="f"/>
    </alternate>
    <elementRef key="then"/>
    <classRef key="model.featureVal"/>
  </sequence>
</content>
```
```xml
<iff>
  (if and only if) separates the condition from the consequence in a `bicond` element. [18.11. Feature System Declaration]
</iff>

Module iso-fs — Feature Structures

Attributes
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by
iso-fs: bicond

May contain Empty element

Note This element is provided primarily to enhance the human readability of the feature-system declaration.

Example

```xml
<feature-system>
  <bicond>
    <fs>
      <f name="FOO">
        <symbol value="42"/>
      </f>
    </fs>
    <iff/>
    <fs>
      <f name="BAR">
        <binary value="true"/>
      </f>
    </fs>
  </bicond>
</feature-system>
```

Content model

```xml
<content> <empty/> </content>
```

Schema Declaration

```xml
element iff
{
  att.global.attributes,

</incipit>
```

<incipit> contains the incipit of a manuscript or similar object item, that is the opening words of the text proper, exclusive of any rubric which might precede it, of sufficient length to identify the work uniquely; such incipits were, in former times, frequently used a means of reference to a work, in place of a title. [10.6.1. The msItem and msItemStruct Elements]

<iNode> (intermediate (or internal) node) represents an intermediate (or internal) node of a tree. [19.2. Trees]

Module nets — Graphs, Networks, and Trees

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style,
    @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility
    (@cert, @resp)) (att.global.source (@source))

@value indicates an intermediate node, which is a feature structure or other analytic element.
    Status Optional
    Datatype teidata.pointer

@children provides a list of identifiers of the elements which are the children of the intermediate
    node.
    Status Required
    Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

@parent provides the identifier of the element which is the parent of this node.
    Status Optional
    Datatype teidata.pointer

@ord (ordered) indicates whether or not the internal node is ordered.
    Status Optional
    Datatype teidata.xTruthValue
    Note The value true indicates that the children of the intermediate node are ordered,
    whereas false indicates the are unordered.
    Use if and only if @ord is specified as partial on the <tree> element and the
    intermediate node has more than one child.

@follow provides the identifier of an element which this node follows.
    Status Optional
    Datatype teidata.pointer
Note: If the tree is unordered or partially ordered, this attribute has the property of fixing the relative order of the intermediate node and the element which is the value of the attribute.

@outDegree gives the out degree of an intermediate node, the number of its children.

Status: Optional

Datatype: [eidata.count]

Note: The in degree of an intermediate node is always 1.

Contained by: [tree]

May contain:
- core: [label]

Example:

```xml
<iNode xml:id="pt1" children="#GD-UP1" parent="#GD-VB1" follow="#GD-PN1" outDegree="1">
  <label>PT</label>
</iNode>
```

Content model:

```xml
<content>
  <elementRef key="label" minOccurs="0"/>
</content>
```

Schema Declaration:

```xml

(interaction) describes the extent, cardinality and nature of any interaction among those producing and experiencing the text, for example in the form of response or interjection, commentary, etc. [15.2.1. The Text Description]

Module corpus — Language Corpora

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype)

@type specifies the degree of interaction between active and passive participants in the text.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Legal values are:

- none no interaction of any kind, e.g. a monologue
- partial some degree of interaction, e.g. a monologue with set responses
- complete complete interaction, e.g. a face to face conversation
- inapplicable this parameter is inappropriate or inapplicable in this case

@active specifies the number of active participants (or addressors) producing parts of the text.

Status Optional

Datatype teidata.enumerated

Suggested values include:

- singular a single addressor
- plural many addressors
- corporate a corporate addressor
- unknown number of addressors unknown or unspecifiable

@passive specifies the number of passive participants (or addressees) to whom a text is directed or in whose presence it is created or performed.

Status Optional

Datatype teidata.enumerated

Suggested values include:

- self text is addressed to the originator e.g. a diary
- single text is addressed to one other person e.g. a personal letter
- many text is addressed to a countable number of others e.g. a conversation in which all participants are identified
- group text is addressed to an undefined but fixed number of participants e.g. a lecture
- world text is addressed to an undefined and indeterminately large number e.g. a published book

```

<interp> (interpretation) summarizes a specific interpretative annotation which can be linked to a span of text. [17.3. Spans and Interpretations]
The TEI Guidelines

gaiji: 
character data

Note Generally, each <interp> element carries an xml:id attribute. This permits the encoder to explicitly associate the interpretation represented by the content of an <interp> with any textual element through its ana attribute.

Alternatively (or, in addition) an <interp> may carry an inst attribute that points to one or more textual elements to which the analysis represented by the content of the <interp> applies.

Example

```xml
<interp type="structuralunit"
       xml:id="ana_am">aftermath</interp>
```

Content model

```xml
<content>
  <alternate minOccurs="0"
             maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.gLike"/>
    <classRef key="model.descLike"/>
    <classRef key="model.certLike"/>
  </alternate>
</content>
```

Schema Declaration

```xml
<interp type="structuralunit"
        xml:id="ana_am">aftermath</interp>
```

Module analysis — Simple Analytic Mechanisms

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition | @rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.interpLike (@inst) att.typed (text | model.gLike | model.descLike | model.certLike )

<interpGrp> (interpretation group) collects together a set of related interpretations which share responsibility or type. [17.3. Spans and Interpretations]

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition | @rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.interpLike (@inst) att.typed (text | model.gLike | model.descLike | model.certLike )

@type indicates what kind of phenomenon is being noted in the passage.

Status Recommended

Datatype teidata.enumerated

1286
Sample values include: **image** identifies an image in the passage.

**character** identifies a character associated with the passage.

**theme** identifies a theme in the passage.

**allusion** identifies an allusion to another text.

Note  May contain simple prose or a sequence of chunks.
Whatever string of characters is used to label a list item in the copy text may be used as the value of the global n attribute, but it is not required that numbering be recorded explicitly. In ordered lists, the n attribute on the <item> element is by definition synonymous with the use of the <label> element to record the enumerator of the list item. In glossary lists, however, the term being defined should be given with the <label> element, not n.

Example

```xml
   <list rend="numbered">
      <head>Here begin the chapter headings of Book IV</head>
      <item n="4.1">The death of Queen Clotild.</item>
      <item n="4.2">How King Lothar wanted to appropriate one third of the Church revenues.</item>
      <item n="4.3">The wives and children of Lothar.</item>
      <item n="4.4">The Counts of the Bretons.</item>
      <item n="4.5">Saint Gall the Bishop.</item>
      <item n="4.6">The priest Cato.</item>
      ...</list>
```

Content model

```xml

  att.datcat.attributes,
  att.lexicographic.normalized.attributes,
  att.typed.attribute.subtype,
  attribute type { text }?,
  macro.paraContent}
```

<join> (join) identifies a possibly fragmented segment of text, by pointing at the possibly contiguous elements which compose it. [16.7. Aggregation]

Module linking — Linking, Segmentation, and Alignment

Attributes att.global (@xmlns, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.pointing (@targetLang, @target, @evaluate) att.typed (@type, @subtype)

@result specifies the name of an element which this aggregation may be understood to represent.
Status: Optional

Datatype: `teidata.name`

@scope indicates whether the targets to be joined include the entire element indicated (the entire subtree including its root), or just the children of the target (the branches of the subtree).

Status: Recommended

Datatype: `teidata.enumerated`

Legal values are:
- root the rooted subtrees indicated by the target attribute are joined, each subtree become a child of the virtual element created by the join[Default]
- branches the children of the subtrees indicated by the target attribute become the children of the virtual element (i.e. the roots of the subtrees are discarded)

Example The following example is discussed in section 16.7. Aggregation
<sp>
  <speaker>Hughie</speaker>
  <p>How does it go? <q>
    <l xml:id="frog_x1">da-da-da</l>
    <l xml:id="frog_l2">gets a new frog</l>
    <l>...</l>
  </q>
</p>
</sp>

<sp>
  <speaker>Louie</speaker>
  <p><q>
    <l xml:id="frog_l1">When the old pond</l>
    <l>...</l>
  </q>
</p>
</sp>

<sp>
  <speaker>Dewey</speaker>
  <p><q>
    ... <l xml:id="frog_l3">It's a new pond.</l>
  </q>
</p>
</sp>

The <join> element here identifies a linegroup (<lg>) comprising the three lines indicated by the target attribute. The value root for the scope attribute indicates that the resulting virtual element contains the three <l> elements linked to at #frog_l1 #frog_l2 #frog_l3, rather than their character data content.

Example In this example, the attribute scope is specified with the value of branches to indicate that the virtual list being constructed is to be made by taking the lists indicated by the target attribute of the <join> element, discarding the <list> tags which enclose them, and combining the items contained within the lists into a single virtual list:

<p>Southern dialect (my own variety, at least) has only <list xml:id="LP1">
  <item>
    <s>I done gone</s>
  </item>
  <item>
    <s>I done went</s>
  </item>
</list> whereas Negro Non-Standard basilect has both these and
</p>

<p>White Southern dialect also has <list xml:id="LP3">
  <item>
    <s>I've done gone</s>
  </item>
  <item>
    <s>I've done went</s>
  </item>
</list> which, when they occur in Negro dialect, should probably be
considered as borrowings from other varieties of English.</p>
<p><join result="list" xml:id="LST1"
target="#LP1 #LP2 #LP3" scope="branches">
<desc>Sample sentences in Southern speech</desc>
</join>

Schematron  
<s:assert test="contains(@target, ', ')">You must supply at least two values for @target on
<s:name/>)</s:assert>

Content model

}

<joinGrp> (join group) groups a collection of <join> elements and possibly pointers. [16.7. Aggregation]

Module linking – Linking, Segmentation, and Alignment

Attributes  
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) (att.pointing (@targetLang, @target, @evaluate)) (att.typed (@type, @subtype))

@result supplies the default value for the result on each <join> included within the group.

Status  Optional

```
<keywords>

Schema Declaration

element joinGrp
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.pointing.group.attributes,
  att.pointing.attributes,
  att.typed.attributes,
  attribute result { text }?,
  ( ( equiv | gloss | model.descLike )* , ( join | ptr )+ )
}

<keywords> (keywords) contains a list of keywords or phrases identifying the topic or nature of a text. [2.4.3]

Module header — The TEI Header

Attributes: att.global ([@xml:id, @n, @xml:lang, @xml:base, @xml:space]) att.global.rendition (@rend, @style, @rendition)) att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@scheme identifies the controlled vocabulary within which the set of keywords concerned is defined, for example by a <taxonomy> element, or by some other resource.

Status: Optional

Datatype: teidata.pointer

Contains: textClass

May contain: core: list term

Core: list

Note: Each individual keyword (including compound subject headings) should be supplied as a <term> element directly within the <keywords> element. An alternative usage, in which each <term> appears within an <item> inside a <list> is permitted for backwards compatibility, but is deprecated.

If no control list exists for the keywords used, then no value should be supplied for the scheme attribute.

Example
The TEI Guidelines

Example

<keywords scheme="http://classificationweb.net">
  <term>Babbage, Charles</term>
  <term>Mathematicians - Great Britain - Biography</term>
</keywords>

Content model

<content>

Example Labels are commonly used for the headwords in glossary lists; note the use of the global xml:lang attribute to set the default language of the glossary list to Middle English, and identify the glosses and headings as modern English or Latin:

```xml
<List type="gloss" xml:lang="enm">
  <Head xml:lang="en">Vocabulary</Head>
  <HeadLabel xml:lang="en">Middle English</HeadLabel>
  <HeadItem xml:lang="en">New English</HeadItem>
  <Label nu>nu</Label>
  <Item xml:lang="en">now</Item>
  <Label lhude>lhude</Label>
  <Item xml:lang="en">loudly</Item>
  <Label bloweth>bloweth</Label>
  <Item xml:lang="en">blooms</Item>
  <Label med>med</Label>
  <Item xml:lang="en">meadow</Item>
  <Label wude>wude</Label>
  <Item xml:lang="en">wood</Item>
  <Label awe>awe</Label>
  <Item xml:lang="en">ewe</Item>
  <Label lhouth>lhouth</Label>
  <Item xml:lang="en">lows</Item>
  <Label sterteth>sterteth</Label>
  <Item xml:lang="en">bounds, frisks (cf. <Cit>
    <Ref Chaucer, K.T.644/>
    <Quote a courser, <Term>sterting</Term> as the fyr</Quote>
  </Cit>
```

1303
Example Labels may also be used to record explicitly the numbers or letters which mark list items in ordered lists, as in this extract from Gibbon’s *Autobiography*. In this usage the `<label>` element is synonymous with the `n` attribute on the `<item>` element:

```
I will add two facts, which have seldom occurred in the composition of six, or at least of five quartos.
<list rend="runon" type="ordered">
  <label>(1)</label>
  <item>My first rough manuscript, without any intermediate copy, has been sent to the press.</item>
  <label>(2)</label>
  <item>Not a sheet has been seen by any human eyes, excepting those of the author and the printer: the faults and the merits are exclusively my own.</item>
</list>
```

Example Labels may also be used for other structured list items, as in this extract from the journal of Edward Gibbon:

```
<list type="gloss">
  <label>March 1757.</label>
  <item>I wrote some critical observations upon Plautus.</item>
  <label>March 8th.</label>
  <item>I wrote a long dissertation upon some lines of Virgil.</item>
  <label>June.</label>
  <item>I saw Mademoiselle Curchod – <quote xml:lang="la">Omnia vincit amor, et nos cedamus amori.</quote></item>
  <label>August.</label>
  <item>I went to Crassy, and staid two days.</item>
</list>
```

Note that the `<label>` might also appear within the `<item>` rather than as its sibling. Though syntactically valid, this usage is not recommended TEI practice.

Example Labels may also be used to represent a label or heading attached to a paragraph or sequence of paragraphs not treated as a structural division, or to a group of verse lines. Note that, in this case, the `<label>` element appears *within* the `<p>` or `<lg>` element, rather than as a preceding sibling of it.

```
<p>...]<lb>& n’entrer en mauvais & mal-heu-
<lb>ré meſnage. Or des que le confente-
<lb>ment des parties y eft le mariage eft<br/>arreſté, quoy que de faict il ne foit</lb>
<label place="margin">Puiffance maritale entre les Romains.</label>
```
<lb/> confommé. Depuis la conſomma-
<lb/>tion du mariage la femme eſt foubs
<lb/> la puiffance du mary, s’il n’eft efcl-
<lb/>ue ou enfant de famille : car en ce
<lb/> cas, la femme, qui a efpouſé vn en-
<lb/>fant de famille, eſt foubs la puiffance
[...]</p>

In this example the text of the label appears in the right hand margin of the original source, next to the paragraph it describes, but approximately in the middle of it. If so desired the type attribute may be used to distinguish different categories of label.

Content model

character data

Note May contain character data mixed with phrase-level elements.

Example

```xml
<entry>
  <form>
    <orth>publish</orth> ... </form>
  <etym>
    <lang>ME.</lang>
    <mentioned>publisshen</mentioned>,
    <lang>F.</lang>
    <mentioned>publier</mentioned>, <lang>L.</lang>
    <mentioned>publicare, publicatum</mentioned>. <xr>See <ref>public</ref>; cf. <ref>2d</ref>-ish</xr>, </XR>
  </etym>
</entry>
```

Content model

```xml
<content>
  <macroRef key="macro.paraContent"/>
</content>
```

Schema Declaration

```xml
element lang
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
}```
<langKnowledge> (language knowledge) summarizes the state of a person’s linguistic knowledge, either as prose or by a list of `<langKnown>` elements. [13.3.2.1. Personal Characteristics]

Module namesdates — Names, Dates, People, and Places

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.datable (@calendar, @period) (att.datable.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.datable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.datable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod)) att.editLike (@evidence, @instant) att.typed (@type, @subtype)

@type characterizes the element in some sense, using any convenient classification scheme or typology.

Derived from att.typed

Status Optional

Datatype leidata.enumerated

Sample values include: listening

speaking

reading

writing

@tags supplies one or more valid language tags for the languages specified

Status Optional

Datatype 1–∞ occurrences of leidata.language separated by whitespace

Note This attribute should be supplied only if the element contains no `<langKnown>` children. Its values are language ‘tags’ as defined in RFC 4646 or its successor

Member of model.persStateLike

Contained by namesdates: person personGrp persona

May contain certainty: precision

core: "p"

linking: "ab"

namesdates: langKnown

Example

```
<langKnowledge tags="en-GB fr">
  <p>British English and French</p>
</langKnowledge>
```

Example
<langKnown>
  (language known) summarizes the state of a person’s linguistic competence, i.e., knowledge of a single language. [15.2.2. The Participant Description]
</langKnown>

Module namesdates — Names, Dates, People, and Places

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) (att.datablue (@calendar, @period)) (att.databind.blue.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.databind.blue.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.databind.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod)) (att.editLike (@evidence, @instant)
@tag supplies a valid language tag for the language concerned.

**Status** Required
**Datatype** teidata.language

**Note** The value for this attribute should be a language ‘tag’ as defined in BCP 47.

@level a code indicating the person’s level of knowledge for this language

**Status** Optional
**Datatype** teidata.word

**Content model**

```xml
<content>
  <macroRef key="macro.phraseSeq.limited"/>
</content>
```

**Schema Declaration**

```xml
element langKnown {
  att.global.attributes,

  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.declarable.attributes,
  ( model.pLike+ | language+ )
}
```

<layout> (layout) describes how text is laid out on the page or surface of the object, including information about any ruling, pricking, or other evidence of page-preparation techniques. [10.7.2. Writing, Decoration, and Other Notations]

Module msdescription — Manuscript Description

Attributes

- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@columns (columns) specifies the number of columns per page

- Status Optional
- Datatype 1–2 occurrences of `teidata.count` separated by whitespace
- Note If a single number is given, all pages referenced have this number of columns. If two numbers are given, the number of columns per page varies between the values supplied. Where columns is omitted the number is assumed to be 1.
- Columns may be independent of page orientation or reading direction, and a single textual stream may have one or more columns.

@streams (textual streams) indicates the number of streams per page, each of which contains an independent textual stream

- Status Optional
- Datatype 1–2 occurrences of `teidata.count` separated by whitespace
Note If a single number is given, all pages referenced have this number of textual streams. If two numbers are given, the number of textual streams per page varies between the values supplied. Where streams is omitted the number is assumed to be 1 and unless specified elsewhere the script orientation of the source is identical to that used in the TEI document.

@ruledLines (ruled lines) specifies the number of ruled lines per column
Status Optional
Datatype 1–2 occurrences of teidata.count separated by whitespace
Note If a single number is given, all columns have this number of ruled lines. If two numbers are given, the number of ruled lines per column varies between the values supplied.

@writtenLines (written lines) specifies the number of written lines per column
Status Optional
Datatype 1–2 occurrences of teidata.count separated by whitespace
Note If a single number is given, all columns have this number of written lines. If two numbers are given, the number of written lines per column varies between the values supplied.
Example

```xml
<layout columns="1" ruledLines="25 32">Most pages have between 25 and 32 long lines ruled in lead.</layout>
```

Example

```xml
<layout columns="2" ruledLines="42">
  <p>2 columns of 42 lines ruled in ink, with central rule between the columns.</p>
</layout>
```

Example

```xml
<layout columns="1 2" writtenLines="40 50">
  <p>Some pages have 2 columns, with central rule between the columns; each column with between 40 and 50 lines of writing.</p>
</layout>
```

Example

```xml
<layout streams="3" columns="3"/>
<!-- Further down in document body -->
<content>
  <macroRef key="macro.specialPara"/>
</content>
```

Content model

```xml
<content>
  <macroRef key="macro.specialPara"/>
</content>
```

Schema Declaration

```xml
element layout
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute columns { list { ? } }?,
  attribute streams { list { ? } }?,
  attribute ruledLines { list { ? } }?,
  attribute writtenLines { list { ? } }?,
  macro.specialPara}
```

1316
<layoutDesc> (layout description) collects the set of layout descriptions applicable to a manuscript or other object. [[10.7.2. Writing, Decoration, and Other Notations]]

Module mdescription — Manuscript Description

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

1318
May contain Empty element

Note By convention, `<lb>` elements should appear at the point in the text where a new line starts. The `n` attribute, if used, indicates the number or other value associated with the text between this point and the next `<lb>` element, typically the sequence number of the line within the page, or other appropriate unit. This element is intended to be used for marking actual line breaks on a manuscript or printed page, at the point where they occur; it should not be used to tag structural units such as lines of verse (for which the `<l>` element is available) except in circumstances where structural units cannot otherwise be marked.

The `type` attribute may be used to characterize the line break in any respect. The more specialized attributes `break`, `ed`, or `edRef` should be preferred when the intent is to indicate whether or not the line break is word-breaking, or to note the source from which it derives.

Example This example shows typographical line breaks within metrical lines, where they occur at different places in different editions:

```
Of Mans First Disobedience, <lb ed="1674"/> and <lb ed="1667"/> the Fruit
Of that Forbidden Tree, whose <lb ed="1667 1674"/> mortal tast
Brought Death into the World, <lb ed="1667"/> and all <lb ed="1674"/> our woe.
```

Example This example encodes typographical line breaks as a means of preserving the visual appearance of a title page. The `break` attribute is used to show that the line break does not (as elsewhere) mark the start of a new word.

```
<titlePart>
  <lb/>With Additions, ne-<lb break="no"/>ver before Printed.
</titlePart>
```

Content model `<content> <empty/> </content>`

Schema Declaration

```

  macro.paraContent
}
```

<leaf> (leaf) encodes the leaves (terminal nodes) of a tree. [19.2. Trees]

Module nets — Graphs, Networks, and Trees

Attributes

- `@xml:id`, `@n`, `@xml:lang`, `@xml:base`, `@xml:space` (att.global rendition) (`@rend`, `@style`, `@rendition`) (att.global linking) (`@corresp`, `@synch`, `@sameAs`, `@copyOf`, `@next`, `@prev`, `@exclude`, `@select`) (att.global analytic) (`@ana`) (att.global facs) (att.global change) (att.global responsibility) (`@cert`, `@resp`) (att.global source)

- `@value` provides a pointer to a feature structure or other analytic element.
  - Status: Optional
  - Datatype: teidata.pointer

- `@parent` provides the identifier of parent of a leaf.
  - Status: Optional
  - Datatype: teidata.pointer

- `@follow` provides an identifier of an element which this leaf follows.
  - Status: Optional
  - Datatype: teidata.pointer
Note: If the tree is unordered or partially ordered, this attribute has the property of fixing the relative order of the leaf and the element which is the value of the attribute.

Content model

```xml
<content>
  <elementRef key="label" minOccurs="0"/>
</content>
```

Schema Declaration

```xml
element leaf
{
  att.global.attributes,

  att.global.source.attributes,
  attribute value { text }?,
  attribute parent { text }?,
  attribute follow { text }?,
  label?
}
```

**<lem>** (lemma) contains the lemma, or base text, of a textual variation. [12.1. The Apparatus Entry, Readings, and Witnesses]

Module textcrit — Critical Apparatus

Attributes  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.textCritical (@type, @cause, @varSeq, @require) (att.written (@hand)) att.witnessed (@wit)

Contained by
textcrit: app rdGp

May contain
analysis: c cl interp interpGp m pc phr s span spanGp w

certainty: certainty precision respons
The term **lemma** is used in text criticism to describe the reading given in the main text, which may be used as a heading in the apparatus itself. This usage connects it to mathematics (where a lemma is a proven proposition used as a step in a proof, a “given”) and natural-language processing (where a lemma is the dictionary headword associated with an inflected form in the running text).

**Example**

```
<app>
  <lem wit="#El #Hg">Experience</lem>
  <rdg wit="#La" type="substantive">Experiment</rdg>
  <rdg wit="#Ra2" type="substantive">Eryment</rdg>
</app>
```

</linkGrp>
```
May contain one or more `<link>` or `<ptr>` elements.

A web or link group is an administrative convenience, which should be used to collect a set of links together for any purpose, not simply to supply a default value for the `type` attribute.

Example

```xml
<linkGrp type="translation">
  <link target="#CCS1 #SW1"/>
  <link target="#CCS2 #SW2"/>
  <link target="#CCS #SW"/>
</linkGrp>
```
```xml
<div type="volume" xml:id="CCS"/>
```
Longtemps, je me suis couché de bonne heure.
Parfois, à peine ma bougie éteinte, mes yeux se fermaient si vite que je n’avais pas le temps de me dire : "Je m’endors."

For a long time I used to go to bed early.
Sometimes, when I had put out my candle, my eyes would close so quickly that I had not even time to say "I’m going to sleep."

---

(list) contains any sequence of items organized as a list. [3.8. Lists]

Module core — Elements Available in All TEI Documents

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
@type (type) describes the nature of the items in the list.

Derived from: att.typed

Status: Optional

Datatype: teidata.enumerated

Suggested values include:

- gloss (gloss) each list item glosses some term or concept, which is given by a <label> element preceding the list item.
- index (index) each list item is an entry in an index such as the alphabetical topical index at the back of a print volume.
- instructions (instructions) each list item is a step in a sequence of instructions, as in a recipe.
- litany (litany) each list item is one of a sequence of petitions, supplications or invocations, typically in a religious ritual.
- syllogism (syllogism) each list item is part of an argument consisting of two or more propositions and a final conclusion derived from them.

Note: Previous versions of these Guidelines recommended the use of type on <list> to encode the rendering or appearance of a list (whether it was bulleted, numbered, etc.). The current recommendation is to use the rend or style attributes for these aspects of a list, while using type for the more appropriate task of characterizing the nature of the content of a list.

The formal syntax of the element declarations allows <label> tags to be omitted from lists tagged <list type="gloss">; this is however a semantic error.
Note May contain an optional heading followed by a series of items, or a series of label and item pairs, the latter being optionally preceded by one or two specialized headings.

Example

```xml
<list rend="numbered">
  <item>a butcher</item>
  <item>a baker</item>
  <item>a candlestick maker, with
  <list rend="bulleted">
    <item>rings on his fingers</item>
    <item>bells on his toes</item>
  </list>
</item>
</list>
```

Example

```xml
<list type="syllogism" rend="bulleted">
  <item>All Cretans are liars.</item>
  <item>Epimenides is a Cretan.</item>
  <item>ERGO Epimenides is a liar.</item>
</list>
```

Example

```xml
<list type="litany" rend="simple">
  <item>God save us from drought.</item>
  <item>God save us from pestilence.</item>
  <item>God save us from wickedness in high places.</item>
  <item>Praise be to God.</item>
</list>
```

Example The following example treats the short numbered clauses of Anglo-Saxon legal codes as lists of items. The text is from an ordinance of King Athelstan (924–939):

```xml
<div1 type="section">
  <head>Athelstan's Ordinance</head>
  <list rend="numbered">
    <item n="1">Concerning thieves. First, that no thief is to be spared who is caught with
      the stolen goods, [if he is] over twelve years and [if the value of the goods is]
      over eightpence.
    </item>
    <list rend="numbered">
      <item n="1.1">And if anyone does spare one, he is to pay for the thief with his
        wergild — and the thief is to be no nearer a settlement on that account — or to
        clear himself by an oath of that amount.</item>
      <item n="1.2">If, however, he [the thief] wishes to defend himself or to
escape, he is not to be spared [whether younger or older than twelve].</item>

<item n="1.3">If a thief is put into prison, he is to be in prison 40 days, and he may then be redeemed with 120 shillings; and the kindred are to stand surety for him that he will desist for ever.</item>

<item n="1.4">And if he steals after that, they are to pay for him with his wergild, or to bring him back there.</item>

<item n="1.5">And if he steals after that, they are to pay for him with his wergild, whether to the king or to him to whom it rightly belongs; and everyone of those who supported him is to pay 120 shillings to the king as a fine.</item>
</item>
</list>

<item n="2">Concerning lordless men. And we pronounced about these lordless men, from whom no justice can be obtained, that one should order their kindred to fetch back such a person to justice and to find him a lord in public meeting.

<list rend="numbered">

<item n="2.1">And if they then will not, or cannot, produce him on that appointed day, he is then to be a fugitive afterwards, and he who encounters him is to strike him down as a thief.</item>

<item n="2.2">And he who harbours him after that, is to pay for him with his wergild or to clear himself by an oath of that amount.</item>
</list>
</item>

<item n="3">Concerning the refusal of justice. The lord who refuses justice and upholds his guilty man, so that the king is appealed to, is to repay the value of the goods and 120 shillings to the king; and he who appeals to the king before he demands justice as often as he ought, is to pay the same fine as the other would have done, if he had refused him justice.

<list rend="numbered">

<item n="3.1">And the lord who is an accessory to a theft by his slave, and it becomes known about him, is to forfeit the slave and be liable to his wergild on the first occasion; if he does it more often, he is to be liable to pay all that he owns.</item>

<item n="3.2">And likewise any of the king's treasurers or of our reeves, who has been an accessory of thieves who have committed theft, is to liable to the same.</item>
</list>
</item>
</item>

<item n="4">Concerning treachery to a lord. And we have pronounced
concerning treachery to a lord, that he [who is accused] is to forfeit his life if he cannot
deny it or is afterwards convicted at the three-fold ordeal.

Note that nested lists have been used so the tagging mirrors the structure indicated by the two-level numbering of the clauses. The clauses could have been treated as a one-level list with irregular numbering, if desired.

Example

These decrees, most blessed Pope Hadrian, we propounded in the public council ... and they confirmed them in our hand in your stead with the sign of the Holy Cross, and afterwards inscribed with a careful pen on the paper of this page, affixing thus the sign of the Holy Cross.

I, Eanbald, by the grace of God archbishop of the holy church of York, have subscribed to the pious and catholic validity of this document with the sign of the Holy Cross.

I, Ælfwold, king of the people across the Humber, consenting have subscribed with the sign of the Holy Cross.

I, Tilberht, prelate of the church of Hexham, rejoicing have subscribed with the sign of the Holy Cross.

I, Higbald, bishop of the church of Lindisfarne, obeying have subscribed with the sign of the Holy Cross.

I, Ethelbert, bishop of Candida Casa, suppliant, have subscribed with the sign of the Holy Cross.

I, Ealdwulf, bishop of the church of Mayo, have subscribed with devout will.

I, Æthelwine, bishop, have subscribed through delegates.

I, Sicga, patrician, have subscribed with serene mind with the sign of the Holy Cross.

Schematron

The content of a “gloss” list should include a sequence of one or more pairs of a label element followed by an item element.

Content model

```
<content>
  <sequence>
    <alternate minOccurs="0" maxOccurs="unbounded">
      <classRef key="model.divTop"/>
      <classRef key="model.global"/>
    </alternate>
  </sequence>
</content>
```

    }
}
```

`<listChange>` groups a number of change descriptions associated with either the creation of a source text or the revision of an encoded text. [2.6. The Revision Description | 11.7. Identifying Changes and Revisions]

Attributes `att.global` (@xml:id, @n, @xml:lang, @xml:base, @xml:space) `att.global.rendition` (@rend, @style, @rendition) `att.global.linking` (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) `att.global.analytic` (@ana) `att.global.facs` (@facs) `att.global.change` (@change) `att.global.responsibility` (@cert, @resp) `att.global.source` (@source) `att.sortable` (@sortKey) `att.typed` (@type, @subtype)

@ordered indicates whether the ordering of its child `<change>` elements is to be considered significant or not.

Status Optional
**Datatype**  \texttt{teidata.truthValue}

**Default**  true

**Member of** \texttt{model.standOffPart}

**Contained by**

header: \texttt{creation listChange revisionDesc}

linking: \texttt{standOff}

**May contain**

core: \texttt{desc}

header: \texttt{change listChange}

**Note**  When this element appears within the \texttt{<creation>} element it documents the set of revision campaigns or stages identified during the evolution of the original text. When it appears within the \texttt{<revisionDesc>} element, it documents only changes made during the evolution of the encoded representation of that text.

**Example**

```
<revisionDesc>
  <change when="1991-11-11" who="#LB"> deleted chapter 10 </change>
<change when="1991-11-02" who="#MSM"> completed first draft </change>
</listChange>
</revisionDesc>
```

**Example**

```
<profileDesc>
  <creation>
    <listChange ordered="true">
      <change xml:id="CHG-1">First stage, written in ink by a writer</change>
      <change xml:id="CHG-2">Second stage, written in Goethe's hand using pencil</change>
      <change xml:id="CHG-3">Fixation of the revised passages and further revisions by Goethe using ink</change>
      <change xml:id="CHG-4">Addition of another stanza in a different hand, probably at a later stage</change>
    </listChange>
  </creation>
</profileDesc>
```

    ( ( model.placeLike | listPlace )+, ( relation | listRelation )* )+
  )
}

<listPrefixDef> (list of prefix definitions) contains a list of definitions of prefixing schemes used in teidata.pointer values, showing how abbreviated URIs using each scheme may be expanded into full URIs. [16.2.3. Using Abbreviated Pointers]

Module header — The TEI Header
Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Member of model.encodingDescPart
Contained by header: encodingDesc listPrefixDef
May contain core: desc

Example In this example, two private URI scheme prefixes are defined and patterns are provided for dereferencing them. Each prefix is also supplied with a human-readable explanation in a [p] element.

<listPrefixDef>
  <prefixDef ident="psn" matchPattern="([A-Z]+)"
               replacementPattern="personography.xml#$1">
    <p> Private URIs using the <code>psn</code> prefix are pointers to <gi>person</gi> elements in the personography.xml file. For example, <code>psn:MDH</code> dereferences to <code>personography.xml#MDH</code>.
  </p>
</prefixDef>

<prefixDef ident="bibl" matchPattern="([a-z]+[a-z0-9]*)"
Private URIs using the <code>bibl</code> prefix can be expanded to form URIs which retrieve the relevant bibliographical reference from www.example.com.

verse: rhyme

May contain  core: desc head p

linking: ab

namesdates: listRelation relation

Note  May contain a prose description organized as paragraphs, or a sequence of <relation> elements.

Example

```xml
<listPerson>
  <person xml:id="pp1"/>
  <!-- data about person pp1 -->
</person>
  <person xml:id="pp2"/>
  <!-- data about person pp1 -->
</person>
  <!-- more person (pp3, pp4) elements here -->
  <listRelation type="personal">
  <relation name="parent" active="#pp1 #pp2" passive="#pp3 #pp4"/>
  <relation name="spouse" mutual="#pp1 #pp2"/>
</listRelation>
  <listRelation type="social">
  <relation name="employer" active="#pp1" passive="#pp3 #pp5 #pp6 #pp7"/>
</listRelation>
</listPerson>
```
The persons with identifiers pp1 and pp2 are the parents of pp3 and pp4; they are also married to each other; pp1 is the employer of pp3, pp5, pp6, and pp7.

Example

```xml
<listPerson>
  <person xml:id="en_pp1">
    <!-- data about person en_pp1 -->
  </person>
  <person xml:id="en_pp2">
    <!-- data about person en_pp2 -->
  </person>
  <!-- more person (en_pp3, en_pp4) elements here -->
</listPerson>

<listPlace>
  <place xml:id="en_pl1">
    <!-- data about place en_pl1 -->
  </place>
  <!-- more place (en_pl2, en_pl3) elements here -->
</listPlace>

<listRelation>
  <relation name="residence"
    active="#en_pp1 #en_pp2" passive="#en_pl1"/>
</listRelation>
```

The persons with identifiers en_pp1 and en_pp2 live in en_pl1.

Example

```xml
<listRelation>
  <p>All speakers are members of the Ceruli family, born in Naples.</p>
</listRelation>
```

Content model

verse: rhyme
May contain
core: desc head
textcrit: listWit witness
Note May contain a series of <witStart> or <listWit> elements.

The provision of a <listWit> element simplifies the automatic processing of the apparatus, e.g. the reconstruction of the readings for all witnesses from an exhaustive apparatus.

Situations commonly arise where there are many more or less fragmentary witnesses, such that there may be quite distinct groups of witnesses for different parts of a text or collection of texts. Such groups may be given separately, or nested within a single <listWit> element at the beginning of the file listing all the witnesses, partial and complete, for the text, with the attestation of fragmentary witnesses indicated within the apparatus by use of the <witStart> and <witEnd> elements described in section 12.1.5.

Fragmentary Witnesses.

Note however that a given witness can only be defined once, and can therefore only appear within a single <listWit> element.

Example

<listWit>
  <witness xml:id="HL26">Ellesmere, Huntingdon Library 26.C.9</witness>
  <witness xml:id="PN392">Hengwrt, National Library of Wales, Aberystwyth, Peniarth 392D</witness>
  <witness xml:id="RP149">Bodleian Library Rawlinson Poetic 149 (see further <ptr target="#MSRP149"/>)</witness>
</listWit>

<localName> (locally-defined property name) contains a locally defined name for some property. [5.2.1, Character Properties]

Deprecated will be removed on 2022-02-15

Module gaiji — Characters, Glyphs, and Writing Modes

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by

gaiji: charProp

May contain Character data only

Note No definitive list of local names is proposed. However, the name entity is recommended as a means of naming the property identifying the recommended character entity name for this character or glyph.

Example

```xml
<localName>daikanwa</localName>
<localName>entity</localName>
```

Content model

```xml
<content> <textNode/></content>
```

Schema Declaration
<localProp> (locally defined property) provides a locally defined character (or glyph) property. [5.2.1]

Module  gaiji — Characters, Glyphs, and Writing Modes
Attributes  att.global (@xmlns:id, @n, @xmlns:lang, @xmlns:base, @xmlns:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @sync, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.gaijiProp (@name, @value, @version)

Contained by  gaiji: char, glyph

May contain  Empty element

Note  No definitive list of local names is proposed. However, the name entity is recommended as a means of naming the property identifying the recommended character entity name for this character or glyph.

Example

```xml
<char xml:id="daikanwaU4EBA">
  <localProp name="name" value="CIRCLED IDEOGRAPH 4EBA"/>
  <localProp name="entity" value="daikanwa"/>
  <unicodeProp name="Decomposition_Mapping" value="circle"/>
  <mapping type="standard">人</mapping>
</char>
```

Content model  <content> <empty/> </content>

Schema Declaration

```xml
element localProp
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.gaijiProp.attributes,
  empty
}
```
<location> (location) defines the location of a place as a set of geographical coordinates, in terms of other named geo-political entities, or as an address. [13.3.4. Places]

Module namesdates — Names, Dates, People, and Places

Attributes

- att.global (@xmlns:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition) (@rend, @style, @rendition) (att.globalBoundingClientRect) (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) (att.global.analytic (@ana)) (att.global.faces (@facets)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype) att.databindable (@calendar, @period) (att.databindable.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.databindable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.databindable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-custom, @to-

<locus> (locus) defines a location within a manuscript, manuscript part, or other object typically as a (possibly discontinuous) sequence of folio references. [10.3.5. References to Locations within a Manuscript]

Module msdescription — Manuscript Description

Attributes
- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) att.global.rendition (@rend, @style, @rendition) att.global.linking (@corresp, @sync, @sameAs, @copyOf, @next, @prev, @exclude, @select) att.global.analytic (@ana) att.global.facs (@facs) att.global.change (@change) att.global.responsibility (@cert, @resp) att.global.source (@source) att.pointing (@targetLang, @target, @evaluate) att.typed (@type, @subtype) @scheme (scheme) identifies the foliation scheme in terms of which the location is being specified by pointing to some <foliation> element defining it, or to some other equivalent resource.
- Status Optional
- Datatype teidata.pointer

@from (from) specifies the starting point of the location in a normalized form, typically a page number.
- Status Optional
- Datatype teidata.word

@to (to) specifies the end-point of the location in a normalized form, typically as a page number.
- Status Optional
- Datatype teidata.word

gaiji: ʂ

msdescription: locus

cymbol data

Note The target attribute should only be used to point to elements that contain or indicate a transcription of
the locus being described, as in the 'Ben Jonson' example.

To associate a <locus> element with a page image or other comparable representation, the global facs
attribute should be used, as shown in the 'Birds Praise of Love' example. The facs attribute may be used
to indicate one or more image files, as in that example, or alternatively it may point to one or more
appropriate XML elements, such as the <surface>, <zone>, <graphic>, or <binaryObject> elements.

When a single page is being cited, use the from and to attributes with an identical value. When no clear
endpoint is provided, the from attribute may be used without to; for example a citation such as ‘p. 3ff’
might be encoded <locus from="3">p. 3ff</locus>.

Example

<!-- within ms description -->
<msItem n="1">
  <locus target="#F1r #F1v #F2r" from="1r" to="2r">ff. 1r-2r</locus>
  <author>Ben Jonson</author>
  <title>Ode to himself</title>
  <rubric>Com leave the loathed stage</rubric>
  <incipit>And see his charriot triumph ore his wayne.</incipit>
  <explicit>Ben leaue the loathed stage</explicit>
  <bibl>
    <name>Beal</name>, <title>Index 1450-1625</title>, JnB 380</bibl>
</msItem>

<!-- within transcription ... -->
<pb xml:id="F1r"/>
<pb xml:id="F1v"/>
<pb xml:id="F2r"/>

Example The facs attribute is available globally when the transcr module is included in a schema. It may be
used to point directly to an image file, as in the following example:
<msItem>
  <locus facs="images/08v.jpg images/09r.jpg images/09v.jpg images/10r.jpg images/10v.jpg">fols. 8v-10v</locus>
  <title>Birds Praise of Love</title>
  <bibl>
    <biblScope>IMEV</biblScope>
    <biblScope>1506</biblScope>
  </bibl>
</msItem>

### Content model

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.gLike"/>
    <elementRef key="hi"/>
    <elementRef key="locus"/>
  </alternate>
</content>
```

### Schema Declaration

```xml
<locusGrp>(locus group) groups a number of locations which together form a distinct but discontinuous item
within a manuscript, manuscript part, or other object. [10.3.5. References to Locations within a Manuscript]
Module: msdescription — Manuscript Description
Attributes
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition) (@rend, @style, @rendition) (att.global.linking) (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)
(att.global.analytic) (@anal) (att.global.facs) (@facs) (att.global.change) (@change) (att.global.responsibility) (@cert, @resp) (att.global.source) (@source)
@scheme (scheme) identifies the foliation scheme in terms of which all the locations contained by
the group are specified by pointing to some <foliation> element defining it, or to some other
equivalent resource.
```

<mapping> (character mapping) contains one or more characters which are related to the parent character or glyph in some respect, as specified by the type attribute. [5.2. Markup Constructs for Representation of Characters and Glyphs]

Module gaiji — Characters, Glyphs, and Writing Modes

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synchrony, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype)

Contained by
gaiji: char glyph
May contain
gaiji:  character data

The suggested values for the type attribute include exact for exact equivalences, uppercasing for uppercase equivalences, lowercasing for lowercase equivalences, and simplified for simplified characters. The <g> elements contained by this element can point to either another <char> or <glyph> element or contain a character that is intended to be the target of this mapping.

Example

```xml
<mapping type="modern">r</mapping>
<mapping type="standard">人</mapping>
```

Content model <content> <macroRef key="macro.xtext"/></content>

Schema Declaration

```
<element mapping
{  
  att.global.attributes,  
  att.global.rendition.attributes,  
  att.global.linking.attributes,  
  att.global.analytic.attributes,  
  att.global.facs.attributes,  
  att.global.change.attributes,  
  att.global.responsibility.attributes,  
  att.global.source.attributes,  
  att.typed.attributes,  
  macro.xtext}>
```

<material> (material) contains a word or phrase describing the material of which the object being described is composed. [10.3.2. Material and Object Type]

Module msdescription — Manuscript Description

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synchrony, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.canonical (@key, @ref) att.typed (@type, @subtype)

@function describes the function or use of the material in relation to the object as a whole.

Status Optional

Datatype leidata.enumerated

Sample values include: binding covering material of a codex
**endband**  sewing at the head or tail of the codex spine to strengthen the binding, often decorative

**slipcase**  removable protective cover for a set of one or more codices

**support**  the surface for writing

**tie**  a ribbon or string used to bind or close a codex or rolled scroll

*Note*  The sample values here are for descriptive bibliography. Other sets of sample values might include armrests, legs, tabletop, pan, and back for furniture; or wall, floor, window, column, ceiling, roof, stairs, chimney for architecture.

@target  identifies one or more elements to which the metamark applies.

**Status**  Optional

**Datatype**  1–∞ occurrences of teidata.pointer separated by whitespace

caracter data

Note The ref attribute may be used to point to one or more items within a taxonomy of types of material, defined either internally or externally.

Example

```xml
<physDesc>
  <p>
    <material>Parchment</material> leaves with a
    <material>sharkskin</material> binding.</p>
</physDesc>
```

Content model

```xml
<content>
  <macroRef key="macro.phraseSeq"/>
</content>
```

Schema Declaration

```xml
element material
  {
    att.global.attributes,
    att.global.rendition.attributes,
    att.global.linking.attributes,
    att.global.analytic.attributes,
    att.global.facs.attributes,
    att.global.change.attributes,
    att.global.responsibility.attributes,
    att.global.source.attributes,
    att.canonical.attributes,
    att.typed.attributes,
    attribute function { text }?,
    attribute target { list { + } }?,
    macro.phraseSeq
  }
```

1386
<measure> contains a word or phrase referring to some quantity of an object or commodity, usually comprising a number, a unit, and a commodity name. [3.6.3. Numbers and Measures]

Attributes

- att.global (@xml:id, @m, @xml:lang, @xml:base, @xml:space) (att.global.rendition) (@rend, @style, @rendition) (att.global.linkling) (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.measurement (@unit, @unitRef, @quantity, @commodity) att.typed (Measure, @subtype)

@type specifies the type of measurement in any convenient typology.

Example
This example references a definition of a measurement unit declared in the TEI header:

```xml
<measure type="weight">
  <num>2</num> pounds of flesh
</measure>
<measure type="currency">£10-11-6d</measure>
<measure type="area" unitRef="#merk">2 <unit>merks</unit> of old extent</measure>
<!-- In the TEI Header: -->
<encodingDesc>
  <unitDecl>
    <unitDef xml:id="merk" type="area">
      <label>merk</label>
      <placeName ref="#Scotland"/>
      <desc>A merk was an area of land determined variably by its agricultural productivity.</desc>
    </unitDef>
  </unitDecl>
</encodingDesc>

Example

```xml
<measure quantity="40" unit="hogshead" commodity="rum">2 score hh rum</measure>
<measure quantity="12" unit="count" commodity="roses">1 doz. roses</measure>
<measure quantity="1" unit="count" commodity="tulips">a yellow tulip</measure>
```

Content model

```xml
<content>
  <macroRef key="macro.phraseSeq"/>
</content>
```

1388
Schema Declaration

```xml
<measureGrp>
  element measure {
    att.global.attributes,
    att.global.rendition.attributes,
    att.global.linking.attributes,
    att.global.analytic.attributes,
    att.global.facs.attributes,
    att.global.change.attributes,
    att.global.responsibility.attributes,
    att.global.source.attributes,
    att.measurement.attributes,
    att.typed.attribute.subtype,
    attribute type { text }?,
    macro.phraseSeq
  }
</measureGrp>
```

<measureGrp> (measure group) contains a group of dimensional specifications which relate to the same object, for example the height and width of a manuscript page. [10.3.4. Dimensions]

Note  The attributes available for this element are not appropriate in all cases. For example, it makes no sense to specify the temporal duration of a graphic. Such errors are not currently detected.

The mimeType attribute must be used to specify the MIME media type of the resource specified by the url attribute.

Example

```xml
<figure>
  <media mimeType="image/png" url="fig1.png"/>
  <head>Figure One: The View from the Bridge</head>
  <figDesc>A Whistleresque view showing four or five sailing boats in the foreground, and a series of buoys strung out between them.</figDesc>
</figure>
```

Example

```xml
<media mimeType="audio/wav" url="dingDong.wav" dur="PT10S">
  <desc>Ten seconds of bellringing sound</desc>
</media>
```

Example

```xml
<media mimeType="video/mp4" url="clip45.mp4" dur="PT45M" width="500px">
  <desc>A 45 minute video clip to be displayed in a window 500 px wide</desc>
</media>
```

Content model

```xml
<content>
  <classRef key="model.descLike" minOccurs="0" maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```xml
element media {
  att.typed.attributes,
  att.global.attributes,
  att.global.rendition.attributes,

<memberOf> specifies class membership of the documented element or class. [22.4.3 Classification of Components]

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@key specifies the identifier for a class of which the documented element or class is a member or subclass

Status Optional

Datatype teidata.name

@mode specifies the effect of this declaration on its parent module.

1394
Status  Optional
Datatype  teidata.enumerated

Legal values are: add this declaration is added to the current definitions [Default]
delete this declaration and all of its children are removed from the current setup

@max supplies the maximum number of times the element can occur in elements which use this
model class in their content model
Status  Optional
Datatype  teidata.numeric

@min supplies the minimum number of times the element must occur in elements which use this
model class in their content model
Status  Optional
Datatype  teidata.numeric

Contained by:  classes
May contain
gaiji:  g
character data

Note  Elements or classes which are members of multiple (unrelated) classes will have more than one
<memberOf> element, grouped by a <classes> element. If an element is a member of a class C1, which is
itself a subclass of a class C2, there is no need to state this, other than in the documentation for class C1.
Any additional comment or explanation of the class membership may be provided as content for this
element.

Example

```xml
<memberOf key="model.divLike"/>
<memberOf key="att.identified"/>
```

This element will appear in any content model which references model.divLike, and will have
attributes defined in att.identified (in addition to any defined explicitly for this element).

Content model
```xml
<content> <macroRef key="macro.xtext"/></content>
```

Schema Declaration
```xml
<memberOf key="model.divLike"/>
<memberOf key="att.identified"/>
```

```xml
element memberOf{
    att.global.attributes,
    att.global.rendition.attributes,
    att.global.linking.attributes,
    att.global.analytic.attributes,

</content>
```

Schema Declaration

```
<atom element="metamark">
  { 
    att."spanning.attributes",
    att."placement.attributes",
  }
```
<metDecl> (metrical notation declaration) documents the notation employed to represent a metrical pattern when this is specified as the value of a met, real, or rhyme attribute on any structural element of a metrical text (e.g. lg, l, or seg). [6.6. Metrical Notation Declaration 6.4. Rhyme and Metrical Analysis]

Module verse – Verse

Attributes
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.declarable (@default)

@type indicates whether the notation conveys the abstract metrical form, its actual prosodic realization, or the rhyme scheme, or some combination thereof.

Status Optional

Datatype 1–3 occurrences of leidata.enumerated separated by whitespace

Legal values are: met (met attribute) declaration applies to the abstract metrical form recorded on the met attribute

real (real attribute) declaration applies to the actual realization of the conventional metrical structure recorded on the real attribute

rhyme declaration applies to the rhyme scheme recorded on the rhyme attribute

Note By default, the <metDecl> element documents the notation used for metrical pattern and realization. It may also be used to document the notation used for rhyme scheme information; if not otherwise documented, the rhyme scheme notation defaults to the traditional 'abab' notation.

@pattern (regular expression pattern) specifies a regular expression defining any value that is legal for this notation.

Status Optional

Datatype leidata.pattern

Note The value must be a valid regular expression per the World Wide Web Consortium’s XML Schema Part 2: Datatypes Second Edition, Appendix F

Member of model.encodingDescPart

Contained by
header: encodingDesc

May contain
core: note noteGrp

linking: ab

verse: metSym

Note The encoder may choose whether to define the notation formally or informally. However, the two methods may not be mixed. That is, <metDecl> may contain either a sequence of <metSym> elements or,
alternately, a series of paragraphs or other components. If the pattern attribute is specified and elements are used, then all the codes appearing within the pattern attribute should be documented.

Only usable within the header if the verse module is used.

Example

```xml
<metDecl xml:id="ip" type="met"
    pattern="((SU|US)USUSUSUS/)">
    <metSym value="S">stressed syllable</metSym>
    <metSym value="U">unstressed syllable</metSym>
    <metSym value="/">metrical line boundary</metSym>
</metDecl>
```

This example is intended for the far more restricted case typified by the Shakespearean iambic pentameter. Only metrical patterns containing exactly ten syllables, alternately stressed and unstressed, (except for the first two which may be in either order) to each metrical line can be expressed using this notation.

Content model

```xml
<content>
  <alternate>
    <alternate minOccurs="1"
        maxOccurs="unbounded">
      <classRef key="model.pLike"/>
      <classRef key="model.noteLike"/>
    </alternate>
    <elementRef key="metSym" minOccurs="1"
        maxOccurs="unbounded"/>
  </alternate>
</content>
```

Schema Declaration

```xml
element metDecl
{
  att.global.attributes, 
  att.global.rendition.attributes, 
  att.global.linking.attributes, 
  att.global.analytic.attributes, 
  att.global.facs.attributes, 
  att.global.change.attributes, 
  att.global.responsibility.attributes, 
  att.global.source.attributes, 
  att.declarable.attributes, 
  attribute type
  {
    list
    {
      ( "met" | "real" | "rhyme" ),
      ( "met" | "real" | "rhyme" )?,
      ( "met" | "real" | "rhyme" )?
    }?,
  }
  attribute pattern { text }?,
  ( ( model.pLike | model.noteLike )+ | metSym+ )
}
```
<metSym> (metrical notation symbol) documents the intended significance of a particular character or character sequence within a metrical notation, either explicitly or in terms of other <metSym> elements in the same <metDecl>. [6.6. Metrical Notation Declaration]

Module in verse — Verse

Attributes:
- `att.global` (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition) (@rend, @style, @rendition) (att.global.linking) (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) (att.global.analytic) (@ana) (att.global.facs) (@facs) (att.global.change) (@change) (att.global.responsibility) (@cert, @resp) (att.global.source) (@source)
- `@value` specifies the character or character sequence being documented.
- Status: Required
- Datatype: 1–∞ occurrences of teidata.word separated by whitespace
- `@terminal` specifies whether the symbol is defined in terms of other symbols (terminal is set to false) or in prose (terminal is set to true).
- Status: Optional
- Datatype: teidata.truthValue
- Default: true

Note: The value true indicates that the element contains a prose definition of its meaning; the value false indicates that the element contains a definition of its meaning given using symbols defined elsewhere in the same <metDecl> element.

Contained by <metDecl>

May contain Empty element

Note For this element, the global n attribute indicates the new number or other value for the unit which changes at this milestone. The special value unnumbered should be used in passages which fall outside the normal numbering scheme, such as chapter or other headings, poem numbers or titles, etc.

The order in which <milestone> elements are given at a given point is not normally significant.

Example

<milestone n="23" ed="La" unit="Dreissiger"/>
... <milestone n="24" ed="AV" unit="verse"/>
...

Content model <content> <empty/></content>

}
```

The TEI Guidelines
@behaviour names the process or function which this processing model uses in order to produce output.
Status Required
Datatype lidata.enumerated
Suggested values include: alternate (default, alternate) support display of alternative visualisations, for example by displaying the preferred content, by displaying both in parallel, or by toggling between the two.
anchor (id) create an identifiable anchor point in the output.
block (content) create a block structure
body (content) create the body of a document.
break (type, label) create a line, column, or page break according to the value of type

cell (content) create a table cell

cit (content, source) show the content, with an indication of the source
document (content) start a new output document
figure (title) make a figure with the title as caption
glyph (uri) show a character by looking up reference to a chardesc at the given URI

graphic (url, width, height, scale, title) if url is present, uses it to display graphic, else display a placeholder image.
heading (content, level) creates a heading.
index (type) generate list according to type.
inline (content, label) creates inline element out of content
link (content, uri) create hyperlink
list (content) create a list.
listItem (content) create a list item.
metadata (content) create metadata section
note (content, place, label) create a note, often out of line, depending on the value of place; could be margin, footnote, endnote, inline
omit do nothing, do not process children
paragraph (content) create a paragraph out of content.
row (content) create a table row
section (content) create a new section of the output document
table (content) create a table
text (content) create literal text
title (content) create document title

@useSourceRendition whether to obey any rendition attribute that is present.
Status Optional
Datatype lidata.truthValue
Note If the useSourceRendition attribute is not specified, or has the value false, any renditional information specified in the source document should be ignored.

@output the intended output.
Status Optional
Datatype lidata.enumerated
Sample values include: web the output is intended for presentation in a web format
print the output is intended for presentation in a print format
plain the output is intended for presentation in a plain text format

Note If the output attribute is not specified, this model is assumed to apply for all forms of output.
The TEI Guidelines

@cssClass the name of a CSS class which should be associated with this element
  Status Optional
  Datatype 1–∞ occurrences of teidata.name separated by whitespace

Contained in: elementSpec|modelGrp|modelSequence
May contain core: desc|gloss
tagdocs: altIdent|equiv|outputRendition|param

Note The intended output to be generated for a particular behaviour of a processing model may be
documented in one or all of the three following ways. Firstly, the cssClass attribute may be used to
specify the name of a CSS style in some associated CSS stylesheet which is to be applied to each
occurrence of a specified element found (in a given context, for a specified output). Secondly, the
attribute useSourceRendition may be used to indicate that the default rendition for occurrences of this
element, as defined by a <rendition> element in the document header, should be applied. Thirdly, the
styling to be applied may be specified explicitly as content of a child <outputRendition> element. When
more than one of these options is used, they are understood to be combined in accordance with the rules
for multiple declaration of the styling language used.

Example

```xml
<model behaviour="inline"/>
```

Example

```xml
<elementSpec mode="change" ident="quote">
  <model predicate="ancestor::p" behaviour="inline">
    <desc versionDate="2015-08-21" xml:lang="en">If it's inside a paragraph then it's inline</desc>
  </model>
  <model predicate="not(ancestor::p)" behaviour="block">
    <desc versionDate="2015-08-21" xml:lang="en">If it's not inside a paragraph then it is block level</desc>
  </model>
</elementSpec>
```

Example

```xml
<model predicate="parent::person" behaviour="inline">
  <desc versionDate="2015-08-21" xml:lang="en">If it is a child of a person element, treat as inline</desc>
</model>
```

Example

```xml
<model behaviour="inline">
  <outputRendition>font-weight:bold</outputRendition>
</model>
```

Example

1408
<model behaviour="inline" output="print"/>

Example

<model predicate="ancestor::p"
  behaviour="inline">
  <param name="content" value="@n"/>
</model>

Example

<elementSpec mode="change" ident="date">
  <model output="print" predicate="text()"
    behaviour="inline"/>
  <model output="print"
    predicate="@when and not(text())" behaviour="inline">
    <param name="content" value="@when"/>
  </model>
  <model predicate="@when" output="web"
    behaviour="alternate">
    <param name="alternate" value="@when"/>
  </model>
</elementSpec>

Example

<elementSpec mode="change" ident="choice">
  <model predicate="sic and corr"
    behaviour="alternate">
    <param name="default" value="corr"/>
    <param name="alternate" value="sic"/>
  </model>
  <model predicate="abbr and expan"
    behaviour="alternate">
    <param name="default" value="expan"/>
    <param name="alternate" value="abbr"/>
  </model>
  <model predicate="orig and reg"
    behaviour="alternate">
    <param name="default" value="reg"/>
    <param name="alternate" value="orig"/>
  </model>
</elementSpec>

Schematron It is ambiguous to have 2 <model>s that have both the same output and have no predicate (and thus select the same set of nodes). <sch:rule context="tei:model[ not( parent::tei:modelSequence ) ][ not( @predicate ) ]"> <sch:let name="output" value="normalize-space( @output )"/>
  <sch:report test="following-sibling::tei:model[ not( @predicate ) ] [ normalize-space( @output ) eq $output ]"> There are 2 (or more) 'model' elements in this  <sch:value-of select="local-name(../)"/> that have no predicate, but are targeted to the same output ("<sch:value-of select="$output, parent::modelGrp/@output, 'all'[1]"/>")</sch:report> </sch:rule>

Schematron It is ambiguous to have 2 <model>s that have both the same output and the same predicate (and thus select the same set of nodes). <sch:rule context="tei:model[ not( parent::tei:modelSequence ) ][ @predicate ]"> <sch:let name="predicate" value="normalize-space( @predicate )"/>
  <sch:let name="output" value="normalize-space( @output )"/>
  <sch:report test="following-sibling::tei:model[ normalize-space( @predicate ) eq $predicate ] [
There are 2 (or more) ‘model’ elements in this
‘<sch:value-of select="local-name(.)"/>’ that have the same predicate, and are targeted to the same output
(‘<sch:value-of select="($output, parent::modelGrp/@output, 'all')[[1]]"/>’)
</sch:report> </sch:rule>

**Content model**

```xml
<content>
  <sequence>
    <alternate minOccurs="0"
      maxOccurs="unbounded">

    "section",
    "table"
  }
```
<modelGrp> any grouping of <model> or <modelSequence> elements with a common output method

Attributes
- `att.global` (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (@att.global.rendition) (@rend, @style, @rendition) (@att.global.blinking) (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) (@att.global.italic) (@facs) (@altIdent) (@equiv) (@model) (@equiv) (@facs) (@altIdent) (@equiv) (@model)
- `@useSourceRendition` whether to obey any rendition attribute which is present
  - Status: Optional
  - Datatype: teidata.truthValue
- `@output` the intended output method
  - Status: Optional
  - Datatype: teidata.enumerated
  - Suggested values include: `web` the output is intended for presentation in a web format
  - `print` the output is intended for presentation in a print format
  - `plaintext` the output is intended for presentation in a plain text format

Contained by: elementSpec
May contain: core: desc gloss
tagdocs: altIdent equiv model modelSequence outputRendition

Note The child <model> elements of a <modelGrp> are always processed independently.

Example
```xml
<elementSpec mode="change" ident="abbr">
  <modelGrp output="web">
    <model predicate="parent::choice"
      behaviour="omit"/>
    <model predicate="ancestor::front"
      behaviour="inline">
      <outputRendition font-style:italic; </outputRendition>
    </model>
    <model predicate="not(parent::choice)"
      behaviour="inline">
      <outputRendition scope="before">content: ' </outputRendition>
      <outputRendition scope="after">content: ')' </outputRendition>
    </model>
  </modelGrp>
  <modelGrp output="print">
    <model predicate="parent::choice"
      behaviour="omit"/>
  </modelGrp>
```

1411
Example

```
<modelGrp output="print">
  <modelSequence>
    <model behaviour="inline">
      <param name="content" value="@n"/>
    </model>
    <model behaviour="note">
      <param name="place" value="'foot'"/>
    </model>
  </modelSequence>
</modelGrp>
```

Content model

```
<content>
  <sequence>

  attribute output { "web" | "print" | "plaintext" }?,
  ( model.glossLike | model.descLike )*,
  outputRendition?,
  ( modelSequence | model )+
}
```
any sequence of model or <modelSequence> elements which is to be processed as a single set of actions [22.5.4.7. Model sequence]

Module tagdocs — Documentation Elements

Attributes

@predicate the condition under which this model applies given as an XPath Predicate Expression

Status Optional

Datatype teidata.xpath

@useSourceRendition whether to obey any rendition attribute that is present

Status Optional

Datatype teidata.truthValue

@output the intended output method

Status Optional

Datatype teidata.enumerated

Suggested values include:

- web the output is intended for presentation in a web format

- print the output is intended for presentation in a print format

- plaintext the output is intended for presentation in a plain text format

Contained by: elementSpec modelGrp

May contain:
core: desc gloss
tagdocs: altIdent equiv model

Note All of the <model> elements inside a <modelSequence> element must be processed. The operations indicated by each <model> child cannot be dependent on any other operation in the sequence. The results must be rendered in the order given by the list of <model> in the <modelSequence>.

Example

```
<modelGrp output="print">
  <modelSequence>
    <model behaviour="inline">
      <param name="content" value="@n"/>
    </model>
    <model behaviour="footnote">
      <param name="place" value="foot"/>
    </model>
  </modelSequence>
</modelGrp>
```

Schematron <sch:report test="tei:model[@output]" role="warning">The 'model' children of a 'modelSequence' element inherit the @output attribute of the parent 'modelSequence', and thus should not have their own</sch:report>

Content model

```
<content>
  <sequence>
```

1413
<alternate minOccurs="0" maxOccurs="unbounded">
  <classRef key="model.glossLike"/>
  <classRef key="model.descLike"/>
</alternate>

<elementRef key="model" minOccurs="2" maxOccurs="unbounded"/>
</sequence>
</content>

**Schema Declaration**

```xml
<element modelSequence{

  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute predicate { text }?,
  attribute useSourceRendition { text }?,
  attribute output { "web" | "print" | "plaintext" }?,
  ( ( model.glossLike | model.descLike )* , ( model, model, model* ))
}
```

**<moduleRef>** (module reference) references a module which is to be incorporated into a schema. [22.2]

**Modules and Schemas**

**Module** tagdocs — Documentation Elements

Attributes

- `att.global` (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition) (@rend, @style, @rendition)) (att.global.linking) (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

- `@prefix` specifies a default prefix which will be prepended to all patterns from the imported module

**Status** Optional

**Datatype** 0–1 occurrences of `teidata.xmlName` separated by whitespace

**Schematron** `<s:rule context="tei:moduleRef"> <s:report test="/" [ not( generate-id( ) eq generate-id( current( ) )) ]/@prefix = @prefix">The prefix attribute of <s:name/> should not match that of any other element (it would defeat the purpose)</s:report>
</s:rule>`

**Note** Use of this attribute avoids name collisions (and thus invalid schemas) when the external schema being mixed in with TEI uses a name the TEI or some other included external schema already uses for a pattern.

- `@include` supplies a list of the elements which are to be copied from the specified module into the schema being defined.

**Status** Optional

**Datatype** 0–∞ occurrences of `teidata.xmlName` separated by whitespace

1414
@except supplies a list of the elements which are not to be copied from the specified module into the schema being defined.

Status Optional

Datatype 0–∞ occurrences of teidata.xmlName separated by whitespace

@key the name of a TEI module

Status Optional

Datatype teidata.xmlName

@url (uniform resource locator) refers to a non-TEI module of RELAX NG code by external location

Status Optional

Datatype teidata.pointer

Member of model.oddRef

Contained by tagdocs: schemaSpec specGrp

May contain tagdocs: content

Note If neither include nor exclude is supplied, the effect of this element is to make all the declarations contained by the referenced module available to the schema being compiled. If both attributes are supplied, an ODD processor should signal an error.

A TEI module is identified by the name supplied as value for the ident attribute on a <moduleSpec> element. The source attribute may be used to specify an online source from which the specification of that module may be read. A URI may alternatively be supplied in the case of a non-TEI module, and this is expected to be written as a RELAX NG schema.

If the uri attribute is used, the <content> element may also be supplied as a child of this element. Its content (which is assumed to be a fragment of RELAX NG code) will be copied along with the content of the resource indicated by the uri attribute into the target RELAX NG schema.

Example

```xml
<moduleRef key="linking"/>
```

This includes all objects available from the linking module.

Example

```xml
<moduleRef key="linking" except="linkGrp link"/>
```

This includes all elements available from the linking module except for the <link> and <linkGrp> elements.

Example

```xml
<moduleRef key="linking" include="linkGrp link"/>
```

This includes only the <link> and <linkGrp> elements from the linking module.

Schematron <s:rule context="tei:moduleRef"><s:report test="" and @key">Child elements of <s:name/> are only allowed when an external module is being loaded</s:report></s:rule>

Content model

```xml
<content>
  <elementRef key="content" minOccurs="0"/>
</content>
```
Schema Declaration

```xml
<moduleSpec>
(module specification) documents the structure, content, and purpose of a single module, i.e. a named and externally visible group of declarations. [22.2. Modules and Schemas]

Module tagdocs — Documentation Elements
Attributes att.global ((@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.identified (@ident, @predeclare, @module) (att.combinable (@mode) (att.deprecated (@validUntil))) att.typed (@type, @subtype)

<monogr> (monographic level) contains bibliographic elements describing an item (e.g. a book or journal) published as an independent item (i.e. as a separate physical object). [3.12.2.1. Analytic, Monographic, and Series Levels]

Module core — Elements Available in All TEI Documents

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by

core: biblStruct
The TEI Guidelines

May contain

core: author biblScope editor imprint meeting note noteGrp ptr ref respStmt textLang title

header: authority availability edition extent funder idno sponsor

Note May contain specialized bibliographic elements, in a prescribed order.

The <monogr> element may only occur only within a <biblStruct>, where its use is mandatory for the description of a monographic-level bibliographic item.

Example

```xml
<biblStruct>
  <analytic>
    <author>Chesnutt, David</author>
    <title>Historical Editions in the States</title>
  </analytic>
  <monogr>
    <title level="j">Computers and the Humanities</title>
    <imprint>
      <date when="1991-12">(December, 1991):</date>
    </imprint>
    <biblScope>25.6</biblScope>
    <biblScope unit="page" from="377" to="380">377–380</biblScope>
  </monogr>
</biblStruct>
```

Example

```xml
<biblStruct type="book">
  <monogr>
    <author>
      <persName>
        <forename>Leo Joachim</forename>
        <surname>Frachtenberg</surname>
      </persName>
    </author>
    <title type="main" level="m">Lower Umpqua Texts</title>
    <imprint>
      <pubPlace>New York</pubPlace>
      <publisher>Columbia University Press</publisher>
      <date>1914</date>
    </imprint>
  </monogr>
  <series>
    <title type="main" level="s">Columbia University Contributions to Anthropology</title>
    <biblScope unit="volume">4</biblScope>
  </series>
</biblStruct>
```

Content model

<move> (movement) marks the actual movement of one or more characters. [7.2.4. Stage Directions]

*Module drama — Performance Texts*

*Attributes* `att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.ascribed.directed (@toWhom) (att.ascribed (@who)) att.typed (@type, @subtype)

@type characterizes the movement, for example as an entrance or exit.

Derived from `att.typed`

Status Optional

Datatype `teidata.enumerated`

Suggested values include: entrance character is entering the stage.
exit character is exiting the stage.
onStage character moves on stage

@where specifies the direction of a stage movement.

Status Optional

Datatype 1–∞ occurrences of `teidata.authority` separated by whitespace

Sample values include: L (left) stage left
R (right) stage right

1422
C (center) centre stage

Note Full blocking information will normally require combinations of values, (for example 'UL' for 'upper stage left') and may also require more detailed encoding of speed, direction etc. Full documentation of any coding system used should be provided in the header. URLs may be used as values.

@perf (performance) identifies the performance or performances in which this movement occurred as specified by pointing to one or more <performance> elements.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Member of model.stageLike

1426
Note Although the `<msDesc>` has primarily been designed with a view to encoding manuscript descriptions, it may also be used for other objects such as early printed books, fasicles, epigraphs, or any text-bearing objects that require substantial description. If an object is not text-bearing or the reasons for describing the object is not primarily the textual content, the more general `<object>` may be more suitable.

Example

```xml
<msDesc>
  <msIdentifier>
    <settlement>Oxford</settlement>
    <repository>Bodleian Library</repository>
    <idno type="Bod">MS Poet. Rawl. D. 169.</idno>
  </msIdentifier>
  <msContents>
    <msItem>
      <author>Geoffrey Chaucer</author>
      <title>The Canterbury Tales</title>
    </msItem>
  </msContents>
  <physDesc>
    <objectDesc>
      <p>A parchment codex of 136 folios, measuring approx 28 by 19 inches, and containing 24 quires.</p>
      <p>The pages are margined and ruled throughout.</p>
      <p>Four hands have been identified in the manuscript: the first 44 folios being written in two cursive anglicana scripts, while the remainder is for the most part in a mixed secretary hand.</p>
    </objectDesc>
  </physDesc>
</msDesc>
```

Content model

```xml
<content>
  <sequence>
    <elementRef key="msIdentifier"/>
    <classRef key="model.headLike" minOccurs="0" maxOccurs="unbounded"/>
    <alternate>
      <classRef key="model.pLike" minOccurs="1" maxOccurs="unbounded"/>
      <sequence>
        <elementRef key="msContents" minOccurs="0"/>
        <elementRef key="physDesc" minOccurs="0"/>
        <elementRef key="history" minOccurs="0"/>
        <elementRef key="additional" minOccurs="0"/>
        <alternate>
```
<elementRef key="msPart" minOccurs="0" maxOccurs="unbounded"/>
</alternate>
</sequence>
</sequence>
</content>

Schema Declaration

```xml
<element msDesc
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,

1436
Note As this last example shows, for compatibility reasons the identifier of a manuscript part may be supplied as a simple `<altIdentifier>` rather than using the more structured `<msIdentifier>` element. This usage is however deprecated.

Example

```xml
<msPart>
  <msIdentifier>
    <idno>A</idno>
    <altIdentifier type="catalog">
      <collection>Becker</collection>
      <idno>48, Nr. 145</idno>
    </altIdentifier>
    <altIdentifier type="catalog">
      <collection>Wiener Liste</collection>
      <idno>4°5</idno>
    </altIdentifier>
  </msIdentifier>
  <head>
    <title xml:lang="la">Gregorius: Homiliae in Ezechielem</title>
    <origPlace key="tgn_7008085">Weissenburg (?)</origPlace>
    <origDate notBefore="0801" notAfter="0815">IX. Jh., Anfang</origDate>
  </head>
</msPart>
```

Example

```xml
<msDesc>
  <msIdentifier>
    <settlement>Amiens</settlement>
    <repository>Bibliothèque Municipale</repository>
    <idno>MS 3</idno>
    <msName>Maurdrannus Bible</msName>
  </msIdentifier>
  <msContents>
    <summary xml:lang="lat">Miscellany of various texts; Prudentius, Psychomachia; Physiologus de natura animantium</summary>
    <textLang mainLang="lat">Latin</textLang>
  </msContents>
</msDesc>
```
Content model

```xml
<content>
  <sequence>
    <elementRef key="msIdentifier"/>
    <classRef key="model.headLike"
      minOccurs="0" maxOccurs="unbounded"/>
    <alternate>
      <classRef key="model.pLike"
        minOccurs="1" maxOccurs="unbounded"/>
      <sequence>
        <elementRef key="msContents"
          minOccurs="0"/>
        <elementRef key="physDesc"
          minOccurs="0"/>
        <elementRef key="history" minOccurs="0"/>
        <elementRef key="additional"
          minOccurs="0"/>
        <elementRef key="msPart" minOccurs="0"
          maxOccurs="unbounded"/>
      </sequence>
    </alternate>
  </sequence>
</content>
```

Schema Declaration

```xml
element msPart
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.typed.attributes,
  {
    msIdentifier,
    model.headLike*,
    {
      model.pLike+
      | ( msContents?, physDesc?, history?, additional?, msPart* )
    }
  }
}
```

`<musicNotation>` (music notation) contains description of type of musical notation. [10.7.2. Writing, Decoration, and Other Notations]
Module msdescription — Manuscript Description

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

    att.global.change.attributes,
    att.global.responsibility.attributes,
    att.global.source.attributes,
    att.typed.attributes,
    macro.phraseSeq
}
```

<namespace> (namespace) supplies the formal name of the namespace to which the elements documented by its children belong. [2.3.4. The Tagging Declaration]

Module header — The TEI Header

Attributes

```xml
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))
```

@name specifies the full formal name of the namespace concerned.

Status Required

Datatype teidata.namespace

Example

```xml
<namespace name="http://www.tei-c.org/ns/1.0">
  <tagUsage gi="hi" occurs="28" withId="2"> Used only to mark English words italicized in the copy text </tagUsage>
</namespace>
```

Content model

```xml
<content>
  <elementRef key="tagUsage" minOccurs="1"
```
<nationality> (nationality) contains an informal description of a person’s present or past nationality or citizenship. [15.2.2. The Participant Description]

Module namesdates — Names, Dates, People, and Places

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.datable (@calendar, @period) att.datable.w3c (@when, @notBefore, @notAfter, @from, @to) att.datable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso) att.datable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod) att.editLike (@evidence, @instant) att.naming (@role, @nymRef) (att.canonical (@key, @ref)) att.typed (@type) att.naming

@type characterizes the element in some sense, using any convenient classification scheme or typology.

Derived from att.typed
Status Optional

<node> (node) encodes a node, a possibly labeled point in a graph. [19.1. Graphs and Digraphs]

Module nets — Graphs, Networks, and Trees

Attributes att.global ([@xml:id, @n, [@xml:lang, [@xml:base, [@xml:space] (@rend, [@style, [@rendition])) (att.global.rendition (@rend, [@style, [@rendition])) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, [@resp])) (att.global.source (@source)) (att.typed (@type, [@subtype]))

@type provides a type for a node.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Suggested values include: initial initial node in a transition network

final final node in a transition network

@value provides the value of a node, which is a feature structure or other analytic element.

Status Optional

Datatype teidata.pointer

@adjTo (adjacent to) gives the identifiers of the nodes which are adjacent to the current node.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

@adjFrom (adjacent from) gives the identifiers of the nodes which are adjacent from the current node.

1447
Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

```xml
<graph>
  <node xml:id="gnex31" type="initial">
    <label>1</label>
  </node>
  <node xml:id="gnex32" adjFrom="#gnex31">
    <label>2</label>
  </node>
  <node xml:id="gnex33" adjFrom="#gnex32" adj="#gnex31" type="final">
    <label>3</label>
  </node>
</graph>
```

@adj (adjacent) gives the identifiers of the nodes which are both adjacent to and adjacent from the current node.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

```xml
<graph>
  <node xml:id="gnex41" adj="#gnex42 #gnex43" type="initial">
    <label>1</label>
  </node>
  <node xml:id="gnex42" adjFrom="#gnex41 #gnex43">
    <label>2</label>
  </node>
  <node xml:id="gnex43" adjFrom="#gnex42 #gnex41" type="final">
    <label>3</label>
  </node>
</graph>
```

Note Use this attribute instead of the adjTo and adjFrom attributes when the graph is undirected and vice versa if the graph is directed.

@inDegree gives the in degree of the node, the number of nodes which are adjacent from the given node.

Status Optional

Datatype teidata.count

```xml
<graph>
  <node xml:id="gnex51" adjTo="#gnex52" adj="#gnex53" inDegree="1" type="initial">
    <label>1</label>
  </node>
  <node xml:id="gnex52" adjFrom="#gnex51" adjTo="#gnex53"
```
inDegree="2">
  <label>2</label>
</node>

<node xml:id="gnex53"
  adjFrom="#gnex52"
  adj="#gnex51"
  inDegree="2"
  type="final">
  <label>3</label>
</node>

</graph>

@outDegree gives the out degree of the node, the number of nodes which are adjacent to the given node.

Status Optional

Datatype teidata.count

<graph>
  <node xml:id="gnex61"
    adjTo="#gnex62"
    adj="#gnex63"
    outDegree="2"
    type="initial">
    <label>1</label>
  </node>

  <node xml:id="gnex62"
    adjFrom="#gnex61"
    adjTo="#gnex63"
    outDegree="1">
    <label>2</label>
  </node>

  <node xml:id="gnex63"
    adjFrom="#gnex62"
    adj="#gnex61"
    outDegree="2"
    type="final">
    <label>3</label>
  </node>

</graph>

@degree gives the degree of the node, the number of arcs with which the node is incident.

Status Optional

Datatype teidata.count

<graph>
  <node xml:id="gnex71"
    adjTo="#gnex72"
    adj="#gnex73"
    outDegree="1"
    inDegree="0"
    degree="1"
    type="initial">
    <label>1</label>
  </node>

  <node xml:id="gnex72"
    adjFrom="#gnex71"
    adjTo="#gnex73"
    outDegree="1"
    inDegree="1"
    degree="0">
    <label>2</label>
  </node>

</graph>
Note Use this attribute instead of the inDegree and outDegree attributes when the graph is undirected and vice versa if the graph is directed.

ContainsBy graph

May contain core: label

Note Zero, one, or two children <label> elements may be present. The first occurrence of <label> provides a label for the arc; the second provides a second label for the arc, and should be used if a transducer is being encoded whose actions are associated with nodes rather than with arcs.

Example

```
<node xml:id="t6" type="final" inDegree="2" outDegree="0">
  <label>6</label>
</node>
```

Content model

```
<content>
  <sequence minOccurs="0">
    <elementRef key="label"/>
    <elementRef key="label" minOccurs="0"/>
  </sequence>
</content>
```

Schema Declaration

It is possible to describe the content of the notation using elements from the `model.labelLike` class and it is possible to point to an external representation using elements from `model.ptrLike`. It is possible to specify the location of digital objects representing the notated music in other media such as images or audio-visual files. The encoder's interpretation of the correspondence between the notated music and these digital objects is not encoded explicitly. We recommend the use of graphic and binaryObject mainly as a fallback mechanism when the notated music format is not displayable by the application using the encoding. The alignment of encoded notated music, images carrying the notation, and audio files is a complex matter for which we refer the encoder to other formats and specifications such as MPEG-SMR.

It is also recommended, when useful, to embed XML-based music notation formats, such as the Music Encoding Initiative format as content of `<notatedMusic>` This must be done by means of customization.

Example

```xml
<notatedMusic>
  <ptr target="bar1.xml"/>
  <graphic url="bar1.jpg"/>
  <desc>First bar of Chopin's Scherzo No.3 Op.39</desc>
</notatedMusic>

1454
And yet it is not only in the great line of Italian renaissance art, but even in the painterly <note> place="bottom" type="gloss" resp="#MDMH"> pictures</note>. This word has, in the German, two distinct meanings, one objective, a quality residing in the object, the other subjective, a mode of apprehension and creation. To avoid confusion, they have been distinguished in English as <mentioned> picturesque</mentioned> and <mentioned> painterly</mentioned> respectively.

<note> style of the
Dutch genre painters of the seventeenth century that drapery has this psychological significance.

For this example to be valid, the code MDMH must be defined elsewhere, for example by means of a responsibility statement in the associated TEI header.

Example The global n attribute may be used to supply the symbol or number used to mark the note’s point of attachment in the source text, as in the following example:

Mevorakh b. Saadya's mother, the matriarch of the family during the second half of the eleventh century, <note n="126" anchored="true"> The alleged mention of Judah Nagid's mother in a letter from 1071 is, in fact, a reference to Judah's children; cf. above, nn. 111 and 54. </note> is well known from Geniza documents published by Jacob Mann.

However, if notes are numbered in sequence and their numbering can be reconstructed automatically by processing software, it may well be considered unnecessary to record the note numbers.

<num> (number) contains a number, written in any form. [3.6.3. Numbers and Measures]

Module core — Elements Available in All TEI Documents
Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.ranging (@atLeast, @atMost, @min, @max, @confidence) att.typed (----- , @subtype)
@type indicates the type of numeric value.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Suggested values include: cardinal absolute number, e.g. 21, 21.5

- ordinal ordinal number, e.g. 21st

- fraction fraction, e.g. one half or three-quarters

- percentage a percentage

Note If a different typology is desired, other values can be used for this attribute.

@value supplies the value of the number in standard form.

Status Optional

Datatype teidata.numeric

Values a numeric value.

Note The standard form used is defined by the TEI datatype teidata.numeric.
Content model

<numeric> (numeric value) represents the value part of a feature-value specification which contains a numeric value or range. [18.3. Other Atomic Feature Values]

Module iso-fs — Feature Structures

Attributes att.global (@id, @n, @xml:lang, @xml:base, @xml:space) att.global.rendition (@rend, @style, @rendition) att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) att.global.analytic (@ana) att.global.facs (@facs) att.global.change (@change) att.global.responsibility (@cert, @resp) att.global.source (@source) att.datcat (@datcat, @valueDatcat)

@value supplies a lower bound for the numeric value represented, and also (if max is not supplied) its upper bound.
  Status Required
  Datatype teidata.numeric

@max supplies an upper bound for the numeric value represented.
  Status Optional
  Datatype teidata.numeric

@trunc specifies whether the value represented should be truncated to give an integer value.
  Status Optional
  Datatype teidata.truthValue
Member of model.featureVal.single
May contain Empty element

Note It is an error to supply the max attribute in the absence of a value for the value attribute.

Example

```xml
<numeric value="42"/>
```

This represents the numeric value 42.

Example

```xml
<numeric value="42.45" max="50" trunc="true"/>
```

This represents any of the nine possible integer values between 42 and 50 inclusive. If the trunc attribute had the value FALSE, this example would represent any of the infinite number of numeric values between 42.45 and 50.0

Content model `<content> <empty/></content>`

Schema Declaration

Member of `model.objectLike`

Contained by

namesdates: `listObject` `object`
textcrit: `witness`

May contain
core: `bibl` `biblStruct` `head` `listBibl` `note` `noteGrp` `p`
header: `biblFull`
linking: `ab` `link` `linkGrp`
msdescription: `additional` `history` `msContents` `msDesc` `physDesc`

names: `object` `objectIdentifier`

Note The `<object>` element is a recent addition to the TEI P5 Guidelines as of version 3.5.0 and as such may be more prone to further revision in the next few releases as its use develops. This may be particularly evident where its contents have been borrowed from `<msDesc>` and have yet to be generalized from their use in the context of manuscript descriptions.

The `<object>` element may be used for describing any object, text-bearing or not, though where the textuality of the object is the primary concern or a collection is mostly composed of manuscripts, encoders may prefer the `<msDesc>` element (a more specific form of `<object>`) which may be used not only to describe manuscripts but any form of text-bearing objects such as early printed books.

Example

```xml
<listObject>
  <object xml:id="Alfred_Jewel">
    <objectIdentifier>
      <country>United Kingdom</country>
      <region>Oxfordshire</region>
      <settlement>Oxford</settlement>
      <institution>University of Oxford</institution>
      <repository>Ashmolean Museum</repository>
      <collection>English Treasures</collection>
      <idno type="ashmolean">AN1836p.135.371</idno>
      <idno type="wikipedia">https://en.wikipedia.org/wiki/Alfred_Jewel</idno>
      <objectName>Alfred Jewel</objectName>
    </objectIdentifier>
    <physDesc>
      <p>The Alfred Jewel is about 6.4 cm in length and is made of combination of filigreed <material>gold</material> surrounding a polished teardrop shaped piece of transparent <material>quartz</material>. Underneath the rock crystal is a cloisonné enamel image of a man with ecclesiastical symbols. The sides of the jewel holding the crystal in place contain an openwork inscription saying "AELFRED MEC HEHT GEWYRCAN", meaning 'Alfred ordered me made'. </p>
    </physDesc>
    <history>
      <origin>It is generally accepted that the Alfred Jewel dates from the late 9th Century</origin> and was most likely made in <origPlace>England</origPlace>. </history>
    <provenance when="1693">The jewel was discovered in 1693 at Petherton Park, North Petherton in the English county of Somerset, on land owned by Sir Thomas Wroth. North Petherton is about 8 miles away from Athelney, where King Alfred founded a monastery. </provenance>
    <provenance when="1698">A description of the Alfred Jewel was first
```
published in 1698, in the Philosophical Transactions of the Royal Society. It was bequeathed to Oxford University by Colonel Nathaniel Palmer (c. 1661-1718) and today is in the Ashmolean Museum in Oxford.

The Minster Lovell Jewel is probably the most similar to the Alfred Jewel and was found in Minster Lovell in Oxfordshire and is kept at the Ashmolean Museum.

Example

Mask of Tutankhamun

The back and shoulders of the mask is inscribed with a protective spell in Egyptian hieroglyphs formed of ten vertical and horizontal lines. This spell first appeared on masks in the Middle Kingdom at least 500 years before Tutankhamun, and comes from chapter 151 of the Book of the Dead.

The mask of Tutankhamun is 54cm x 39.3cm x 49cm. It is constructed from two layers of high-karat gold that varies in thickness from 1.5-3mm. It weighs approximately 10.23kg and x-ray crystallography shows that it is composed of two alloys of gold with a lighter 18.4 karat shade being used for the face and neck while a heavier 22.5 karat gold was used for the rest of the mask.

In the mask Tutankhamun wears a nemes headcloth which has the royal insignia of a cobra (Wadjet) and vulture (Nekhbet) on it. These are thought respectively to symbolise
Tutankhamun's rule of both Lower Egypt and Upper Egypt. His ears are pierced for earrings. The mask has rich inlays of coloured glass and gemstones, including lapis lazuli surrounding the eye and eyebrows, quartz for the eyes, obsidian for the pupils. The broad collar is made up of carnelian, feldspar, turquoise, amazonite, faience and other stones.

The mask of Tutankhamun was created in Egypt around 1323 BC. It is a death mask of the 18th-dynasty ancient Egyptian Pharaoh Tutankhamun who reigned 1332–1323 BC.

The mask of Tutankhamun was found in his burial chamber at Theban Necropolis in the Valley of the Kings in 1922. On 28 October 1925 the excavation team led by English archaeologist Howard Carter opened the heavy sarcophagus and three coffins and were the first people in around 3,250 years to see the mask of Tutankhamun.

Carter wrote in his diary: The pins removed, the lid was raised. The penultimate scene was disclosed – a very neatly wrapped mummy of the young king, with golden mask of sad but tranquil expression, symbolizing Osiris – the mask bears that god's attributes, but the likeness is that of Tut.Ankh.Amen – placid and beautiful, with the same features as we find upon his statues and coffins. The mask has fallen slightly back, thus its gaze is straight up to the heavens.

The mask of Tutankhamun was found in his burial chamber at Theban Necropolis in the Valley of the Kings in 1922. On 28 October 1925 the excavation team led by English archaeologist Howard Carter opened the heavy sarcophagus and three coffins and were the first people in around 3,250 years to see the mask of Tutankhamun.

Carter wrote in his diary: The pins removed, the lid was raised. The penultimate scene was disclosed – a very neatly wrapped mummy of the young king, with golden mask of sad but tranquil expression, symbolizing Osiris – the mask bears that god's attributes, but the likeness is that of Tut.Ankh.Amen – placid and beautiful, with the same features as we find upon his statues and coffins. The mask has fallen slightly back, thus its gaze is straight up to the heavens.

The pins removed, the lid was raised. The penultimate scene was disclosed – a very neatly wrapped mummy of the young king, with golden mask of sad but tranquil expression, symbolizing Osiris – the mask bears that god's attributes, but the likeness is that of Tut.Ankh.Amen – placid and beautiful, with the same features as we find upon his statues and coffins. The mask has fallen slightly back, thus its gaze is straight up to the heavens.

When it was discovered in 1925, the 2.5kg narrow gold beard was no longer attached to the mask and was reattached with use of a wooden dowel in 1944. In August 2014 when the mask was removed from its display case for cleaning, the beard fell off again. Those working in the museum unadvisedly used a quick-drying epoxy to attempt to fix it, but left the beard off-centre. The damage was noticed and repaired in January 2015 by a German-Egyptian team who used beeswax, a material known to be used as adhesives by the ancient Egyptians.

```
<objectDesc> (object description) contains a description of the physical components making up the object which is being described. [10.7.1. Object Description]

Module msdescription – Manuscript Description

Attributes
- @form (form) a short project-specific name identifying the physical form of the carrier, for example as a codex, roll, fragment, partial leaf, cutting etc.
- @status (status) Optional
- @datatype leidata.enumerated
- @note Definitions for the terms used may typically be provided by a `<valList>` element in the project schema specification.

Member of model.physDescPart

Contained by msdescription: physDesc

May contain
- core: p
- linking: ab

Example

```xml
<objectDesc form="codex">
  <supportDesc material="mixed">
    <p>Early modern <material>parchment</material> and <material>paper</material>.</p>
  </supportDesc>
  <layoutDesc ruledLines="25 32"/>
</objectDesc>
```

    <objectName>Alfred Jewel</objectName>
</objectIdentifier>
```

Example

1471
Excalibur is the name for the legendary sword of King Arthur, in Welsh it is called Caledfwlch, in Cornish it is called Calesvol, in Breton it is called Kaledvoulc'h, and in Latin it is called Caliburnus.

In some versions Excalibur's blade was engraved with phrases on opposite sides which in translation read:
"Take me up" and "Cast me away" (or similar).

**Status** Optional

**Datatype** 1–∞ occurrences of teidata.enumerated separated by whitespace

**Note** Values for this attribute may be locally defined by a project, using arbitrary keywords such as artist, employer, familyGroup, or politicalParty, each of which should be associated with a definition. Such local definitions will typically be provided by a <desc> for each <valItem> element in the schema specification of the project’s customization.

}
```

<orig> (original form) contains a reading which is marked as following the original, rather than being normalized or corrected. [3.5.2. Regularization and Normalization [12. Critical Apparatus]}

Module core — Elements Available in All TEI Documents

Attributes att.global (@xml:id, @n, @xml:lang, @xml-base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synchronized, @sameAs, @copyOf, @next, @prev, @exclude, @select))
Example If all that is desired is to call attention to the original version in the copy text, `<orig>` may be used alone:

```xml
<l>But this will be a `<orig>meere</orig>` confusion</l>
<l>And hardly shall we all be `<orig>vnderstoode</orig>`</l>
```

Example More usually, an `<orig>` will be combined with a regularized form within a `<choice>` element:

```xml
<l>But this will be a `<choice>`
   `<orig>meere</orig>`
   `<reg>mere</reg>`
   `<choice>` confusion`</l>
<l>And hardly shall we all be `<choice>`
   `<orig>vnderstoode</orig>`
   `<reg>understood</reg>`
   `<choice>`
   `</choice>`
</l>
```

Content model

```xml
<content>
   <macroRef key="macro.paraContent"/>
</content>
```

Schema Declaration

```xml
element orig
{
   att.global.attributes,
   att.global.rendition.attributes,

<outputRendition> describes the rendering or appearance intended for all occurrences of an element in a specified context for a specified type of output.

### Module: tagdocs — Documentation Elements

#### Attributes

- `att.global(@xml:id, @n, @xml:lang, @xml:base, @xml:space)`
- `att.global.rendition(@rend, @style, @rendition)`
- `att.global.linking(@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)`
- `att.global.analytic(@ana)`
- `att.global.facs(@facs)`
- `att.global.change(@change)`
- `att.global.responsibility(@cert, @resp)`
- `att.global.source(@source)`

#### @scope

Provides a way of defining 'pseudo-elements', that is, styling rules applicable to specific sub-portions of an element.

- **Status**: Optional
- **Datatype**: `teidata.enumerated`

#### Sample values include:

- **first-line**: Styling applies to the first line of the target element.
- **first-letter**: Styling applies to the first character of the target element.
- **before**: Styling should be applied immediately before the content of the target element.
- **after**: Styling should be applied immediately after the content of the target element.

### Member of: model.oddDecl

- **textcrit**: `lem rdg witness`

1498
May contain  Character data only

Note  This component of an element specification describes the rendering or appearance intended for all
occurrences of the element in a specified context for a specified type of output. The <rendition> element,
by contrast, describes the actual rendering or appearance of all occurrences of the specified element in a
source document. The useSourceRendition attribute may however be used to indicate that formatting
information provided by a <rendition> element is to be combined with any provided by an
$outputRendition$ element.

It is strongly recommended that the W3C Cascading Stylesheet language (CSS2 or later) be used to
express the required formatting information.

Example

```xml
<model predicate="ancestor::p"
    behaviour="inline">
  <outputRendition>font-style: italic;</outputRendition>
</model>

<model behaviour="block">
  <outputRendition>left-margin: 2em;</outputRendition>
</model>
```

Content model  

```

character data

Example

1500
Hallgerd was outside. "There is blood on your axe," she said. "What have you done?"

I have now arranged that you can be married a second time," replied Thjostolf.

Then you must mean that Thorvald is dead," she said.

Yes," said Thjostolf. "And now you must think up some plan for me."
The TEI Guidelines

(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@name a name for the parameter being supplied

  Status Required
  Datatype leidata.enumerated
  Suggested values include: alternate when used with behaviour alternate, a parameter of this name supplies one of the pair of possible values; for example the regularized form rather than the original form within a <choice> element.
  default when used with behaviour alternate, a parameter of this name supplies one of the pair of possible values; for example the original form rather than the regularized form within a <choice> element.
  height when used with behaviour graphic, a parameter of this name supplies a value for the height of the graphic e.g. "300px", "50%".
  id a parameter of this name should supply a unique identifier for the element being processed; as for example with the anchor behaviour
  label a parameter of this name should supply an expression to be used to label something, for example concat('Page ', @n) for a page break or @n for a footnote reference; typically used with the note or break behaviours
  level when used with the heading behaviour, a parameter of this name supplies a positive integer indicating the hierarchic level of a heading.
  link when used with the link behaviour, a parameter of this name should supply a URL to be used as the target of a link.
  place when used with the note behaviour, a parameter of this name should provide a string which describes the intended placement of some text; typical values include "margin", "footnote", "endnote", "inline", "bottom"
  type a parameter of this name can be used to categorize the specified behaviour in any way; for example the kind of break (when used with the break behaviour) or the kind of index to be generated (if used with the index behaviour) etc.
  url when used with behaviour graphic, a parameter of this name supplies a URL indicating the graphic intended.
  width when used with behaviour graphic, a parameter of this name supplies a value for the width of the graphic e.g. "400px", "70%".

@value supplies an XPath expression which when evaluated provides the value for the parameter

  Status Required
  Datatype leidata.xpath

Contained types: model

May contain Empty element

Note An implementation may require parameters other than those listed here, and is not required to follow this partial specification.

  The names and datatypes of the expected parameters should be documented in the corresponding customization using a <paramSpec> element. Literal strings provided in an XPath expression should be quoted.

Example In this example, which will be processed for a <choice> element which has both <sic> and <corr> child elements, the default parameter will provide the value of the child <corr> element, and the alternate parameter will provide that of the child <sic> elements. If neither <param> element was supplied, both elements would still be available to an application, but the application would need to distinguish them for itself.
<paramList>

<elementSpec ident="choice">
  <model predicate="sic and corr"
            behaviour="alternate">
    <param name="default" value="corr"/>
    <param name="alternate" value="sic"/>
  </model>
</elementSpec>

Example

<elementSpec ident="graphic" mode="change">
  <model behaviour="graphic">
    <param name="url" value="@url"/>
    <param name="width" value="@width"/>
    <param name="height" value="@height"/>
  </model>
</elementSpec>

Content model  
<content>  <empty/> </content>

Schema Declaration

```
<element param {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute name
  {
    "alternate"
    | "default"
    | "height"
    | "id"
    | "label"
    | "level"
    | "link"
    | "place"
    | "type"
    | "url"
    | "width"
  },
  attribute value { text },
  empty
}
```

<paramList> list of parameter specifications

Module tagdocs — Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
The TEI Guidelines

contained by tagdocs: valItem
may contain tagdocs: paramSpec

note The <paramList> element provides a mechanism to document parameter specifications using child <paramSpec> elements.

example

```xml
<valItem ident="alternate">
  <desc versionDate="2015-08-21" xml:lang="en">create a specialized display of alternating elements for displaying the preferred version and an alternative, both at once or by some method of toggling between the two.</desc>
  <paramList>
    <paramSpec ident="default">
      <desc>preferred content</desc>
    </paramSpec>
    <paramSpec ident="alternate">
      <desc>alternate content</desc>
    </paramSpec>
  </paramList>
</valItem>
```

content model

```xml
<content>
  <elementRef minOccurs="0" maxOccurs="unbounded" key="paramSpec"/>
</content>
```

schema declaration

```xml
element paramList
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  paramSpec*
}
```

<paramSpec> supplies specification for one parameter of a model behaviour [22.5.4.8. Defining a processing model]

module tagdocs — Documentation Elements

attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) att.global.rendition (@rend, @style, @rendition) att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)
Note Where a model behaviour uses more than one parameter, individual `<paramSpec>` elements should be grouped together using a `<paramList>` element, as above. Parameter specifications are provided within the `<valItem>` used to define a particular behaviour, which forms part of the specification of a `<model>` element’s `behaviour` attribute. In the example above, the behaviour `link` has two parameters: content and link.

Using a `<desc>` element within a `<paramSpec>` is optional but recommended practice.

Example

```
<valItem ident="link">
  <desc>create a hyperlink</desc>
  <paramList>
    <paramSpec ident="content">
      <desc>supplies the location of some content describing the link</desc>
    </paramSpec>
    <paramSpec ident="link">
      <desc>supplies the location of the intended URL</desc>
    </paramSpec>
  </paramList>
</valItem>
```

Content model

```
<content>
  <alternate minOccurs="0" maxOccurs="unbounded">
    <classRef key="model.glossLike"/>
    <classRef key="model.descLike"/>
  </alternate>
</content>
```

Schema Declaration

```xml
element paramSpec
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.identified.attributes,
  att.combinable.attributes,
  att.deprecated.attributes,
  (model.glossLike | model.descLike)*)
}
```
<particDesc> (participation description) describes the identifiable speakers, voices, or other participants in any kind of text or other persons named or otherwise referred to in a text, edition, or metadata. [15.2 Contextual Information]

Module corpus — Language Corpora

Attributes att.global (@xml:id, @p, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.declarable (@default)

Member of model.profileDescPart

Contained by

header: profileDesc

May contain

core: p

linking: ab

namesdates: listOrg listPerson org person personGrp

Note May contain a prose description organized as paragraphs, or a structured list of persons and person groups, with an optional formal specification of any relationships amongst them.

Example

<particDesc>
  <listPerson>
    <person xml:id="P-1234" sex="2" age="mid">
    </person>
    <person xml:id="P-4332" sex="1">
      <persName>
        <surname>Hancock</surname>
        <forename>Antony</forename>
        <forename>Aloysius</forename>
        <forename>St John</forename>
      </persName>
      <residence notAfter="1959">
        <street>Railway Cuttings</street>
        <settlement>East Cheam</settlement>
      </residence>
      <occupation>comedian</occupation>
    </person>
  </listPerson>
</particDesc>

This example shows both a very simple person description, and a very detailed one, using some of the more specialized elements from the module for Names and Dates.

Content model
<path>

(path) defines any line passing through two or more points within a <surface> element.  

Attributes  att.global (@xmlns, @n, @xml:lang, @xml:base, @xml:space)  
att.global.rendition (@rend, @style,  
@rendition))  
att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))  
att.global.facs (@facs))  
att.global.change (@change))  
att.global.responsibility (@cert, @resp))  
att.global.source (@source))  
att.typed (@type, @subtype)  
att.written (@hand)  
att.coordinated (@points, @start, @ulx, @uly, @lrx, @lry)  

@points identifies a line within the container or bounding box specified by the parent element by means of a series of two or more pairs of numbers, each of which gives the x,y coordinates of a point on the line.  
Derived from att.coordinated  
Status Optional  
Datatype 2–∞ occurrences of teidata.point separated by whitespace  

Member of model.linePart  
Contained by transcr: line surface zone  
May contain Empty element  

Note Although the simplest form of a path is a straight line between two points, a line with more than two points may bend at any point. The order of coordinates in points is significant, because the line follows the coordinate sequence.  

1507
To specify a closed polygon, use the `<zone>` element rather than the `<path>` element.

Example

```<surface ulx="0" uly="0" lrx="443" lry="272">
    <graphic url="facs-fig3.jpg"/>
    <path points="74,73 171,244"/>
    <path points="71,203 173,116"/>
</surface>```

Schematron `<sch:rule context="tei:path[@points]"> <!-- For a <path> element, we should ensure that the last coordinate does not repeat the first coordinate, otherwise we have a closed polygon, not a path. -->
    <sch:let name="firstPair" value="tokenize( normalize-space( @points ), ', ')[1]"/>
    <sch:let name="lastPair" value="tokenize( normalize-space( @points ), ', ')[last()]"/>
    <sch:let name="firstX" value="xs:float( substring-before( $firstPair, ',' ) )"/>
    <sch:let name="firstY" value="xs:float( substring-before( $firstPair, ',' ) )"/>
    <sch:let name="lastX" value="xs:float( substring-before( $lastPair, ',' ) )"/>
    <sch:let name="lastY" value="xs:float( substring-after( $lastPair, ',' ) )"/>
    <sch:report test="$firstX eq $lastX and $firstY eq $lastY">The first and last elements of this path are the same. To specify a closed polygon, use the zone element rather than the path element. </sch:report>
</sch:rule>```

Content model `<content> <empty/></content>`

Schema Declaration

```
<element path>
  {  
    att.global.attributes, 
    att.global.rendition.attributes, 
    att.global.linking.attributes, 
    att.global.analytic.attributes,

    att.global.source.attributes, 
    att.typed.attributes, 
    att.written.attributes, 
    att.coordinated.attribute.start, 
    att.coordinated.attribute.ulx, 
    att.coordinated.attribute.uly, 
    att.coordinated.attribute.lrx, 
    att.coordinated.attribute.lry, 
    attribute points { list { * } },
    empty
  }
```

**<pause>** (pause) marks a pause either between or within utterances. [8.3.2. Pausing]

**Module** spoken — Transcriptions of Speech

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.timed (@start, @end) att.duration (att.duration.w3c (@dur)) (att.duration.iso (@dur-iso)) att.typed (@type, @subtype) att.ascribed.directed (@toWhom) att.ascribed (@who))

**Member of** model.global.spoken

**Contained by**

1508
May contain Empty element

Note A \texttt{pb} element should appear at the start of the page which it identifies. The global \texttt{n} attribute indicates the number or other value associated with this page. This will normally be the page number or signature printed on it, since the physical sequence number is implicit in the presence of the \texttt{pb} element itself.

The \texttt{type} attribute may be used to characterize the page break in any respect. The more specialized attributes \texttt{break, ed, or edRef} should be preferred when the intent is to indicate whether or not the page break is word-breaking, or to note the source from which it derives.

Example Page numbers may vary in different editions of a text.

\begin{verbatim}
<p> ... <pb n="145" ed="ed2"/>
<!-- Page 145 in edition "ed2" starts here --> ... <pb n="283" ed="ed1"/>
<!-- Page 283 in edition "ed1" starts here--> ... </p>
\end{verbatim}

Example A page break may be associated with a facsimile image of the page it introduces by means of the \texttt{facs} attribute

\begin{verbatim}
<body>
<pb n="1" facs="page1.png"/>
<!-- page1.png contains an image of the page; the text it contains is encoded here -->
<p>
<!-- ... -->
</p>
<pb n="2" facs="page2.png"/>
<!-- similarly, for page 2 -->
<p>
<!-- ... -->
</p>
</body>
\end{verbatim}

Content model \texttt{<content> <empty/></content>}

Schema Declaration

```
<element pb {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.typed.attributes,
  att.edition.attributes,
  att.spanning.attributes,
  att.breaking.attributes,
  empty
}
```

\texttt{<pc>} (punctuation character) contains a character or string of characters regarded as constituting a single punctuation mark. [[17.1.2. Below the Word Level [17.4.2. Lightweight Linguistic Annotation]]

Module analysis — [Simple Analytic Mechanisms]
Attributes

- **@force** indicates the extent to which this punctuation mark conventionally separates words or phrases.
  - **Status**: Optional
  - **Datatype**: teidata.enumerated
  - **Legal values**:
    - **strong**: the punctuation mark is a word separator
    - **weak**: the punctuation mark is not a word separator
  - **@unit** provides a name for the kind of unit delimited by this punctuation mark.
    - **Status**: Optional
    - **Datatype**: teidata.enumerated
  - **@pre** indicates whether this punctuation mark precedes or follows the unit it delimits.
    - **Status**: Optional
    - **Datatype**: teidata.truthValue

<person> (person) provides information about an identifiable individual, for example a participant in a language interaction, or a person referred to in a historical source. [13.3.2. The Person Element | 15.2.2. The Participant]

Module namesdates — Names, Dates, People, and Places
Attributes att.global (@xml:id, @n, @xml:lang, @xml-base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global/linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global/analytic (@ana)) (att.global/facs (@facs)) (att.global/change (@change)) (att.global/responsibility (@cert, @resp)) (att.global/source (@source)) att.editLike (@evidence, @instant) att.sortable (@sortKey)

@role specifies a primary role or classification for the person.
Status Optional
Datatype 1–∞ occurrences of teidata.enumerated separated by whitespace
Note Values for this attribute may be locally defined by a project, using arbitrary keywords such as artist, employer, author, relative, or servant, each of which should be associated with a definition. Such local definitions will typically be provided by a <valList> element in the project schema specification.

@sex specifies the sex of the person.
Status Optional
Datatype 1–∞ occurrences of teidata.sex separated by whitespace
Note Values for this attribute may be locally defined by a project, or may refer to an external standard, such as vCard’s sex property http://microformats.org/wiki/gender-formats (in which M indicates male, F female, O other, N none or not applicable, U unknown), or the often used ISO 5218:2004 Representation of Human Sexes http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266_ISO_IEC_5218_2004(E_F).zip (in which 0 indicates unknown; 1 male; 2 female; and 9 not applicable, although the ISO standard is widely considered inadequate); cf. CETH’s Recommendations for Inclusive Data Collection of Trans People http://transhealth.ucsf.edu/trans?page=lib-data-collection.

@age specifies an age group for the person.
Status Optional
Datatype teidata.enumerated
Note Values for this attribute may be locally defined by a project, using arbitrary keywords such as infant, child, teen, adult, or senior, each of which should be associated with a definition. Such local definitions will typically be provided by a <valList> element in the project schema specification.
Content model

- `att.global.responsibility` (@cert, @resp)
- `att.global.source` (@source)
- `att.editLike` (@evidence, @instant)
- `att.sortable` (@sortKey)

**@role** specifies a primary role or classification for the persona.

- **Status**: Optional
- **Datatype**: 1–∞ occurrences of `teidata.enumerated` separated by whitespace
- **Note**: Values for this attribute may be locally defined by a project, using arbitrary keywords such as artist, employer, author, relative, or servant, each of which should be associated with a definition. Such local definitions will typically be provided by a `<valList>` element in the project schema specification.

**@sex** specifies the sex of the persona.

- **Status**: Optional
- **Datatype**: 1–∞ occurrences of `teidata.sex` separated by whitespace
- **Note**: Values for this attribute may be locally defined by a project, or may refer to an external standard, such as vCard’s sex property [http://microformats.org/wiki/gender-formats](http://microformats.org/wiki/gender-formats) (in which M indicates male, F female, O other, N none or not applicable, U unknown), or the often used ISO 5218:2004 Representation of Human Sexes [http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266_ISO_IEC_5218_2004(E_F).zip](http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266_ISO_IEC_5218_2004(E_F).zip) (in which 0 indicates unknown; 1 male; 2 female; and 9 not applicable, although the ISO standard is widely considered inadequate); cf. CETH’s Recommendations for Inclusive Data Collection of Trans People [http://transhealth.ucsf.edu/trans?page=lib-data-collection](http://transhealth.ucsf.edu/trans?page=lib-data-collection).

1522
@age specifies an age group for the persona.

Status Optional

Datatype leidata.enumerated

Note Values for this attribute may be locally defined by a project, using arbitrary keywords such as infant, child, teen, adult, or senior, each of which should be associated with a definition. Such local definitions will typically be provided by a <valList> element in the project schema specification.

Note Note that a persona is not the same as a role. A role may be assumed by different people on different occasions, whereas a persona is unique to a particular person, even though it may resemble others. Similarly, when an actor takes on or enacts the role of a historical person, they do not thereby acquire a new persona.

Example

```xml
<person sex="M" age="adult">
  <persona sex="M">
    <persName>Dr Henry Jekyll</persName>
  </persona>
  <persona sex="M" age="youth">
    <persName>Edward Hyde</persName>
  </persona>
</person>
```

}

<personGrp> (personal group) describes a group of individuals treated as a single person for analytic purposes. [15.2.2. The Participant Description]

Module namesdates — Names, Dates, People, and Places

Attributes
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.sortable (@sortKey)

@role specifies the role of this group of participants in the interaction.
Status Optional
Datatype teidata.enumerated

Note Values for this attribute may be locally defined by a project, using arbitrary keywords such as movement, employers, relatives, or servants, each of which should be associated with a definition. Such local definitions will typically be provided by a <valList> element in the project schema specification.

@sex specifies the sex of the participant group.
Status Optional
Datatype 1–∞ occurrences of teidata.sex separated by whitespace

Note Values for this attribute may be locally defined by a project, or may refer to an external standard, such as vCard’s sex property http://microformats.org/wiki/gender-formats (in which M indicates male, F female, O other, N none or not applicable, U unknown), or the often used ISO 5218:2004 Representation of Human Sexes http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266_ISO_IEC_5218_2004(E_F).zip (in which 0 indicates unknown; 1 male; 2 female; and 9 not applicable, although the ISO standard is widely considered inadequate); cf. CETH’s Recommendations for Inclusive Data Collection of Trans People http://transhealth.ucsf.edu/trans?page=lib-data-collection For a mixed group, a value such as “mixed” may also be supplied.

1524
@age specifies the age group of the participants.
Status  Optional
Datatype  leidata.enumerated
Note  Values for this attribute may be locally defined by a project, using arbitrary
keywords such as infant, child, teen, adult, or senior, each of which should be
associated with a definition. Such local definitions will typically be provided by a
<valList> element in the project schema specification.

@size describes informally the size or approximate size of the group for example by means of a
number and an indication of accuracy e.g. approx 200.
Status  Optional
Datatype  1–∞ occurrences of leidata.word separated by whitespace

Member of  model.personLike

```
<persPronouns> (personal pronouns) indicates the personal pronouns used, or assumed to be used, by the individual being described. [13.3.2.1. Personal Characteristics]

Module namesdates — Names, Dates, People, and Places
Attributes att.global (@xml:id, @n, @xml:lang, @xml-base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.datable (@calendar, @period) (att.datable.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.datable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.datable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod)) att.typed (@type, @subtype)
@evidence (evidence) indicates support for the listed personal pronouns.
Status Recommended
Datatype teidata.enumerated
Suggested values include: conjecture (conjecture) The given value was selected based on assumptions by someone besides the person to whom this pronoun applies. As a result, the value may be erroneous.
selfIdentification (self identification) The given value has been explicitly stated or confirmed by the person to whom this pronoun applies.
trustedThirdParty (trusted third party) The given value has been supplied by another individual trusted by the encoder to know the preferences of the person to whom this pronoun applies.
@value (value) supplies a regularized value for personal pronouns.
Status Recommended
Datatype 1–∞ occurrences of teidata.enumerated separated by whitespace
Sample values include: e (e) e/eirs
he (he) he/him/his
she (she) she/her/hers
they (they) they/them/their
Note: The sample values list shown here is intended to be reflective of English usage. There is nothing restricting users from defining lists reflective of other languages, e.g. elle, il, and ils.

</content>
```
<pRef> (pronunciation reference) in a dictionary example, indicates a reference to the pronunciation(s) of the headword. [9.4. Headword and Pronunciation References]</p>
<prefixDef> (prefix definition) defines a prefixing scheme used in teidata pointer values, showing how abbreviated URIs using the scheme may be expanded into full URIs. [16.2.3. Using Abbreviated Pointers]

Module header — The TEI Header
Attributes

@att.global[@xml:id, @n, @xml:lang, @xml:base, @xml:space] (@att.global.rendition[@rend, @style, @rendition]) (@att.global.linking[@corresp, @synchrony, @sameAs, @copyOf, @next, @prev, @exclude, @select]) (@att.global.analytic[@ana]) (@att.global.facs[@facs]) (@att.global.change[@change]) (@att.global.responsibility[@cert, @resp]) (@att.global.source[@source]) @att.patternReplacement[@matchPattern, @replacementPattern]

@ident supplies a name which functions as the prefix for an abbreviated pointing scheme such as a private URI scheme. The prefix constitutes the text preceding the first colon.

Status Required
Datatype teidata.prefix

Note The value is limited to teidata.prefix so that it may be mapped directly to a URI prefix.

Contained by listPrefixDef

May contain core: p linking: ab

Note The abbreviated pointer may be dereferenced to produce either an absolute or a relative URI reference. In the latter case it is combined with the value of xml:base in force at the place where the pointing attribute occurs to form an absolute URI in the usual manner as prescribed by XML Base.

Example

```xml
<prefixDef ident="ref" matchPattern="([a-z]+)" replacementPattern="../../references/references.xml#$1">
  <p>In the context of this project, private URIs with the prefix "ref" point to <gi>div</gi> elements in the project's global references.xml file.</p>
</prefixDef>
```

Content model

```xml
<content>
  <classRef key="model.pLike" minOccurs="0" maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```xml
element prefixDef
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.patternReplacement.attributes,
  attribute ident { text },
  model.pLike*
}
```
<preparedness> (preparedness) describes the extent to which a text may be regarded as prepared or spontaneous. [15.2.1. The Text Description]

Module corpus – Language Corpora

Attributes att.global (@xml:id, @n, @xml:lang, @xml-base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype)

@type a keyword characterizing the type of preparedness.
- Derived from att.typed
- Status Optional
- Datatype teidata.enumerated

Sample values include: none spontaneous or unprepared
- scripted follows a script
- formulaic follows a predefined set of conventions
- revised polished or revised before presentation

The TEI Guidelines

<publicationStmt> (publication statement) groups information concerning the publication or distribution of an electronic or other text. [2.2.4. Publication, Distribution, Licensing, etc. 2.2. The File Description]

Module header — The TEI Header

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by header: biblFull fileDesc

May contain core: address date ptr pubPlace publisher ref

header: authority availability distributor idno

linking: ab

Note Where a publication statement contains several members of the model.publicationStmtPart.agency or model.publicationStmtPart.detail classes rather than one or more paragraphs or anonymous blocks, care should be taken to ensure that the repeated elements are presented in a meaningful order. It is a conformance requirement that elements supplying information about publication place, address, identifier, availability, and date be given following the name of the publisher, distributor, or authority concerned, and preferably in that order.

Example

```xml
<publicationStmt>
  <publisher>C. Muquardt</publisher>
  <pubPlace>Bruxelles & Leipzig</pubPlace>
  <date when="1846"/>
</publicationStmt>
```

Example

```xml
<publicationStmt>
  <publisher>Chadwyck Healey</publisher>
  <pubPlace>Cambridge</pubPlace>
  <availability>
    <p>Available under licence only</p>
  </availability>
  <date when="1992">1992</date>
</publicationStmt>
```

Example

```xml
<publicationStmt>
  <publisher>Zea Books</publisher>
  <pubPlace>Lincoln, NE</pubPlace>
  <date>2017</date>
  <availability>
    <p>This is an open access work licensed under a Creative Commons Attribution 4.0 International license.</p>
  </availability>
```

<punctuation>

 specifies editorial practice adopted with respect to punctuation marks in the original. [2.3.3]

 Module header – The TEI Header

 Attributes att.declarable (@default) att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)
  (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
  (att.global.analytic (@ana)) (att.global.facs (@facs))
  (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

 @marks indicates whether or not punctuation marks have been retained as content within the text.
 Status Optional
 Datatype teidata.enumerated
 Legal values are: none no punctuation marks have been retained
 some some punctuation marks have been retained
 all all punctuation marks have been retained

 @placement indicates the positioning of punctuation marks that are associated with marked up text as being encoded within the element surrounding the text or immediately before or after it.
 Status Optional
 Datatype teidata.enumerated
 Legal values are: internal punctuation marks found at the start or end of a marked up text component are included within its surrounding element;
 external punctuation marks found at the start or end of a marked up text component appear immediately before or after the surrounding element

 Member of model.editorialDeclPart
 Contained by
 header: editorialDecl
May contain core: \[ p \]
linking: \[ ab \]

Example

```xml
<punctuation marks="all"
placement="internal">
  <p>
  All punctuation marks in the source text have been retained and represented using the appropriate Unicode code point. In cases where a punctuation mark and nearby markup convey the same information (for example, a sentence ends with a question mark and is also tagged as <gi>s</gi>) the punctuation mark is captured as content within the element.</p>
</punctuation>
```

Example  External placement of punctuation:

```xml
<p>
  I would agree with Saint Augustine that “<em>"An unjust law is no law at all."</em>”
</p>
```

Example  Internal placement of punctuation:

```xml
<p>
  I would agree with Saint Augustine that <em>“An unjust law is no law at all.”</em>
</p>
```

Content model

```xml
<content>
  <classRef key="model.pLike" minOccurs="0"
    maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```xml
element punctuation
{
  att.declarable.attributes,

  model.pLike*
}
```

<purpose> characterizes a single purpose or communicative function of the text. [15.2.1. The Text Description]
Module corpus — Language Corpora

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (type, @subtype)

@type specifies a particular kind of purpose.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Suggested values include: persuade didactic, advertising, propaganda, etc.

express self expression, confessional, etc.

inform convey information, educate, etc.

entertain amuse, entertain, etc.

@degree specifies the extent to which this purpose predominates.

Status Optional

Datatype teidata.certainty

Note Values should be interpreted as follows.

high this purpose is predominant

medium this purpose is intermediate

low this purpose is weak

unknown extent unknown

Contained by: textDesc

  att.typed.attribute.subtype,
  attribute type { "persuade" | "express" | "inform" | "entertain" }?,
  attribute degree { text }?,
  macro.phraseSeq.limited}
```

<q> (quoted) contains material which is distinguished from the surrounding text using quotation marks or a similar method, for any one of a variety of reasons including, but not limited to: direct speech or thought, technical terms or jargon, authorial distance, quotations from elsewhere, and passages that are mentioned but not used. [3.3.3. Quotation]

Module core — Elements Available in All TEI Documents

Attributes

| att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) | att.global.rendition (@rend, @style, @rendition) | att.global.linking (@corresp, @synchrony, @sameAs, @copyOf, @next, @prev, @exclude, @select) | att.global.facs (@facs) | att.global.change (@change) | att.global.responsibility (@cert, @response) | att.global.source (@source) | att.ascribed.directed (@toWhom) | att.ascribed (@who) |
|---|---|---|---|---|---|---|---|
| @type (type) may be used to indicate whether the offset passage is spoken or thought, or to characterize it more finely. |
| Status | Optional |
| Datatype | teidata.enumerated |

Suggested values include: spoken (spoken) representation of speech

| thought (thought) representation of thought, e.g. internal monologue |
| written (written) quotation from a written source |
| soCalled (so called) authorial distance |
| foreign (foreign) |
| distinct (distinct) linguistically distinct |
| term technical term |
| emph (emph) rhetorically emphasized |
| mentioned (mentioned) referring to itself, not its normal referent |

Member of model.common model.hiLike
May be used to indicate that a passage is distinguished from the surrounding text for reasons concerning which no claim is made. When used in this manner, \<q>\> may be thought of as syntactic sugar for \<hi>\> with a value of rend that indicates the use of such mechanisms as quotation marks.

Example

It is spelled \<q>Tübingen</q> — to enter the letter \<q>u</q> with an umlaut hold down the \<q>option</q> key and press \<q>0 0 f c</q>.
<quotation> (quotation) specifies editorial practice adopted with respect to quotation marks in the original.

[2.3.3. The Editorial Practices Declaration [15.3.2. Declarable Elements]]

Module header — The TEI Header

Attributes
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.declarable (@default)

@marks (quotation marks) indicates whether or not quotation marks have been retained as content within the text.
Status Optional
Datatype teidata.enumerated
Legal values are:
none no quotation marks have been retained
some some quotation marks have been retained
all all quotation marks have been retained

Member of model.editorialDeclPart
Contained by
header: editorialDecl

May contain
core: p
linking: ab

Example

<quotation marks="none">
  <p>No quotation marks have been retained. Instead, the <att>rend</att> attribute on the <gi>q</gi> element is used to specify what kinds of quotation mark was used, according to the following list: <list type="gloss">
    <item>double quotes, open and close</item>
    <item>single quotes, open and close</item>
    <item>long dash open, no close</item>
    <item>double guillemets, open and close</item>
  </list>
</p>
</quotation>

Example

<quotation marks="all">
  <p>All quotation marks are retained in the text and are represented by appropriate Unicode characters.</p>
</quotation>

Schematron  <s:report test="not(@marks) and not(tei:p)">On <s:name/>, either the @marks attribute should be used, or a paragraph of description provided.</s:report>

Content model
<quote>(quotation) contains a phrase or passage attributed by the narrator or author to some agency external to the text. [3.3.3. Quotation 4.3.1. Grouped Texts]

<rdgGrp> (reading group) within a textual variation, groups two or more readings perceived to have a genetic relationship or other affinity. [12.1. The Apparatus Entry, Readings, and Witnesses]

Module textcrit — Critical Apparatus

Attributes
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) att.global.rendition (@rend, @style, @rendition) att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) att.global.analytic (@ana) att.global.facs (@facs) att.global.change (@change) att.global.responsibility (@cert, @resp) att.global.source (@source) att.textCritical (@type, @cause, @varSeq, @require) att.written (@hand)

Contained by
textcrit: app rdgGrp

May contain
core: note noteGrp
textcrit: lem rdg rdgGrp wit witDetail

Note
May contain readings and nested reading groups.

Usually, only one <lem> element should appear within a single apparatus entry, whether it appears outside a <rdgGrp> element or within it.
Example

```xml
<app>
  <lem wit="#El #Ra2">though</lem>
  <rdgGrp type="orthographic">
    <rdg wit="#Hg">thogh</rdg>
    <rdg wit="#La">thouhe</rdg>
  </rdgGrp>
</app>
```

Schematron: `<sch:assert test="count(tei:lem) < 2"> Only one <lem> element may appear within a <rdgGrp></sch:assert>`

Content model

```xml
<content>
  <sequence>
    <elementRef key="lem" minOccurs="0"/>
    <alternate maxOccurs="unbounded" minOccurs="0">
      <classRef key="model.rdgLike"/>
      <classRef key="model.noteLike"/>
      <elementRef key="witDetail"/>
      <elementRef key="wit"/>
      <elementRef key="rdgGrp"/>
    </alternate>
  </sequence>
</content>
```

Schema Declaration

```xml
element rdgGrp
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.textCritical.attributes,
  att.written.attributes,
  ( lem?, ( model.rdgLike | model.noteLike | witDetail | wit | rdgGrp )* )
}
```

<re> (related entry) contains a dictionary entry for a lexical item related to the headword, such as a compound phrase or derived form, embedded inside a larger entry. [9.3.6. Related Entries]

Module dictionaries — Dictionaries

\texttt{verse: caesura rhyme} 

\texttt{character data} 

\textbf{Note} May contain character data mixed with any other elements defined in the dictionary tag set.

Identical in sub-elements to an \texttt{<entry>} tag, and used where a dictionary has embedded information inside one entry which could have formed a separate entry. Some authorities distinguish related entries, run-on entries, and various other types of degenerate entries; no such typology is attempted here.

\textbf{Example} The following example from \textit{Webster’s New Collegiate Dictionary} (Springfield, Mass.: G. & C. Merriam Company, 1975) shows a single related entry for which no definition is given, since its meaning is held to be readily derivable from the root entry:

\begin{verbatim}
<entry>
  <form>
    <orth>neu·ral</orth>
    <pron>’n(y)ūr-əl</pron>
  </form>
  <gramGrp>
    <pos>adj</pos>
  </gramGrp>
  <sense n="1">
    <def>of, relating to, or affecting a nerve or the nervous system</def>
  </sense>
  <sense n="2"> ... </sense>
  <re>
    ... 
  </re>
</entry>
\end{verbatim}
Example  The following example from Diccionario de la Universidad de Chicago Inglés-Español y Español-Inglés / The University of Chicago Spanish Dictionary, Fourth Edition, compiled by Carlos Castillo and Otto F. Bond (Chicago: University of Chicago Press, 1987) shows a number of related entries embedded in the main entry. The original entry resembles the following:

abeja [a·bé·xa] f. bee; abejera [a·be·xé·ra] f. beehive; abejón [a·be·xóon] m. drone; bumblebee; abejorro [a·be·xó·rro] m. bumble bee.

One encoding for this entry would be:
Example In the much larger Simon & Schuster Spanish-English dictionary (*Tana de Gámez, ed., Simon and Schuster’s International Dictionary* (New York: Simon and Schuster, 1973)) these derived forms of *abeja* are treated as separate main entries, but there are other embedded phrases shown as <re> in its main entry for *abeja*:

*abeja*, f. 1. (ento.) bee. 2. busy bee, hard worker. 3. (astron.) *A.*, *Musca*. — a. albanila, mason bee; a. carpintera, carpenter bee; a. reina or maestra, queen bee; a. neutra or obrera, worker bee.

This entry may be encoded thus:
Content model

}
```

<refsDecl> (references declaration) specifies how canonical references are constructed for this text. [2.3.6.3. Milestone Method 2.3. The Encoding Description 2.3.6. The Reference System Declaration]

Module header — The TEI Header

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synchron, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.declarable (@default)

Member of model.encodingDescPart

Contained by header: encodingDesc

May contain

core: P

header: cRefPattern citeStructure refState

linking: ab
Example

```xml
<refsDecl>
</refsDecl>
```

This example is a formal representation for the referencing scheme described informally in the following example.

Example

```xml
<refsDecl>
  <p>References are made up by concatenating the value for the <att>n</att> attribute on the highest level <gi>div</gi> element, followed by a space, followed by the sequential number of the next level <gi>div</gi> followed by a colon followed by the sequential number of the next (and lowest) level <gi>div</gi>.</p>
</refsDecl>
```

Content model

```xml
<content>
  <alternate>
    <classRef key="model.pLike" minOccurs="1" maxOccurs="unbounded"/>
    <elementRef key="citeStructure" minOccurs="1" maxOccurs="unbounded"/>
    <elementRef key="cRefPattern" minOccurs="1" maxOccurs="unbounded"/>
    <elementRef key="refState" minOccurs="1" maxOccurs="unbounded"/>
  </alternate>
</content>
```

Schema Declaration

```xml
element refsDecl
{
  att.global.attributes, 
  att.global.rendition.attributes, 
  att.global.linking.attributes, 
  att.global.analytic.attributes, 
  att.global.facs.attributes, 
  att.global.change.attributes, 
  att.global.responsibility.attributes, 
  att.global.source.attributes, 
  att.declarable.attributes, 
  ( model.pLike+ | citeStructure+ | cRefPattern+ | refState+ )
}
```

<refState> (reference state) specifies one component of a canonical reference defined by the milestone method. [2.3.6.3. Milestone Method 2.3.6. The Reference System Declaration]
Attributes  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.milestoneUnit (@unit) att.edition (@ed, @edRef)

@length specifies the fixed length of the reference component.

Status  Optional

Datatype  teidata.count

Note  When constructing a reference, if the reference component found is of numeric type, the length is made up by inserting leading zeros; if it is not, by inserting trailing blanks. In either case, reference components are truncated if necessary at the right hand side.

When seeking a reference, the length indicates the number of characters which should be compared. Values longer than this will be regarded as matching, if they start correctly. If no value is provided, the length is unlimited and goes to the next delimiter or to the end of the value.

@delim (delimiter) supplies a delimiting string following the reference component.

Status  Optional

Datatype  teidata.text

Contained by:  refsDecl

May contain  Empty element

Example

```xml
<refState unit="book" delim=":"/>
<refState unit="line" length="4"/>
```

Content model  <content>  <empty/></content>

Schema Declaration

```xml
element refState
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.milestoneUnit.attributes,
  att.edition.attributes,
  attribute length { text }?,
  attribute delim { text }?,
  empty
}
```

<reg> (regularization) contains a reading which has been regularized or normalized in some sense. [3.5.2 Regularization and Normalization] [12. Critical Apparatus]

Module  core — Elements Available in All TEI Documents

Attributes  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
The TEI Guidelines
If all that is desired is to call attention to the fact that the copy text has been regularized, `<reg>` may be used alone:

```
<q>Please <reg>knock</reg> if an <reg>answer</reg> is <reg>required</reg></q>
```

It is also possible to identify the individual responsible for the regularization, and, using the `<choice>` and `<orig>` elements, to provide both the original and regularized readings:

```
<q>Please <choice>
  <reg resp="#LB">knock</reg>
  <orig>cnk</orig>
</choice> if an <choice>
  <reg>answer</reg>
  <orig>nsr</orig>
</choice> is <choice>
  <reg>required</reg>
  <orig>reqd</orig>
</choice>
</q>
```

Content model

```
<content>
  <macroRef key="macro.paraContent"/>
</content>
```

Schema Declaration

```xml
element reg
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.editLike.attributes,
  att.typed.attributes,
  macro.typed.attributes,
  macro.paraContent}
```
<region> contains the name of an administrative unit such as a state, province, or county, larger than a settlement, but smaller than a country. [13.2.3. Place Names]

Module namesdates — Names, Dates, People, and Places

<relation> (relationship) describes any kind of relationship or linkage amongst a specified group of places, events, persons, objects or other items. [13.3.2.3. Personal Relationships]

Module names dates — Names, Dates, People, and Places

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition) (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@una)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility) (@vert, @resp)) (att.global.source (@source)) att.datable (@calendar, @period) att.datable.w3c (@when, @notBefore, @notAfter, @from, @to)) att.datable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.datable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod)) att.editLike (@evidence, @instant) att.canonical (@key, @ref) att.sortable (@sortKey) att.typed (@type, @subtype)

@name supplies a name for the kind of relationship of which this is an instance.

Status Optional

Datatype teidata.enumerated

@active identifies the ‘active’ participants in a non-mutual relationship, or all the participants in a mutual one.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace
@mutual supplies a list of participants amongst all of whom the relationship holds equally.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

@passive identifies the ‘passive’ participants in a non-mutual relationship.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Contained by [listBib]

namesdates: [listEvent | listNym | listObject | listOrg | listPerson | listPlace | listRelation]

May contain core: desc

Note Only one of the attributes active and mutual may be supplied; the attribute passive may be supplied only if the attribute active is supplied. Not all of these constraints can be enforced in all schema languages.

Example

<relation type="social" name="supervisor"
active="#p1" passive="#p2 #p3 #p4"/>

This indicates that the person with identifier p1 is supervisor of persons p2, p3, and p4.

Example

<relation type="personal" name="friends"
mutual="#p2 #p3 #p4"/>

This indicates that p2, p3, and p4 are all friends.

Example

<relation type="CRM"
name="P89_falls_within"
active="http://id.clarosnet.org/places/metamorphoses/place/italy-orvieto"
passive="http://id.clarosnet.org/places/metamorphoses/country/IT"/>

This indicates that there is a relation, defined by CIDOC CRM, between two resources identified by URLs.

Example

<relation resp="http://viaf.org/viaf/44335536/
ref="http://purl.org/saws/ontology#isVariantOf"

This example records a relationship, defined by the SAWS ontology, between a passage of text identified by a CTS URN, and a variant passage of text in the Perseus Digital Library, and assigns the identification of the relationship to a particular editor (all using resolvable URIs).

Schematron <s:assert test="@ref or @key or @name">One of the attributes 'name', 'ref' or 'key' must be supplied</s:assert>

Schematron <!-- Note: this constraint is pointless in RELAX NG land, where the org=choice works. It is useful in DTD land, where the attList/@org has no effect. It looks to me like it is useful in W3C XML Schema land, too, which I find suprising, as I thought XSD could express a disjuntion like that w/o difficulty. (But I may be reading the XSD incorrectly.) -- Syd, 2018-05-01 --> <s:report test="@active and @mutual">Only one of the attributes @active and @mutual may be supplied</s:report>

Schematron <s:report test="@passive and not(@active)">the attribute 'passive' may be supplied only if the attribute 'active' is supplied</s:report>

<rendition>
  (rendition) supplies information about the rendition or appearance of one or more elements in
  the source text. [2.3.4. The Tagging Declaration]
</rendition>
```

Module header — The TEI Header

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style,
                    @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
(att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility
                    (@cert, @resp)) (att.global.source (@source)) att.styleDef (@scheme, @schemeVersion)
@scope where CSS is used, provides a way of defining 'pseudo-elements', that is, styling rules
  applicable to specific sub-portions of an element.
Status Optional
Datatype leidata.enumerated
Sample values include: first-line styling applies to the first line of the target element
first-letter styling applies to the first letter of the target element
before styling should be applied immediately before the content of the target element
after styling should be applied immediately after the content of the target element
@selector contains a selector or series of selectors specifying the elements to which the
  contained styled description applies, expressed in the language specified in the scheme attribute.
Status Optional
Note: Since the default value of the `scheme` attribute is assumed to
be CSS, the default expectation for this attribute, in the
absence of `scheme`, is that CSS selector syntax will be used.
While `rendition` is used to point from an element in the
transcribed source to a `<rendition>` element in the header which
describes how it appears, the `selector` attribute allows the
encoder to point in the other direction: from a `<rendition>` in
the header to a collection of elements which all share the same
renditional features. In both cases, the intention is to record
the appearance of the source text, not to prescribe any
particular output rendering.

Example:

```xml
<tagsDecl>
  <rendition xml:id="r-center" scheme="css">text-align: center;</rendition>
  <rendition xml:id="r-small" scheme="css">font-size: small;</rendition>
  <rendition xml:id="r-large" scheme="css">font-size: large;</rendition>

<residence>

(residence) describes a person’s present or past places of residence. [15.2.2. The Participant Description]

Module namesdates — Names, Dates, People, and Places

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.datable (@calendar, @period) att.datable.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.datable.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.datable.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod)) att.editLike (@evidence, @instant) att.naming (@role, @nymRef) (att.canonical (@key, @ref)) att.typed (type, @subtype)

@type characterizes the element in some sense, using any convenient classification scheme or typology.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Sample values include: primary

Example

<msIdentifier>
  <settlement>Oxford</settlement>
  <institution>University of Oxford</institution>
  <repository>Bodleian Library</repository>
  <idno>MS. Bodley 406</idno>
</msIdentifier>

Note  The attribute ref, inherited from the class att.canonical may be used to indicate the kind of responsibility in a normalized form by referring directly to a standardized list of responsibility types, such as that maintained by a naming authority, for example the list maintained at http://www.loc.gov/marc/relators/relacode.html for bibliographic usage.

Example

```xml
<respStmt>
  <resp ref="http://id.loc.gov/vocabulary/relators/com.html">compiler</resp>
  <name>Edward Child</name>
</respStmt>
```

Content model

```xml

  att.global.source.attributes,
  att.canonical.attributes,
  att.observable.attributes,
  att.observable.w3c.attributes,
  att.observable.iso.attributes,
  att.observable.custom.attributes,
  macro.phraseSeq.limited
}
```

<resp> (responsibility) identifies the individual(s) responsible for some aspect of the content or markup of particular element(s).  [21.3. Attribution of Responsibility]

Module certainty — Certainty, Precision, and Responsibility

Attributes  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.scoping (@target, @match)
@locus indicates the specific aspect of the encoding (markup or content) for which responsibility is being assigned.

**Status** Required

**Datatype** 1–∞ occurrences of teidata.enumerated separated by whitespace

**Legal values are:**

- **name** responsibility is being assigned concerning the name of the element or attribute used.
- **start** responsibility is being assigned concerning the start of the element concerned.
- **end** responsibility is being assigned concerning the end of the element concerned.
- **location** responsibility is being assigned concerning the location of the element concerned.
- **value** responsibility is being assigned concerning the content (for an element) or the value (for an attribute)

**Member of** model.certLike model.global.meta

May contain

**certainty:** certainty precision respons
The <resp> element is designed for cases in which fine-grained information about specific aspects of the markup of a text is desirable for whatever reason. Global responsibility for certain aspects of markup is usually more simply indicated in the TEI header, using the <respStmt> element within the title statement, edition statement, or change log.

Example

```xml
<resp target="#p1" locus="name location" resp="#encoder1"/>
<resp target="#p2" match="@rend" locus="value" resp="#encoder2"/>
<list type="encoders">
  <item xml:id="encoder1"/>
  <item xml:id="encoder2"/>
</list>
```

Example In this (partially fictional) example the entire document was transcribed and encoded by a single encoder, except for one passage which was transcribed and encoded by the proofreader.

```xml
<!-- in the <teiHeader>: -->
<respStmt xml:id="enc01">
  <name>C. Colin Backslash</name>
  <resp>transcription</resp>
  <resp>encoding</resp>
</respStmt>
<respStmt xml:id="prf01">
  <name>Erin Spelling</name>
  <resp>proofreading</resp>
</respStmt>
<!-- in the <text>: -->
<p>Θερινὴ τροπή
  <lb/>
  <foreign xml:lang="hbo" xml:id="mp0a8">[]</foreign>
</p>
<!-- elsewhere: -->
<respons target="#mp0a8" locus="name value" resp="#prf01"/>
```

Example In this (partially fictional) example an initial encoder (‘across.dta’) encoded most of the document; a later encoder (‘rcapolung.ewo’) encoded a particular passage; and a third encoder (‘sbauman.emt’) fixed some of that encoding.

```xml
<!-- in the <teiHeader>: --><respStmt xml:id="enc03">
  <persName ref="../contextual/persons.xml#across.dta"/>
  <resp>encoding</resp>
</respStmt>
<respStmt xml:id="sgrp05">
  <spGrp rend="braced(atonce1)" xml:id="sgrp05">
    <sp who="#mo">
      <speaker rend="align(left)slant(italic)"
        sql:lang="en">Mor</speaker>.
    </sp>
    <p rend="break(no)">So, so, so!</p>
```
<sp who="#hg">
  <speaker rend="align(left)slant(italic)"
    persName="Mr. H"></persName>
  <p rend="break(no)">What, without my Leave!</p>
</sp>

<sp who="#la">
  <speaker rend="align(left)slant(italic)"
    persName="Lady D"></persName>
  <p rend="break(no)">Amazing!</p>
</sp>

<spGrp>
  <stage rend="align(right)slant(italic)"
    type="delivery" xml:id="atonce1">All together.</stage>
</spGrp>

<desc>
  Ashley did not know what to do with this; I have decided it
  best fits as a braced <spGrp></spGrp>
</desc>

<desc>
  fixed <att rend>attributes</att></desc>
</respons>

Content model

  {
    list { ( "name" | "start" | "end" | "location" | "value" )+ } }
}
(m model.descLike | model.certLike )*
```
<respStmt> (statement of responsibility) supplies a statement of responsibility for the intellectual content of a text, edition, recording, or series, where the specialized elements for authors, editors, etc. do not suffice or do not apply. May also be used to encode information about individuals or organizations which have played a role in the production or distribution of a bibliographic work. 

Module core — Elements Available in All TEI Documents

Multiple retraces are indicated by nesting one <retrace> within another. In principle, a retrace differs from a substitution in that second and subsequent retraces do not materially alter the content of an element. Where minor changes have been made during the retracing action however these may be marked up using <del>, <add>, etc. with an appropriate value for the change attribute.

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype)

@label provides a label (usually a single letter) to identify which part of a rhyme scheme this rhyming string instantiates.

Status Recommended

Datatype teidata.word

Note Within a particular scope, all `<rhyme>` elements with the same value for their label attribute are assumed to rhyme with each other. The scope is defined by the nearest ancestor element for which the rhyme attribute has been supplied.

A `<roleName>` may be distinguished from an `<addName>` by virtue of the fact that, like a title, it typically exists independently of its holder.

Example

```xml
<persName>
  <forename>William</forename>
  <surname>Poulteny</surname>
  <roleName>Earl of Bath</roleName>
</persName>
```

Example
The <roleName role="#solicitor_general">S.G.</roleName> is the only national public official, including the Supreme Court justices, required by statute to be “learned in the law.”

Example

<p>
<persName ref="#NJF">Solicitor General</persName> Noel J. Francisco representing the administration, asserted in rebuttal that there was nothing to disavow (...)
<persName ref="#NJF">Francisco</persName> had violated the scrupulous standard of candor about the facts and the law that <roleName role="#solicitor_general">S.G.s</roleName>, in Republican and Democratic administrations alike, have repeatedly said they must honor.
</p>

The TEI Guidelines

**Datatype**  `teidata.pointer`

@children identifies the elements which are the children of the root node.

**Status** Required

**Datatype** 1–∞ occurrences of `teidata.pointer` separated by whitespace

**Note** If the root has no children (i.e., the tree is 'trivial'), then the `children` attribute should be omitted.

@ord (ordered) indicates whether or not the root is ordered.

**Status** Optional

**Datatype**  `teidata.xTruthValue`

**Note** The value true indicates that the children of the root are ordered, whereas false indicates the are unordered.

Use if and only if `ord` is specified as partial on the `<tree>` element and the root has more than one child.

@outDegree gives the out degree of the root, the number of its children.

**Status** Optional

**Datatype**  `teidata.count`

**Note** The in degree of the root is always 0.

**Contained by** `<tree>`

**May contain** `<core>`

**Example**

```xml
<root xml:id="vp1" children="#vb1 #pn1"
outDegree="2">
  <label>VP</label>
</root>
<leaf xml:id="vb1"/>
<leaf xml:id="pn1"/>
```

**Content model**

```xml
<content>
  <elementRef key="label" minOccurs="0"/>
</content>
```

**Schema Declaration**

```xml
element root {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute value { text }?,
  attribute children { list { + } },
  attribute ord { text }?,
  attribute outDegree { text }?,
```
(row) contains one row of a table. [14.1.1. TEI Tables]

Module figures — Tables, Formulas, Graphics, and Notated Music

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) att.global.rendition (@rend, @style, @rendition) att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) att.global.analytic (@ana) att.global.facs (@facs) att.global.change (@change) att.global.responsibility (@cert, @resp) att.global.source (@source) att.tableDecoration (@role, @rows, @cols)

Contained by figures: table

May contain figures: cell

Example

```xml
<row role="data">
  <cell role="label">Classics</cell>
  <cell>Idle listless and unimproving</cell>
</row>
```

Content model

  att.global.source.attributes,
  att.naming.attributes,
  att.canonical.attributes,
  att.typed.attributes,
  macro.phraseSeq
}
```

(rt) (ruby text) contains a ruby text, an annotation closely associated with a passage of the main text. [3.4.2. Ruby Annotations]

Module core — Elements Available in All TEI Documents

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype) att.placement (@place) att.transcriptional (@status, @cause, @seq) att.editLike (@evidence, @instant) (att.written (@hand))

@target supplies a pointer to the base being glossed by this ruby text.

Status Optional
Datatype leidata.pointer

Schematron Enforce that either target or both from and to (or none) are used, but not target in combination with either from or to. When target is present, neither from nor to should be.

Note Should point to a single <rb> or an element that is inside an <rb>. To refer to multiple elements or text nodes at once use from and to.

@from points to the starting point of the span of text being glossed by this ruby text.

Status Optional

Datatype leidata.pointer

Schematron Enforce the presence of to iff there is a from. When from is present, the to attribute of <sch:name/> is required.

@to points to the ending point of the span of text being glossed.

Status Optional

Datatype leidata.pointer

Schematron Enforce the presence of from iff there is a to.

Note Where the place attribute is not provided on the <rt> element, the default assumption is that the ruby gloss is above where the text is horizontal, and to the right of the text where it is vertical.

Example The word だいとうりょう (president) is glossed character by character in hiragana to provide a pronunciation guide.
<rubric>

Content model

<main-content>

<content>

<macroRef key="macro.phraseSeq"/>
</content>

</main-content>

Schema Declaration

  ( rb, rt+ )
}
```

<s> (s-unit) contains a sentence-like division of a text. [17.1. Linguistic Segment Categories][8.4.1. Segmentation]

Module analysis — Simple Analytic Mechanisms
The TEI Guidelines

Note  The <s> element may be used to mark orthographic sentences, or any other segmentation of a text, provided that the segmentation is end-to-end, complete, and non-nesting. For segmentation which is partial or recursive, the <seg> should be used instead.

The type attribute may be used to indicate the type of segmentation intended, according to any convenient typology.

Example

<s>A short affair</s>
<s>When are you leaving?</s>
<s>Tomorrow.</s>

Schematron  <s:report test="tei:s">You may not nest one s element within another: use seg instead</s:report>

```
<said> (speech or thought) indicates passages thought or spoken aloud, whether explicitly indicated in the source or not, whether directly or indirectly reported, whether by real people or fictional characters. [3.3.3. Quotation]

Module: core — Elements Available in All TEI Documents

Attributes
att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.ascribed.directed (@toWhom) (att.ascribed (@who))

@aloud may be used to indicate whether the quoted matter is regarded as having been vocalized or signed.
Status: Optional
Datatype: teidata.xTruthValue

Default: false

Note: The value true indicates the encoded passage was expressed outwardly (whether spoken, signed, sung, screamed, chanted, etc.); the value false indicates that the encoded passage was thought, but not outwardly expressed.

@direct may be used to indicate whether the quoted matter is regarded as direct or indirect speech.
Status: Optional
Datatype: teidata.xTruthValue

Default: true

Note: The value true indicates the speech or thought is represented directly; the value false that speech or thought is represented indirectly, e.g. by use of a marked verbal aspect.
"Our minstrel here will warm the old man's heart with song, dazzle him with jewels and gold", a troublemaker simpered. "He'll trample on the Duke's camellias, spill his wine, and blunt his sword, and say his name begins with X, and in the end the Duke will say, 'Take Saralinda, with my blessing, O lordly Prince of Rags and Tags, O rider of the sun!'", a troublemaker simpered. "He'll trample on the Duke's camellias, spill his wine, and blunt his sword, and say his name begins with X, and in the end the Duke will say, 'Take Saralinda, with my blessing, O lordly Prince of Rags and Tags, O rider of the sun!'", a troublemaker simpered.

Hmmm, said a small voice in his ear. Difficult. Very difficult. Plenty of courage, I see. Not a bad mind either. there's talent, oh my goodness, yes — and a nice thirst to prove yourself, now that's interesting. ... So where shall I put you?

Harry gripped the edges of the stool and thought, Not Slytherin, not Slytherin.
<salute> (salutation) contains a salutation or greeting prefixed to a foreword, dedicatory epistle, or other division of a text, or the salutation in the closing of a letter, preface, etc. [4.2.2. Openers and Closers]

Note This element records all information about systematic inclusion or omission of portions of the text, whether a reflection of sampling procedures in the pure sense or of systematic omission of material deemed either too difficult to transcribe or not of sufficient interest.

Example

```xml
<samplingDecl>
  <p>Samples of up to 2000 words taken at random from the beginning, middle, or end of each text identified as relevant by respondents.</p>
</samplingDecl>
```

Content model

```xml
<content>
  <classRef key="model.pLike" minOccurs="1" maxOccurs="unbounded"/>
</content>
```
Schema Declaration

```xml
element samplingDecl
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.declarable.attributes,
  model.pLike+
}
```

```xml
<schemaRef>
(schema reference) describes or points to a related customization or schema file [2.3.10. The
Schema Specification]
```

Module header — The TEI Header

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)
(att.global.rendition (@rend, @style, @rendition))
(att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
(att.global.analytic (@ana))
(att.global.facs (@facs))
(att.global.change (@change))

  att.globalResponsibility.attributes,
  att.global.source.attributes,
  att.typed.attributes,
  att.resourced.attributes,
  attribute key { text }?,
  model.descLike?
}
Note Specifications for the `except` attribute of `<anyElement>` RELAX NG validation (unless DTD Compatibility Mode is turned off) requires that any elements which may take an `xml:id` be excluded from the content of `anyName` name classes. For normal TEI purposes, this includes anything in the TEI namespace and the `<egXML>` element. The `defaultExceptions` attribute sets the global defaults for these exclusions. Element prefixes must be declared using a namespace declaration on the parent or an ancestor element.

Member of `model.divPart` `model.encodingDescPart` `model.frontPart`

contained by

Core: `item` `note` `quote` `said` `stage`

Names/Dates: `occupation`

TagDoc: `specGrp`

textCrit: `lem` `rdg`

textStructure: `argument` `back` `body` `div1` `div2` `div3` `div4` `div5` `div6` `div7` `epigraph` `front` `postscript`

transcr: `metamark`

May contain

Core: `desc` `gloss`

TagDoc: `allIdent` `classRef` `classSpec` `constraintSpec` `dataRef` `dataSpec` `elementRef` `elementSpec` `equiv` `listRef` `macroRef` `macroSpec` `moduleRef` `moduleSpec` `outputRendition` `specGrp` `specGrpRef`

Note A `<schemaSpec>` combines references to elements that document a schema with individual specification elements that document a schema to form a unified schema. It should be a child of `<front>`, `<body>`, `<back>`, `<encodingDesc>`, `<div>`, `<div1>`, `<div2>`, `<div3>`, `<div4>`, `<div5>`, `<div6>`, or `<div7>`.

The processing of the `<schemaSpec>` element must resolve any conflicts amongst the declarations it either contains or refers to. Different ODD processors may generate schemas and documentation using different concrete syntaxes.

The source may be specified (on the `source` attribute) in the form of a private URI, for which the recommended format is `tei:x.y.z`, where `x.y.z` indicates the version number, e.g. `tei:1.5.1` for 1.5.1 release of TEI P5 or (as a special case) `tei:current` for whatever is the latest release. The source indicated must provide a set of TEI-conformant specifications in a form directly usable by an ODD processor. By default, this will be the location of the current release of the TEI Guidelines.

Example

```xml
<schemaSpec prefix="TEI_" ident="testsvg"
  start="TEI svg">
  <moduleRef source="tei:current"
    key="header"/>
  <moduleRef source="tei:current"
    key="core"/>
  <moduleRef source="tei:current"
    key="drama"/>
  <moduleRef url="svg11.rng"/>
</schemaSpec>
```

This schema combines elements from the current versions of the drama and core modules, the current release version of the header module, and elements from an existing RELAX NG schema available from the URL indicated.

Example
This schema starts with a pre-existing customization of the TEI called TEI Bare (a customization with a minimal selection of elements). The `<q>` element is not available in TEI Bare, but it can be brought back. In this case, we will get the version defined in TEI P5 release 3.0.0

Schematron enforces the deprecation of `<schemaSpec>` as a child of anything other than `<front>`, `<body>`, `<back>`, `<encodingDesc>`, `<div>`, or any of the numbered division elements. `<sch:rule context="tei:schemaSpec|teix:schemaSpec"> <sch:assert test="parent::teix:egXML | parent::tei:encodingDesc | parent::tei:front | parent::tei:back | parent::tei:body | parent::tei:div | parent::tei:div1 | parent::tei:div2 | parent::tei:div3 | parent::tei:div4 | parent::tei:div5 | parent::tei:div6 | parent::tei:div7" role="nonfatal">WARNING: use of deprecated construct — the "schemaSpec" element will no longer be a valid child of "<sch:value-of select="name(.)"/>" as of 2021-10-23; instead, it should be a child of "front", "body", "back", "encodingDesc", or a division element.</sch:assert> </sch:rule>

Note: The `<seg>` element may be used at the encoder’s discretion to mark any segments of the text of interest for processing. One use of the element is to mark text features for which no appropriate markup is otherwise defined. Another use is to provide an identifier for some segment which is to be pointed at by some other element—i.e., to provide a target, or a part of a target, for a `<ptr>` or other similar element.

Example

```xml
<seg>When are you leaving?</seg>
<seg>Tomorrow.</seg>
```

Example

```xml
<s>
  <seg rend="caps" type="initial-cap">So father's only</seg> glory was the ballfield.
</s>
```

Example

```xml
<seg type="preamble">
  <seg>Sigmund, <seg type="patronym">the son of Volsung</seg>, was a king in Frankish country.</seg>
  <seg>Sinfiotli was the eldest of his sons ...</seg>
  <seg>Borghild, Sigmund's wife, had a brother ...</seg>
</seg>

  att.datcat.attributes,
  att.lexicographic.normalized.attributes,
  attribute level { text }?,
  {
    text
    | model.gLike | sense | model.entryPart.top | model.phrase | model.global
  }
}

<sequence> indicates that the constructs referenced by its children form a sequence [22.5.1. Defining Content Models]

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.repeatable (@minOccurs, @maxOccurs)
@preserveOrder if true, indicates that the order in which component elements of a sequence appear in a document must correspond to the order in which they are given in the content model.

Status Optional

1658
**Datatype** teidata.truthValue

**Member of** model.contentPart

**Contained by**

**tagdocs:** alternate content sequence

**May contain**

**tagdocs:** alternate anyElement classRef dataRef elementRef empty macroRef sequence textNode

**Example**

```xml
<content>
  <sequence>
    <alternate>
      <elementRef key="name"/>
      <elementRef key="persName"/>
    </alternate>
    <elementRef key="placeName" minOccurs="0" maxOccurs="5"/>
  </sequence>
</content>
```

This example content model matches a sequence consisting of either a `<name>` or a `<persName>` followed by nothing, or by a sequence of up to five `<placeName>` elements.

**Schematron** `<sch:assert test="count(*)>1">The sequence element must have at least two child elements</sch:assert>`

<SEX> (sex) specifies the sex of a person. [[13.3.2.1. Personal Characteristics]]

Module names: Dates, People, and Places

Attributes

- `@xml:id` (unique, identifies the element)
- `@n` (name)
- `@xml:lang` (language)
- `@xml:base` (base)
- `@xml:space` (space)
- `@rend` (rendition)
- `@style` (style)
- `@corresp` (correspondence)
- `@synch` (synchronous)
- `@sameAs` (same as)
- `@copyOf` (copy of)
- `@next` (next)
- `@prev` (previous)
- `@exclude` (exclude)
- `@select` (select)
- `@ana` (analytic)
- `@facs` (facs)
- `@change` (change)
- `@cert` (certainty)
- `@resp` (responsibility)
- `@source` (source)
- `@evidence` (evidence)
- `@instant` (instant)
- `@when` (when)
- `@notBefore` (not before)
- `@notAfter` (not after)
- `@from` (from)
- `@to` (to)
- `@when-iso` (when-ISO)
- `@notBefore-iso` (not before-ISO)
- `@notAfter-iso` (not after-ISO)
- `@from-iso` (from-ISO)
- `@to-iso` (to-ISO)
- `@when-custom` (when-custom)
- `@notBefore-custom` (not before-custom)
- `@notAfter-custom` (not after-custom)
- `@from-custom` (from-custom)
- `@to-custom` (to-custom)
- `@datingPoint` (dating point)
- `@datingMethod` (dating method)

@type characterizes the element in some sense, using any convenient classification scheme or typology.

Derived from `att.typed

Status Optional

1668
Datatype: teidata.enumerated

Sample values include: explicit
  implicit

@value supplies a coded value for sex

Status: Optional

Datatype: 1–∞ occurrences of teidata.sex separated by whitespace

Note: Values for this attribute may be locally defined by a project, or may refer to an external standard, such as vCard’s sex property

http://microformats.org/wiki/gender-formats (in which M indicates male, F female, O other, N none or not applicable, U unknown), or the often used ISO 5218:2004 Representation of Human Sexes

http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266_ISO_IEC_5218_2004(E_F).zip (in which 0 indicates unknown; 1 male; 2 female; and 9 not applicable, although the ISO standard is widely considered inadequate); cf. CETH’s Recommendations for Inclusive Data Collection of Trans People

character data

Note: As with other culturally-constructed traits such as age, the way in which this concept is described in different cultural contexts may vary. The normalizing attributes are provided only as an optional means of simplifying that variety to one or more external standards for purposes of interoperability, or project-internal taxonomies for consistency, and should not be used where that is inappropriate or
unhelpful. The content of the element may be used to describe the intended concept in more detail, using plain text.

**Example**

```xml
<sex value="M">male</sex>
```

**Example**

```xml
<sex value="2">female</sex>
```

**Example**

```xml
<sex value="I">Intersex</sex>
```

**Example**

```xml
<sex value="TG F">Female (TransWoman)</sex>
```

**Content model**

```xml
<content>
  <macroRef key="macro.phraseSeq"/>
</content>
```

**Schema Declaration**

```xml
element sex
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.editLike.attributes,
  att.datable.attributes,
  att.datable.w3c.attributes,
  att.datable.iso.attributes,
  att.datable.custom.attributes,
  att.typed.attribute.subtype,
  attribute type { text }?,
  attribute value { list { + } }?,
  macro.phraseSeq}
```

**<shift>** (shift) marks the point at which some paralinguistic feature of a series of utterances by any one speaker changes. \[8.3.6. Shifts\]

**Module** spoken — Transcriptions of Speech

**Attributes**

- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synchrony, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) (att.ascribed (@who))

@feature a paralinguistic feature.
Status Optional
Datatype teidata.enumerated
Suggested values include: tempo speed of utterance.
  loud loudness.
  pitch pitch range.
  tension tension or stress pattern.
  rhythm rhythmic qualities.
  voice voice quality.

@new specifies the new state of the paralinguistic feature specified.
Status Recommended
Datatype teidata.enumerated
Default normal

Note Some possible values for this attribute are provided in section 8.4.2. Synchronization and Overlap. The special value normal should be used to indicate that the feature concerned ceases to be remarkable at this point. In earlier versions of these Guidelines, a null value for this attribute was understood to have the same effect; this practice is now deprecated and will be removed at a future release.
The TEI Guidelines

**Example**

```xml
<u who="#LB">
  <shift feature="loud" new="f"/>Elizabeth
</u>
<u who="#EB">Yes</u>
<u who="#LB">
  <shift feature="loud" new="normal"/>Come and try this
  <pause/>
  <shift feature="loud" new="ff"/>come on
</u>
<!---- ... --->
<listPerson type="speakers">
  <person xml:id="LB"/>
  <person xml:id="EB"/>
</listPerson>
```

The word 'Elizabeth' is spoken loudly, the words 'Yes' and 'Come and try this' with normal volume, and the words 'come on' very loudly.

**Schematron**

```xml
<s:assert test="@new" role="warning"> The @new attribute should always be supplied; use the special value "normal" to indicate that the feature concerned ceases to be remarkable at this point.</s:assert>
```

**Content model**

```xml
<content> <empty/></content>
```

**Schema Declaration**

```xml
element shift {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.ascribed.attributes,
  attribute feature {
    "tempo" | "loud" | "pitch" | "tension" | "rhythm" | "voice"
  },
  attribute new { text },
  empty
}
```

**<sic>** (Latin for thus or so) contains text reproduced although apparently incorrect or inaccurate. [3.5.1. Apparent Errors]

**Module** core – Elements Available in All TEI Documents

Attributes att.global (@xml:id, @n, @xml:lang, @xml-base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
1673
Example

for his nose was as sharp as
a pen, and <sic>a Table</sic> of green fields.

Example

If all that is desired is to call attention to the apparent problem in the copy text, <sic> may be used alone:

I don't know, Juan. It's so far in the past now
– how <sic>we can</sic> prove or disprove anyone's theories?

Example

It is also possible, using the <choice> and <corr> elements, to provide a corrected reading:

I don't know, Juan. It's so far in the past now
– how <choice>
  <sic>we can</sic>
  <corr>can we</corr>
</choice> prove or disprove anyone's theories?

Example

for his nose was as sharp as
a pen, and <choice>
  <sic>a Table</sic>
  <corr>a' babbld</corr>
</choice> of green fields.

  att.global.responsibility.attributes,
  att.global.source.attributes,
  macro.phraseSeq
}
```

<socsecStatus> (socio-economic status) contains an informal description of a person’s perceived social or economic status. [15.2.2. The Participant Description]

Attributes

- `attributes` (att.global)
- `rendition` (att.global.rendition)
- `linking` (att.global.linking)
- `analytic` (att.global.analytic)
- `facs` (att.global.facs)
- `change` (att.global.change)
- `responsibility` (att.global.responsibility)
- `source` (att.global.source)

@type characterizes the element in some sense, using any convenient classification scheme or typology.

- `att.typed`
- `@scheme` identifies the classification system or taxonomy in use, for example by pointing to a locally-defined `<taxonomy>` element or by supplying a URI for an externally-defined system.

@scheme

- teidata.enumerated
- teidata.pointer
@code identifies a status code defined within the classification system or taxonomy defined by the
scheme attribute.

Status Optional

Datatype teidata.pointer

The TEI Guidelines

```xml
<sound>
(sound) describes a sound effect or musical sequence specified within a screen play or radio script.

### 7.3.1. Technical Information

#### 7.3. Other Types of Performance Text

**Module** drama — Performance Texts

**Attributes**
- `att.global` (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))
- `att.typed` (type, @subtype)

- **@type** categorizes the sound in some respect, e.g. as music, special effect, etc.
  - `Derived from` `att.typed`
  - `Status` Optional
  - `Datatype` teidata.enumerated

- **@discrete** indicates whether the sound overlaps the surrounding speeches or interrupts them.
  - `Status` Optional
  - `Datatype` teidata.xTruthValue

- **Note** The value true indicates that the sound is heard between the surrounding speeches; the value false indicates that the sound overlaps one or more of the surrounding speeches.

**Member of** model.stageLike

**Contained by**
- `core`: add, corr, del, desc, emph, head, hi, item, li, meeting, note, orig, p, q, quote, ref, reg, said, sic, sp, stage, title, unclear
- `dictionaries`: case, colloc, def, dictScrap, entryFree, etym, form, gen, gram, gramGrp, hyph, itype, lang, lb, mood, number, orth, per, pos, pron, stress, sub, syll, tns, u, xr
- `drama`: camera, caption, castList, epilogue, performance, prologue, set, sound, spGrp, tech, view
- `figures`: cell, figDesc, figure
- `header`: change, handNote, licence, rendition, scriptNote, tagUsage
- `iso-fs`: fDesc, fsDesc, ...
```

1682
A specialized form of stage direction.

**Example**

```xml
<sp>
  <speaker>Benjy</speaker>
  <p>Now to business.</p>
</sp>

<sp>
  <speaker>Ford and Zaphod</speaker>
  <p>To business.</p>
</sp>
```
Glasses clink.<sound discrete="true">Glasses clink.</sound>

<speaker>Benjy</speaker>
<p>I beg your pardon?</p>

<speaker>Ford</speaker>
<p>I'm sorry, I thought you were proposing a toast.</p>

@synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) att.global.facs (@facs) att.global.change (@change)
att.global.responsibility (@resp) att.global.source (@source)

@resp (responsible party) (responsible party) indicates the individual responsible for identifying
and measuring the space

Derived from att.global.responsibility

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

@dim (dimension) indicates whether the space is horizontal or vertical.
```

<space> (space) indicates the location of a significant space in the text. [11.4.1. Space]
Status  Recommended

Datatype  teidata.enumerated

Legal values are:  horizontal  the space is horizontal.
vertical  the space is vertical.

Note  For irregular shapes in two dimensions, the value for this attribute should reflect the more important of the two dimensions. In conventional left-right scripts, a space with both vertical and horizontal components should be classed as vertical.

<span> associates an interpretative annotation directly with a span of text. [17.3. Spans and Interpretations]

Module analysis – Simple Analytic Mechanisms

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
@type indicates what kind of phenomenon is being noted in the passage.

Status  Recommended

Datatype  leidata.enumerated

Sample values include: image identifies an image in the passage.
character identifies a character associated with the passage.
theme identifies a theme in the passage.
allusion identifies an allusion to another text.

@from gives the identifier of the node which is the starting point of the span of text being annotated; if not accompanied by a to attribute, gives the identifier of the node of the entire span of text being annotated.

Status  Optional

Datatype  leidata.pointer

@to gives the identifier of the node which is the end-point of the span of text being annotated.

Status  Optional

Datatype  leidata.pointer

```

<specDesc> (specification description) indicates that a description of the specified element, class, or macro should be included at this point within a document. [22.1.2. Element and Attribute Descriptions]

Module tagdocs — Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@key (identifier) supplies the identifier of the documentary element or class for which a description is to be obtained.

Status Required

Datatype teidata.name

```
<specDesc key="emph"/>
```

Note The value should match the ident of a documentary element (that is, a member of att.identified).

@atts (attributes) supplies attribute names for which descriptions should additionally be obtained.

Status Recommended

Datatype 0–∞ occurrences of teidata.name separated by whitespace

```
<specDesc key="foreign"
  atts="usage xml:lang"/>
```
Note The attribute names listed may include both attributes inherited from a class and those defined explicitly for the associated element.

tagdocs: classRef classSpec constraintSpec dataRef dataSpec elementRef elementSpec listRef macroRef macroSpec moduleRef moduleSpec outputRendition schemaSpec specGrp specGrpRef

1700
Note A specification group is referenced by means of its xml:id attribute. The declarations it contains may be included in a <schemaSpec> or <moduleSpec> element only by reference (using a <specGrpRef> element): it may not be nested within a <moduleSpec> element.

Different ODD processors may generate representations of the specifications contained by a <specGrp> in different concrete syntaxes.

Example

```xml
<specGrp xml:id="xDAILC">
  <elementSpec ident="s">
    <!-- ... -->
  </elementSpec>
  <elementSpec ident="cl">
    <!-- ... -->
  </elementSpec>
  <elementSpec ident="w">
    <!-- ... -->
  </elementSpec>
  <elementSpec ident="m">
    <!-- ... -->
  </elementSpec>
  <elementSpec ident="c">
    <!-- ... -->
  </elementSpec>
</specGrp>
```

This specification group with identifier xDAILC contains specifications for the elements <s>, <cl>, <w>, etc.

Content model

```xml
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <classRef key="model.oddDecl"/>
    <classRef key="model.oddRef"/>
    <classRef key="model.divPart"/>
  </alternate>
</content>
```

Schema Declaration

```xml
element specGrp
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  ( model.oddDecl | model.oddRef | model.divPart )*`
}
<specGrpRef> (reference to a specification group) indicates that the declarations contained by the <specGrp> referenced should be inserted at this point. [22.2 Modules and Schemas]

Module tagdocs — Documentation Elements

Attributes
att.global (@xmlns, @n, @xml:lang, @xml:base, @xml:space) (att.global rendition (@rend, @style, @rendition)) (att.global linking (@corresp, @synchronise, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global analytic (@ana)) (att.global facets (@facets)) (att.global change (@change)) (att.global responsibility (@certify, @responsibility)) (att.global source (@source))

@target points at the specification group which logically belongs here.

   Status Required
   Datatype teidata.pointer

Member of model.oddDecl

Contained by

May contain Empty element

Note In ODD documentation processing, a <specGrpRef> usually produces a comment indicating that a set of declarations printed in another section will be inserted at this point in the <specGrp> being discussed. In schema processing, the contents of the specified <specGrp> are made available for inclusion in the generated schema.

The specification group identified by the target attribute will normally be part of the current ODD document.

Example

<p>This part of the module contains declarations for names of persons, places, and organisations: <specGrpRef target="#names.pers"/>
<specGrpRef target="#names.place"/>
<specGrpRef target="#names.org"/>
</p>
<specList>

<specGrp xml:id="names.place">

</specGrp>

</specList>

---

<specList> (specification list) marks where a list of descriptions is to be inserted into the prose documentation.

<sponsor> (sponsor) specifies the name of a sponsoring organization or institution. [2.2.1. The Title Statement]

Module header — The TEI Header

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition) (@rend, @style, @rendition) (att.global.linking) (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)
Sponsors give their intellectual authority to a project; they are to be distinguished from funders (see element `<funder>`), who provide the funding but do not necessarily take intellectual responsibility.

Example

```xml
<sponsor>Association for Computers and the Humanities</sponsor>
<sponsor>Association for Computational Linguistics</sponsor>
<sponsor ref="http://www.allc.org/">Association for Literary and Linguistic Computing</sponsor>
```

Content model

```xml
<content>
  <macroRef key="macro.phraseSeq.limited"/>
</content>
```

Schema Declaration

```xml
element sponsor
{
  att.global.attributes,
  att.global.rendition.attributes,
}
<stage> (stage direction) contains any kind of stage direction within a dramatic text or fragment. 

Attributes: 
- att.ascribed.directed (@toWhom) (att.ascribed (@who))
- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))
- att.placement (@place)

@type indicates the kind of stage direction.

Module: core — Elements Available in All TEI Documents

Datatype: 0–∞ occurrences of teidata.enumerated separated by whitespace

Suggested values include: setting describes a setting.
- entrance describes an entrance.
- exit describes an exit.
- business describes stage business.
- novelistic is a narrative, motivating stage direction.
- delivery describes how a character speaks.
- modifier gives some detail about a character.
- location describes a location.
- mixed more than one of the above

Note: If the value mixed is used, it must be the only value. Multiple values may however be supplied if a single stage direction performs multiple functions, for example is both an entrance and a modifier.

character data

Note The who attribute may be used to indicate more precisely the person or persons participating in the action described by the stage direction.

Example

```
<stage type="setting">A curtain being drawn.</stage>
<stage type="setting">Music</stage>
<stage type="entrance">Enter Husband as being thrown off his horse and falls.</stage>
</!-- Middleton : Yorkshire Tragedy -->
<stage type="exit">Exit pursued by a bear.</stage>
<stage type="business">He quickly takes the stone out.</stage>
<stage type="delivery">To Lussurioso.</stage>
```
Having had enough, and embarrassed for the family.

Disguised as Ansaldo.

Enter Latrocinio disguised as an empiric

At a window.

Aside.

Example

Behold. Here the vp<lb/>per part of the <hi>Scene</hi> open'd; when straight appear'd a Heauen, and all the <hi>Pure Artes</hi> sitting on two semi<lb/>circular ben<lb/>ches, one a<lb/>boue another: who sate thus till the rest of the <hi>Prologue</hi> was spoken, which being ended, they descended in order within the <hi>Scene</hi> whiles the Musicke plaid</stag> Our Poet knowing our free hearts

Member of: model.orgStateLike | model.persStateLike | model.placeStateLike

Contained by:

analysis: c|phr|s|pan
Note Where there is confusion between <trait> and <state>, the more general purpose element <state> should be used even for unchanging characteristics. If you wish to distinguish between characteristics that are generally perceived to be time-bound states and those assumed to be fixed traits, then <trait> is available for the more static of these. The <state> element encodes characteristics which are sometimes assumed to change, often at specific times or over a date range, whereas the <trait> elements are used to record characteristics, such as eye-colour, which are less subject to change. Traits are typically, but not necessarily, independent of the volition or action of the holder.

Example

```xml
<state ref="#SCHOL" type="status">
  <label>scholar</label>
</state>
```

Example
<org>
  <orgName notAfter="1960">The Silver Beetles</orgName>
  <orgName notBefore="1960">The Beatles</orgName>
  <state type="membership" from="1960-08" to="1962-05">
    <desc>
      <persName>John Lennon</persName>
      <persName>Paul McCartney</persName>
      <persName>George Harrison</persName>
      <persName>Stuart Sutcliffe</persName>
      <persName>Pete Best</persName>
    </desc>
  </state>
  <state type="membership" notBefore="1963">
    <desc>
      <persName>John Lennon</persName>
      <persName>Paul McCartney</persName>
      <persName>George Harrison</persName>
      <persName>Ringo Starr</persName>
    </desc>
  </state>
</org>

\end{align*}

\text{@attachment} describes the method by which this surface is or was connected to the main surface

\textbf{Status} Optional

\textbf{Datatype} teidata.enumerated

\textbf{Sample values include:}

\begin{itemize}
\item glued glued in place
\item pinned pinned or stapled in place
\item sewn sewn in place
\end{itemize}

\text{@flipping} indicates whether the surface is attached and folded in such a way as to provide two writing surfaces

\textbf{Status} Optional

\textbf{Datatype} teidata.truthValue

\begin{itemize}
\item contains facsimile sourceDoc surface surfaceGrp zone
\item May contain
\item analysis: interp interpGrp span spanGrp
\item certainty: certainty precision respons
\item core: binaryObject ch desc ellipse gap gb graphic index label lb media milestone note noteGrp pb
\item figures: figure formula notatedMusic
\item iso-fs: fLib fs fvLib

\item spoken: incident kinesic pause shift vocal writing
\item textcrit: app witDetail
\item transcr: addSpan damageSpan delSpan fw line listTranspose metamark path space substJoin surface surfaceGrp zone
\end{itemize}

\textbf{Note}

The \texttt{<surface>} element represents any two-dimensional space on some physical surface forming part of the source material, such as a piece of paper, a face of a monument, a billboard, a scroll, a leaf etc.

The coordinate space defined by this element may be thought of as a grid \texttt{lrx - ulx} units wide and \texttt{uly - lry} units high.

The \texttt{<surface>} element may contain graphic representations or transcriptions of written zones, or both. The coordinate values used by every \texttt{<zone>} element contained by this element are to be understood with reference to the same grid.

Where it is useful or meaningful to do so, any grouping of multiple \texttt{<surface>} elements may be indicated using the \texttt{<surfaceGrp>} element.

\textbf{Example}

\begin{verbatim}
<facsimile>
  <surface ulx="0" uly="0" lrx="200" lry="300">
    <graphic url="Bovelles-49r.png"/>
  </surface>
</facsimile>
\end{verbatim}

\textbf{Content model}

\begin{verbatim}
<content>
  <sequence>
    <alternate minOccurs="0" maxOccurs="unbounded"/>
  </sequence>
</content>
\end{verbatim}

1738
<surfaceGrp>

defines any kind of useful grouping of written surfaces, for example the recto and verso of a single leaf, which the encoder wishes to treat as a single unit. [11.1. Digital Facsimiles]

Module transcr — Representation of Primary Sources

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.declaring (@decls) att.typed (@type, @subtype)

Contained by transcr: facsimile sourceDoc surface surfaceGrp

May contain analysis: interp interpGrp span spanGrp
Where it is useful or meaningful to do so, any grouping of multiple <surface> elements may be indicated using the <surfaceGrp> elements.

Example

```xml
<sourceDoc>
  <surfaceGrp>

<symbol> (symbolic value) represents the value part of a feature-value specification which contains one of a finite list of symbols. [18.3. Other Atomic Feature Values]

Module iso-fs — Feature Structures

Attributes att.global ([@xml:id, @n, @xml:lang, @xml:base, @xml:space]) att.global.rendition (@rend, @style, @rendition) att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select) att.global.facs (@facs) att.global.change (@change) att.global.responsibility (@cert, @resp) att.global.source (@source) att.datcat (@datcat, @valueDatcat)

@value supplies a symbolic value for the feature, one of a finite list that may be specified in a feature declaration.

Status Required

Datatype teidata.word
The TEI Guidelines

Member of `model.featureVal.single`

Contained by

`iso-fs:` `fvLib` `vAlt` `vColl` `vDefault` `vLabel` `vMerge` `vNot` `vRange`

May contain Empty element

Example

```xml
<f name="gender">
  <symbol value="feminine"/>
</f>
```

Content model `&lt;content&gt; &lt;empty/&gt;&lt;/content&gt;`

Schema Declaration

```xml
element symbol {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.datcat.attributes,
  attribute value { text },
  empty
}
```

`<table>` (table) contains text displayed in tabular form, in rows and columns. [14.1.1. TEI Tables]

Module figures — Tables, Formulæ, Graphics, and Notated Music

Attributes `att.global` (`@xml:id`, `@n`, `@xml:lang`, `@xml:base`, `@xml:space`) (att.global.rendition (`@rend`, `@style`, `@rendition`)) (att.global.linking (`@corresp`, `@synch`, `@sameAs`, `@copyOf`, `@next`, `@prev`, `@exclude`, `@select`)) (att.global.analytic (`@ana`)) (att.global.facs (`@facs`)) (att.global.change (`@change`)) (att.global.responsibility (`@cert`, `@resp`)) (att.global.source (`@source`)) att.typed (`@type`, `@subtype`) `@rows` (rows) indicates the number of rows in the table.

Status Optional

Datatype `teidata.count`

Note If no number is supplied, an application must calculate the number of rows.

Rows should be presented from top to bottom.

`@cols` (columns) indicates the number of columns in each row of the table.

Status Optional

Datatype `teidata.count`

Note If no number is supplied, an application must calculate the number of columns.

Within each row, columns should be presented left to right.

Member of `model.listLike`

Contained by

core: `add` `corr` `del` `desc` `emph` `head` `hi` `item` `meeting` `note` `orig` `p` `q` `quote` `ref` `reg` `said` `sic` `sp` `stage` `title` `unclear`

**tag** (tag) contains text of a complete start- or end-tag, possibly including attribute specifications, but excluding the opening and closing markup delimiter characters. [22. Documentation Elements]

**Module** tagdocs — Documentation Elements

**Attributes**

- `attr.global` (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (attr.global.rendition (@rend, @style, @rendition)) (attr.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (attr.global.analytic (@ana)) (attr.global.facs (@facs)) (attr.global.change (@change)) (attr.global.responsibility (@cert, @resp)) (attr.global.source (@source)) (att.typed (@type, @subtype))

- `@type` indicates the type of XML tag intended
  - Derived from `att.typed`
  - Status Optional

**Datatype** `teidata.enumerated`

**Legal values are:**
- `start` a start-tag, with delimiters `< and `>` is intended
- `end` an end-tag, with delimiters `</ and `>` is intended
- `empty` an empty tag, with delimiters `< and `>` is intended
- `pi` a pi (processing instruction), with delimiters `<? and `?> is intended
- `comment` a comment, with delimiters `<!– and –> is intended
- `ms` a marked-section, with delimiters `<[CDATA[ and `]]> is intended

- `@scheme` supplies the name of the schema in which this tag is defined.
  - Status Optional

**Datatype** `teidata.enumerated`

**Sample values include:**
- TEI (text encoding initiative) This tag is defined as part of the TEI scheme [Default]
- DBK (docbook) this tag is part of the Docbook scheme.
- XX (unknown) this tag is part of an unknown scheme.
- Schematron
- HTML

**Member of** `model.phrase.xml`

**Contained by**

- `analysis`: clahr, span
- `core`: abbr, add, addrLine, author, biblScope, citedRange, corr, date, desc, distinct, editor, email, emph, expan, foreign, gloss, head, headItem, headLabel, hi, item, l, label, measure, meeting, mentioned, name, note, num, orig, p, pubPlace, publisher, q, quote, rb, ref, reg, resp, rs, rt, said, sic, soCalled, speaker, stage, street, term, textLang, title, unclear, unit
- `corpus`: activity, channel, constitution, derivation, domain, factuality, interaction, locale, preparedness, purpose
- `dictionaries`: case, colloc, def, dictScrap, entryFree, etym, form, gen, gram, gramGrp, hyph, iType, lang, lb, mood, number, orth, per, pos, pron, re, sense, stress, subc, syll, tns, usg, xt
- `drama`: actor, camera, caption, castItem, role, roleDesc, sound, tech, view
- `figures`: cell, figDesc

1751
Mark the start of each italicised phrase with a `<tag type="hi" rend="it">` tag, and its end with a `<tag type="end">hi</tag>` tag.

Example updated on 2008-04-05

Content model `<content> <textNode/></content>`

Schema Declaration

```
<element tag=
{att.global.attributes,
attrib.local.attributes,
att.global.rendition.attributes,
att.global.linking.attributes,
att.global.analytic.attributes,
att.global.facets.attributes,
att.global.change.attributes,
att.global.responsibility.attributes,
att.global.source.attributes,
attrib.typed.attribute.subtype,
attribute type { "start" | "end" | "empty" | "pi" | "comment" | "ms" }?,
attribute scheme { text }?,
text}
```

(tagsDecl) (tagging declaration) provides detailed information about the tagging applied to a document. [2.3.4 The Tagging Declaration 2.3. The Encoding Description]

Module header — The TEI Header

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facets (@facets)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))
@partial indicates whether the element types listed exhaustively include all those found within <text>, or represent only a subset.

**Status** Recommended

**Datatype** teidata.truthValue

**Note** TEI recommended practice is to specify this attribute. When the <tagUsage> elements inside <tagsDecl> are used to list each of the element types in the associated <text>, the value should be given as false. When the <tagUsage> elements inside <tagsDecl> are used to provide usage information or default renditions for only a subset of the elements types within the associated <text>, the value should be true.

**Member of** model.encodingDescPart

**Contained by**
header: encodingDesc

**May contain**
header: namespace rendition

**Example**

```xml
<tagsDecl partial="true">
  <rendition xml:id="rend-it" scheme="css"
    selector="emph, hi, name, title">font-style: italic;</rendition>
  <namespace name="http://www.tei-c.org/ns/1.0">
    <tagUsage gi="hi" occurs="467"/>
    <tagUsage gi="title" occurs="45"/>
  </namespace>
  <namespace name="http://docbook.org/ns/docbook">
    <tagUsage gi="para" occurs="10"/>
  </namespace>
</tagsDecl>
```

If the partial attribute were not specified here, the implication would be that the document in question contains only <hi>, <title>, and <para> elements.

**Content model**

```xml
<content>
  <sequence>
    <elementRef key="rendition" minOccurs="0"
      maxOccurs="unbounded"/>
    <elementRef key="namespace" minOccurs="0"
      maxOccurs="unbounded"/>
  </sequence>
</content>
```

**Schema Declaration**

```xml
element tagsDecl
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute partial { text }?,
}
```
<tagUsage> (element usage) documents the usage of a specific element within a specified document. [2.3.4. The Tagging Declaration]

Module header — The TEI Header

Attributes

@gi (generic identifier) specifies the name (generic identifier) of the element indicated by the tag, within the namespace indicated by the parent <namespace> element.

  Status Required
  Datatype teidata.name

@occurs specifies the number of occurrences of this element within the text.

  Status Recommended
  Datatype teidata.count

@withId (with unique identifier) specifies the number of occurrences of this element within the text which bear a distinct value for the global xml:id attribute.

  Status Recommended
  Datatype teidata.count

1757
<tech> (technical stage direction) describes a special-purpose stage direction that is not meant for the actors.

[7.3.1. Technical Information]

Module drama — Performance Texts

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (type, @subtype)

@type categorizes the technical stage direction.

Derived from att.typed

Status Optional

Datatype teidata.enumerated

Suggested values include: light a lighting cue

sound a sound cue

prop a prop cue

block a blocking instruction

@perf (performance) points to one or more <performance> elements documenting the performance or performances to which this technical direction applies.

Status Optional

Datatype 1–∞ occurrences of teidata.pointer separated by whitespace

Member of model.stageLike
Example
Red spot on his face

Content model

<content>
  <macroRef key="macro.paraContent"/>
</content>

Schema Declaration

element tech {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.typed.attribute.subtype,
  attribute type { "light" | "sound" | "prop" | "block" }?,
  attribute perf { list { + } }?,
  macro.paraContent
}

<TEI> (TEI document) contains a single TEI-conformant document, combining a single TEI header with one or more members of the model.resource class. Multiple <TEI> elements may be combined within a <TEI> (or <teiCorpus>) element. [4. Default Text Structure 15.1. Varieties of Composite Text]

Module textstructure — Default Text Structure

Attributes

att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype)

@version specifies the version number of the TEI Guidelines against which this document is valid.

Status Optional

Datatype teidata.version

Note Major editions of the Guidelines have long been informally referred to by a name made up of the letter P (for Proposal) followed by a digit. The current release is one of the many releases of the fifth major edition of the Guidelines, known as P5. This attribute may be used to associate a TEI document with a specific release of the P5 Guidelines, in the absence of a more precise association provided by the source attribute on the associated <schemaSpec>.

Member of model.describedResource

Contained by

core: teiCorpus
textstructure: TEI

May contain

header: teiHeader
iso-fs: fsdDecl
This element is required. It is customary to specify the TEI namespace http://www.tei-c.org/ns/1.0 on it, using the xmlns attribute.

Example

```xml
<TEI version="3.3.0" xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <fileDesc>
      <titleStmt>
        <title>The shortest TEI Document Imaginable</title>
      </titleStmt>
      <publicationStmt>
        <p>First published as part of TEI P2, this is the P5 version using a name space.</p>
      </publicationStmt>
      <sourceDesc>
        <p>No source: this is an original work.</p>
      </sourceDesc>
    </fileDesc>
    <text>
      <body>This is about the shortest TEI document imaginable.</body>
    </text>
  </teiHeader>
</TEI>
```

Example

```xml
<TEI version="2.9.1" xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader>
    <fileDesc>
      <titleStmt>
        <title>A TEI Document containing four page images</title>
      </titleStmt>
      <publicationStmt>
        <p>Unpublished demonstration file.</p>
      </publicationStmt>
      <sourceDesc>
        <p>No source: this is an original work.</p>
      </sourceDesc>
    </fileDesc>
  </teiHeader>
  <facsimile>
    <graphic url="page1.png"/>
    <graphic url="page2.png"/>
    <graphic url="page3.png"/>
    <graphic url="page4.png"/>
  </facsimile>
</TEI>

    ( teiHeader, ( ( model.resource+, TEI* ) | TEI+ ) )
}

<teiCorpus> (TEI corpus) contains the whole of a TEI encoded corpus, comprising a single corpus header and one or more <TEI> elements, each containing a single text header and a text. [4. Default Text Structure 15.1. Varieties of Composite Text]
Module core — Elements Available in All TEI Documents
Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype)
@version (version) specifies the version number of the TEI Guidelines against which this document is valid.
Status Optional
Datatype teidata.version
Note Major editions of the Guidelines have long been informally referred to by a name made up of the letter P (for Proposal) followed by a digit. The current release is one of the many releases of the fifth major edition of the Guidelines, known as P5. This attribute may be used to associate a TEI document with a specific release of the P5 Guidelines, in the absence of a more precise association provided by the source attribute on the associated <schemaSpec>.
Member of \texttt{model.describedResource}

Contained by
\begin{itemize}
  \item \texttt{teiCorpus}
\end{itemize}

May contain
\begin{itemize}
  \item \texttt{teiCorpus}
  \item \texttt{teiHeader}
  \item \texttt{fsdDecl}
  \item \texttt{standOff}
  \item \texttt{TEI text}
  \item \texttt{facsimile sourceDoc}
\end{itemize}

Note  Should contain one TEI header for the corpus, and a series of \texttt{<TEI>} elements, one for each text.

Example
\begin{verbatim}
<teiCorpus version="3.3.0" xmlns="http://www.tei-c.org/ns/1.0">
  <teiHeader> <!-- header for corpus -->
  </teiHeader>
  <TEI>
    <teiHeader> <!-- header for first text -->
    </teiHeader>
    <text> <!-- content of first text -->
    </text>
    </TEI>
    <teiHeader> <!-- header for second text -->
    </teiHeader>
    <text> <!-- content of second text -->
    </text>
    </TEI>
    <!-- more TEI elements here -->
</teiCorpus>
\end{verbatim}

Content model
\begin{verbatim}
<content>
  <sequence>
    <elementRef key="teiHeader"/>
    <classRef key="model.resource"
      minOccurs="0" maxOccurs="unbounded"/>
    <classRef key="model.describedResource"
      minOccurs="1" maxOccurs="unbounded"/>
  </sequence>
</content>
\end{verbatim}

Schema Declaration
\begin{verbatim}
element teiCorpus
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
}
\end{verbatim}
The TEI Guidelines

att.global.analytic.attributes,
att.global.facs.attributes,
att.global.change.attributes,
att.global.responsibility.attributes,
att.global.source.attributes,
att.typed.attributes,
attribute version { text }?,
( teiHeader, model.resource*, model.describedResource+ )

<teiHeader> (TEI header) supplies descriptive and declarative metadata associated with a digital resource or set of resources. [2.1.1. The TEI Header and Its Components | 15.1. Varieties of Composite Text]

Module header — The TEI Header
Attributes att.global (xhr:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by

</publisherStmt>
<sourceDesc>
<bibl>The first folio of Shakespeare, prepared by Charlton Hinman (The
Originally prepared for use in the production of a series of old-spelling concordances in 1968, this text was extensively checked and revised for use during the editing of the new Oxford Shakespeare (Wells and Taylor, 1989).

Turned letters are silently corrected.

Original spelling and typography is retained, except that long s and ligatured forms are not encoded.

A reference is created by assembling the following, in the reverse order as that listed here:

- the `n` value of the preceding `<gi>lb</gi>`
- a period
- the `n` value of the ancestor `<gi>div2</gi>`
- a space
- the `n` value of the parent `<gi>div1</gi>`
The TEI Guidelines

Schema Declaration

```xml
<element teiHeader
{
att.global.attributes,

When this element appears within an `<index>` element, it is understood to supply the form under which an index entry is to be made for that location. Elsewhere, it is understood simply to indicate that its content is to be regarded as a technical or specialised term. It may be associated with a `<gloss>` element by means of its `ref` attribute; alternatively a `<gloss>` element may point to a `<term>` element by means of its `target` attribute.

In formal terminological work, there is frequently discussion over whether terms must be atomic or may include multi-word lexical items, symbolic designations, or phraseological units. The `<term>` element may be used to mark any of these. No position is taken on the philosophical issue of what a term can be; the looser definition simply allows the `<term>` element to be used by practitioners of any persuasion.

As with other members of the `att.canonical` class, instances of this element occurring in a text may be associated with a canonical definition, either by means of a URI (using the `ref` attribute), or by means of some system-specific code value (using the `key` attribute). Because the mutually exclusive `target`
and cRef attributes overlap with the function of the ref attribute, they are deprecated and may be removed at a subsequent release.

Example

A computational device that infers structure from grammatical strings of words is known as a <term>parser</term>, and much of the history of NLP over the last 20 years has been occupied with the design of parsers.

Example

We may define <term xml:id="TDPV1" rend="sc">discoursal point of view</term> as <gloss target="#TDPV1">the relationship, expressed through discourse structure, between the implied author or some other addressee, and the fiction.</gloss>

Example

We may define <term ref="#TDPV2" rend="sc">discoursal point of view</term> as <gloss xml:id="TDPV2">the relationship, expressed through discourse structure, between the implied author or some other addressee, and the fiction.</gloss>

Example

We discuss Leech's concept of <term ref="myGlossary.xml#TDPV2" rend="sc">discoursal point of view</term> below.

 spoken: incident kinesic pause shift vocal writing

 textcrit: app witDetail

 textstructure: back body front group

 transcr: addSpan damageSpan delSpan fw listTranspose metamark space substJoin

 Note This element should not be used to represent a text which is inserted at an arbitrary point within the structure of another, for example as in an embedded or quoted narrative; the <floatingText> is provided for this purpose.

 Example

```xml
<text>
  <front>
    <docTitle>
      Autumn Haze</docTitle>
    </docTitle>
  </front>
  <body>
    <p>Is it a dragonfly or a maple leaf?</p>
    <p>That settles softly down upon the water?</p>
  </body>
</text>
```

1771
Example  The body of a text may be replaced by a group of nested texts, as in the following schematic:

```
<text>
  <front>
  <!-- front matter for the whole group -->
  </front>
  <group>
    <text>
    <!-- first text -->
    </text>
    <text>
    <!-- second text -->
    </text>
  </group>
</text>
```

Content model

  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.declaring.attributes,
```
<textClass> (text classification) groups information which describes the nature or topic of a text in terms of a standard classification scheme, thesaurus, etc. [2.4.3. The Text Classification]

Module header — The TEI Header
Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.declarable (@default)

Member of model.profileDescPart
Contained by header: profileDesc
May contain header: catRef classCode keywords
Example

<taxonomy>
  <category xml:id="acprose">
    <catDesc>Academic prose</catDesc>
  </category>
</taxonomy>

<textClass>
  <catRef target="#acprose"/>
  <classCode scheme="http://www.udcc.org">001.9</classCode>
  <keywords scheme="http://authorities.loc.gov">
    <list>
      <item>End of the world</item>
      <item>History - philosophy</item>
    </list>
  </keywords>
</textClass>

Content model

<content>
  <alternate minOccurs="0" maxOccurs="unbounded">
    <elementRef key="classCode"/>
    <elementRef key="catRef"/>
    <elementRef key="keywords"/>
  </alternate>
</content>
<textDesc>
  (text description) provides a description of a text in terms of its situational parameters. 

  **Module** corpus — Language Corpora
  Attributes
  \[\text{att.global}(@xml:id, @n, @xml:lang, @xml:base, @xml:space) (\text{att.global.rendition} (@rend, @style, @rendition)) (\text{att.global.linking} (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (\text{att.global.analytic} (@ana)) (\text{att.global.facs} (@facs)) (\text{att.global.change} (@change)) (\text{att.global.responsibility} (@cert, @resp)) (\text{att.global.source} (@source)) \text{att.declarable} (@default)\]

  **Member of** model.catDescPart | model.profileDescPart
  **Contained by**
  header: catDesc | profileDesc
  **May contain**
  corpus: channel | constitution | derivation | domain | factuality | interaction | preparedness | purpose

  **Example**

  ```xml
  <textDesc n="Informal domestic conversation">
    <channel mode="s"/>
    <constitution type="single"/>
    <derivation type="original"/>
    <domain type="domestic"/>
    <factuality type="mixed"/>
    <interaction type="complete"
      active="plural" passive="many"/>
    <preparedness type="spontaneous"/>
    <purpose type="entertain" degree="high"/>
    <purpose type="inform" degree="medium"/>
  </textDesc>
  ```

  **Content model**

  ```xml
  <content>
    <sequence>
      <classRef key="model.textDescPart" expand="sequence"/>
      <elementRef key="purpose" minOccurs="1"
  ```
Schema Declaration

```xml
<textLang>
  element textDesc
  {
    att.global.attributes,
    att.global.rendition.attributes,
    att.global.linking.attributes,
    att.global.analytic.attributes,

    att.global.change.attributes,
    att.global.responsibility.attributes,
    att.global.source.attributes,
    att.declarable.attributes,
    {
      channel,
      constitution,
      derivation,
      domain,
      factuality,
      interaction,
      preparedness,
      purpose+
    }
  }
<textLang>
```

**textDesc** (text language) describes the languages and writing systems identified within the bibliographic work being described, rather than its description. [3.12.2.4. Imprint, Size of a Document, and Reprint Information] [10.6.6. Languages and Writing Systems]

**Module** core — Elements Available in All TEI Documents

**Attributes**
- `att.global` (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (@att.global.rendition (@rend, @style, @rendition)) (@att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (@att.global.analytic (@ana)) (@att.global.facs (@facs)) (@att.global.change (@change)) (@att.global.responsibility (@cert, @resp)) (@att.global.source (@source))
- `@mainLang` (main language) supplies a code which identifies the chief language used in the bibliographic work.
  - **Status** Optional
  - **Datatype** teidata.language
- `@otherLangs` (other languages) one or more codes identifying any other languages used in the bibliographic work.
  - **Status** Optional
  - **Datatype** 0–∞ occurrences of teidata.language separated by whitespace

**Member of** model.biblPart | model.msItemPart
**Contained by**
- core: analytic bibl monogr series
- msdescription: msContents msItem msItemStruct
**May contain**

1775
This element should not be used to document the languages or writing systems used for the bibliographic or manuscript description itself: as for all other TEI elements, such information should be provided by means of the global xml:lang attribute attached to the element containing the description.

In all cases, languages should be identified by means of a standardized ‘language tag’ generated according to BCP 47. Additional documentation for the language may be provided by a <language> element in the TEI header.

Example

```xml
<textLang mainLang="en" otherLangs="la"> Predominantly in English with Latin glosses</textLang>
```

Content model

```xml
<content>
  <macroRef key="macro.phraseSeq"/>
</content>
```
att.global.source.attributes,
attribute mainLang { text }?,
attribute otherLangs { list { * } }?,
macro.phraseSeq}

<textNode> indicates the presence of a text node in a content model [22. Documentation Elements]
Module tagdocs — Documentation Elements
Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Member of model.contentPart
Contained by tagdocs alternate content sequence
May contain Empty element
Example

<content>
<alternate minOccurs="0"
maxOccurs="unbounded">

```

<timeline> (timeline) provides a set of ordered points in time which can be linked to elements of a spoken text to create a temporal alignment of that text. [16.4.2. Placing Synchronous Events in Time]

Module linking – Linking, Segmentation, and Alignment

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))
@origin designates the origin of the timeline, i.e. the time at which it begins.

Status Optional

Datatype leidata.pointer

Note If this attribute is not supplied, the implication is that the time of origin is not known. If it is supplied, it must point either to one of the <when> elements in its content, or to another <timeline> element.

@unit specifies the unit of time corresponding to the interval value of the timeline or of its constituent points in time.

Status Optional

Datatype leidata.enumerated

Suggested values include: d (days)

h (hours)

min (minutes)

s (seconds)

ms (milliseconds)

@interval specifies a time interval either as a positive integral value or using one of a set of predefined codes.

Status Optional

Datatype leidata.interval

Note The value irregular indicates uncertainty about all the intervals in the timeline; the value regular indicates that all the intervals are evenly spaced, but the size of the intervals is not known; numeric values indicate evenly spaced values of the size specified. If individual points in time in the timeline are given different values for the interval attribute, those values locally override the value given in the timeline.

```
<title> (title) contains a title for any kind of work. [3.12.2. Titles, Authors, and Editors | 2.2.1. The Title Statement | 2.2.5. The Series Statement]

Module: core — Elements Available in All TEI Documents

Attributes: att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) (att.canonical (@key, @ref)) (att.datable (@calendar, @period) (@when, @notBefore, @notAfter, @from, @to) (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso) (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @to-custom, @datingMethod))

@type classifies the title according to some convenient typology.

Derived from: att.typed

Status: Optional

Datatype: teidata.enumerated

Sample values include: main main title
sub (subordinate) subtitle, title of part
alt (alternate) alternate title, often in another language, by which the work is also known
short abbreviated form of title
desc (descriptive) descriptive paraphrase of the work functioning as a title

Note: This attribute is provided for convenience in analysing titles and processing them according to their type; where such specialized processing is not necessary, there is no need for such analysis, and the entire title, including subtitles and any parallel titles, may be enclosed within a single <title> element.

@level indicates the bibliographic level for a title, that is, whether it identifies an article, book, journal, series, or unpublished material.

Status: Optional

Datatype: teidata.enumerated

Legal values are: a (analytic) the title applies to an analytic item, such as an article, poem, or other work published as part of a larger item.
m (monographic) the title applies to a monograph such as a book or other item considered to be a distinct publication, including single volumes of multi-volume works
j (journal) the title applies to any serial or periodical publication such as a journal, magazine, or newspaper
s (series) the title applies to a series of otherwise distinct publications such as a collection
u (unpublished) the title applies to any unpublished material (including theses and dissertations unless published by a commercial press)

Note: The level of a title is sometimes implied by its context: for example, a title appearing directly within an <analytic> element is ipso facto of level ‘a’, and one appearing within a <series> element of level ‘s’. For this reason, the level attribute is not required in contexts where its value can be unambiguously inferred. Where it is supplied in such contexts, its value should not contradict the value implied by its parent element.

Member of: model.emphLike, model.msQuoteLike

Contained by: cl phr s span
The attributes key and ref, inherited from the class att.canonical may be used to indicate the canonical form for the title; the former, by supplying (for example) the identifier of a record in some external library system; the latter by pointing to an XML element somewhere containing the canonical form of the title.

Example

```
```

Example

```
<title>Hardy's Tess of the D'Urbervilles: a machine readable edition</title>
```

Example

```
<title type="full">Synthèse</title>
<title type="main">an international journal for epistemology, methodology and history of science</title>
```

1785
<titlePage> (title page) contains the title page of a text, appearing within the front or back matter. [4.6. Title Pages]

Module textstructure — Default Text Structure

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype)

@type classifies the title page according to any convenient typology.

Derived from att.typed

Status Optional

Datatype leidata.enumerated

Note This attribute allows the same element to be used for volume title pages, series title pages, etc., as well as for the 'main' title page of a work.

linking: ab

msdescription: msDesc

namesdates: trait

Note  Where there is confusion between <trait> and <state> the more general purpose element <state> should be used even for unchanging characteristics. If you wish to distinguish between characteristics that are generally perceived to be time-bound states and those assumed to be fixed traits, then <trait> is available for the more static of these. The <state> element encodes characteristics which are sometimes assumed to change, often at specific times or over a date range, whereas the <trait> elements are used to record characteristics, such as eye-colour, which are less subject to change. Traits are typically, but not necessarily, independent of the volition or action of the holder.

Example

    <trait type="physical">
        <label>Eye colour</label>
        <desc>Blue</desc>
    </trait>

<transcriptionDesc>

describes the set of transcription conventions used, particularly for spoken material.

8.2. Documenting the Source of Transcribed Speech

Module spoken — Transcriptions of Speech
Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))
@ident supplies an identifier for the encoding convention, independent of any version number.
  Status Required
  Datatype teidata.name
@version supplies a version number for the encoding conventions used, if any.
  Status Optional
  Datatype teidata.versionNumber

Member of model.encodingDescPart

Contained by header: encodingDesc

May contain core: desc label p ptr ref

linking: ab

Example

1796
<transpose>

<transcriptionDesc ident="HIAT" version="2004"/>

Content model

<content>
<alternate minOccurs="0" maxOccurs="unbounded">
<classRef key="model.labelLike"/>
<classRef key="model.ptrLike"/>
<classRef key="model.pLike"/>
</alternate>
</content>

Schema Declaration

```
<transcriptionDesc>
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute ident { text },
  attribute version { text }?,
  ( model.labelLike | model.ptrLike | model.pLike )*
}
```

<transpose> describes a single textual transposition as an ordered list of at least two pointers specifying the order in which the elements indicated should be re-combined. [11.3.4.5. Transpositions]

Module transcr – Representation of Primary Sources

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by transcr: listTranspose

May contain core: ptr

Note Transposition is usually indicated in a document by a metamark such as a wavy line or numbering.

The order in which <ptr> elements appear within a <transpose> element should correspond with the desired order, as indicated by the metamark.

Example

```
<transpose>
<ptr target="#ib02"/>
```

1797
The transposition recorded here indicates that the content of the element with identifier ib02 should appear before the content of the element with identifier ib01.

Content model

```
<content>
  <elementRef key="ptr" minOccurs="2" maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```
element transpose {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  ( ptr, ptr, ptr* )
}
```

```tree>
<tree> (tree) encodes a tree, which is made up of a root, internal nodes, leaves, and arcs from root to leaves. [19.2
Trees]
Module nets — Graphs, Networks, and Trees
Attributes att.global ((@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition) (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))
@arity gives the maximum number of children of the root and internal nodes of the tree.
  Status Optional
  Datatype teidata.count
@ord (ordered) indicates whether or not the tree is ordered, or if it is partially ordered.
  Status Required
  Datatype teidata.enumerated
Legal values are: true indicates that all of the branching nodes of the tree are ordered.
  partial indicates that some of the branching nodes of the tree are ordered and some are unordered.
  false indicates that all of the branching nodes of the tree are unordered.
@order gives the order of the tree, i.e., the number of its nodes.
  Status Optional
  Datatype teidata.count
Note The size of a tree is always one less than its order, hence there is no need for both a size and order attribute.
```

<trans (transition) indicates the nature of the transition between this utterance and the previous one.

#### Status
Optional

#### Datatype
teidata.enumerated

**Legal values are:**
- **smooth** this utterance begins without unusual pause or rapidity.[Default]
- **latching** this utterance begins with a markedly shorter pause than normal.
- **overlap** this utterance begins before the previous one has finished.
- **pause** this utterance begins after a noticeable pause.

---

1804
Prose and a mixture of speech elements

Although individual transcriptions may consistently use \(<u>\) elements for turns or other units, and although in most cases a \(<u>\) will be delimited by pause or change of speaker, \(<u>\) is not required to
The TEI Guidelines

represent a turn or any communicative event, nor to be bounded by pauses or change of speaker. At a minimum, a `<u>` is some phonetic production by a given speaker.

Example

```xml
<u who="#spkr1">if did you set</u>
<u trans="latching" who="#spkr2">well Joe and I set it between us</u>
```

```
<list type="speakers">
  <item xml:id="spkr1"/>
  <item xml:id="spkr2"/>
</list>
```

Content model

```
<content>
  <macroRef key="macro.paraContent"/>
</content>
```

Schema Declaration

```
element u
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.timed.attributes,
  att.duration.w3c.attributes,
  att.duration.iso.attributes,
  att.declaring.attributes,
  att.ascribed.directed.attributes,
  att.ascribed.attributes,
  att.notated.attributes,
  attribute trans { "smooth" | "latching" | "overlap" | "pause" }?,
  macro.paraContent
}
```

<unclear> (unclear) contains a word, phrase, or passage which cannot be transcribed with certainty because it is illegible or inaudible in the source. [11.3.3.1. Damage, Illegibility, and Supplied Text; 3.5.3. Additions, Deletions, and Omissions]
Note: One or more words may be used to describe the reason; usually each word will refer to a single cause.

@agent Where the difficulty in transcription arises from damage, categorizes the cause of the damage, if it can be identified.

Status Optional

Datatype leidata.enumerated

Sample values include:

- **mildew** damage results from mildew on the leaf surface
- **smoke** damage results from smoke

---

**eccentric ductus** (eccentric_ductus) indicates illegibility due to an unusual, awkward, or incompetent execution of a glyph or glyphs.
The same element is used for all cases of uncertainty in the transcription of element content, whether for
written or spoken material. For other aspects of certainty, uncertainty, and reliability of tagging and
transcription, see chapter 21. Certainty, Precision, and Responsibility.

The <damage>, <gap>, <del>, <unclear> and <supplied> elements may be closely allied in use. See
section 11.3.3.2. Use of the gap, del, damage, unclear, and supplied Elements in Combination for discussion
of which element is appropriate for which circumstance.

The hand attribute points to a definition of the hand concerned, as further discussed in section 11.3.2.1.

Example

```
<u> ...and then <unclear reason="background-noise">Nathalie</unclear> said ...</u>
```

Content model

```
<content>
 <macroRef key="macro.paraContent"/>
</content>
```

Schema Declaration

```

linking: ab seg
This is <del change="#s2" rend="overstrike">just some</del> sample <seg xml:id="undo-a">text</seg>, we need <del change="#s2">not</del> a real example. <line>
<undo target="#undo-a #undo-b" rend="dotted" change="#s3"/>
</line>

This encoding represents the following sequence of events:

- "This is just some sample text, we need a real example" is written
- At stage s2, "just some sample text, we need" is deleted by overstriking, and "not" is added
- At stage s3, parts of the deletion are cancelled by underdotting, thus reinstating the words "just some" and "text".

<unicodeName> (Unicode property name) contains the name of a registered Unicode normative or informative property. [5.2.1. Character Properties]

**Deprecated** will be removed on 2022-02-15

**Module** gaiji — Characters, Glyphs, and Writing Modes

**Attributes**
- `att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)`
- `att.global.rendition (@rend, @style, @rendition)`
- `att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)`
- `att.global.analytic (@ana)`
- `att.global.facs (@facs)`
- `att.global.change (@change)`
- `att.global.responsibility (@cert, @resp)`
- `att.global.source (@source)`

**@version** specifies the version number of the Unicode Standard in which this property name is defined.

- **Status** Optional
- **Datatype** `teidata.version`

**Contains** `charProp`

**May contain** Character data only

**Note** A definitive list of current Unicode property names is provided in The Unicode Standard.

**Example**

```xml
<unicodeName>Decomposition_Mapping</unicodeName>
<unicodeName>General_Category</unicodeName>
```

**Content model**

```
<content> <textNode/></content>
```

**Schema Declaration**

```xml
element unicodeName
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute version { text }?,
  text
}
```

<unicodeProp> (unicode property) provides a Unicode property for a character (or glyph). [5.2.1. Character Properties]

**Module** gaiji — Characters, Glyphs, and Writing Modes

**Attributes**
- `att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)`
- `att.global.rendition (@rend, @style, @rendition)`
- `att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)`
- `att.global.analytic (@ana)`
- `att.global.facs (@facs)`
- `att.global.change (@change)`
- `att.global.responsibility (@cert, @resp)`
- `att.global.source (@source)`

**@version** specifies the normalized name of a Unicode property.

- **Status** Required
- **Datatype** `teidata.xmlName`
- **Legal values are** Age

@value specifies the value of a named Unicode property.

Status Required
Datatype teidata.text

Example

```xml
<char xml:id="U4EBA_circled">
  <unicodeProp name="Decomposition_Mapping" value="circle" version="12.1"/>
</char>
```

Note A definitive list of current Unicode property names is provided in The Unicode Standard.
<localProp name="Name" value="CIRCLED IDEOGRAPH 4EBA"/>
<localProp name="daikanwa" value="36"/>
<mapping type="standard">人</mapping>

<unihanProp>

(unihan property) holds the name and value of a normative or informative Unihan character (or glyph) property as part of its attributes. [5.2.1. Character Properties]

Module gaiji — Characters, Glyphs, and Writing Modes

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.gaijiProp (@name, @version)

@name specifies the normalized name of a unicode han database (Unihan) property

Status Required

Datatype teidata.xmlName

Legal values are: kZVariant

<unit>

contains a symbol, a word or a phrase referring to a unit of measurement in any kind of formal or informal system. [3.6.3. Numbers and Measures]

Module core — Elements Available in All TEI Documents

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.typed (@type, @subtype) att.measurement (@unit, @unitRef, @quantity, @commodity)

Member of model.measureLike
Example Here is an example of a `<unit>` element holding a `unitRef` attribute that points to a definition of the unit in the TEI header.

```xml
<measure>
   <unit unitRef="#ell">ells</unit>
</measure>
```

Example

```xml
<measure>
   <num>2</num>
   <unit>kg</unit>
</measure>
```

Example

```xml
<measure type="value">
   <num>3</num>
   <unit type="time" unit="min">minute</unit>
</measure>
```

Example

```xml
<measure type="interval">
   <num atleast="1.2">1.2</num> to <num atMost="5.6">5.6</num>
   <unit type="velocity" unit="km/h">km/h</unit>
</measure>
```

Example

```xml
<p>Light travels at <num value="3E10">3×10^10</num>
   <unit type="rate" unit="cm/s">
      <unit type="space">cm</unit> per <unit type="time">second</unit>
   </unit>.<p>
```

Content model

```xml
<content>
   <macroRef key="macro.phraseSeq"/>
</content>
```
<unitDecl> (unit declarations) provides information about units of measurement that are not members of the International System of Units. [2.3.9. The Unit Declaration]

Module header — [The TEI Header]

Attributes
att.canonical (@key, @ref) att.datablue (@calendar, @period) (att.datablue.w3c (@when, @notBefore, @notAfter, @from, @to)) (att.datablue.iso (@when-iso, @notBefore-iso, @notAfter-iso, @from-iso, @to-iso)) (att.datablue.custom (@when-custom, @notBefore-custom, @notAfter-custom, @from-custom, @to-custom, @datingPoint, @datingMethod)) att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Member of model.encodingDescPart

Contained by
header: encodingDesc

May contain
header: unitDef

Example

<unitDecl>
  <unitDef xml:id="[]" type="weight">
    <label xml:lang="ja">斤</label>
    <label xml:lang="ja-Latn">kin</label>
    <conversion fromUnit="#" toUnit="#" formula="16"/>
  </unitDef>
  <unitDef xml:id="[]" type="weight">
    <label xml:lang="ja">両</label>
    <label xml:lang="ja-Latn">ryo</label>
    <conversion fromUnit="#" toUnit="#" formula="4"/>
  </unitDef>
  <unitDef xml:id="[]" type="weight">
    <label xml:lang="ja">分</label>
    <label xml:lang="ja-Latn">Bu</label>
  </unitDef>
</unitDecl>
<unitDecl>
  \(<\text{unitDef} xml:id="" type="weight">\)

**<usg>** (usage) contains usage information in a dictionary entry. [9.3.5.2. Usage Information and Other Labels]

**Module** dictionaries — Dictionaries

**Attributes**
- `att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)`
- `att.global.rendition (@rend, @style, @rendition)`
- `att.global.analytic (@ana)`
- `att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)`
- `att.global.change (@change)`
- `att.global.responsibility (@cert, @resp)`
- `att.global.source (@source)`
- `att.lexicographic (@expand, @split, @value, @location, @mergedIn, @opt)`
- `att.typed (type, @subtype)`

@type classifies the usage information using any convenient typology.

Derived from `att.typed`

Status Optional

Datatype teidata.enumerated

Sample values include:
- **geo** (geographic) geographic area
- **time** temporal, historical era (archaic, old, etc.)
- **dom** domain or subject matter (e.g. scientific, literary etc.)
- **register** (register)
- **style** style (figurative, literal, etc.)
- **plev** (preference level) preference level (chiefly, usually, etc.)
- **lang** (language) name of a language mentioned in etymological or other linguistic discussion.
- **gram** (grammatical) grammatical usage
- **syn** (synonym) synonym given to show use
- **hyper** (hypernym) hypernym given to show usage
- **colloc** (collocation) typical collocate of the headword.
- **comp** (complement) typical complement
- **obj** (object) typical object
- **subj** (subject) typical subject
- **verb** typical verb
- **hint** unclassifiable piece of information to guide sense choice

Character data

Example

<valDesc>must point to another <gi>align</gi> element logically preceding this one.</valDesc>

Content model

<content>
  <macroRef key="macro.phraseSeq.limited"/>
</content>

Schema Declaration

element valDesc

<vallItem> documents a single value in a predefined list of values. 

Module tagdocs — Documentation Elements

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.combinable (@mode) att.deprecated (@validUntil)

@ident specifies the value concerned.

Status Required

Datatype teidata.text

Contained by tagdocs: valList

May contain core: desc gloss
tagdocs: altIdent equiv paramList remarks

Example

```xml
<vallItem ident="dub">
  <altIdent xml:lang="fr">dou</altIdent>
  <equiv name="unknown"/>
  <gloss>dubious</gloss>
  <desc>used when the application of this element is doubtful or uncertain</desc>
</vallItem>
```

Example The <vallItem> element is only allowed within <valList> if the <desc> element is also present:

```xml
<valList type="closed">
  <vallItem ident="border">
    <desc>used to signify that there is border around a page.</desc>
  </vallItem>
  <vallItem ident="border-rule">
    <desc>used to signify that there is a border made of ruled lines.</desc>
  </vallItem>
  <vallItem ident="border-ornamental">
    <desc>used to signify that there is an ornamental border.</desc>
  </vallItem>
  <vallItem ident="catch">
    <gloss>catchword</gloss>
    <desc>for catch words.</desc>
  </vallItem>
```

  att.global.responsibility.attributes,
  att.global.source.attributes,
  macro.xtext}
```

 variantEncoding 
 (variant encoding) declares the method used to encode text-critical variants.

 Attributes

- `@method` indicates which method is used to encode the apparatus of variants.
  - **Status**: Required
  - **Datatype**: teidata.enumerated
  - **Legal values are**:
    - **location-referenced**: apparatus uses line numbers or other canonical reference scheme referenced in a base text.
    - **double-end-point**: apparatus indicates the precise locations of the beginning and ending of each lemma relative to a base text.
    - **parallel-segmentation**: alternate readings of a passage are given in parallel in the text; no notion of a base text is necessary.
  - **Note**: The value ‘parallel-segmentation’ requires in-line encoding of the apparatus.

- `@location` indicates whether the apparatus appears within the running text or external to it.
  - **Status**: Required
  - **Datatype**: teidata.enumerated
  - **Legal values are**:
    - **internal**: apparatus appears within the running text.
    - **external**: apparatus appears outside the base text.
  - **Note**: The value ‘external’ is inconsistent with the parallel-segmentation method of apparatus markup.

Member of

- `model.encodingDescPart`

Contained by

- `header: encodingDesc`

May contain

- Empty element

Example

1840
<variantEncoding  method="location-referenced"
    location="external"/>

Content model
<content> <empty/> </content>

Schema Declaration

element variantEncoding
{
    att.global.attributes,
    att.global.rendition.attributes,
    att.global.linking.attributes,
    att.global.analytic.attributes,
    att.global.facs.attributes,
    att.global.change.attributes,
    att.global.responsibility.attributes,
    att.global.source.attributes,
    attribute method
    {
        "location-referenced" | "double-end-point" | "parallel-segmentation"
    },
    attribute location { "internal" | "external" },
    empty
}

<vColl> (collection of values) represents the value part of a feature-value specification which contains multiple values organized as a set, bag, or list. [18.7. Collections as Complex Feature Values]

Module iso-fs — Feature Structures

Attributes
 att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@org (organization) indicates organization of given value or values as set, bag or list.

Status Optional

Datatype teidata.enumerated

Legal values are: set indicates that the given values are organized as a set.

    bag indicates that the given values are organized as a bag (multiset).

    list indicates that the given values are organized as a list.

Member of model.featureVal.complex

Contained by
iso-fs: fvLib if vAlt vDefault vLabel vMerge vNot vRange

May contain
iso-fs: binary default fs numeric string symbol vAlt vLabel

Example

<f name="name">
    <vColl>
        <string>Jean</string>
        <string>Luc</string>
        <string>Godard</string>
    </vColl>
</f>
Example

```
<fs>
  <f name="lex">
    <symbol value="auxquels"/>
  </f>
  <f name="maf">
    <vColl org="list">
      <fs>
        <f name="cat">
          <symbol value="prep"/>
        </f>
      </fs>
      <fs>
        <f name="cat">
          <symbol value="pronoun"/>
        </f>
        <f name="kind">
          <symbol value="rel"/>
        </f>
        <f name="num">
          <symbol value="pl"/>
        </f>
        <f name="gender">
          <symbol value="masc"/>
        </f>
      </fs>
    </vColl>
  </f>
</fs>
```

Content model

```
<content>
  <alternate minOccurs="0" maxOccurs="unbounded">
    <elementRef key="fs"/>
    <classRef key="model.featureVal.single"/>
  </alternate>
</content>
```

Schema Declaration

```
element vColl
{
    att.global.attributes,
    att.global.rendition.attributes,
    att.global.linking.attributes,
    att.global.analytic.attributes,
    att.global.facs.attributes,
    att.global.change.attributes,
    att.global.responsibility.attributes,
    att.global.source.attributes,
    attribute org { "set" | "bag" | "list" }?,
}```
<vDefault> (value default) declares the default value to be supplied when a feature structure does not contain an instance of <f> for this name; if unconditional, it is specified as one (or, depending on the value of the org attribute of the enclosing <fDecl> more <fs> elements or primitive values; if conditional, it is specified as one or more <if> elements; if no default is specified, or no condition matches, the value none is assumed. [18.11. Feature System Declaration]

Module iso-fs — Feature Structures

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Contained by
iso-fs: fDecl

May contain
iso-fs: binary default fs if numeric string symbol vAlt vColl vLabel vMerge vNot

Note May contain a legal feature value, or a series of <if> elements.

Example

```xml
<fDecl name="INV">
  <fDescr>inverted sentence</fDescr>
  <vRange>
    <vAlt>
      <binary value="true"/>
      <binary value="false"/>
    </vAlt>
  </vRange>
  <vDefault>
    <binary value="false"/>
  </vDefault>
</fDecl>
```

1844
A view is a particular form of stage direction.

Example

```
<view>
  <name>Max</name> joins his daughter at the window. <hi>Rain</hi> sprays his face--
</view>

<view>
  <camera>Max's POV</camera> He sees occasional windows open, and just across from his apartment house, a <hi>man</hi> opens the front door of a brownstone--
</view>
```

Example

```
<div type="shot">
  <view>BBC World symbol</view>
  <sp>
    <speaker>Voice Over</speaker>
    <p>Monty Python's Flying Circus tonight comes to you live from the Grillomat Snack Bar, Paignton.</p>
  </sp>
</div>

<div type="shot">
  <view>Interior of a nasty snack bar. Customers around, preferably real people. Linkman sitting at one of the plastic tables.</view>
  <sp>
    <speaker>Linkman</speaker>
    <p>Hello to you live from the Grillomat Snack Bar.</p>
  </sp>
</div>
```

Content model

```
<content>
  <macroRef key="macro.specialPara"/>
```
<vLabel> (value label) represents the value part of a feature-value specification which appears at more than one point in a feature structure. [18.6. Re-entrant Feature Structures]

Module   iso-fs — Feature Structures

Attributes   att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)   (att.global.rendition (@rend, @style, @rendition))   (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select))   (att.global.analytic (@ana))   (att.global.facs (@facs))   (att.global.change (@change))   (att.global.responsibility (@cert, @resp))   (att.global.source (@source))

@name supplies a name identifying the sharing point.

Status   Required

Datatype   leidata.word

Member of   model.featureVal.single

Contained by

iso-fs:   f   fvLib   f   vAlt   vColl   vDefault   vLabel   vMerge   vNot   vRange

May contain

Example

```xml
<fs>
  <f name="nominal">
    <fs>
      <f name="nm-num">
        <vLabel name="L1">
          <symbol value="singular"/>
        </vLabel>
      </f>
    </fs>
  </f>  <!-- other nominal features -->
</fs>

<f name="verbal">
  <fs>
    <f name="vb-num">
      <vLabel name="L1"/>
    </f>
  </fs>
</f>
```

1846
Content model

```xml
<content>
  <classRef key="model.featureVal"
    minOccurs="0"/>
</content>
```

Schema Declaration

```xml
element vLabel
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute name { text },
  model.featureVal?
}
```

`<vMerge>` (merged collection of values) represents a feature value which is the result of merging together the feature values contained by its children, using the organization specified by the `org` attribute. [18.8.3]

**Collection of Values**

Module iso-fs – Feature Structures

Attributes

- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)
- att.global.rendition (@rend, @style, @rendition)
- att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)
- att.global.analytic (@ana)
- att.global.facs (@facs)
- att.global.change (@change)
- att.global.responsibility (@cert, @resp)
- att.global.source (@source)

@org indicates the organization of the resulting merged values as set, bag or list.

- Status Optional
- Datatype teidata.enumerated

- Legal values are:
  - set indicates that the resulting values are organized as a set.
  - bag indicates that the resulting values are organized as a bag (multiset).
  - list indicates that the resulting values are organized as a list.

Member of model.featureVal.complex

Contains by iso-fs: f vLib | vAlt | vDefault | vLabel | vMerge | vNot | vRange

May contain iso-fs: binary | default | f | numeric | string | symbol | vAlt | vColl | vLabel | vMerge | vNot

Example

1847
This example returns a list, concatenating the indeterminate value with the set of values masculine, neuter and feminine.

Content model

```
<content>
  <classRef key="model.featureVal"
    minOccurs="1" maxOccurs="unbounded"/>
</content>
```

Schema Declaration

```
element vMerge
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  attribute org { "set" | "bag" | "list" }?,
  model.featureVal+
}
```

<vNot> (value negation) represents a feature value which is the negation of its content. [18.8.2. Negation]

Module iso-fs — Feature Structures

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

Member of model.featureVal.complex

Contained by

iso-fs: fvLib fvAlt vDefault vLabel vMerge vNot vRange

May contain

iso-fs: binary default fs numeric string symbol fvAlt fvColl fvLabel fvMerge fvNot

Example

```
<vNot>
  <symbol value="masculine"/>
</vNot>
```
Example

```xml
<vf name="mode">
  <vnot>
    <valt>
      <symbol value="infinitive"/>
      <symbol value="participle"/>
    </valt>
  </vnot>
</vf>
```

Content model

```xml
<content>
  <classRef key="model.featureVal"/>
</content>
```

Schema Declaration

```xml
element vnot {
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  model.featureVal}
```

<vocal> (vocal) marks any vocalized but not necessarily lexical phenomenon, for example voiced pauses, non-lexical backchannels, etc. [8.3.3. Vocal, Kinesic, Incident]

Module spoken — Transcriptions of Speech

Attributes

- `id` (ID)
- `@xml:id`
- `@n`
- `@xml:lang`
- `@xml:base`
- `@xml:space`
- `rend` (Rendition)
- `@rend`
- `@style`
- `@rendition`

The TEI Guidelines

Example

```xml
<support>
<p>
   <material>Rag paper</material> with <watermark>anchor</watermark>
   watermark</p>
</support>

Content model

```xml
<content>
   <macroRef key="macro.phraseSeq"/>
</content>
``` 

Schema Declaration

```xml
<element watermark>
   {
      att.global.attributes,
      att.global.rendition.attributes,
      att.global.linking.attributes,
      att.global.analytic.attributes,
   }
```
<when> indicates a point in time either relative to other elements in the same timeline tag, or absolutely. [16.4.2: Placing Synchronous Events in Time]

Module linking — Linking, Segmentation, and Alignment

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source))

@absolute supplies an absolute value for the time.

Status Optional

Datatype teidata.temporal.w3c

Note This attribute should always be specified on a <when> element which serves as the target for the origin attribute of a <timeline>.

@unit specifies the unit of time in which the interval value is expressed, if this is not inherited from the parent <timeline>.

Status Optional

Datatype teidata.enumerated

Suggested values include: d (days)

h (hours)

min (minutes)

s (seconds)

ms (milliseconds)

@interval specifies a time interval either as a number or as one of the keywords defined by the datatype teidata.interval

Status Optional

Datatype teidata.interval

@since identifies the reference point for determining the time of the current <when> element, which is obtained by adding the interval to the time of the reference point.

Status Optional

Datatype teidata.pointer

Note This attribute should point to another <when> element in the same <timeline>. If no value is supplied, and the absolute attribute is also unspecified, then the reference point is understood to be the origin of the enclosing <timeline> tag.

Contained by: timeline

May contain Empty element

Note On this element, the global xml:id attribute must be supplied to specify an identifier for this point in time. The value used may be chosen freely provided that it is unique within the document and is a syntactically valid name. There is no requirement for values containing numbers to be in sequence.

Example
<when xml:id="TW3" interval="20" since="#w2"/>

Content model

```
<content> <empty/> </content>
```

Schema Declaration

```
element when {
  att.global.attributes,

character data

Note The content of the <witness> element may give bibliographic information about the witness or witness group, or it may be empty.

Example

<witness xml:id="EL">Ellesmere, Huntingdon Library 26.C.9</witness>
<witness xml:id="HG">Hengwrt, National Library of Wales, Aberystwyth, Peniarth 392D</witness>
<witness xml:id="RA2">Bodleian Library Rawlinson Poetic 149 (see further <ptr target="http://www.examples.com/MSdescs#MSRP149"/>)</witness>

Content model

<content>

<alternate minOccurs="0"/>
<witStart> (fragmented witness start) indicates the beginning, or resumption, of the text of a fragmentary witness. [12.1.5. Fragmentary Witnesses]

Module textcrit — Critical Apparatus

Attributes

- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space)
- att.global.rendition (@rend, @style)
- att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)
- att.global.analytic (@ana)
- att.global.facs (@facs)
- att.global.change (@change)
- att.global.responsibility (@cert, @resp)
- att.global.source (@source)
- att.rdgPart (@wit)

Member of model.rdgPart

Contained by textcrit: lem rdg

May contain Empty element

Example

```xml
<app>
  <lem wit="#El #Hg">Auctoritee</lem>
  <rdg wit="#La #Ra2">auctorite</rdg>
  <rdg vit="#X"/>
  <witStart/>auctorite</rdg>
</app>
```

Content model <content> <empty/> </content>

Schema Declaration

```xml
element witStart
{
  att.global.attributes,
  att.global.rendition.attributes,
  maxOccurs="unbounded">
  <textNode/>
  <classRef key="model.limitedPhrase"/>
  <classRef key="model.inter"/>
  <elementRef key="note"/>
  <elementRef key="object"/>
  </alternate>
  </content>

```

1865
<writing> (writing) contains a passage of written text revealed to participants in the course of a spoken text.

Module spoken — Transcriptions of Speech

Attributes att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.defining (@primary, @transcription)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.ascribed.directed (@toWhom) att.typed (@type, @subtype) att.timed (@start, @end) (att.duration.w3c (@dur)) (att.duration.iso (@dur-iso))

@gradual indicates whether the writing is revealed all at once or gradually.

Status Optional

Datatype teidata.xTruthValue

Note The value true indicates the writing is revealed gradually; the value false that the writing is revealed all at once.

nets: graph
The `<writing>` element will usually be short and most simply transcribed as a character string; the content model also allows a sequence of paragraphs and paragraph-level elements, in case the writing has enough internal structure to warrant such markup. In either case the usual phrase-level tags for written text are available.

**Example**

```xml
<writing>man in a coonskin cap</writing>
<writing>coonskin</writing>
<writing>in a pig pen</writing>
<writing>pig pen</writing>
<writing>wants eleven dollar bills</writing>
```
<writing>20 dollar bills</writing>
<l>you only got ten</l>
<writing>10</writing>

Content model

```xml
<content>
  <macroRef key="macro.paraContent"/>
</content>
```

Schema Declaration

```xml
element writing
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,

  att.ascribed.directed.attributes,
  att.ascribed.attributes,
  att.timed.attributes,
  att.duration.w3c.attributes,
  att.duration.iso.attributes,
  attribute gradual { text }?,
  macro.paraContent
}
```

<xenoData> (non-TEI metadata) provides a container element into which metadata in non-TEI formats may be placed. [2.5. Non-TEI Metadata]

Module header — The TEI Header

Attributes  att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.rendition (@rend, @style, @rendition)) (att.global.linking (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) att.declarable (@default) att.typed (@type, @subtype)

Member of  model.teiHeaderPart

Contained by  header: teiHeader

May contain  ANY

Example This example presumes that the prefix dc has been bound to the namespace http://purl.org/dc/elements/1.1/ and the prefix rdf is bound to the namespace http://www.w3.org/1999/02/22-rdf-syntax-ns#. Note: The about attribute on the <rdf:Description> in this example gives a URI indicating the resource to which the metadata contained therein refer. The <rdf:Description> in the second <xenoData> block has a blank about, meaning it is pointing at the current document, so the RDF is about the document within which it is contained, i.e. the TEI document containing the <xenoData> block. Similarly, any kind of relative URI may be used, including fragment identifiers (see v6.2 Identifiers and Indicators). Do note, however, that if
the contents of the `<xenoData>` block are to be extracted and used elsewhere, any relative URIs will have to be resolved accordingly.

Example In this example, the prefix `rdf` is bound to the namespace `http://www.w3.org/1999/02/22-rdf-syntax-ns#`, the prefix `dc` is bound to the namespace `http://purl.org/dc/elements/1.1/`, and the prefix `cc` is bound to the namespace `http://web.resource.org/cc/`.

```
<xenoData
  xmlns:cc="http://web.resource.org/cc/
  xmlns:dc="http://purl.org/dc/elements/1.1/
  xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#">
  <rdf:RDF>
    <rdf:Description rdf:about="">
      <dc:title>The Description of a New World, Called the Blazing-World, 1668</dc:title>
      <dc:creator>Cavendish, Margaret (Lucas), Duchess of Newcastle</dc:creator>
      <dc:publisher>Women Writers Project</dc:publisher>
      <dc:date>2002-02-12</dc:date>
      <dc:subject>utopian fiction</dc:subject>
    </rdf:Description>
  </rdf:RDF>
</xenoData>
```

Example In this example, the prefix `dc` is again bound to the namespace `http://www.openarchives.org/OAI/2.0/oai_dc/`, and the prefix `oai_dc` is bound to the namespace `http://www.openarchives.org/OAI/2.0/oai_dc/`.

```
<xenoData
  xmlns:cc="http://web.resource.org/cc/
  xmlns:dc="http://purl.org/dc/elements/1.1/
  xmlns:rdf="http://www.w3.org/1999/02/22-rdf-syntax-ns#">
  <rdf:RDF>
    <cc:Work rdf:about="">
      <dc:title>Applied Software Project Management - review</dc:title>
      <dc:license rdf:resource="http://creativecommons.org/licenses/by-sa/2.0/uk/"/>
    </cc:Work>
    <cc:License rdf:about="http://creativecommons.org/licenses/by-sa/2.0/uk/">
      <cc:requires rdf:resource="http://web.resource.org/cc/Notice"/>
      <cc:requires rdf:resource="http://web.resource.org/cc/Attribution"/>
      <cc:requires rdf:resource="http://web.resource.org/cc/ShareAlike"/>
    </cc:License>
  </rdf:RDF>
</xenoData>
```
Example In this example, the prefix mods is bound to the namespace http://www.loc.gov/mods/v3.

```xml
<mods>
  <titleInfo>
    <title>Academic adaptation and cross-cultural learning experiences of Chinese students at American universities</title>
    <subTitle>a narrative inquiry</subTitle>
  </titleInfo>
  <name type="personal" authority="Local">
    <namePart/>
  </name>
  <role>
    <roleTerm authority="marcrelator" type="text">Author</roleTerm>
  </role>
</mods>
```
Example This example shows GeoJSON embedded in <xenoData>. Note that JSON does not permit newlines inside string values. These must be escaped as \n. To avoid the accidental insertion of newlines by software, the use of xml:space is recommended. Blocks of JSON should be wrapped in CDATA sections, as they may contain characters illegal in XML.

```json
<![[CDATA[
{
  "features": [
    {
      "geometry": {
        "type": "Point",
        "coordinates": [
          68.388483,
          33.498616
        ]
      },
      "type": "Feature",
      "properties": {
        "id": 1871
      }
    }
  ]
}
]]>
```
"@type": "Place"

\]]>
</xenoData>

Note: the example above has been trimmed for legibility. The original may be found linked from Arachosiorum Oppidum/Alexandria. The contributors, listed per the license terms, are R. Talbert, Jeffrey Becker, W. Röllig, Tom Elliott, H. Kopp, DARMC, Sean Gillies, B. Siewert-Mayer, Francis Deblauwe, and Eric Kansa.

Content model

```xml
<content>
  <alternate>
    <textNode/>
    <anyElement/>
  </alternate>
</content>
```

Schema Declaration

```xml
element xenoData
{
  att.global.attributes,
  att.global.rendition.attributes,
  att.global.linking.attributes,
  att.global.analytic.attributes,
  att.global.facs.attributes,
  att.global.change.attributes,
  att.global.responsibility.attributes,
  att.global.source.attributes,
  att.declarable.attributes,
  att.typed.attributes,
  ( text | anyElement-xenoData )
}
```

<xref> (cross-reference phrase) contains a phrase, sentence, or icon referring the reader to some other location in this or another text. [9.3.5.3. Cross-References to Other Entries]

Module dictionaries – Dictionaries

Attributes

- att.global (@xml:id, @n, @xml:lang, @xml:base, @xml:space) (att.global.renditioni (@rend, @style, @rendition)) (att.global.linkingi (@corresp, @synch, @sameAs, @copyOf, @next, @prev, @exclude, @select)) (att.global.analytic (@ana)) (att.global.facs (@facs)) (att.global.change (@change)) (att.global.responsibility (@cert, @resp)) (att.global.source (@source)) (att.lexicographic (@expand, @split, @value, @location, @mergedIn, @opt)) (att.datcat (@datcat, @valueDatcat)) (att.lexicographic.normalized (@norm, @orig))
- att.typed (type, @subtype)
- @type indicates the type of cross reference, using any convenient typology.
  - Derived from att.typed
  - Status Recommended
  - Datatype teidata.enumerated

Sample values include: syn (synonym) cross reference for synonym information
  - etym (etymological) etymological information
  - cf (compare or consult) related or similar term

character data

Note May contain character data and phrase-level elements; usually contains a <ref> or a <ptr> element.

This element encloses both the actual indication of the location referred to, which may be tagged using the <ref> or <ptr> elements, and any accompanying material which gives more information about why the reader is being referred there.

Example

```xml
<entry>
  <form>
    <orth>lavage</orth>
  </form>
  <etym>[Fr. &lt; <mentioned>laver</mentioned>; L. &lt;mentioned>lavare</mentioned>, to wash;]
  <xr>see <ref>lather</ref>
</entry>
```

1874
Example

```xml
<entry>
  <form>
  </form>
  <orth>lawful</orth>
</entry>
```

```xml
<xr type="syn">SYN. see <ref>legal</ref></xr>
```

Content model

```xml

transcr: addSpan damage damageSpan delSpan fw handShift line listTranspose metamark mod path redo restore retrace space substJoin surface undo zone

character data

Note

The position of every zone for a given surface is always defined by reference to the coordinate system defined for that surface.

A graphic element contained by a zone represents the whole of the zone.

A zone may be of any shape. The attribute points may be used to define a polygonal zone, using the coordinate system defined by its parent surface.

A zone is always a closed polygon. Repeating the initial coordinate at the end of the sequence is optional. To encode an unclosed path, use the <path> element.

Example

```
<surface ulx="14.54" uly="16.14" lrx="0"

lry="0">
<graphic url="stone.jpg"/>

<zone points="4.6,6.3 5.25,5.85 6.2,6.6 8.19222,7.4125 7.89222,6.5875 10.9422,6.1375 11.4422,6.7125 8.21722,8.3125 6.2,7.65"/>
</surface>
```

This example defines a non-rectangular zone: see the illustration in section 11.2.2.1. Advanced Uses of surface and zone.

Example
This example defines a zone which has been defined as larger than its parent surface in order to match the dimensions of the graphic it contains.

**Content model**

```xml
<content>
  <alternate minOccurs="0" maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.gLike"/>
    <classRef key="model.graphicLike"/>
    <classRef key="model.global"/>
    <elementRef key="surface"/>
    <classRef key="model.linePart"/>
  </alternate>
</content>
```

**Schema Declaration**

### D Attributes

#### D.1 About the Attributes Appendix

This appendix gives you a list of attributes and links to the reference pages for the elements on which they appear. There are 268 distinctly-named attributes in revision b4f72b1ff of TEI P5 Version 4.3.0 of the TEI Guidelines.

E Datatypes and Other Macros

E.1 About the Datatypes and Macros Appendix

This appendix gives you a list of datatypes and links to the reference pages for them. There are 34 distinctly-named data specifications in revision b4f72b1ff of TEI P5 Version 4.3.0 of the TEI Guidelines.

---

**macro.limitedContent** (paragraph content) defines the content of prose elements that are not used for transcription of extant materials. [1.3. The TEI Class System]

**Module** tei — The TEI Infrastructure

**Used by** desc | fDescr | figDescr | fsDescr | meeting | rendition | tagUsage

**Content model**

```xml
<content>
  <alternate minOccurs="0" maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.limitedPhrase"/>
    <classRef key="model.inter"/>
  </alternate>
</content>
```

**Declaration**

```plaintext
macro.limitedContent = ( text | model.limitedPhrase | model.inter )*
```

---

**macro.paraContent** (paragraph content) defines the content of paragraphs and similar elements. [1.3. The TEI Class System]

**Module** tei — The TEI Infrastructure

**Used by** ab | add | camera | caption | case | colloc | corr | damage | def | del | docEdition | emph | gen | gram | hi | hyph | iType | imprimatur | lang | lb | mod | mood | number | orig | orth | p | per | pron | ref | reg | restore | retrace | rhyme | salute | secl | seg | sic | signed | sound | stress | subc | supplied | surplus | syll | tech | title | titlePart | tns | unclear | usg | writing

**Content model**

```xml
<content>
  <alternate minOccurs="0" maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.gLike"/>
    <classRef key="model.phrase"/>
    <classRef key="model.inter"/>
    <classRef key="model.global"/>
    <elementRef key="lg"/>
    <classRef key="model.lLike"/>
  </alternate>
</content>
```

**Declaration**

```plaintext
macro.paraContent = ( text | model.gLike | model.phrase | model.inter | model.global | model.lLike | lg | model.lLike )*
```
macro.phraseSeq (phrase sequence) defines a sequence of character data and phrase-level elements. [1.4.1: Standard Content Models]

Module tei – The TEI Infrastructure

Used by abbr actor addName addrLine affiliation author biblScope birth bloc catchwords citedRange cl colophon country death distinct distributor district docAuthor docDate edition editor education eg email expand explicit extent faith finalRubric floruit foreign forename fw genName geoDecl geogFeat geogName gloss headItem headLabel heraldry incipit label material measure mentioned name nameLink nationality num objectName objectType offset orgName origPlace persName persPronouns phi placeName pubPlace publisher region residence role roleDesc roleName rs rt rubric secFol settlement sex soCalled socsecStatus speaker stamp street surname term textLang unit watermark wit

Content model

```
<content>
  <alternate minOccurs="0" maxOccurs="unbounded">
    <TextNode/>
    <ClassRef key="model.gLike"/>
    <ClassRef key="model.attributable"/>
    <ClassRef key="model.phrase"/>
    <ClassRef key="model.global"/>
  </alternate>
</content>
```

Declaration

```
macro.phraseSeq =
  ( text | model.gLike | model.attributable | model.phrase | model.global )*
```

macro.phraseSeq.limited (limited phrase sequence) defines a sequence of character data and those phrase-level elements that are not typically used for transcribing extant documents. [1.4.1. Standard Content Models]

Module tei – The TEI Infrastructure

Used by activity age authority channel classCode collection constitution derivation domain factuality funder institution interaction langKnown language locale metSym preparedness principal purpose repository resp span sponsor valDesc

Content model

```
<content>
  <alternate minOccurs="0" maxOccurs="unbounded">
    <TextNode/>
    <ClassRef key="model.limitedPhrase"/>
    <ClassRef key="model.global"/>
  </alternate>
</content>
```
macro.specialPara ('special' paragraph content) defines the content model of elements such as notes or list items, which either contain a series of component-level elements or else have the same structure as a paragraph, containing a series of phrase-level and inter-level elements. [1.3. The TEI Class System]

The TEI Class System
Module tei — The TEI Infrastructure
Used by accMat acquisition additions cell change collation condition custEvent decoNote filiation foliation handNote item layout licence metamark musicNotation note occupation origin provenance q quote said scriptNote signatures source stage summary support surrogates typeNote view

Content model

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.gLike"/>
    <classRef key="model.phrase"/>
    <classRef key="model.inter"/>
    <classRef key="model.divPart"/>
    <classRef key="model.global"/>
  </alternate>
</content>
```

Declaration

```
macro.specialPara =
  {
    text
    | model.gLike | model.phrase | model.inter | model.divPart | model.global
  }*
```

macro.xtext (extended text) defines a sequence of character data and gaiji elements.

Module tei — The TEI Infrastructure
Used by c depth dim ex height mapping memberOf string value width

Content model

```
<content>
  <alternate minOccurs="0"
    maxOccurs="unbounded">
    <textNode/>
    <classRef key="model.gLike"/>
  </alternate>
</content>
```

Declaration

```
macro.xtext = ( text | model.gLike )*
```
**teidata.authority** defines attribute values which derive from an authority list, which may be an enumerated list defined in the document’s schema, a list or taxonomy elsewhere in the document, or an online taxonomy, gazetteer, or other authority.

*Module*  
[tei — The TEI Infrastructure](#)  

*Used by*  
Element:  
- move/@where  

*Content model*

```xml
<content>
  <alternate>
    <dataRef key="teidata.enumerated"/>
    <dataRef key="teidata.pointer"/>
  </alternate>
</content>
```

*Declaration*

```plaintext
teidata.authority = teidata.enumerated | teidata.pointer
```

*Note*  
Attribute values with this datatype should either come from a value list in the attribute specification (teidata.enumerated) or be a valid URI (teidata.pointer).

**teidata.certainty** defines the range of attribute values expressing a degree of certainty.

*Module*  
[tei — The TEI Infrastructure](#)  

*Used by*  
leidata.probCertElement:  
- certainty/@cert  
- precision/@precision  
- purpose/@degree  

*Content model*

```xml
<content>
  <valList type="closed">
    <valItem ident="high"/>
    <valItem ident="medium"/>
    <valItem ident="low"/>
    <valItem ident="unknown"/>
  </valList>
</content>
```

*Declaration*  

```plaintext
teidata.certainty = "high" | "medium" | "low" | "unknown"
```

*Note*  
Certainty may be expressed by one of the predefined symbolic values high, medium, or low. The value unknown should be used in cases where the encoder does not wish to assert an opinion about the matter.

**teidata.count** defines the range of attribute values used for a non-negative integer value used as a count.

*Module*  
[tei — The TEI Infrastructure](#)  

*Used by*  
Element:
The TEI Guidelines

- `age/@value`
- `datatype/@minOccurs`
- `graph/@order`
- `graph/@size`
- `handDesc/@hands`
- `iNode/@outDegree`
- `layout/@columns`
- `layout/@streams`
- `layout/@ruledLines`
- `layout/@writtenLines`
- `node/@inDegree`
- `node/@outDegree`
- `refState/@length`
- `root/@outDegree`
- `sense/@level`
- `table/@rows`
- `table/@cols`
- `tagUsage/@occurs`
- `tagUsage/@withId`
- `tree/@arity`
- `tree/@order`
- `zone/@rotate`

Content model

```xml
<content>
  <dataRef name="nonNegativeInteger"/>
</content>
```

Declaration  
`teidata.count = xsd:nonNegativeInteger`

Note  
Any positive integer value or zero is permitted

---

**teidata.duration.iso** defines the range of attribute values available for representation of a duration in time using ISO 8601 standard formats

*Module*  
tei — The TEI Infrastructure

*Used by*  
Content model

```xml
<content>
  <dataRef name="token"
    restriction="[0-9,.DHMPRSTWYZ/:\-]+"/>
</content>
```
Declaration

```
teidata.duration.iso = token { pattern = "[0-9.,DHMPRSTWYZ/:+\-]+" }
```

Example

```
<time dur-iso="PT0.75H">three-quarters of an hour</time>
```

Example

```
<date dur-iso="P1,5D">a day and a half</date>
```

Example

```
<date dur-iso="P14D">a fortnight</date>
```

Example

```
<time dur-iso="PT0.02S">20 ms</time>
```

Note  A duration is expressed as a sequence of number-letter pairs, preceded by the letter P; the letter gives the unit and may be Y (year), M (month), D (day), H (hour), M (minute), or S (second), in that order. The numbers are all unsigned integers, except for the last, which may have a decimal component (using either . or , as the decimal point; the latter is preferred). If any number is 0, then that number-letter pair may be omitted. If any of the H (hour), M (minute), or S (second) number-letter pairs are present, then the separator T must precede the first 'time' number-letter pair.

For complete details, see ISO 8601 Data elements and interchange formats — Information interchange — Representation of dates and times.

`teidata.duration.w3c` defines the range of attribute values available for representation of a duration in time using W3C datatypes.

Module  tei — The TEI Infrastructure

Used by

Content model

```
<content> <dataRef name="duration"/></content>
```

Declaration

```
teidata.duration.w3c = xsd:duration
```

Example

```
<time dur="PT45M">forty-five minutes</time>
```

Example

```
<date dur="P1DT12H">a day and a half</date>
```

Example

```
<date dur="P7D">a week</date>
```

Example

```
<time dur="PT0.02S">20 ms</time>
```

Note  A duration is expressed as a sequence of number-letter pairs, preceded by the letter P; the letter gives the unit and may be Y (year), M (month), D (day), H (hour), M (minute), or S (second), in that order. The
numbers are all unsigned integers, except for the S number, which may have a decimal component (using . as the decimal point). If any number is 0, then that number-letter pair may be omitted. If any of the H (hour), M (minute), or S (second) number-letter pairs are present, then the separator T must precede the first ‘time’ number-letter pair.

For complete details, see the W3C specification.

teidata.enumerated defines the range of attribute values expressed as a single XML name taken from a list of documented possibilities.

teidata.interval defines attribute values used to express an interval value.

*Module* tei – The TEI Infrastructure

*Used by* Element:
- `timeline/@interval`
- `when/@interval`

*Content model*

```
<content>
  <alternate>
    <dataRef name="float"/>
    <valList>
      <valItem ident="regular"/>
      <valItem ident="irregular"/>
    </valList>
  </alternate>
</content>
```
Any value greater than zero or any one of the values regular, irregular, unknown.

**teidata.language** defines the range of attribute values used to identify a particular combination of human language and writing system. [vi.1 Language Identification]

**Module**  
tei — The TEI Infrastructure

**Used by**  
- langKnowledge/@tags
- langKnown/@tag
- language/@ident
- schemaSpec/@targetLang
- schemaSpec/@docLang
- textLang/@mainLang
- textLang/@otherLangs

**Content model**

```xml
<content>
  <alternate>
    <dataRef name="language"/>
    <valList>
      <valItem ident=""/>
    </valList>
  </alternate>
</content>
```

**Declaration**

```
teidata.language = xsd:language | ( "" )
```

**Note**  
The values for this attribute are language 'tags' as defined in BCP 47. Currently BCP 47 comprises RFC 5646 and RFC 4647; over time, other IETF documents may succeed these as the best current practice.

A 'language tag', per BCP 47, is assembled from a sequence of components or subtags separated by the hyphen character (\- U+002D). The tag is made of the following subtags, in the following order. Every subtag except the first is optional. If present, each occurs only once, except the fourth and fifth components (variant and extension), which are repeatable.

**language**  
The IANA-registered code for the language. This is almost always the same as the ISO 639 2-letter language code if there is one. The list of available registered language subtags can be found at [http://www.iana.org/assignments/language-subtag-registry](http://www.iana.org/assignments/language-subtag-registry). It is recommended that this code be written in lower case.

**script**  
The ISO 15924 code for the script. These codes consist of 4 letters, and it is recommended they be written with an initial capital, the other three letters in lower case. The canonical list of codes is maintained by the Unicode Consortium, and is available at
The IETF recommends this code be omitted unless it is necessary to make a distinction you need.

**region** Either an ISO 3166 country code or a UN M.49 region code that is registered with IANA (not all such codes are registered, e.g. UN codes for economic groupings or codes for countries for which there is already an ISO 3166 2-letter code are not registered). The former consist of 2 letters, and it is recommended they be written in upper case; the list of codes can be searched or browsed at [https://www.iso.org/obp/ui/#search/code/](https://www.iso.org/obp/ui/#search/code/). The latter consist of 3 digits; the list of codes can be found at [http://unstats.un.org/unsd/methods/m49/m49.htm](http://unstats.un.org/unsd/methods/m49/m49.htm).

**variant** An IANA-registered variation. These codes are used to indicate additional, well-recognized variations that define a language or its dialects that are not covered by other available subtags.

**extension** An extension has the format of a single letter followed by a hyphen followed by additional subtags. These exist to allow for future extension to BCP 47, but as of this writing no such extensions are in use.

**private use** An extension that uses the initial subtag of the single letter x (i.e., starts with X-) has no meaning except as negotiated among the parties involved. Since they interfere with the interoperability that use of RFC 4646 is intended to promote, in order for a document that makes use of these subtags to be TEI-conformant, a corresponding `<language>` element must be present in the TEI header.

There are two exceptions to the above format. First, there are language tags in the IANA registry that do not match the above syntax, but are present because they have been 'grandfathered' from previous specifications.

Second, an entire language tag can consist of only a private use subtag. These tags start with X- and do not need to follow any further rules established by the IETF and endorsed by these Guidelines. Like all language tags that make use of private use subtags, the language in question must be documented in a corresponding `<language>` element in the TEI header.

Examples include:

- sn Shona
- zh-TW Taiwanese
- zh-Hant-HK Chinese written in traditional script as used in Hong Kong
- en-SL English as spoken in Sierra Leone
- pl Polish
- es-MX Spanish as spoken in Mexico
- es-419 Spanish as spoken in Latin America

The W3C Internationalization Activity has published a useful introduction to BCP 47, Language tags in HTML and XML.

---

**teidata.name** defines the range of attribute values expressed as an XML Name.

**Module** tei — The TEI Infrastructure

**Used by** att\[\]Element:

- application/@ident
- attRef/@name
- equiv/@name
- f/@name
- fDecl/@name
- fsDecl/@baseTypes
teidata.name defines the range of attribute values used to indicate XML namespaces as defined by the W3C Namespaces in XML Technical Recommendation.

Module  tei — The TEI Infrastructure

Used by  Element:

• anyElement/@require

• attDef/@ns

• namespace/@name

Content model

<content> <dataRef name="anyURI"/> </content>

Declaration  

teidata.name = xsd:Name

Note  The range of syntactically valid values is defined by RFC 3986 Uniform Resource Identifier (URI): Generic Syntax.

teidata.namespaceOrName defines attribute values which contain either an absolute namespace URI or a qualified XML name.

Module  tei — The TEI Infrastructure

Used by  Element:

• anyElement/@except

• schemaSpec/@defaultExceptions

Content model

<content>
  <alternate>
    <dataRef name="anyURI"/>
    <dataFacet name="pattern" value="[^/]+:.*"/>
  </dataRef>
</content>
teidata.nullOrName defines attribute values which contain either the null string or an XML name.

Module tei — The TEI Infrastructure

Used by

Content model

```
<content>
  <alternate>
    <valList>
      <valItem ident=""/>
    </valList>
    <dataRef name="NCName"/>
  </alternate>
</content>
```

Declaration **teidata.nullOrName** = (""") | xsd:NCName

Note The rules defining an XML name form a part of the XML Specification.

teidata.numeric defines the range of attribute values used for numeric values.

Module tei — The TEI Infrastructure

Used by Element:

- `memberOf/@max`
- `memberOf/@min`
- `num/@value`
- `numeric/@value`
- `numeric/@max`
- `precision/@stdDeviation`

Content model

```
<content>
  <alternate>
    <dataRef name="double"/>
    <dataRef name="token" restriction="(\-?\d+[\./]?\d*)"/>
    <dataRef name="decimal"/>
  </alternate>
</content>
```

Declaration

```xml
<content>
  <alternate>
    <dataRef name="pattern" value=".*:+.*"/>
  </alternate>
</content>
```
Note Any numeric value, represented as a decimal number, in floating point format, or as a ratio.

To represent a floating point number, expressed in scientific notation, ‘E notation’, a variant of ‘exponential notation’, may be used. In this format, the value is expressed as two numbers separated by the letter E. The first number, the significand (sometimes called the mantissa) is given in decimal format, while the second is an integer. The value is obtained by multiplying the mantissa by 10 the number of times indicated by the integer. Thus the value represented in decimal notation as 1000.0 might be represented in scientific notation as 10E3.

A value expressed as a ratio is represented by two integer values separated by a solidus (/) character. Thus, the value represented in decimal notation as 0.5 might be represented as a ratio by the string 1/2.

**teidata.outputMeasurement** defines a range of values for use in specifying the size of an object that is intended for display.

**Module** tei — The TEI Infrastructure

**Used by**

**Content model**

```xml
<content>
  <dataRef name="token"
    restriction="[\-+]?\d+(\.\d+)?(%|cm|mm|in|pt|pc|px|em|ex|gd|rem|vw|vh|vm)="/>
</content>
```

**Declaration**

```xml
teidata.outputMeasurement =
  token
  { 
    pattern = "[\-+]?\d+(\.\d+)?(%|cm|mm|in|pt|pc|px|em|ex|gd|rem|vw|vh|vm)"
  }
```

**Example**

```xml
<figure>
  <head>The TEI Logo</head>
  <figDesc>Stylized yellow angle brackets with the letters <mentioned>TEI</mentioned> in between and <mentioned>text encoding initiative</mentioned> underneath, all on a white background.</figDesc>
  <graphic height="600px" width="600px"
    url="http://www.tei-c.org/logos/TEI-600.jpg"/>
</figure>
```

**Note** These values map directly onto the values used by XSL-FO and CSS. For definitions of the units see those specifications; at the time of this writing the most complete list is in the CSS3 working draft.

**teidata.pattern** defines attribute values which are expressed as a regular expression.
teidata.point defines the data type used to express a point in cartesian space.

**Module** tei — The TEI Infrastructure

**Used by** Element:

- [path](#)/@points

**Content model**

```xml
<content>
</content>
```

**Declaration**

```xml
```

**Example**

```xml
<facsimile>
  <surface ulx="0" uly="0" lrx="400" lry="280">
    <zone points="220,100 300,210 170,250 123,234">
      <graphic url="handwriting.png "/>
    </zone>
  </surface>
</facsimile>
```

**Note** A point is defined by two numeric values, which should be expressed as decimal numbers. Neither number can end in a decimal point. E.g., both 0.0,84.2 and 0,84 are allowed, but 0.,84. is not.

---

teidata.pointer defines the range of attribute values used to provide a single URI, absolute or relative, pointing to some other resource, either within the current document or elsewhere.

**Module** tei — The TEI Infrastructure

**Used by** teidata.authority/Element:
The TEI Guidelines

- alt/@target
- annotation/@target
- app/@from
- app/@to
- arc/@from
- arc/@to
- catRef/@scheme
- certainty/@given
- change/@target
- classCode/@scheme
- conversion/@fromUnit
- conversion/@toUnit
- dataRef/@ref
- eLeaf/@value
- cTree/@value
- equiv/@uri
- equiv/@filter
- f/@fVal
- fs/@feats
- fsdLink/@target
- g/@ref
- handShift/@new
- iNode/@value
- iNode/@children
- iNode/@parent
- iNode/@follow
- keywords/@scheme
- leaf/@value
- leaf/@parent
- leaf/@follow
- locus/@scheme
- locusGrp/@scheme
- material/@target
- metamark/@target
- moduleRef/@url
- move/@perf
- node/@value
- node/@adjTo
- node/@adjFrom
- node/@adj
teidata.prefix defines a range of values that may function as a URI scheme name.

Module tei — The TEI Infrastructure

Used by Element:
  • prefixDef/@ident

Content model

```xml
<content>
  <dataRef name="anyURI"/>
</content>
```

Declaration

```
teidata.pointer = xsd:anyURI
```

Note The range of syntactically valid values is defined by RFC 3986 Uniform Resource Identifier (URI): Generic Syntax. Note that the values themselves are encoded using RFC 3987 Internationalized Resource Identifiers (IRIs) mapping to URIs. For example, https://secure.wikimedia.org/wikipedia/en/wiki/% is encoded as https://secure.wikimedia.org/wikipedia/en/wiki/%25 while http://موقع.وزارة-الاتصالات.مصر is encoded as http://xn--4gbrim.xn----rmckbbajlc6dj7bxne2c.xn--wgbh1c/
**The TEI Guidelines**

```xml
<content>
  <dataRef name="token"
    restriction="[a-z][a-z0-9\+\.-]*"/>
</content>
```

**Declaration**

```
teidata.prefix = token { pattern = "[a-z][a-z0-9\+\.-]*" }
```

**Note**

This datatype is used to constrain a string of characters to one that can be used as a URI scheme name according to RFC 3986, section 3.1. Thus only the 26 lowercase letters a–z, the 10 digits 0–9, the plus sign, the period, and the hyphen are permitted, and the value must start with a letter.

---

**teidata.probability** defines the range of attribute values expressing a probability.

*Module* tei — [The TEI Infrastructure]

*Used by* teidata.probCert

*Content model*

```
<content> <dataRef name = "double" /></content>
```

**Declaration**

```
teidata.probability = xsd:double
```

**Note**

Probability is expressed as a real number between 0 and 1; 0 representing *certainly false* and 1 representing *certainly true*.

---

**teidata.probCert** defines a range of attribute values which can be expressed either as a numeric probability or as a coded certainty value.

*Module* tei — [The TEI Infrastructure]

*Used by* teidata.probCert

*Content model*

```
<content>
  <alternate>
    <dataRef key = "teidata.probability"/>
    <dataRef key = "teidata.certainty"/>
  </alternate>
</content>
```

**Declaration**

```
teidata.probCert = teidata.probability | teidata.certainty
```

---

**teidata.replacement** defines attribute values which contain a replacement template.

*Module* tei — [The TEI Infrastructure]

*Used by* teidata.replacement

*Content model*

```
<content> <textNode/> </content>
```

1902
teidata.sex defines the range of attribute values used to identify human or animal sex.

Module tei — The TEI Infrastructure

Used by Element:
- person/@sex
- personGrp/@sex
- persona/@sex
- sex/@value

Content model

```
<content> <dataRef key="teidata.word"/></content>
```

Declaration

```
teidata.sex = teidata.word
```

Note
Values for attributes using this datatype may be locally defined by a project, or may refer to an external standard, such as vCard’s sex property [http://microformats.org/wiki/gender-formats](http://microformats.org/wiki/gender-formats) (in which M indicates male, F female, O other, N none or not applicable, U unknown), or the often used ISO 5218:2004 [Representation of Human Sexes](http://standards.iso.org/ittf/PubliclyAvailableStandards/c036266_ISO_IEC_5218_2004(E_F).zip) (in which 0 indicates unknown; 1 male; 2 female; and 9 not applicable, although the ISO standard is widely considered inadequate); cf. CETH’s [Recommendations for Inclusive Data Collection of Trans People](http://transhealth.ucsf.edu/trans?page=lib-data-collection).

---

teidata.temporal.iso defines the range of attribute values expressing a temporal expression such as a date, a time, or a combination of them, that conform to the international standard [Data elements and interchange formats – Information interchange – Representation of dates and times](http://www.iso.org/iso/iso_catalogue/catalogue_tc/catalogue_detail.htm?csnumber=48952).

Module tei — The TEI Infrastructure

Used by

Content model

```
<content>
  <alternate>
    <dataRef name="date"/>
    <dataRef name="gYear"/>
    <dataRef name="gMonth"/>
    <dataRef name="gDay"/>
    <dataRef name="gYearMonth"/>
    <dataRef name="gMonthDay"/>
    <dataRef name="time"/>
    <dataRef name="dateTime"/>
    <dataRef name="token"
      restriction="[0-9.,DHMPRSTWYZ/:+\-]+"/>
  </alternate>
</content>
```

Declaration

```
teidata.temporal.iso = xsd:date | xsd:gYear | xsd:gMonth
```

1903
The TEI Guidelines

| xsd:gDay       |
| xsd:gYearMonth |
| xsd:gMonthDay  |
| xsd:time       |
| xsd:dateTime   |

Note  If it is likely that the value used is to be compared with another, then a time zone indicator should always
be included, and only the dateTime representation should be used.

For all representations for which ISO 8601 describes both a basic and an extended format, these
Guidelines recommend use of the extended format.

While ISO 8601 permits the use of both 00:00 and 24:00 to represent midnight, these Guidelines
strongly recommend against the use of 24:00.

`teidata.temporal.w3c` defines the range of attribute values expressing a temporal expression such as a
date, a time, or a combination of them, that conform to the W3C XML Schema Part 2: Datatypes Second
Edition specification.

Module  ![The TEI Infrastructure](image)

Used by  Element:
- `docDate/@when`
- `when/@absolute`

Content model

```
<content>
  <alternate>
    <dataRef name="date"/>
    <dataRef name="gYear"/>
    <dataRef name="gMonth"/>
    <dataRef name="gDay"/>
    <dataRef name="gYearMonth"/>
    <dataRef name="gMonthDay"/>
    <dataRef name="time"/>
    <dataRef name="dateTime"/>
  </alternate>
</content>
```

Declaration

```
teidata.temporal.w3c =
  xsd:date
  | xsd:gYear
  | xsd:gMonth
  | xsd:gDay
  | xsd:gYearMonth
  | xsd:gMonthDay
  | xsd:time
  | xsd:dateTime
```

Note  If it is likely that the value used is to be compared with another, then a time zone indicator should always
be included, and only the dateTime representation should be used.
**teidata.temporal.working** defines the range of values, conforming to the W3C XML Schema Part 2: Datatypes Second Edition specification, expressing a date or a date and a time within the working life of the document.

*Module*  
tei — The TEI Infrastructure

*Used by*

*Content model*

```xml
<content>
  <alternate>
    <dataRef name="date"
      restriction="(19\[789\][0-9]|2-9)[0-9]{3}).*"/>
    <dataRef name="dateTime"
      restriction="(19\[789\][0-9]|2-9)[0-9]{3}).*"/>
  </alternate>
</content>
```

*Declaration*

```xml
teidata.temporal.working =
  xsd:date { pattern = "(19\[789\][0-9]|2-9)[0-9]{3}).*" } |
  xsd:dateTime { pattern = "(19\[789\][0-9]|2-9)[0-9]{3}).*" }
```

*Note*  
If it is likely that the value used is to be compared with another, then a time zone indicator should always be included, and only the dateTime representation should be used.

The earliest time expressable with this datatype is 01 January 1970 (the Unix Epoch), which could be written as either 1970-01-01 or 1970-01-01T00:00:00Z.

---

**teidata.text** defines the range of attribute values used to express some kind of identifying string as a single sequence of Unicode characters possibly including whitespace.

*Module*  
tei — The TEI Infrastructure

*Used by*  
Element:
- distinct/@time
- distinct/@space
- distinct/@social
- refState/@delim
- remarks/@ident
- rendition/@selector
- unicodeProp/@value
- valItem/@ident

*Content model*

```xml
<content> <dataRef name="string"/></content>
```

*Declaration*

```xml
teidata.text = string
```

*Note*  
Attributes using this datatype must contain a single 'token' in which whitespace and other punctuation characters are permitted.

---

**teidata.truthValue** defines the range of attribute values used to express a truth value.

*Module*  
tei — The TEI Infrastructure
The TEI Guidelines

Used by Element:
- binary/@value
- content/@autoPrefix
- fDecl/@optional
- listChange/@ordered
- metSym/@terminal
- model/@useSourceRendition
- modelGrp/@useSourceRendition
- modelSequence/@useSourceRendition
- numeric/@trunc
- pc/@pre
- sequence/@preserveOrder
- surface/@flipping
- tagsDecl/@partial

Content model

```
<content> <dataRef name="boolean"/></content>
```

Declaration

```
teidata.truthValue = xsd:boolean
```

Note

The possible values of this datatype are 1 or true, or 0 or false.

This datatype applies only for cases where uncertainty is inappropriate; if the attribute concerned may have a value other than true or false, e.g. unknown, or inapplicable, it should have the extended version of this datatype: teidata.xTruthValue.

---

teidata.unboundedInt defines an attribute value which can be either any non-negative integer or the string "unbounded".

Module tei — The TEI Infrastructure

Used by Element:
- datatype/@maxOccurs

Content model

```
<content> <alternate>
    <dataRef name="nonNegativeInteger"/>
    <valList type="closed">
        <valItem ident="unbounded"/>
    </valList>
</alternate>
</content>
```

Declaration

```
teidata.unboundedInt = xsd:nonNegativeInteger | ( "unbounded" )
```

---

teidata.version defines the range of attribute values which may be used to specify a TEI or Unicode version number.

Module tei — The TEI Infrastructure

1906
teidata.versionNumber defines the range of attribute values used for version numbers.

Module tei — The TEI Infrastructure

Used by Element:
- TEI/@version
- teiCorpus/@version
- unicodeName/@version

Content model

```xml
<content>
  <dataRef name="token"
    restriction="[\d]+(\.[\d]+){0,2}"/>
</content>
```

Declaration

```python
teidata.version = token { pattern = "[\d]+(\.[\d]+){0,2}" }
```

Note The value of this attribute follows the pattern specified by the Unicode consortium for its version number (http://unicode.org/versions/). A version number contains digits and fullstop characters only. The first number supplied identifies the major version number. A second and third number, for minor and sub-minor version numbers, may also be supplied.

---

teidata.word defines the range of attribute values expressed as a single word or token.

Module tei — The TEI Infrastructure

Used by teidata.enumerated teidata.sex Element:
- app/@loc
- attRef/@class
- binaryObject/@encoding
- certainly/@assertedValue
- code/@lang
The TEI Guidelines

- dataFacet/@name
- langKnown/@level
- locus/@from
- locus/@to
- m/@baseForm
- media/@mimeType
- metSym/@value
- metamark/@function
- personGrp/@size
- rhyme/@label
- secl/@reason
- supplied/@reason
- surplus/@reason
- symbol/@value
- unihanProp/@value
- vLabel/@name

Content model

```xml
<content>
  <dataRef name="token"
    restriction="[^\p{C}\p{Z}]+"/>
</content>
```

Declaration  

```
teidata.word = token { pattern = "[^\p{C}\p{Z}]+" }
```

Note  Attributes using this datatype must contain a single ‘word’ which contains only letters, digits, punctuation characters, or symbols: thus it cannot include whitespace.

**teidata.xmlName** defines attribute values which contain an XML name.

*Module* tei – [The TEI Infrastructure]

*Used by*  

- classRef/@key
- classRef/@include
- classRef/@except
- dataRef/@key
- dataRef/@name
- elementRef/@key
- elementSpec/@prefix
- macroRef/@key
- moduleRef/@prefix
- moduleRef/@include
- moduleRef/@except
- moduleRef/@key

1908
teidata.xpath defines attribute values which contain an XPath expression.

Module tei — The TEI Infrastructure
Used by Element:
- citeStructure/@match
- modelSequence/@predicate
- param/@value

Content model `<content> <textNode/></content>`

Declaration `teidata.xpath = text`

Note Any XPath expression using the syntax defined in Kay (ed.) (2007).

When writing programs that evaluate XPath expressions, programmers should be mindful of the possibility of malicious code injection attacks. For further information about XPath injection attacks, see the article at OWASP.

teidata.xTruthValue (extended truth value) defines the range of attribute values used to express a truth value which may be unknown.

Module tei — The TEI Infrastructure
Used by Element:
- binding/@contemporary
- iNode/@ord
- kinesic/@iterated
- root/@ord
- said/@aloud
- said/@direct
- seal/@contemporary
- sound/@discrete
- vocal/@iterated
- writing/@gradual

Content model
```
<content>
  <alternate>
    <dataRef name="boolean"/>
    <valList>
      <valItem ident="unknown"/>
      <valItem ident="inapplicable"/>
    </valList>
  </alternate>
</content>
```
Declaration

\[
\text{teidata.xTruthValue} = \text{xsd:boolean} \mid (\text{"unknown"} \mid \text{"inapplicable"})
\]

*Note*  In cases where uncertainty is inappropriate, use the datatype `teidata.TruthValue`.

The TEI Guidelines

G Deprecations
G.1 Items Scheduled to be Removed

This appendix provides a partial list of items (elements, attributes, attribute values, datatypes etc.) which are deprecated in this revision of the TEI Guidelines (revision b4f72b1ff of TEI P5 Version 4.3.0).

- The use of `<schemaSpec>` as a child of any element other than `<front>`, `<body>`, `<back>`, `<encodingDesc>`, `<div>`, or one of the numbered division elements is being withdrawn. will be removed on 2021-10-23.

- The use of `<value>` inside `<charProp>` to specify a character or glyph property value is being replaced by either `<unicodeProp>`, `<localProp>`, or `<unihanProp>`, will be removed on 2022-02-15.

- The use of `<unicodeName>` to specify a character or glyph name is being replaced by `<unicodeProp>` (or perhaps `<unihanProp>`) with a `name` of Name. will be removed on 2022-02-15.

- The use of `<localName>` to specify a local character or glyph name is being replaced with either `<unicodeProp>`, `<localProp>`, or `<unihanProp>`, likely with a `name` of Name. will be removed on 2022-02-15.

- The use of `<glyphName>` to specify a glyph name is being replaced by either `<unicodeProp>`, `<localProp>`, or `<unihanProp>`, likely with a `name` of Name. will be removed on 2022-02-15.

- The use of `<charProp>` to specify a character property is being replaced by either `<unicodeProp>`, `<localProp>`, or `<unihanProp>`, will be removed on 2022-02-15.

- The use of `<charName>` is being replaced by either `<unicodeProp>`, `<unihanProp>`, or `<localProp>`, likely with a `name` value of Name. will be removed on 2022-02-15.
Prefatory Notes

This Appendix contains (in reverse chronological order) the 'Introductory Notes' prefixed to each revision of the TEI Guidelines since its first publication in 1994.

H.1 Prefatory Note (March 2002)

The primary goal of this revision has been to make available a new and corrected version of the TEI Guidelines which:

- is expressed in XML and conforms to a TEI-conformant XML DTD;
- generates a set of DTD fragments that can be combined together to form either SGML or XML document type definitions;
- corrects blatant errors, typographical mishaps, and other egregious editorial oversights;
- can be processed and maintained using readily available XML tools instead of the special-purpose ad hoc software originally used for TEI P3.

A second major design goal of this revision has been to ensure that the DTD fragments generated would not break existing documents: in other words, that any document conforming to the original TEI P3 SGML DTD would also conform to the new XML version of it. Although full backwards compatibility cannot be guaranteed, we believe our implementation is consistent with that goal.

In most respects, the TEI Guidelines have stood the test of time remarkably well. The present edition makes no substantial attempt to rewrite those few parts of them which have now been rendered obsolete by changes since their first publication, though an indication is given in the text of where such rewriting is now considered necessary. Neither does the present version attempt to address any of the many possible new areas of digital activity in which the TEI approach to standardization may have something to offer. Both these tasks require the existence of an informed and active TEI Council to direct and validate such extension and maintenance work, in response to the changing needs and priorities of the TEI user community.

Two exceptions to the above principles may be cited: firstly, the chapter which originally provided a 'Gentle Introduction' to SGML has been completely rewritten to provide a similarly gentle introduction to XML; secondly the chapter on character sets has been completely revised in light of the close connexion between Unicode and XML.

The editors gratefully acknowledge the assistance of the ad hoc workgroup chaired by Christian Wittern, which undertook to provide expert advice and correction at very short notice, in the latter task.

The preparation of this new version relied extensively on preliminary work carried out by the former North American editor of the TEI Guidelines, C.M. Sperberg-McQueen. In a TEI working paper written in 1999 he sketched out a precise blueprint for the conversion of the TEI from SGML to XML, which we have implemented, with only slight modification.

The Editors would also like to express thanks to the team of volunteers from the TEI community who helped us with the task of proofreading the first draft during the summer of 2001; and to Sebastian Rahtz of Oxford University Computing Services, without whose skill and enthusiasm this new edition would not have been possible.

A substantial proportion of the work of preparing this new edition was funded with the assistance of a grant from the US National Endowment for the Humanities, whose continued support of the TEI has also been crucial to the effort of setting up the TEI Consortium.

Finally, we would like to thank all our colleagues on the interim management board of the TEI Consortium, in particular its Chairman John Unsworth, for their continued support of the TEI’s work, and their willingness to devote effort to the difficult task of overseeing its transition to a new organizational infrastructure.

Summary details of the changes made in the present and previous editions are given in their Prefatory Notes, all of which are now reproduced in an Appendix to the present edition: see Appendix H Prefatory Notes.

Lou Burnard and Syd Bauman (TEI Editors)
Oxford and Providence, March 2002.

H.2 Introductory Note (November 2001)

To complete the work started in June of this year, the TEI Editors asked for volunteers from the TEI community to proofread the preliminary XML version. 24 volunteers responded to this call during August, and gave invaluable

---

help both by identifying a number of previously un-noticed errors, and by suggesting areas in which more substantial revision should be undertaken in the future. The Editors gratefully acknowledge the assistance of the following individuals during this exercise:

Jimmy Adair, Syd Bauman, Michael Beddow, Steven Bird, Lisa Charlong, Matthew Driscoll, Patrick Durusau, Tomaz Erjavec, Nick Finke, Tim Finney, Julia Flanders, Mike Fraser, Pankaj Kamthan, François Lachance, Terry Langendoen, Anne Mahoney, Gregory Murphy, Daniel Pitti, Rafal Prinke, Laurent Romary, Stewart Russell, Gary Simons, Elisabeth Solopova, Christian Wittern, Martin Wynne.

In addition to error correction, and clear delineation of those sections in which substantial revision is yet to be undertaken for TEI P5, the present draft differs from earlier ones in the following respects:

- Formal Public Identifiers have been introduced as a means of constructing TEI DTDs and an SGML Open Catalog is now included with the standard release;
- Some systematic errors and omissions in the reference section have been removed; the format of this section has been substantially changed, we hope for the better;
- The chapters on obtaining the TEI DTDs and WSDs have been brought up to date; the chapter on modification has been expanded to include a discussion of the TEI Lite customization;
- All examples and cited markup has been checked for XML validity against the published DTDs, and corrected where faulty; examples have been formatted in a (more or less) consistent style.

Lou Burnard and Syd Bauman (Editors)

H.3 Introductory Note (June 2001)

This is a preliminary version of a revised and fully XML-compliant edition of the TEI Guidelines. Although work on revising and correcting the text of the document is incomplete, by making available this preliminary version we hope to facilitate testing of the XML document type declarations which it describes by as wide a range of TEI users as possible.

The primary goal of this revision is to make available the corrected (May 1999) edition of the Guidelines in a new version which:

- is expressed in XML and itself conforms to a TEI-conformant XML DTD;
- generates a set of XML DTD fragments that can be combined together in the same way as the existing TEI (P3) SGML DTD fragments to form true TEI XML DTD fragments without loss of functionality;
- can be processed and maintained using readily available XML tools instead of the special-purpose ad hoc software originally used for TEI P3.

As noted elsewhere, a number of errors were corrected in the May 1999 edition. A (much) smaller number of errors have also been corrected in this edition, but no new material has been added. We expect the expansion and modification of the Guidelines to become a real possibility in the context of the newly formed TEI Consortium, which has funded the preparation of this present edition.

A major design goal of both this and the previous revision has been to ensure that the DTD fragments generated would not break existing documents: in other words, that any document conforming to the original TEI P3 SGML DTD would also conform to the new XML version of it. Although full backwards compatibility cannot be guaranteed, we believe our implementation is consistent with that goal.

In making this new version, we relied extensively on preliminary work carried out by the outgoing North American editor of the TEI Guidelines, Michael Sperberg-McQueen. In a TEI working paper written in 1999, TEI ED W69, Michael sketched out a precise blueprint for the conversion of the TEI from SGML to XML, which we have implemented, with only slight modification. The current TEI editors wish to express here our admiration for the detailed care put into that paper, without which our task would have been forbiddingly difficult, if not impossible. We would also like to express our thanks to Sebastian Rahtz of Oxford University Computing Services, for his invaluable assistance in preparing this new edition.

We list here in summary form all the changes made in the present edition. Full technical details are provided in documents TEI EDW69 and TEI EDW70, available from the TEI web site.
1. A new keyword TEI.XML has been added. By setting its value to INCLUDE, rather than the default IGNORE, the user can request generation of an XML rather than an SGML DTD;

2. The content models of all elements have been checked, and, where necessary, changed so that they are equally valid as SGML or as XML;

3. The declared value for all attributes has been changed to a form which is equally valid as SGML or as XML;

4. All the examples have been checked for conformance and converted to use XML syntax, where possible. (This process is currently incomplete.)

5. Some errors and duplications in the class membership of elements from the names and dates tagsets have been corrected.

To implement the first of these, we have parameterized the tag omissibility indicators ‘- o’ and ‘-’ used within element declarations in the DTD. When XML is to be generated, the parameter entities concerned are redeclared with the null string as their value.

The second change was achieved by removing SGML-specific features (ampersand connectors, inclusion and exclusion exceptions, various types of attribute content) from the DTD and revising the syntax of the DTD to conform to XML requirements (specifically in the representation of mixed-content models, and by removing redundant parentheses). In making these changes, we took care to ensure that the resulting content model would continue to accept existing valid documents, though in the nature of things it could not be guaranteed to reject the same set of documents. As further discussed in EDW69 and EDW70, some constraints (exclusion exceptions, for example) which could be carried out by a generic SGML parser using TEI P3 will have to be implemented by a special purpose TEI validator using TEI P4.

Much work remains to be done, firstly in testing the new DTD fragments against as wide a range of TEI materials as possible, secondly in revising the discussion of markup theory and practice within the text to reflect current thinking. A few sections of the current text (the Gentle Introduction to SGML and the discussion of Extended Pointer syntax are two examples) will need substantial rewriting. For the most part, however, we think the Guidelines have stood the test of time well and can be recommended to a new generation of text encoders scarcely born at the time they were first formulated.

Lou Burnard and Steve De Rose (Editors)

H.4 Introductory Note (May 1999)

No work of the size and complexity of the TEI Guidelines could reasonably be expected to be error-free on publication, nor to remain long uncorrected. It has however taken rather longer than might have been anticipated to complete production of the present corrected reprint of the first edition, for which we present our apologies, both to the many individuals and institutions whose enthusiastic adoption and promotion of the TEI encoding scheme have ensured its continued survival in the rapidly changing world of digital scholarship, and also to the many helpfully critical users whose assiduous uncovering and reporting of our errors have made possible the present revision.

At its first meeting in Bergen, in June 1996, the TEI Technical Review Committee (TRC) approved the setting up of a small working committee to oversee the production of a revised edition of the TEI Guidelines, to include corrections of as many as possible of the ‘corrigible errors’ notified to the editors since publication of the first edition in May 1994, the bulk of which are summarized in a TEI working paper (TEI EDW67, available from the TEI web site).

During the spring of 1997, this TRC Core Subcommittee reviewed nearly 200 comments and proposals which the editors had collected from public debate and discussion over the preceding two years, and provided invaluable technical guidance in disposition of them. We are glad to take this opportunity of expressing our thanks to this subcommittee, whose members were Elli Mylonas, Dominic Dunlop, and David T. Barnard.

The work of making the corrections and regenerating the text proceeded rather fitfully during 1998 and 1999, largely because of increasing demands on the editors’ time from their other responsibilities. With the establishment of the new TEI Consortium, it is be hoped that maintenance of the Guidelines will be placed on a more secure footing. Some specific areas in which we anticipate future revisions being carried out are listed below.

**Typographic Corrections Made**
- examples of TEI markup throughout the text were all checked against the relevant DTD fragment and an embarassingly large number of tagging errors corrected;
• various minor typographic and spelling errors were corrected;
• the ‘corrigible errors’ listed in working paper TEI EDW67 were all corrected: some of these required specific changes to the DTD which are listed in the next section.

Specific Changes in the DTD

A major goal of this revision was to avoid changes which might invalidate existing data, even where existing constructs seemed erroneous in retrospect. To that end, wherever changes have been made in content models for existing elements, they have as far as possible been made so that the DTD will now accept a superset of what was previously legal. Only one new element (<ab>) has been added.

Where possible, a few content models have been changed in such a way as to facilitate conversion to XML, but XML compatibility is not a goal of this revision.

Brief details of all changes made in the DTD follow:

• Several changes were made in class membership, in order to correct unreachability problems. Specifically:
  - elements <geogName>, <persName>, <placeName> were added to the m.data class;
  - <geogName> and <placeName> were removed from the m.placepart class;
  - the elements <addSpan>, <delSpan>, <gap>, were added to the m.Edit class;
  - a new class m.editIncl was defined, with members <addSpan>, <delSpan>, and <gap>; this class was then added to the global inclusion class m.globIncl along with <anchor> (erroneously a member of the m.Seg class, from which it is now removed), m.metadata and m.refsys;
• added <name> element to m.addrPart class;
• added <dateline> to m.divtop and m.divbot classes;
• added <epilogue> and <castList> to m.dramafront class;
• added <divGen> to m.front class;
• added <dateline> to m.divtop and m.divbot classes;
• added <u> element to a.declaring class;
• defined new class m.fmchunk (front matter chunk), comprising <argument>, <byline>, <docAuthor>, <docDate>, <docEdition>, <docImprint>, <docTitle>, <epigraph>, <head>, and <titlePart> for use in simplification of the content model for <front> element;
• defined new element <ab> (anonymous block), and added it to the m.chunk class;
• corrected an error whereby global attributes were not properly defined for elements specifying a non-default value for any of the a.global attributes: elements affected include: <foreign>, <hi>, <del>, <pb>, <lb>, <cb>, <language>, <anchor>, and <when>;
• changed content models to permit empty <list> and empty <availability> elements;
• changed content model for <series> element to permit #PCDATA;
• changed content model for <setting> element to permit <date> element as a direct child;
• added a key attribute to the <distance> element, for consistency with other elements in its class;
• changed content model for <orgName> element to make it more consistent with e.g. <persName>;
• changed content model for <opener> element to include <argument>, <byline>, and <epigraph>;
• changed content models for <app>, <rdgGrp>, and <wit> elements;
• revised attributes on <hand> element.

A number of content models were changed with a view to easing the creation of an XML compatible version of the Guidelines. Specifically:
• removed ampersand connectors from <cit>, <respStmt>, <publicationStmt>, and <graph>;
• changed the mixed content models for <sense>, <re>, <persName>, <placeName>, <geogName>, <dateStruct>, <timeStruct>, and <dateline> to make them XML-conformant.
Outstanding Errors

A small number of other known problems remain uncorrected in this version and are briefly listed below. Please watch the TEI mailing list for announcements of their correction.

- elements of class `model.inter` don’t always behave as they should (e.g. one cannot insert a `<table>` before anything else in a `<div>`);
- some mixed-content problems consequent on the definition of `macro.specialPara` need to be addressed systematically; in particular, the treatment of list items or notes which contain several paragraphs continues to surprise many users: no whitespace is allowed between the paragraphs;
- the `resp` attributes on editorial elements are not consistently defined;
- the discussions of DTD invocation, and the DTD itself, all use system identifiers instead of formal public identifiers.

Our next priority however will be the production of a fully XML-compliant version of the TEI DTD, work on which is already well advanced.

C.M. Sperberg-McQueen and Lou Burnard, May 1999

H.5 Preface (April 1994)

These Guidelines are the result of over five years’ effort by members of the research and academic community within the framework of an international cooperative project called the Text Encoding Initiative (TEI), established in 1987 under the joint sponsorship of the Association for Computers and the Humanities, the Association for Computational Linguistics, and the Association for Literary and Linguistic Computing.

The impetus for the project came from the humanities computing community, which sought a common encoding scheme for complex textual structures in order to reduce the diversity of existing encoding practices, simplify processing by machine, and encourage the sharing of electronic texts. It soon became apparent that a sufficiently flexible scheme could provide solutions for text encoding problems generally. The scope of the TEI was therefore broadened to meet the varied encoding requirements of any discipline or application. Thus, the TEI became the only systematized attempt to develop a fully general text encoding model and set of encoding conventions based upon it, suitable for processing and analysis of any type of text, in any language, and intended to serve the increasing range of existing (and potential) applications and use.

What is published here is a major milestone in this effort. It provides a single, coherent framework for all kinds of text encoding which is hardware-, software- and application-independent. Within this framework, it specifies encoding conventions for a number of key text types and features. The ongoing work of the TEI is to extend the scheme presented here to cover additional text types and features, as well as to continue to refine its encoding recommendations on the basis of extensive experience with their actual application and use.

We therefore offer these Guidelines to the user community for use in the same spirit of active collaboration and cooperation with which they have so far been developed. The TEI is committed to actively supporting the widespread and large-scale use of the Guidelines which, with the publication of this volume, is now for the first time possible. In addition, we anticipate that users of the TEI Guidelines will in some instances adapt and extend them as necessary to suit particular needs; we invite such users to engage in the further development of these Guidelines by working with us as they do so.

Like any standard which is actually used, these Guidelines do not represent a static finished work, but rather one which will evolve over time with the active involvement of its community of users. We invite and encourage the participation of the user community in this process, in order to ensure that the TEI Guidelines become and remain useful in all sorts of work with machine-readable texts.

This document was made possible in part by financial support from the U.S. National Endowment for the Humanities, an independent federal agency; Directorate General XIII of the Commission of the European Communities; the Andrew W. Mellon Foundation; and the Social Science and Humanities Research Council of Canada. Direct and indirect support has also been received from the University of Illinois at Chicago, the Oxford University Computing Services, the University of Arizona, the University of Oslo and Queen’s University (Kingston, Ont.), Bellcore (Bell Communications Research), the Istituto di Linguistica Computazionale (C.N.R.) Pisa, the British Academy, and Ohio State University, as well as the employers and host institutions of the members of the TEI working committees and work groups listed in the acknowledgments.
The production of this document has been greatly facilitated by the willingness of many software vendors to provide us with evaluation versions of their products. Most parts of this text have been processed at some time by almost every currently available SGML-aware software system. In particular, we gratefully acknowledge the assistance of the following vendors:

- Berger-Levrault AIS s.a. (for Balise);
- E2S n.v. (for E2S Advanced SGML Editor);
- Electronic Book Technology (for DynaText);
- SEMA Group and Yard Software (for Mark-It and Write-It);
- Software Exoterica (for CheckMark and Xtran);
- SoftQuad, Inc., (for Author/Editor and RulesBuilder);
- Xerox Corporation (for Ventura Publisher).

Details of the software actually used to produce the current document are given in the colophon at the end of the work.

H.6 Acknowledgments

Many people have given of their time, energy, expertise, and support in the creation of this document; it is unfortunately not possible to thank them all adequately. Below are listed those who have served as formal members of the TEI’s Work Groups and Working Committees during its six-year history; others not so officially enfranchised also contributed much to the quality of the result.

The editors take this opportunity to acknowledge our debt to those who have patiently endured and corrected our misunderstandings of their work; we hope that they will feel the wait has not been in vain. For any errors and inconsistencies remaining, we must accept responsibility; any virtue in what is here presented, we gladly ascribe to the energies of the keen intellects listed below.

C. M. Sperberg-McQueen and Lou Burnard

TEI Working Committees (1990-1993)

Not all members listed were able to serve throughout the development of the Guidelines.

Committee on Text Documentation: Chair: Dominik Wujastyk (Wellcome Institute for the History of Medicine)

Members 1990–1992: J. D. Byrum (Library of Congress); Marianne Gaunt (Rutgers University); Richard Giordano (Manchester University); Barbara Ann Kipfer (Independent Consultant); Hans Jørgen Marker (Danish Data Archive, Odense); Marcia Taylor (University of Essex);

Committee on Text Representation: Chair: Stig Johansson (University of Oslo)

Members 1990–1992: Roberto Cencioni (Commission of the European Communities); David R. Chesnutt (University of South Carolina); Robin C. Cover (Dallas Theological Seminary); Steven J. DeRose (Electronic Book Technology Inc); David G. Durand (Boston University); Susan M. Hockey (Oxford University Computing Service); Claus Huitfeldt (University of Bergen); Francisco Marcos-Marin (University Madrid); Elli Mylonas (Harvard University); Wilhelm Ott (University of Tübingen); Allen H. Rerear (Brown University); Manfred Thaller (Max-Planck-Institut für Geschichte, Göttingen)

Committee on Text Analysis and Interpretation: Chair: D. Terence Langendoen (University of Arizona)

Members 1990–1992: Robert Amsler (Bell Communications Research); Stephen Anderson (Johns Hopkins University); Branimir Boguraev (IBM T. J. Watson Research Center); Nicoletta Calzolari (University of Pisa); Robert Ingria (Bolt Beranek Newman Inc); Winfried Lenders (University of Bonn); Mitch Marcus (University of Pennsylvania); Nelleke Oostdijk (University of Nijmegen); William Poser (Stanford University); Beatrice Santorini (University of Pennsylvania); Gary Simons (Summer Institute of Linguistics); Antonio Zampolli, University of Pisa.

Committee on Metalanguage and Syntax: Chair: David T. Barnard (Queen’s University)

Members 1990–1994: David G. Durand (Boston University); Jean-Pierre Gaspart (Associated Consultants and Software Engineers sa/nv); Nancy M. Ide (Vassar College); Lynne A. Price (Software Exoterica / Xerox PARC); Frank Tompa (University of Waterloo); Giovanni Battista Varile (Commission of the European Communities).
In addition, the two TEI editors served ex officio on each committee.

Following publication of the first draft of the TEI Guidelines (P1) in November 1990, a number of specialist work groups were charged with responsibility for drafting revisions and extensions, which, together with material already presented in P1, constitute the basis of the present work.

In addition, many members of the work groups listed below met on three occasions to review the emerging proposals in detail at technical review meetings convened by the TEI Steering Committee. These meetings, held in Myrdal, Norway (November 1991), Chicago (May 1992) and Oxford (May 1993), were largely responsible for the technical content and organization of the present work. Attendants at these meetings are starred in the list below.

TR1 **Character sets**  Chair: Harry Gaylord* (University of Groningen); Syun Tutiya* (Chiba University).

TR2 **Text criticism**  Chair: Peter Robinson* (Oxford University); David Chesnutt* (University of South Carolina); Robin Cover* (Dallas Theological Seminary); Robert Kraft (University of Pennsylvania); Peter Shillingsburg (Mississippi State University).

TR3 **Hypertext and hypermedia**  Chair: Steven J. DeRose* (Electronic Book Technologies Inc); David Durand (Boston University); Edward A. Fox (Virginia State University); Eve Wilson (University of Kent).

TR4 **Formulæ, Tables, figures, and graphics**  Chair: Paul Ellison* (University of Exeter); Anders Berglund (Independent Consultant); Dale Waldt (Thompson Professional Publishing).

TR6 **Language corpora**  Chair: Douglas Biber* (University of Northern Arizona); Jeremy Clear (Birmingham University); Gunnel Engwall (University of Stockholm).

TR9 **Manuscripts and codicology**  Chair: Claus Huftfeldt* (University of Bergen); Dino Buzzetti (University of Bologna); Jacqueline Hamesse (University of Louvain); Mary Keeler (Georgetown University); Christian Kloesel (Indiana University); Allen Rennar* (Brown University); Donald Spaeth (Glasgow University).

TR10 **Verse**  Chair: David Robey* (University of Manchester); Elaine Brennan* (Brown University); David Chisholm (University of Arizona); Willard McCarty (University of Toronto).

TR11 **Drama and performance texts**  Chair: Elli Mylonas* (Harvard University); John Lavagnino* (Brandeis University); Rosanne Potter (University of Iowa).

TR12 **Literary prose**  Chair Thomas N. Cohn* (University of Wales); Christian Delcourt (University of Liège).

AI1 **Linguistic description**  Chair: D. Terence Langendoen* (University of Arizona); Stephen R. Anderson (Johns Hopkins University); Nicoletta Calzolari (University of Pisa); Geoffrey Sampson* (University of Sussex); Gary Simons* (Summer Institute of Linguistics).

AI2 **Spoken text**  Chair: Stig Johansson* (University of Oslo); Jane Edwards (University of California at Berkeley); Andrew Rosta (University College London).

AI3 **Literary studies**  Chair: Paul Fortier* (University of Manitoba); Christian Delcourt (University of Liège); Ian Lancashire (University of Toronto); Rosanne Potter (University of Iowa); David Robey* (University of Manchester).

AI4 **Historical studies**  Chair: Daniel Greenstein* (University of Glasgow); Peter Denley (Queen Mary Westfield College, London); Ingo Kropac (University of Graz); Hans Jørgen Marker (Danish Data Archive, Odense); Jan Oldervoll (University of Tromsø); Kevin Schurer (University of Cambridge); Donald Spaeth (Glasgow University); Manfred Thaller (Max-Planck-Institut für Geschicht, Göttingen).

AI5 **Print dictionaries**  Chairs: Robert Amsler* (Bell Communications Research) and Nicoletta Calzolari (University of Pisa); Susan Armstrong-Warwick (University of Geneva); John Fought (University of Pennsylvania); Louise Guthrie (University of New Mexico); Nancy M. Ide* (Vassar College); Frank Tompa (University of Waterloo); Carol Van Ess-Dykema (US Department of Defense); Jean Veronis (University of Aix-en-Provence).

AI6 **Machine lexica**  Chair: Robert Ingrin* (Bolt Beranek Newman Inc); Susan Armstrong-Warwick (University of Geneva); Nicoletta Calzolari (University of Pisa).

AI7 **Terminological data**  Chair: Alan Melby* (Brigham Young University) Gerhard Budin (University of Vienna); Gregory Shreve (Kent State University); Richard Strehlow (Oak Ridge National Laboratory); Sue Ellen Wright (Kent State University).

---

*This Workgroup was jointly sponsored by the Association for History and Computing.
Advisory Board
Members of the TEI Advisory Board during the lifetime of the project are listed below, grouped under the name of the organization represented.

**American Anthropological Association:** Chad McDaniel (University of Maryland).

**American Historical Association:** Elizabeth A. R. Brown (Brooklyn College, CUNY).

**American Philological Association:** Jocelyn Penny Small (Rutgers University).

**American Philosophical Association:** Allen Renear (Brown University).

**American Society for Information Science:** Clifford A. Lynch (University of California).

**Association for Computing Machinery, Special Interest Group for Information Retrieval:** 1989–93: Scott Deerwester (University of Chicago); 1993- : Martha Evens (Illinois Institute of Technology).

**Association for Documentary Editing:** David Chesnutt (University of South Carolina).

**Association for History and Computing:** 1989–91: Manfred Thaller, Max-Planck-Institut für Geschichte, Göttingen; 1991- : Daniel Greenstein (Glasgow University).

**Association Internationale Bible et Informatique** 1989–93: Wilhelm Ott (University of Tübingen); 1993- : Winfried Bader (University of Tübingen).

**Canadian Linguistic Association:** Anne-Maria di Sciullo (Université du Québec à Montréal)

**Dictionary Society of North America:** Barbara Ann Kipfer (Independent Consultant).

**AAP Electronic Publishing Special Interest Group:** 1989–92: Betsy Kiser (OCLC); 1992- : Deborah Bendig and Andrea Keyhani (OCLC).

**International Federation of Library Associations and Institutions:** J. D. Byrum Jr. (The Library of Congress).

**Linguistic Society of America:** Stephen Anderson (The Johns Hopkins University)

**Modern Language Association:** Randall Jones (Brigham Young University) and Ian Lancashire (University of Toronto).

Steering Committee Membership
Members of the Steering Committee of the TEI during the preparation of this work were:

**Association for Computational Linguistics:**
- 1987–1993: Robert A. Amsler (Bell Communications Research);
- 1987–1993: Donald E. Walker (Bell Communications Research);
- 1993–1994: Susan Armstrong-Warwick (University of Geneva);

**Association for Computers and the Humanities:**
- 1987–1999: Nancy M. Ide (Vassar College);
- 1987–1994: C. M. Sperberg-McQueen (University of Illinois at Chicago);
- 1994–1999: David Barnard (Queen’s University).

**Association for Literary and Linguistic Computing:**
- 1987–1999: Susan M. Hockey (Center for Electronic Texts in the Humanities);
I Colophon

The text of this manual was prepared electronically on a variety of systems. Most sections were originally drafted by members of the work groups and working committees of the TEI; all have been revised by the editors to achieve greater uniformity of style and greater consistency in the tag set.

The web release of the Guidelines was created using a library of XSLT stylesheets to convert to XHTML; the PDF version for printing was produced by conversion to LaTeX markup, processed using XeLaTeX. The XSLT libraries were written by Sebastian Rahtz.

Almost every available SGML and XML editor or processing program has been used at one time or another by the TEI; but without the open source implementations of XML parsers, editors and XSLT engines by James Clark, Richard Stallman, Michael Kay, and Daniel Veillard, the TEI could not survive, and we thank these individuals. We would also like to thank the staff at SyncRO Soft SRL, creators of the oXygen editor, for their support for the TEI during the creation on P5.

Many volunteers contributed to the preparation of this release of the Guidelines; we particularly note the work of Sabine Krott, Eva Radermacher and Arianna Ciula for their work in structuring the bibliographies.

The production and release process for TEI P5 was originally developed by Sebastian Rahtz for the TEI Technical Council.
